single-repeat , etc. Therefore over-the-spot style becomes the default now. This should work fine for most people, however if you have any problem with it, try using on-the-spot style.

'include' 'inc'

'include' 'inc' string (default "^\s*#\s*include")
global or local to buffer global-local
{not in Vi}
{not available when compiled without the +find_in_path feature}

Pattern to be used to find an include command. It is a search pattern, just like for the "/" command (See pattern). The default value is for C programs. This option is used for the commands "[i", "]I", "[d", etc.
Normally the 'isfname' option is used to recognize the file name that comes after the matched pattern. But if "\zs" appears in the pattern then the text matched from "\zs" to the end, or until "\ze" if it appears, is used as the file name. Use this to include characters that are not in 'isfname', such as a space. You can then use 'includeexpr' to process the matched text.
See option-backslash about including spaces and backslashes.

'includeexpr' 'inex'

'includeexpr' 'inex' string (default "")
local to buffer
{not in Vi}
{not available when compiled without the +find_in_path or +eval features}

Expression to be used to transform the string found with the 'include' option to a file name. Mostly useful to change "." to "/" for Java:

```
:set includeexpr=substitute(v:fname,'\\.','/','g')
```

The "v:fname" variable will be set to the file name that was detected.

Also used for the gf command if an unmodified file name can't be found. Allows doing "gf" on the name after an 'include' statement. Also used for <cfile> .

The expression will be evaluated in the sandbox when set from a modeline, see sandbox-option .

It is not allowed to change text or jump to another window while evaluating 'includeexpr' textlock .

'incsearch' 'is' 'noincsearch' 'nois'

'incsearch' 'is' boolean (default off, set in defaults.vim if the +reltime feature is supported)
global
{not in Vi}
{not available when compiled without the +extra_search features}

While typing a search command, show where the pattern, as it was typed so far, matches. The matched string is highlighted. If the pattern is invalid or not found, nothing is shown. The screen will be updated often, this is only useful on fast terminals.

```
Note that the match will be shown, but the cursor will return to its
original position when no match is found and when pressing <Esc>.  You
still need to finish the search command with <Enter> to move the
cursor to the match.
You can use the CTRL-G and CTRL-T keys to move to the next and
previous match.  c_CTRL-G   c_CTRL-T
When compiled with the  +reltime  feature Vim only searches for about
half a second.  With a complicated pattern and/or a lot of text the
match may not be found.  This is to avoid that Vim hangs while you
are typing the pattern.
The highlighting can be set with the 'i' flag in 'highlight'.
When 'hlsearch' is on, all matched strings are highlighted too while
typing a search command. See also: 'hlsearch'.
If you don't want turn 'hlsearch' on, but want to highlight all matches
while searching, you can turn on and off 'hlsearch' with autocmd.
Example:
        augroup vimrc-incsearch-highlight
          autocmd!
          autocmd CmdlineEnter /,\? :set hlsearch
          autocmd CmdlineLeave /,\? :set nohlsearch
        augroup END

CTRL-L can be used to add one character from after the current match
to the command line.  If 'ignorecase' and 'smartcase' are set and the
command line has no uppercase characters, the added character is
converted to lowercase.
CTRL-R CTRL-W can be used to add the word at the end of the current
match, excluding the characters that were already typed.
NOTE: This option is reset when 'compatible' is set.

                                                 'indentexpr'   'inde'
'indentexpr' 'inde'     string  (default "")
                        local to buffer
                        {not in Vi}
                        {not available when compiled without the  +cindent
                        or  +eval  features}
        Expression which is evaluated to obtain the proper indent for a line.
        It is used when a new line is created, for the  =  operator and
        in Insert mode as specified with the 'indentkeys' option.
        When this option is not empty, it overrules the 'cindent' and
        'smartindent' indenting.  When 'lisp' is set, this option is
        overridden by the Lisp indentation algorithm.
        When 'paste' is set this option is not used for indenting.
        The expression is evaluated with  v:lnum  set to the line number for
        which the indent is to be computed.  The cursor is also in this line
        when the expression is evaluated (but it may be moved around).
        The expression must return the number of spaces worth of indent.  It
        can return "-1" to keep the current indent (this means 'autoindent' is
        used for the indent).
        Functions useful for computing the indent are  indent() ,  cindent()
        and  lispindent() .
        The evaluation of the expression must not have side effects!  It must
        not change the text, jump to another window, etc.  Afterwards the
        cursor position is always restored, thus the cursor may be moved.
```

Normally this option would be set to call a function:
:set indentexpr=GetMyIndent()
Error messages will be suppressed, unless the 'debug' option contains "msg".
See indent-expression .
NOTE: This option is set to "" when 'compatible' is set.

The expression will be evaluated in the sandbox when set from a modeline, see sandbox-option .

It is not allowed to change text or jump to another window while evaluating 'indentexpr' textlock .

'indentkeys' 'indk'

'indentkeys' 'indk' string (default "0{,0},:,0#,!^F,o,O,e")
local to buffer
{not in Vi}
{not available when compiled without the +cindent feature}
A list of keys that, when typed in Insert mode, cause reindenting of the current line. Only happens if 'indentexpr' isn't empty.
The format is identical to 'cinkeys', see indentkeys-format .
See C-indenting and indent-expression .

'infercase' 'inf' 'noinfercase' 'noinf'

'infercase' 'inf' boolean (default off)
local to buffer
{not in Vi}
When doing keyword completion in insert mode ins-completion , and 'ignorecase' is also on, the case of the match is adjusted depending on the typed text. If the typed text contains a lowercase letter where the match has an upper case letter, the completed part is made lowercase. If the typed text has no lowercase letters and the match has a lowercase letter where the typed text has an uppercase letter, and there is a letter before it, the completed part is made uppercase.
With 'noinfercase' the match is used as-is.

'insertmode' 'im' 'noinsertmode' 'noim'

'insertmode' 'im' boolean (default off)
global
{not in Vi}
Makes Vim work in a way that Insert mode is the default mode. Useful if you want to use Vim as a modeless editor. Used for evim .
These Insert mode commands will be useful:
- Use the cursor keys to move around.
- Use CTRL-O to execute one Normal mode command i_CTRL-O . When this is a mapping, it is executed as if 'insertmode' was off. Normal mode remains active until the mapping is finished.
- Use CTRL-L to execute a number of Normal mode commands, then use <Esc> to get back to Insert mode. Note that CTRL-L moves the cursor left, like <Esc> does when 'insertmode' isn't set. i_CTRL-L

These items change when 'insertmode' is set:

- when starting to edit of a file, Vim goes to Insert mode.
- <Esc> in Insert mode is a no-op and beeps.
- <Esc> in Normal mode makes Vim go to Insert mode.
- CTRL-L in Insert mode is a command, it is not inserted.
- CTRL-Z in Insert mode suspends Vim, see CTRL-Z . i_CTRL-Z

However, when <Esc> is used inside a mapping, it behaves like 'insertmode' was not set. This was done to be able to use the same mappings with 'insertmode' set or not set.
When executing commands with :normal 'insertmode' is not used.

NOTE: This option is reset when 'compatible' is set.

'isfname' 'isf' string (default for MS-DOS, Win32 and OS/2: "@,48-57,/,\,.,-,_,+,,,#,$,%,{,},[,],:,@-@,!,~,=" for AMIGA: "@,48-57,/,.,-,_,+,,,$,:" for VMS: "@,48-57,/,.,-,_,+,,,#,$,%,<,>,[,],:,;,~" for OS/390: "@,240-249,/,.,-,_,+,,,#,$,%,~,=" otherwise: "@,48-57,/,.,-,_,+,,,#,$,%,~,=") global {not in Vi}

The characters specified by this option are included in file names and path names. Filenames are used for commands like "gf", "[i" and in the tags file. It is also used for "\f" in a pattern .
Multi-byte characters 256 and above are always included, only the characters up to 255 are specified with this option.
For UTF-8 the characters 0xa0 to 0xff are included as well.
Think twice before adding white space to this option. Although a space may appear inside a file name, the effect will be that Vim doesn't know where a file name starts or ends when doing completion. It most likely works better without a space in 'isfname'.

Note that on systems using a backslash as path separator, Vim tries to do its best to make it work as you would expect. That is a bit tricky, since Vi originally used the backslash to escape special characters. Vim will not remove a backslash in front of a normal file name character on these systems, but it will on Unix and alikes. The '&' and '^' are not included by default, because these are special for cmd.exe.

The format of this option is a list of parts, separated with commas. Each part can be a single character number or a range. A range is two character numbers with '-' in between. A character number can be a decimal number between 0 and 255 or the ASCII character itself (does not work for digits). Example:

```
"_,-,128-140,#-43"      (include '_' and '-' and the range
                         128 to 140 and '#' to 43)
```

If a part starts with '^', the following character number or range will be excluded from the option. The option is interpreted from left to right. Put the excluded character after the range where it is included. To include '^' itself use it as the last character of the option or the end of a range. Example:

```
"^a-z,#,^"      (exclude 'a' to 'z', include '#' and '^')
```

If the character is '@', all characters where isalpha() returns TRUE

are included. Normally these are the characters a to z and A to Z,
plus accented characters. To include '@' itself use "@-@". Examples:
	"@,^a-z"	All alphabetic characters, excluding lower
			case ASCII letters.
	"a-z,A-Z,@-@"	All letters plus the '@' character.
A comma can be included by using it where a character number is
expected. Example:
	"48-57,,,_"	Digits, comma and underscore.
A comma can be excluded by prepending a '^'. Example:
	" -~,^,,9"	All characters from space to '~', excluding
			comma, plus <Tab>.
See option-backslash about including spaces and backslashes.

'isident' 'isi'
'isident' 'isi'		string (default for MS-DOS, Win32 and OS/2:
				    "@,48-57,_,128-167,224-235"
			otherwise: "@,48-57,_,192-255")
			global
			{not in Vi}
The characters given by this option are included in identifiers.
Identifiers are used in recognizing environment variables and after a
match of the 'define' option. It is also used for "\i" in a
 pattern . See 'isfname' for a description of the format of this
option.
Careful: If you change this option, it might break expanding
environment variables. E.g., when '/' is included and Vim tries to
expand "$HOME/.viminfo". Maybe you should change 'iskeyword' instead.

'iskeyword' 'isk'
'iskeyword' 'isk'	string (Vim default for MS-DOS and Win32:
				    "@,48-57,_,128-167,224-235"
			   otherwise: "@,48-57,_,192-255"
			Vi default: "@,48-57,_")
			local to buffer
			{not in Vi}
Keywords are used in searching and recognizing with many commands:
"w", "*", "[i", etc. It is also used for "\k" in a pattern . See
'isfname' for a description of the format of this option. For C
programs you could use "a-z,A-Z,48-57,_,.,-,>".
For a help file it is set to all non-blank printable characters except
'*', '"' and '|' (so that CTRL-] on a command finds the help for that
command).
When the 'lisp' option is on the '-' character is always included.
This option also influences syntax highlighting, unless the syntax
uses :syn-iskeyword .
NOTE: This option is set to the Vi default value when 'compatible' is
set and to the Vim default value when 'compatible' is reset.

'isprint' 'isp'
'isprint' 'isp' string (default for MS-DOS, Win32, OS/2 and Macintosh:
			    "@,~-255"; otherwise: "@,161-255")
			global
			{not in Vi}
The characters given by this option are displayed directly on the

screen. It is also used for "\p" in a pattern . The characters from space (ASCII 32) to '~' (ASCII 126) are always displayed directly, even when they are not included in 'isprint' or excluded. See 'isfname' for a description of the format of this option.

Non-printable characters are displayed with two characters:

```
          0 -  31       "^@" - "^_"
         32 - 126       always single characters
            127         "^?"
        128 - 159       "~@" - "~_"
        160 - 254       "| " - "|~"
            255         "~?"
```

When 'encoding' is a Unicode one, illegal bytes from 128 to 255 are displayed as <xx>, with the hexadecimal value of the byte.
When 'display' contains "uhex" all unprintable characters are displayed as <xx>.
The SpecialKey highlighting will be used for unprintable characters.
 hl-SpecialKey

Multi-byte characters 256 and above are always included, only the characters up to 255 are specified with this option. When a character is printable but it is not available in the current font, a replacement character will be shown.
Unprintable and zero-width Unicode characters are displayed as <xxxx>.
There is no option to specify these characters.

'joinspaces' 'js' 'nojoinspaces' 'nojs'
'joinspaces' 'js' boolean (default on)
global
{not in Vi}

Insert two spaces after a '.', '?' and '!' with a join command.
When 'cpoptions' includes the 'j' flag, only do this after a '.'.
Otherwise only one space is inserted.
NOTE: This option is set when 'compatible' is set.

'key'
'key' string (default "")
local to buffer
{not in Vi}
{only available when compiled with the +cryptv feature}

The key that is used for encrypting and decrypting the current buffer.
See encryption and 'cryptmethod'.
Careful: Do not set the key value by hand, someone might see the typed key. Use the :X command. But you can make 'key' empty:

```
:set key=
```

It is not possible to get the value of this option with ":set key" or "echo &key". This is to avoid showing it to someone who shouldn't know. It also means you cannot see it yourself once you have set it, be careful not to make a typing error!
You can use "&key" in an expression to detect whether encryption is enabled. When 'key' is set it returns "*****" (five stars).

'keymap' 'kmp' E544

'keymap' 'kmp'		string	(default "")
			local to buffer
			{not in Vi}
			{only available when compiled with the +keymap
			feature}
	Name of a keyboard mapping. See mbyte-keymap .
	Setting this option to a valid keymap name has the side effect of
	setting 'iminsert' to one, so that the keymap becomes effective.
	'imsearch' is also set to one, unless it was -1
	Only normal file name characters can be used, "/*?[|<>" are illegal.

'keymodel' 'km'		string	(default "")
			global
			{not in Vi}
	List of comma separated words, which enable special things that keys
	can do. These values can be used:
	   startsel	Using a shifted special key starts selection (either
			Select mode or Visual mode, depending on "key" being
			present in 'selectmode').
	   stopsel	Using a not-shifted special key stops selection.
	Special keys in this context are the cursor keys, <End>, <Home>,
	<PageUp> and <PageDown>.
	The 'keymodel' option is set by the :behave command.

'keywordprg' 'kp'	string	(default "man" or "man -s", DOS: ":help",
				VMS: "help")
			global or local to buffer global-local
			{not in Vi}
	Program to use for the K command. Environment variables are
	expanded :set_env . ":help" may be used to access the Vim internal
	help. (Note that previously setting the global option to the empty
	value did this, which is now deprecated.)
	When the first character is ":", the command is invoked as a Vim
	Ex command prefixed with [count].
	When "man", "man -s" or an Ex command is used, Vim will automatically
	translate a count for the "K" command and pass it as the first
	argument. For "man -s" the "-s" is removed when there is no count.
	See option-backslash about including spaces and backslashes.
	Example:
		:set keywordprg=man\ -s
	This option cannot be set from a modeline or in the sandbox , for
	security reasons.

'langmap' 'lmap'	string	(default "")
			global
			{not in Vi}
			{only available when compiled with the +langmap
			feature}
	This option allows switching your keyboard into a special language
	mode. When you are typing text in Insert mode the characters are
	inserted directly. When in Normal mode the 'langmap' option takes

care of translating these special characters to the original meaning
of the key. This means you don't have to change the keyboard mode to
be able to execute Normal mode commands.
This is the opposite of the 'keymap' option, where characters are
mapped in Insert mode.
Also consider resetting 'langremap' to avoid 'langmap' applies to
characters resulting from a mapping.
This option cannot be set from a modeline or in the sandbox , for
security reasons.

Example (for Greek, in UTF-8):   greek
    :set langmap=AA,BB,ΨC,ΔD,EE,ΦF,ΓG,HH,II,ΞJ,KK,ΛL,MM,NN,OO,ΠP,QQ,PR,ΣS,TT,ΘU,ΩV
Example (exchanges meaning of z and y for commands):
    :set langmap=zy,yz,ZY,YZ

The 'langmap' option is a list of parts, separated with commas. Each
part can be in one of two forms:
1. A list of pairs. Each pair is a "from" character immediately
    followed by the "to" character. Examples: "aA", "aAbBcC".
2. A list of "from" characters, a semi-colon and a list of "to"
    characters. Example: "abc;ABC"
Example: "aA,fgh;FGH,cCdDeE"
Special characters need to be preceded with a backslash. These are
";", ',' and backslash itself.

This will allow you to activate vim actions without having to switch
back and forth between the languages. Your language characters will
be understood as normal vim English characters (according to the
langmap mappings) in the following cases:
 o Normal/Visual mode (commands, buffer/register names, user mappings)
 o Insert/Replace Mode: Register names after CTRL-R
 o Insert/Replace Mode: Mappings
Characters entered in Command-line mode will NOT be affected by
this option.   Note that this option can be changed at any time
allowing to switch between mappings for different languages/encodings.
Use a mapping to avoid having to type it each time!

                                        'langmenu'   'lm'
'langmenu' 'lm'   string (default "")
                        global
                        {not in Vi}
                        {only available when compiled with the +menu and
                         +multi_lang features}
Language to use for menu translation. Tells which file is loaded
from the "lang" directory in 'runtimepath':
        "lang/menu_" . &langmenu . ".vim"
(without the spaces). For example, to always use the Dutch menus, no
matter what $LANG is set to:
        :set langmenu=nl_NL.ISO_8859-1
When 'langmenu' is empty, v:lang is used.
Only normal file name characters can be used, "/*?[|<>" are illegal.
If your $LANG is set to a non-English language but you do want to use
the English menus:
        :set langmenu=none

This option must be set before loading menus, switching on filetype detection or syntax highlighting. Once the menus are defined setting this option has no effect. But you could do this:

```
:source $VIMRUNTIME/delmenu.vim
:set langmenu=de_DE.ISO_8859-1
:source $VIMRUNTIME/menu.vim
```

Warning: This deletes all menus that you defined yourself!

'langnoremap' 'lnr' 'nolangnoremap' 'nolnr'
'langnoremap' 'lnr' boolean (default off, set in defaults.vim)
global
{not in Vi}
{only available when compiled with the +langmap feature}

This is just like 'langremap' but with the value inverted. It only exists for backwards compatibility. When setting 'langremap' then 'langnoremap' is set to the inverted value, and the other way around.

'langremap' 'lrm' 'nolangremap' 'nolrm'
'langremap' 'lrm' boolean (default on, reset in defaults.vim)
global
{not in Vi}
{only available when compiled with the +langmap feature}

When off, setting 'langmap' does not apply to characters resulting from a mapping. This basically means, if you noticed that setting 'langmap' disables some of your mappings, try resetting this option. This option defaults to on for backwards compatibility. Set it off if that works for you to avoid mappings to break.

'laststatus' 'ls'
'laststatus' 'ls' number (default 1)
global
{not in Vi}

The value of this option influences when the last window will have a status line:

```
0: never
1: only if there are at least two windows
2: always
```

The screen looks nicer with a status line if you have several windows, but it takes another screen line. status-line

'lazyredraw' 'lz' 'nolazyredraw' 'nolz'
'lazyredraw' 'lz' boolean (default off)
global
{not in Vi}

When this option is set, the screen will not be redrawn while executing macros, registers and other commands that have not been typed. Also, updating the window title is postponed. To force an update use :redraw .

'linebreak' 'lbr' 'nolinebreak' 'nolbr'
'linebreak' 'lbr' boolean (default off)
local to window

{not in Vi}
{not available when compiled without the +linebreak feature}

If on, Vim will wrap long lines at a character in 'breakat' rather than at the last character that fits on the screen. Unlike 'wrapmargin' and 'textwidth', this does not insert <EOL>s in the file, it only affects the way the file is displayed, not its contents. If 'breakindent' is set, line is visually indented. Then, the value of 'showbreak' is used to put in front of wrapped lines. This option is not used when the 'wrap' option is off.
Note that <Tab> characters after an <EOL> are mostly not displayed with the right amount of white space.

'lines' E593

'lines' number (default 24 or terminal height)
global

Number of lines of the Vim window.
Normally you don't need to set this. It is done automatically by the terminal initialization code. Also see posix-screen-size .
When Vim is running in the GUI or in a resizable window, setting this option will cause the window size to be changed. When you only want to use the size for the GUI, put the command in your gvimrc file.
Vim limits the number of lines to what fits on the screen. You can use this command to get the tallest window possible:

```
:set lines=999
```

Minimum value is 2, maximum value is 1000.
If you get fewer lines than expected, check the 'guiheadroom' option.
When you set this option and Vim is unable to change the physical number of lines of the display, the display may be messed up.

'linespace' 'lsp'

'linespace' 'lsp' number (default 0, 1 for Win32 GUI)
global
{not in Vi}
{only in the GUI}

Number of pixel lines inserted between characters. Useful if the font uses the full character cell height, making lines touch each other. When non-zero there is room for underlining.
With some fonts there can be too much room between lines (to have space for ascents and descents). Then it makes sense to set 'linespace' to a negative value. This may cause display problems though!

'lisp' 'nolisp'

'lisp' boolean (default off)
local to buffer
{not available when compiled without the +lispindent feature}

Lisp mode: When <Enter> is typed in insert mode set the indent for the next line to Lisp standards (well, sort of). Also happens with "cc" or "S". 'autoindent' must also be on for this to work. The 'p' flag in 'cpoptions' changes the method of indenting: Vi compatible or better. Also see 'lispwords'.
The '-' character is included in keyword characters. Redefines the

"=" operator to use this same indentation algorithm rather than
calling an external program if 'equalprg' is empty.
This option is not used when 'paste' is set.
{Vi: Does it a little bit differently}

'lispwords' 'lw'

'lispwords' 'lw'	string (default is very long)
global or local to buffer global-local
{not in Vi}
{not available when compiled without the +lispindent
feature}
Comma separated list of words that influence the Lisp indenting.
'lisp'

'list' 'nolist'

'list'	boolean (default off)
local to window
List mode: Show tabs as CTRL-I is displayed, display $ after end of
line. Useful to see the difference between tabs and spaces and for
trailing blanks. Further changed by the 'listchars' option.

The cursor is displayed at the start of the space a Tab character
occupies, not at the end as usual in Normal mode. To get this cursor
position while displaying Tabs with spaces, use:
:set list lcs=tab:\ \

Note that list mode will also affect formatting (set with 'textwidth'
or 'wrapmargin') when 'cpoptions' includes 'L'. See 'listchars' for
changing the way tabs are displayed.

'listchars' 'lcs'

'listchars' 'lcs'	string (default "eol:$")
global
{not in Vi}
Strings to use in 'list' mode and for the :list command. It is a
comma separated list of string settings.

lcs-eol
eol:c	Character to show at the end of each line. When
omitted, there is no extra character at the end of the
line.

lcs-tab
tab:xy	Two characters to be used to show a tab. The first
char is used once. The second char is repeated to
fill the space that the tab normally occupies.
"tab:>-" will show a tab that takes four spaces as
">---". When omitted, a tab is show as ^I.

lcs-space
space:c	Character to show for a space. When omitted, spaces
are left blank.

lcs-trail
trail:c	Character to show for trailing spaces. When omitted,
trailing spaces are blank. Overrides the "space"
setting for trailing spaces.

lcs-extends

```
            extends:c     Character to show in the last column, when 'wrap' is
                          off and the line continues beyond the right of the
                          screen.
                                                                lcs-precedes
            precedes:c    Character to show in the first column, when 'wrap'
                          is off and there is text preceding the character
                          visible in the first column.
                                                                lcs-conceal
            conceal:c     Character to show in place of concealed text, when
                          'conceallevel' is set to 1.
                                                                lcs-nbsp
            nbsp:c        Character to show for a non-breakable space character
                          (0xA0 (160 decimal) and U+202F).  Left blank when
                          omitted.

          The characters ':' and ',' should not be used.  UTF-8 characters can
          be used when 'encoding' is "utf-8", otherwise only printable
          characters are allowed.  All characters must be single width.

          Examples:
              :set lcs=tab:>-,trail:-
              :set lcs=tab:>-,eol:<,nbsp:%
              :set lcs=extends:>,precedes:<
        The "NonText" highlighting will be used for "eol", "extends" and
         "precedes".  "SpecialKey" for "nbsp", "space", "tab" and "trail".
          hl-NonText   hl-SpecialKey

                                'lpl'   'nolpl'   'loadplugins'   'noloadplugins'
'loadplugins' 'lpl'     boolean (default on)
                        global
                        {not in Vi}
          When on the plugin scripts are loaded when starting up  load-plugins .
          This option can be reset in your  vimrc  file to disable the loading
          of plugins.
          Note that using the "-u NONE", "-u DEFAULTS" and "--noplugin" command
          line arguments reset this option.  See  -u  and  --noplugin .

                                                        'luadll'
'luadll'                string  (default depends on the build)
                        global
                        {not in Vi}
                        {only available when compiled with the  +lua/dyn
                        feature}
          Specifies the name of the Lua shared library. The default is
          DYNAMIC_LUA_DLL, which was specified at compile time.
          Environment variables are expanded  :set_env .
          This option cannot be set from a  modeline  or in the  sandbox , for
          security reasons.

                                                        'macatsui'   'nomacatsui'
'macatsui'              boolean (default on)
                        global
                        {only available in Mac GUI version}
          This is a workaround for when drawing doesn't work properly.  When set
```

and compiled with multi-byte support ATSUI text drawing is used. When not set ATSUI text drawing is not used. Switch this option off when you experience drawing problems. In a future version the problems may be solved and this option becomes obsolete. Therefore use this method to unset it:

```
if exists('&macatsui')
   set nomacatsui
endif
```

Another option to check if you have drawing problems is 'termencoding'.

'magic' 'nomagic'

'magic' boolean (default on)
global

Changes the special characters that can be used in search patterns. See pattern .
WARNING: Switching this option off most likely breaks plugins! That is because many patterns assume it's on and will fail when it's off. Only switch it off when working with old Vi scripts. In any other situation write patterns that work when 'magic' is on. Include "\M" when you want to /\M .

'makeef' 'mef'

'makeef' 'mef' string (default: "")
global
{not in Vi}
{not available when compiled without the +quickfix feature}

Name of the errorfile for the :make command (see :make_makeprg) and the :grep command.
When it is empty, an internally generated temp file will be used. When "##" is included, it is replaced by a number to make the name unique. This makes sure that the ":make" command doesn't overwrite an existing file.
NOT used for the ":cf" command. See 'errorfile' for that.
Environment variables are expanded :set_env .
See option-backslash about including spaces and backslashes.
This option cannot be set from a modeline or in the sandbox , for security reasons.

'makeencoding' 'menc'

'makeencoding' 'menc' string (default "")
global or local to buffer global-local
{only available when compiled with the +multi_byte feature}
{not in Vi}

Encoding used for reading the output of external commands. When empty, encoding is not converted.
This is used for `:make`, `:lmake`, `:grep`, `:lgrep`, `:grepadd`, `:lgrepadd`, `:cfile`, `:cgetfile`, `:caddfile`, `:lfile`, `:lgetfile`, and `:laddfile`.

This would be mostly useful when you use MS-Windows and set 'encoding' to "utf-8". If +iconv is enabled and GNU libiconv is used, setting

'makeencoding' to "char" has the same effect as setting to the system
locale encoding. Example:
	:set encoding=utf-8
	:set makeencoding=char " system locale is used

'makeprg' 'mp'
'makeprg' 'mp'		string (default "make", VMS: "MMS")
			global or local to buffer global-local
			{not in Vi}
Program to use for the ":make" command. See :make_makeprg .
This option may contain '%' and '#' characters (see :_% and :_#),
which are expanded to the current and alternate file name. Use ::S
to escape file names in case they contain special characters.
Environment variables are expanded :set_env . See option-backslash
about including spaces and backslashes.
Note that a '|' must be escaped twice: once for ":set" and once for
the interpretation of a command. When you use a filter called
"myfilter" do it like this:
    :set makeprg=gmake\ \\\|\ myfilter
The placeholder "$*" can be given (even multiple times) to specify
where the arguments will be included, for example:
    :set makeprg=latex\ \\\\nonstopmode\ \\\\input\\{$*}
This option cannot be set from a modeline or in the sandbox , for
security reasons.

'matchpairs' 'mps'
'matchpairs' 'mps'	string (default "(:),{:},[:]")
			local to buffer
			{not in Vi}
Characters that form pairs. The % command jumps from one to the
other.
Only character pairs are allowed that are different, thus you cannot
jump between two double quotes.
The characters must be separated by a colon.
The pairs must be separated by a comma. Example for including '<' and
'>' (HTML):
	:set mps+=<:>

A more exotic example, to jump between the '=' and ';' in an
assignment, useful for languages like C and Java:
	:au FileType c,cpp,java set mps+==:;

For a more advanced way of using "%", see the matchit.vim plugin in
the $VIMRUNTIME/pack/dist/opt/matchit directory. add-local-help

'matchtime' 'mat'
'matchtime' 'mat'	number (default 5)
			global
			{not in Vi}{in Nvi}
Tenths of a second to show the matching paren, when 'showmatch' is
set. Note that this is not in milliseconds, like other options that
set a time. This is to be compatible with Nvi.

'maxcombine' 'mco'

'maxcombine' 'mco'	number (default 2)
			global
			{not in Vi}
			{only available when compiled with the +multi_byte
			feature}
	The maximum number of combining characters supported for displaying.
	Only used when 'encoding' is "utf-8".
	The default is OK for most languages. Hebrew may require 4.
	Maximum value is 6.
	Even when this option is set to 2 you can still edit text with more
	combining characters, you just can't see them. Use g8 or ga .
	See mbyte-combining .

'maxfuncdepth' 'mfd'
'maxfuncdepth' 'mfd'	number (default 100)
			global
			{not in Vi}
			{not available when compiled without the +eval
			feature}
	Maximum depth of function calls for user functions. This normally
	catches endless recursion. When using a recursive function with
	more depth, set 'maxfuncdepth' to a bigger number. But this will use
	more memory, there is the danger of failing when memory is exhausted.
	Increasing this limit above 200 also changes the maximum for Ex
	command recursion, see E169 .
	See also :function .

'maxmapdepth' 'mmd' E223
'maxmapdepth' 'mmd'	number (default 1000)
			global
			{not in Vi}
	Maximum number of times a mapping is done without resulting in a
	character to be used. This normally catches endless mappings, like
	":map x y" with ":map y x". It still does not catch ":map g wg",
	because the 'w' is used before the next mapping is done. See also
	key-mapping .

'maxmem' 'mm'
'maxmem' 'mm'	number (default between 256 to 5120 (system
			dependent) or half the amount of memory
			available)
			global
			{not in Vi}
	Maximum amount of memory (in Kbyte) to use for one buffer. When this
	limit is reached allocating extra memory for a buffer will cause
	other memory to be freed.
	The maximum usable value is about 2000000. Use this to work without a
	limit.
	The value is ignored when 'swapfile' is off.
	Also see 'maxmemtot'.

'maxmempattern' 'mmp'
'maxmempattern' 'mmp'	number (default 1000)
			global

{not in Vi}
Maximum amount of memory (in Kbyte) to use for pattern matching.
The maximum value is about 2000000. Use this to work without a limit.
E363
When Vim runs into the limit it gives an error message and mostly
behaves like CTRL-C was typed.
Running into the limit often means that the pattern is very
inefficient or too complex. This may already happen with the pattern
"\(.\)*" on a very long line. ".*" works much better.
Might also happen on redraw, when syntax rules try to match a complex
text structure.
Vim may run out of memory before hitting the 'maxmempattern' limit, in
which case you get an "Out of memory" error instead.

'maxmemtot' 'mmt'
'maxmemtot' 'mmt' number (default between 2048 and 10240 (system dependent) or half the amount of memory available)
global
{not in Vi}
Maximum amount of memory in Kbyte to use for all buffers together.
The maximum usable value is about 2000000 (2 Gbyte). Use this to work
without a limit.
On 64 bit machines higher values might work. But hey, do you really
need more than 2 Gbyte for text editing? Keep in mind that text is
stored in the swap file, one can edit files > 2 Gbyte anyway. We do
need the memory to store undo info.
Buffers with 'swapfile' off still count to the total amount of memory
used.
Also see 'maxmem'.

'menuitems' 'mis'
'menuitems' 'mis' number (default 25)
global
{not in Vi}
{not available when compiled without the +menu feature}
Maximum number of items to use in a menu. Used for menus that are
generated from a list of items, e.g., the Buffers menu. Changing this
option has no direct effect, the menu must be refreshed first.

'mkspellmem' 'msm'
'mkspellmem' 'msm' string (default "460000,2000,500")
global
{not in Vi}
{not available when compiled without the +syntax feature}
Parameters for :mkspell . This tunes when to start compressing the
word tree. Compression can be slow when there are many words, but
it's needed to avoid running out of memory. The amount of memory used
per word depends very much on how similar the words are, that's why
this tuning is complicated.

There are three numbers, separated by commas:

{start},{inc},{added}

For most languages the uncompressed word tree fits in memory. {start} gives the amount of memory in Kbyte that can be used before any compression is done. It should be a bit smaller than the amount of memory that is available to Vim.

When going over the {start} limit the {inc} number specifies the amount of memory in Kbyte that can be allocated before another compression is done. A low number means compression is done after less words are added, which is slow. A high number means more memory will be allocated.

After doing compression, {added} times 1024 words can be added before the {inc} limit is ignored and compression is done when any extra amount of memory is needed. A low number means there is a smaller chance of hitting the {inc} limit, less memory is used but it's slower.

The languages for which these numbers are important are Italian and Hungarian. The default works for when you have about 512 Mbyte. If you have 1 Gbyte you could use:

```
:set mkspellmem=900000,3000,800
```

If you have less than 512 Mbyte :mkspell may fail for some languages, no matter what you set 'mkspellmem' to.

'modeline' 'ml' 'nomodeline' 'noml'
'modeline' 'ml' boolean (Vim default: on (off for root), Vi default: off)
local to buffer

'modelines' 'mls'
'modelines' 'mls' number (default 5)
global
{not in Vi}

If 'modeline' is on 'modelines' gives the number of lines that is checked for set commands. If 'modeline' is off or 'modelines' is zero no lines are checked. See modeline .
NOTE: 'modeline' is set to the Vi default value when 'compatible' is set and to the Vim default value when 'compatible' is reset.

'modifiable' 'ma' 'nomodifiable' 'noma'
'modifiable' 'ma' boolean (default on)
local to buffer
{not in Vi} E21

When off the buffer contents cannot be changed. The 'fileformat' and 'fileencoding' options also can't be changed.
Can be reset on startup with the -M command line argument.

'modified' 'mod' 'nomodified' 'nomod'
'modified' 'mod' boolean (default off)
local to buffer
{not in Vi}

When on, the buffer is considered to be modified. This option is set when:

1. A change was made to the text since it was last written. Using the undo command to go back to the original text will reset the option. But undoing changes that were made before writing the buffer will set the option again, since the text is different from when it was written.
2. 'fileformat' or 'fileencoding' is different from its original value. The original value is set when the buffer is read or written. A ":set nomodified" command also resets the original values to the current values and the 'modified' option will be reset.
   Similarly for 'eol' and 'bomb'.

This option is not set when a change is made to the buffer as the result of a BufNewFile, BufRead/BufReadPost, BufWritePost, FileAppendPost or VimLeave autocommand event. See gzip-example for an explanation.
When 'buftype' is "nowrite" or "nofile" this option may be set, but will be ignored.
Note that the text may actually be the same, e.g. 'modified' is set when using "rA" on an "A".

'more' 'nomore'

'more' boolean (Vim default: on, Vi default: off)
global
{not in Vi}

When on, listings pause when the whole screen is filled. You will get the more-prompt . When this option is off there are no pauses, the listing continues until finished.
NOTE: This option is set to the Vi default value when 'compatible' is set and to the Vim default value when 'compatible' is reset.

'mouse' E538

'mouse' string (default "", "a" for GUI, MS-DOS and Win32, set to "a" in defaults.vim)
global
{not in Vi}

Enable the use of the mouse. Only works for certain terminals (xterm, MS-DOS, Win32 win32-mouse , QNX pterm, *BSD console with sysmouse and Linux console with gpm). For using the mouse in the GUI, see gui-mouse .
The mouse can be enabled for different modes:

n	Normal mode and Terminal modes
v	Visual mode
i	Insert mode
c	Command-line mode
h	all previous modes when editing a help file
a	all previous modes
r	for hit-enter and more-prompt prompt

Normally you would enable the mouse in all four modes with:

```
:set mouse=a
```

When the mouse is not enabled, the GUI will still use the mouse for modeless selection. This doesn't move the text cursor.

See mouse-using . Also see 'clipboard' .

Note: When enabling the mouse in a terminal, copy/paste will use the "* register if there is access to an X-server. The xterm handling of the mouse buttons can still be used by keeping the shift key pressed. Also see the 'clipboard' option.

'mousefocus' 'mousef' 'nomousefocus' 'nomousef'
'mousefocus' 'mousef' boolean (default off)
global
{not in Vi}
{only works in the GUI}
The window that the mouse pointer is on is automatically activated. When changing the window layout or window focus in another way, the mouse pointer is moved to the window with keyboard focus. Off is the default because it makes using the pull down menus a little goofy, as a pointer transit may activate a window unintentionally.

'mousehide' 'mh' 'nomousehide' 'nomh'
'mousehide' 'mh' boolean (default on)
global
{not in Vi}
{only works in the GUI}
When on, the mouse pointer is hidden when characters are typed. The mouse pointer is restored when the mouse is moved.

'mousemodel' 'mousem'
'mousemodel' 'mousem' string (default "extend", "popup" for MS-DOS and Win32)
global
{not in Vi}
Sets the model to use for the mouse. The name mostly specifies what the right mouse button is used for:

extend	Right mouse button extends a selection. This works like in an xterm.
popup	Right mouse button pops up a menu. The shifted left mouse button extends a selection. This works like with Microsoft Windows.
popup_setpos	Like "popup", but the cursor will be moved to the position where the mouse was clicked, and thus the selected operation will act upon the clicked object. If clicking inside a selection, that selection will be acted upon, i.e. no cursor move. This implies of course, that right clicking outside a selection will end Visual mode.

Overview of what button does what for each model:

mouse	extend	popup(_setpos)
left click	place cursor	place cursor
left drag	start selection	start selection
shift-left	search word	extend selection
right click	extend selection	popup menu (place cursor)
right drag	extend selection	-
middle click	paste	paste

In the "popup" model the right mouse button produces a pop-up menu. You need to define this first, see popup-menu .
In a terminal the popup menu works if Vim is compiled with the

+insert_expand option.

Note that you can further refine the meaning of buttons with mappings.
See gui-mouse-mapping . But mappings are NOT used for modeless
selection (because that's handled in the GUI code directly).

The 'mousemodel' option is set by the :behave command.

'mouseshape' 'mouses' E547
'mouseshape' 'mouses' string (default "i:beam,r:beam,s:updown,sd:cross,
m:no,ml:up-arrow,v:rightup-arrow")
global
{not in Vi}
{only available when compiled with the +mouseshape
feature}
This option tells Vim what the mouse pointer should look like in
different modes. The option is a comma separated list of parts, much
like used for 'guicursor'. Each part consist of a mode/location-list
and an argument-list:
mode-list:shape,mode-list:shape,..
The mode-list is a dash separated list of these modes/locations:
In a normal window:
n Normal mode
v Visual mode
ve Visual mode with 'selection' "exclusive" (same as 'v',
if not specified)
o Operator-pending mode
i Insert mode
r Replace mode

Others:
c appending to the command-line
ci inserting in the command-line
cr replacing in the command-line
m at the 'Hit ENTER' or 'More' prompts
ml idem, but cursor in the last line
e any mode, pointer below last window
s any mode, pointer on a status line
sd any mode, while dragging a status line
vs any mode, pointer on a vertical separator line
vd any mode, while dragging a vertical separator line
a everywhere

The shape is one of the following:

avail	name	looks like
w x	arrow	Normal mouse pointer
w x	blank	no pointer at all (use with care!)
w x	beam	I-beam
w x	updown	up-down sizing arrows
w x	leftright	left-right sizing arrows
w x	busy	The system's usual busy pointer
w x	no	The system's usual 'no input' pointer
x	udsizing	indicates up-down resizing
x	lrsizing	indicates left-right resizing

```
          x     crosshair       like a big thin +
          x     hand1           black hand
          x     hand2           white hand
          x     pencil          what you write with
          x     question        big ?
          x     rightup-arrow   arrow pointing right-up
        w x     up-arrow        arrow pointing up
          x     <number>        any X11 pointer number (see X11/cursorfont.h)

        The "avail" column contains a 'w' if the shape is available for Win32,
        x for X11.
        Any modes not specified or shapes not available use the normal mouse
        pointer.

        Example:
                :set mouseshape=s:udsizing,m:no
       will make the mouse turn to a sizing arrow over the status lines and
        indicate no input when the hit-enter prompt is displayed (since
        clicking the mouse has no effect in this state.)

                                                        'mousetime'   'mouset'
'mousetime' 'mouset'    number  (default 500)
                        global
                        {not in Vi}
        Only for GUI, MS-DOS, Win32 and Unix with xterm.  Defines the maximum
        time in msec between two mouse clicks for the second click to be
        recognized as a multi click.

                                                        'mzschemedll'
'mzschemedll'           string  (default depends on the build)
                        global
                        {not in Vi}
                        {only available when compiled with the  +mzscheme/dyn
                        feature}
        Specifies the name of the MzScheme shared library. The default is
        DYNAMIC_MZSCH_DLL which was specified at compile time.
        Environment variables are expanded  :set_env .
        The value must be set in the  vimrc  script or earlier.  In the
        startup, before the  load-plugins  step.
        This option cannot be set from a  modeline  or in the  sandbox , for
        security reasons.

                                                        'mzschemegcdll'
'mzschemegcdll'         string  (default depends on the build)
                        global
                        {not in Vi}
                        {only available when compiled with the  +mzscheme/dyn
                        feature}
        Specifies the name of the MzScheme GC shared library. The default is
        DYNAMIC_MZGC_DLL which was specified at compile time.
        The value can be equal to 'mzschemedll' if it includes the GC code.
        Environment variables are expanded  :set_env .
        This option cannot be set from a  modeline  or in the  sandbox , for
        security reasons.
```

'mzquantum' 'mzq'

'mzquantum' 'mzq'	number (default 100)
		global
		{not in Vi}
		{not available when compiled without the +mzscheme
		feature}
	The number of milliseconds between polls for MzScheme threads.
	Negative or zero value means no thread scheduling.
	NOTE: This option is set to the Vim default value when 'compatible'
	is reset.

'nrformats' 'nf'

'nrformats' 'nf'	string (default "bin,octal,hex",
				set to "bin,hex" in defaults.vim)
		local to buffer
		{not in Vi}
	This defines what bases Vim will consider for numbers when using the
	CTRL-A and CTRL-X commands for adding to and subtracting from a number
	respectively; see CTRL-A for more info on these commands.
	alpha	If included, single alphabetical characters will be
		incremented or decremented. This is useful for a list with a
		letter index a), b), etc.		octal-nrformats
	octal	If included, numbers that start with a zero will be considered
		to be octal. Example: Using CTRL-A on "007" results in "010".
	hex	If included, numbers starting with "0x" or "0X" will be
		considered to be hexadecimal. Example: Using CTRL-X on
		"0x100" results in "0x0ff".
	bin	If included, numbers starting with "0b" or "0B" will be
		considered to be binary. Example: Using CTRL-X on
		"0b1000" subtracts one, resulting in "0b0111".
	Numbers which simply begin with a digit in the range 1-9 are always
	considered decimal. This also happens for numbers that are not
	recognized as octal or hex.

'number' 'nu' 'nonumber' 'nonu'

'number' 'nu'		boolean (default off)
		local to window
	Print the line number in front of each line. When the 'n' option is
	excluded from 'cpoptions' a wrapped line will not use the column of
	line numbers (this is the default when 'compatible' isn't set).
	The 'numberwidth' option can be used to set the room used for the line
	number.
	When a long, wrapped line doesn't start with the first character, '-'
	characters are put before the number.
	See hl-LineNr and hl-CursorLineNr for the highlighting used for
	the number.

number_relativenumber

	The 'relativenumber' option changes the displayed number to be
	relative to the cursor. Together with 'number' there are these
	four combinations (cursor in line 3):

		'nonu'		'nu'		'nonu'		'nu'
		'nornu'		'nornu'		'rnu'		'rnu'

```
            |apple          |  1 apple      |  2 apple      |  2 apple
            |pear           |  2 pear       |  1 pear       |  1 pear
            |nobody         |  3 nobody     |  0 nobody     |3   nobody
            |there          |  4 there      |  1 there      |  1 there
```

'numberwidth' *'nuw'*

'numberwidth' *'nuw'* number (Vim default: 4 Vi default: 8)
local to window
{not in Vi}
{only available when compiled with the +linebreak feature}

Minimal number of columns to use for the line number. Only relevant when the 'number' or 'relativenumber' option is set or printing lines with a line number. Since one space is always between the number and the text, there is one less character for the number itself.
The value is the minimum width. A bigger width is used when needed to fit the highest line number in the buffer respectively the number of rows in the window, depending on whether 'number' or 'relativenumber' is set. Thus with the Vim default of 4 there is room for a line number up to 999. When the buffer has 1000 lines five columns will be used.
The minimum value is 1, the maximum value is 10.
NOTE: This option is set to the Vi default value when 'compatible' is set and to the Vim default value when 'compatible' is reset.

'omnifunc' *'ofu'*

'omnifunc' *'ofu'* string (default: empty)
local to buffer
{not in Vi}
{not available when compiled without the +eval or +insert_expand features}

This option specifies a function to be used for Insert mode omni completion with CTRL-X CTRL-O. i_CTRL-X_CTRL-O
See complete-functions for an explanation of how the function is invoked and what it should return.
This option is usually set by a filetype plugin:
:filetype-plugin-on
This option cannot be set from a modeline or in the sandbox , for security reasons.

'opendevice' *'odev'* *'noopendevice'* *'noodev'*

'opendevice' *'odev'* boolean (default off)
global
{not in Vi}
{only for MS-DOS, MS-Windows and OS/2}

Enable reading and writing from devices. This may get Vim stuck on a device that can be opened but doesn't actually do the I/O. Therefore it is off by default.
Note that on MS-Windows editing "aux.h", "lpt1.txt" and the like also result in editing a device.

'operatorfunc' *'opfunc'*

'operatorfunc' 'opfunc' string (default: empty)
                        global
                        {not in Vi}
        This option specifies a function to be called by the g@ operator.
        See :map-operator for more info and an example.

        This option cannot be set from a modeline or in the sandbox , for
        security reasons.

                                              'osfiletype' 'oft'
'osfiletype' 'oft'   string (default: "")
                        local to buffer
                        {not in Vi}
        This option was supported on RISC OS, which has been removed.

                                    'packpath' 'pp'
'packpath' 'pp'   string (default: see 'runtimepath')
                        {not in Vi}
        Directories used to find packages. See packages .

                                                'paragraphs' 'para'
'paragraphs' 'para'   string (default "IPLPPPQPP TPHPLIPpLpItpplpipbp")
                        global
        Specifies the nroff macros that separate paragraphs. These are pairs
        of two letters (see object-motions).

                                                'paste' 'nopaste'
'paste'   boolean (default off)
                        global
                        {not in Vi}
        Put Vim in Paste mode. This is useful if you want to cut or copy
        some text from one window and paste it in Vim. This will avoid
        unexpected effects.
        Setting this option is useful when using Vim in a terminal, where Vim
        cannot distinguish between typed text and pasted text. In the GUI, Vim
        knows about pasting and will mostly do the right thing without 'paste'
        being set. The same is true for a terminal where Vim handles the
        mouse clicks itself.
        This option is reset when starting the GUI. Thus if you set it in
        your .vimrc it will work in a terminal, but not in the GUI. Setting
        'paste' in the GUI has side effects: e.g., the Paste toolbar button
        will no longer work in Insert mode, because it uses a mapping.
        When the 'paste' option is switched on (also when it was already on):
                - mapping in Insert mode and Command-line mode is disabled
                - abbreviations are disabled
                - 'autoindent' is reset
                - 'expandtab' is reset
                - 'formatoptions' is used like it is empty
                - 'revins' is reset
                - 'ruler' is reset
                - 'showmatch' is reset

- 'smartindent' is reset
- 'smarttab' is reset
- 'softtabstop' is set to 0
- 'textwidth' is set to 0
- 'wrapmargin' is set to 0

These options keep their value, but their effect is disabled:
- 'cindent'
- 'indentexpr'
- 'lisp'

NOTE: When you start editing another file while the 'paste' option is on, settings from the modelines or autocommands may change the settings again, causing trouble when pasting text. You might want to set the 'paste' option again.
When the 'paste' option is reset the mentioned options are restored to the value before the moment 'paste' was switched from off to on.
Resetting 'paste' before ever setting it does not have any effect.
Since mapping doesn't work while 'paste' is active, you need to use the 'pastetoggle' option to toggle the 'paste' option with some key.

'pastetoggle' 'pt' string (default "")
global
{not in Vi}

When non-empty, specifies the key sequence that toggles the 'paste' option. This is like specifying a mapping:
```
:map {keys} :set invpaste<CR>
```
Where {keys} is the value of 'pastetoggle'.
The difference is that it will work even when 'paste' is set.
'pastetoggle' works in Insert mode and Normal mode, but not in Command-line mode.
Mappings are checked first, thus overrule 'pastetoggle'. However, when 'paste' is on mappings are ignored in Insert mode, thus you can do this:
```
:map <F10> :set paste<CR>
:map <F11> :set nopaste<CR>
:imap <F10> <C-O>:set paste<CR>
:imap <F11> <nop>
:set pastetoggle=<F11>
```
This will make <F10> start paste mode and <F11> stop paste mode.
Note that typing <F10> in paste mode inserts "<F10>", since in paste mode everything is inserted literally, except the 'pastetoggle' key sequence.
When the value has several bytes 'ttimeoutlen' applies.

'patchexpr' 'pex' string (default "")
global
{not in Vi}
{not available when compiled without the +diff feature}

Expression which is evaluated to apply a patch to a file and generate the resulting new version of the file. See diff-patchexpr .

'patchmode' 'pm' E205 E206

'patchmode' 'pm'		string	(default "")
			global
			{not in Vi}
	When non-empty the oldest version of a file is kept. This can be used
	to keep the original version of a file if you are changing files in a
	source distribution. Only the first time that a file is written a
	copy of the original file will be kept. The name of the copy is the
	name of the original file with the string in the 'patchmode' option
	appended. This option should start with a dot. Use a string like
	".orig" or ".org". 'backupdir' must not be empty for this to work
	(Detail: The backup file is renamed to the patchmode file after the
	new file has been successfully written, that's why it must be possible
	to write a backup file). If there was no file to be backed up, an
	empty file is created.
	When the 'backupskip' pattern matches, a patchmode file is not made.
	Using 'patchmode' for compressed files appends the extension at the
	end (e.g., "file.gz.orig"), thus the resulting name isn't always
	recognized as a compressed file.
	Only normal file name characters can be used, "/*?[|<>" are illegal.

				'path'	'pa'	E343	E345	E347	E854
'path' 'pa'		string	(default on Unix: ".,/usr/include,,"
				  on OS/2:	 ".,/emx/include,,"
				  other systems: ".,,")
			global or local to buffer	global-local
			{not in Vi}
	This is a list of directories which will be searched when using the
	 gf , [f,]f, ^Wf, :find , :sfind , :tabfind and other commands,
	provided that the file being searched for has a relative path (not
	starting with "/", "./" or "../"). The directories in the 'path'
	option may be relative or absolute.
	- Use commas to separate directory names:
		:set path=.,/usr/local/include,/usr/include
      - Spaces can also be used to separate directory names (for backwards
	compatibility with version 3.0). To have a space in a directory
	name, precede it with an extra backslash, and escape the space:
		:set path=.,/dir/with\\\ space
      - To include a comma in a directory name precede it with an extra
	backslash:
		:set path=.,/dir/with\\,comma
      - To search relative to the directory of the current file, use:
		:set path=.
      - To search in the current directory use an empty string between two
	commas:
		:set path=,,
      - A directory name may end in a ':' or '/'.
       - Environment variables are expanded :set_env .
       - When using netrw.vim URLs can be used. For example, adding
	"http://www.vim.org" will make ":find index.html" work.
       - Search upwards and downwards in a directory tree using "*", "**" and
	";". See file-searching for info and syntax.
	{not available when compiled without the |+path_extra| feature}
       - Careful with '\' characters, type two to get one in the option:
		:set path=.,c:\\include

Or just use '/' instead:
:set path=.,c:/include
Don't forget "." or files won't even be found in the same directory as the file!
The maximum length is limited. How much depends on the system, mostly it is something like 256 or 1024 characters.
You can check if all the include files are found, using the value of 'path', see :checkpath .
The use of :set+= and :set-= is preferred when adding or removing directories from the list. This avoids problems when a future version uses another default. To remove the current directory use:
:set path-=
To add the current directory use:
:set path+=
To use an environment variable, you probably need to replace the separator. Here is an example to append $INCL, in which directory names are separated with a semi-colon:
:let &path = &path . "," . substitute($INCL, ';', ',', 'g')
Replace the ';' with a ':' or whatever separator is used. Note that this doesn't work when $INCL contains a comma or white space.

'perldll'
'perldll' string (default depends on the build)
global
{not in Vi}
{only available when compiled with the +perl/dyn feature}
Specifies the name of the Perl shared library. The default is DYNAMIC_PERL_DLL, which was specified at compile time.
Environment variables are expanded :set_env .
This option cannot be set from a modeline or in the sandbox , for security reasons.

'preserveindent' 'pi' 'nopreserveindent' 'nopi'
'preserveindent' 'pi' boolean (default off)
local to buffer
{not in Vi}
When changing the indent of the current line, preserve as much of the indent structure as possible. Normally the indent is replaced by a series of tabs followed by spaces as required (unless 'expandtab' is enabled, in which case only spaces are used). Enabling this option means the indent will preserve as many existing characters as possible for indenting, and only add additional tabs or spaces as required. 'expandtab' does not apply to the preserved white space, a Tab remains a Tab.
NOTE: When using ">>" multiple times the resulting indent is a mix of tabs and spaces. You might not like this.
NOTE: This option is reset when 'compatible' is set.
Also see 'copyindent'.
Use :retab to clean up white space.

'previewheight' 'pvh'
'previewheight' 'pvh' number (default 12)
global

{not in Vi}
{not available when compiled without the +windows or +quickfix features}
Default height for a preview window. Used for :ptag and associated commands. Used for CTRL-W_} when no count is given.

'previewwindow' 'pvw' 'previewwindow' 'nopreviewwindow' 'pvw' 'nopvw' E590
boolean (default off)
local to window
{not in Vi}
{not available when compiled without the +windows or +quickfix features}
Identifies the preview window. Only one window can have this option set. It's normally not set directly, but by using one of the commands :ptag , :pedit , etc.

'printdevice' 'pdev' 'printdevice' 'pdev'
string (default empty)
global
{not in Vi}
{only available when compiled with the +printer feature}
The name of the printer to be used for :hardcopy .
See pdev-option .
This option cannot be set from a modeline or in the sandbox , for security reasons.

'printencoding' 'penc' 'printencoding' 'penc'
String (default empty, except for some systems)
global
{not in Vi}
{only available when compiled with the +printer and +postscript features}
Sets the character encoding used when printing.
See penc-option .

'printexpr' 'pexpr' 'printexpr' 'pexpr'
String (default: see below)
global
{not in Vi}
{only available when compiled with the +printer and +postscript features}
Expression used to print the PostScript produced with :hardcopy .
See pexpr-option .
This option cannot be set from a modeline or in the sandbox , for security reasons.

'printfont' 'pfn' 'printfont' 'pfn'
string (default "courier")
global
{not in Vi}
{only available when compiled with the +printer feature}

The name of the font that will be used for :hardcopy .
See pfn-option .

'printheader' 'pheader'
'printheader' 'pheader' string (default "%<%f%h%m%=Page %N")
global
{not in Vi}
{only available when compiled with the +printer
feature}
The format of the header produced in :hardcopy output.
See pheader-option .

'printmbcharset' 'pmbcs'
'printmbcharset' 'pmbcs' string (default "")
global
{not in Vi}
{only available when compiled with the +printer ,
+postscript and +multi_byte features}
The CJK character set to be used for CJK output from :hardcopy .
See pmbcs-option .

'printmbfont' 'pmbfn'
'printmbfont' 'pmbfn' string (default "")
global
{not in Vi}
{only available when compiled with the +printer ,
+postscript and +multi_byte features}
List of font names to be used for CJK output from :hardcopy .
See pmbfn-option .

'printoptions' 'popt'
'printoptions' 'popt' string (default "")
global
{not in Vi}
{only available when compiled with |+printer| feature}
List of items that control the format of the output of :hardcopy .
See popt-option .

'prompt' 'noprompt'
'prompt' boolean (default on)
global
When on a ":" prompt is used in Ex mode.

'pumheight' 'ph'
'pumheight' 'ph' number (default 0)
global
{not available when compiled without the
+insert_expand feature}
{not in Vi}
Determines the maximum number of items to show in the popup menu for
Insert mode completion. When zero as much space as available is used.
ins-completion-menu .

'pumwidth' 'pw'

'pumwidth' 'pw'		number (default 15)
			global
			{not available when compiled without the
			 +insert_expand feature}
			{not in Vi}
	Determines the minimum width to use for the popup menu for Insert mode
	completion. ins-completion-menu .

'pythondll'
'pythondll'		string (default depends on the build)
			global
			{not in Vi}
			{only available when compiled with the +python/dyn
			feature}
	Specifies the name of the Python 2.x shared library. The default is
	DYNAMIC_PYTHON_DLL, which was specified at compile time.
	Environment variables are expanded :set_env .
	This option cannot be set from a modeline or in the sandbox , for
	security reasons.

'pythonhome'
'pythonhome'		string (default "")
			global
			{not in Vi}
			{only available when compiled with the +python/dyn
			feature}
	Specifies the name of the Python 2.x home directory. When 'pythonhome'
	and the PYTHONHOME environment variable are not set, PYTHON_HOME,
	which was specified at compile time, will be used for the Python 2.x
	home directory.
	Environment variables are expanded :set_env .
	This option cannot be set from a modeline or in the sandbox , for
	security reasons.

'pythonthreedll'
'pythonthreedll'	string (default depends on the build)
			global
			{not in Vi}
			{only available when compiled with the +python3/dyn
			feature}
	Specifies the name of the Python 3 shared library. The default is
	DYNAMIC_PYTHON3_DLL, which was specified at compile time.
	Environment variables are expanded :set_env .
	This option cannot be set from a modeline or in the sandbox , for
	security reasons.

'pythonthreehome'
'pythonthreehome'	string (default "")
			global
			{not in Vi}
			{only available when compiled with the +python3/dyn
			feature}
	Specifies the name of the Python 3 home directory. When
	'pythonthreehome' and the PYTHONHOME environment variable are not set,

PYTHON3_HOME, which was specified at compile time, will be used for the Python 3 home directory.
Environment variables are expanded :set_env .
This option cannot be set from a modeline or in the sandbox , for security reasons.

'pyxversion' 'pyx'

'pyxversion' 'pyx' number (default depends on the build)
global
{not in Vi}
{only available when compiled with the +python or the +python3 feature}

Specifies the python version used for pyx* functions and commands python_x . The default value is as follows:

Compiled with	Default
+python and +python3	0
only +python	2
only +python3	3

Available values are 0, 2 and 3.
If 'pyxversion' is 0, it is set to 2 or 3 after the first execution of any python2/3 commands or functions. E.g. `:py` sets to 2, and `:py3` sets to 3. `:pyx` sets it to 3 if Python 3 is available, otherwise sets to 2 if Python 2 is available.
See also: has-pythonx

If Vim is compiled with only +python or +python3 setting 'pyxversion' has no effect. The pyx* functions and commands are always the same as the compiled version.

This option cannot be set from a modeline or in the sandbox , for security reasons.

'quoteescape' 'qe'

'quoteescape' 'qe' string (default "\")
local to buffer
{not in Vi}

The characters that are used to escape quotes in a string. Used for objects like a', a" and a` a` .
When one of the characters in this option is found inside a string, the following character will be skipped. The default value makes the text "foo\"bar\\" considered to be one string.

'readonly' 'ro' 'noreadonly' 'noro'

'readonly' 'ro' boolean (default off)
local to buffer

If on, writes fail unless you use a '!'. Protects you from accidentally overwriting a file. Default on when Vim is started in read-only mode ("vim -R") or when the executable is called "view".
When using ":w!" the 'readonly' option is reset for the current buffer, unless the 'Z' flag is in 'cpoptions'.
{not in Vi:} When using the ":view" command the 'readonly' option is set for the newly edited buffer.

See 'modifiable' for disallowing changes to the buffer.

'redrawtime' 'rdt' 'redrawtime' 'rdt' number (default 2000)
global
{not in Vi}
{only available when compiled with the +reltime feature}
The time in milliseconds for redrawing the display. This applies to searching for patterns for 'hlsearch', :match highlighting and syntax highlighting.
When redrawing takes more than this many milliseconds no further matches will be highlighted.
For syntax highlighting the time applies per window. When over the limit syntax highlighting is disabled until CTRL-L is used.
This is used to avoid that Vim hangs when using a very complicated pattern.

'regexpengine' 're' 'regexpengine' 're' number (default 0)
global
{not in Vi}
This selects the default regexp engine. two-engines
The possible values are:

0	automatic selection
1	old engine
2	NFA engine

Note that when using the NFA engine and the pattern contains something that is not supported the pattern will not match. This is only useful for debugging the regexp engine.
Using automatic selection enables Vim to switch the engine, if the default engine becomes too costly. E.g., when the NFA engine uses too many states. This should prevent Vim from hanging on a combination of a complex pattern with long text.

'relativenumber' 'rnu' 'norelativenumber' 'nornu' 'relativenumber' 'rnu' boolean (default off)
local to window
{not in Vi}
Show the line number relative to the line with the cursor in front of each line. Relative line numbers help you use the count you can precede some vertical motion commands (e.g. j k + -) with, without having to calculate it yourself. Especially useful in combination with other commands (e.g. y d c < > gq gw =).
When the 'n' option is excluded from 'cpoptions' a wrapped line will not use the column of line numbers (this is the default when 'compatible' isn't set).
The 'numberwidth' option can be used to set the room used for the line number.
When a long, wrapped line doesn't start with the first character, '-' characters are put before the number.
See hl-LineNr and hl-CursorLineNr for the highlighting used for the number.

The number in front of the cursor line also depends on the value of 'number', see number_relativenumber for all combinations of the two options.

'remap' 'noremap'
'remap' boolean (default on)
global
Allows for mappings to work recursively. If you do not want this for a single entry, use the :noremap[!] command.
NOTE: To avoid portability problems with Vim scripts, always keep this option at the default "on". Only switch it off when working with old Vi scripts.

'renderoptions' 'rop'
'renderoptions' 'rop' string (default: empty)
global
{not in Vi}
{only available when compiled with GUI and DIRECTX on MS-Windows}
Select a text renderer and set its options. The options depend on the renderer.

Syntax:
set rop=type:{renderer}(,{name}:{value})*

Currently, only one optional renderer is available.

render behavior
directx Vim will draw text using DirectX (DirectWrite). It makes drawn glyphs more beautiful than default GDI.
It requires 'encoding' is "utf-8", and only works on MS-Windows Vista or newer version.

Options:

name	meaning	type	value
gamma	gamma	float	1.0 - 2.2 (maybe)
contrast	enhancedContrast	float	(unknown)
level	clearTypeLevel	float	(unknown)
geom	pixelGeometry	int	0 - 2 (see below)
renmode	renderingMode	int	0 - 6 (see below)
taamode	textAntialiasMode	int	0 - 3 (see below)
scrlines	Scroll Lines	int	(deprecated)

See this URL for detail (except for scrlines):
https://msdn.microsoft.com/en-us/library/dd368190.aspx

For geom: structure of a device pixel.
0 - DWRITE_PIXEL_GEOMETRY_FLAT
1 - DWRITE_PIXEL_GEOMETRY_RGB
2 - DWRITE_PIXEL_GEOMETRY_BGR

See this URL for detail:
https://msdn.microsoft.com/en-us/library/dd368114.aspx

```
For renmode: method of rendering glyphs.
  0 - DWRITE_RENDERING_MODE_DEFAULT
  1 - DWRITE_RENDERING_MODE_ALIASED
  2 - DWRITE_RENDERING_MODE_GDI_CLASSIC
  3 - DWRITE_RENDERING_MODE_GDI_NATURAL
  4 - DWRITE_RENDERING_MODE_NATURAL
  5 - DWRITE_RENDERING_MODE_NATURAL_SYMMETRIC
  6 - DWRITE_RENDERING_MODE_OUTLINE

See this URL for detail:
  https://msdn.microsoft.com/en-us/library/dd368118.aspx

For taamode: antialiasing mode used for drawing text.
  0 - D2D1_TEXT_ANTIALIAS_MODE_DEFAULT
  1 - D2D1_TEXT_ANTIALIAS_MODE_CLEARTYPE
  2 - D2D1_TEXT_ANTIALIAS_MODE_GRAYSCALE
  3 - D2D1_TEXT_ANTIALIAS_MODE_ALIASED

See this URL for detail:
  https://msdn.microsoft.com/en-us/library/dd368170.aspx

For scrlines:
This was used for optimizing scrolling behavior, however this
is now deprecated.  If specified, it is simply ignored.

Example:
  set encoding=utf-8
  set gfn=Ricty_Diminished:h12
  set rop=type:directx

If select a raster font (Courier, Terminal or FixedSys which
have ".fon" extension in file name) to 'guifont', it will be
drawn by GDI as a fallback.

NOTE: It is known that some fonts and options combination
causes trouble on drawing glyphs.

  - 'renmode:5' and 'renmode:6' will not work with some
    special made fonts (True-Type fonts which includes only
    bitmap glyphs).
  - 'taamode:3' will not work with some vector fonts.

NOTE: With this option, you can display colored emoji
(emoticon) in Windows 8.1 or later.  To display colored emoji,
there are some conditions which you should notice.

  - If your font includes non-colored emoji already, it will
    be used.
  - If your font doesn't have emoji, the system chooses an
    alternative symbol font.  On Windows 10, "Segoe UI Emoji"
    will be used.
  - When this alternative font didn't have fixed width glyph,
    emoji might be rendered beyond the bounding box of drawing
    cell.
```

Other render types are currently not supported.

'report'
'report'		number (default 2)
		global
Threshold for reporting number of lines changed. When the number of
changed lines is more than 'report' a message will be given for most
":" commands. If you want it always, set 'report' to 0.
For the ":substitute" command the number of substitutions is used
instead of the number of lines.

'restorescreen' 'rs' 'norestorescreen' 'nors'
'restorescreen' 'rs'	boolean (default on)
		global
		{not in Vi} {only in Windows 95/NT console version}
When set, the screen contents is restored when exiting Vim. This also
happens when executing external commands.

For non-Windows Vim: You can set or reset the 't_ti' and 't_te'
options in your .vimrc. To disable restoring:
	set t_ti= t_te=
To enable restoring (for an xterm):
	set t_ti=^[7^[[r^[[?47h t_te=^[[?47l^[8
(Where ^[is an <Esc>, type CTRL-V <Esc> to insert it)

'revins' 'ri' 'norevins' 'nori'
'revins' 'ri'		boolean (default off)
		global
		{not in Vi}
		{only available when compiled with the +rightleft
		feature}
Inserting characters in Insert mode will work backwards. See "typing
backwards" ins-reverse . This option can be toggled with the CTRL-_
command in Insert mode, when 'allowrevins' is set.
NOTE: This option is reset when 'compatible' is set.
This option is reset when 'paste' is set and restored when 'paste' is
reset.

'rightleft' 'rl' 'norightleft' 'norl'
'rightleft' 'rl'	boolean (default off)
		local to window
		{not in Vi}
		{only available when compiled with the +rightleft
		feature}
When on, display orientation becomes right-to-left, i.e., characters
that are stored in the file appear from the right to the left.
Using this option, it is possible to edit files for languages that
are written from the right to the left such as Hebrew and Arabic.
This option is per window, so it is possible to edit mixed files
simultaneously, or to view the same file in both ways (this is
useful whenever you have a mixed text file with both right-to-left
and left-to-right strings so that both sets are displayed properly
in different windows). Also see rileft.txt .

'rightleftcmd' 'rlc'
'rightleftcmd' 'rlc'	string (default "search")
local to window
{not in Vi}
{only available when compiled with the +rightleft
feature}
Each word in this option enables the command line editing to work in
right-to-left mode for a group of commands:

search "/" and "?" commands

This is useful for languages such as Hebrew, Arabic and Farsi.
The 'rightleft' option must be set for 'rightleftcmd' to take effect.

'rubydll'
'rubydll'	string (default: depends on the build)
global
{not in Vi}
{only available when compiled with the +ruby/dyn
feature}
Specifies the name of the Ruby shared library. The default is
DYNAMIC_RUBY_DLL, which was specified at compile time.
Environment variables are expanded :set_env .
This option cannot be set from a modeline or in the sandbox , for
security reasons.

'ruler' 'ru' 'noruler' 'noru'
'ruler' 'ru'	boolean (default off, set in defaults.vim)
global
{not in Vi}
{not available when compiled without the
+cmdline_info feature}
Show the line and column number of the cursor position, separated by a
comma. When there is room, the relative position of the displayed
text in the file is shown on the far right:
Top	first line is visible
Bot	last line is visible
All	first and last line are visible
45%	relative position in the file
If 'rulerformat' is set, it will determine the contents of the ruler.
Each window has its own ruler. If a window has a status line, the
ruler is shown there. Otherwise it is shown in the last line of the
screen. If the statusline is given by 'statusline' (i.e. not empty),
this option takes precedence over 'ruler' and 'rulerformat'
If the number of characters displayed is different from the number of
bytes in the text (e.g., for a TAB or a multi-byte character), both
the text column (byte number) and the screen column are shown,
separated with a dash.
For an empty line "0-1" is shown.
For an empty buffer the line number will also be zero: "0,0-1".
This option is reset when 'paste' is set and restored when 'paste' is
reset.
If you don't want to see the ruler all the time but want to know where

```
        you are, use "g CTRL-G"  g_CTRL-G .
        NOTE: This option is reset when 'compatible' is set.

                                                    'rulerformat'   'ruf'
'rulerformat' 'ruf'     string  (default empty)
                        global
                        {not in Vi}
                        {not available when compiled without the  +statusline
                        feature}
        When this option is not empty, it determines the content of the ruler
        string, as displayed for the 'ruler' option.
        The format of this option is like that of 'statusline'.
        The default ruler width is 17 characters.  To make the ruler 15
        characters wide, put "%15(" at the start and "%)" at the end.
        Example:
                :set rulerformat=%15(%c%V\ %p%%)

                                    'runtimepath'   'rtp'   vimfiles
'runtimepath' 'rtp'     string  (default:
                                        Unix: "$HOME/.vim,
                                                $VIM/vimfiles,
                                                $VIMRUNTIME,
                                                $VIM/vimfiles/after,
                                                $HOME/.vim/after"
                                        Amiga: "home:vimfiles,
                                                $VIM/vimfiles,
                                                $VIMRUNTIME,
                                                $VIM/vimfiles/after,
                                                home:vimfiles/after"
                                        PC, OS/2: "$HOME/vimfiles,
                                                $VIM/vimfiles,
                                                $VIMRUNTIME,
                                                $VIM/vimfiles/after,
                                                $HOME/vimfiles/after"
                                        Macintosh: "$VIM:vimfiles,
                                                $VIMRUNTIME,
                                                $VIM:vimfiles:after"
                                        RISC-OS: "Choices:vimfiles,
                                                $VIMRUNTIME,
                                                Choices:vimfiles/after"
                                        VMS: "sys$login:vimfiles,
                                                $VIM/vimfiles,
                                                $VIMRUNTIME,
                                                $VIM/vimfiles/after,
                                                sys$login:vimfiles/after")
                        global
                        {not in Vi}
        This is a list of directories which will be searched for runtime
        files:
          filetype.vim  filetypes by file name  new-filetype
          scripts.vim   filetypes by file contents  new-filetype-scripts
          autoload/     automatically loaded scripts  autoload-functions
          colors/       color scheme files  :colorscheme
          compiler/     compiler files  :compiler
```

```
  doc/          documentation  write-local-help
  ftplugin/     filetype plugins  write-filetype-plugin
  indent/       indent scripts  indent-expression
  keymap/       key mapping files  mbyte-keymap
  lang/         menu translations  :menutrans
  menu.vim      GUI menus  menu.vim
  pack/         packages  :packadd
  plugin/       plugin scripts  write-plugin
  print/        files for printing  postscript-print-encoding
  spell/        spell checking files  spell
  syntax/       syntax files  mysyntaxfile
  tutor/        files for vimtutor  tutor

And any other file searched for with the  :runtime  command.

The defaults for most systems are setup to search five locations:
1. In your home directory, for your personal preferences.
2. In a system-wide Vim directory, for preferences from the system
   administrator.
3. In $VIMRUNTIME, for files distributed with Vim.
                                                    after-directory
4. In the "after" directory in the system-wide Vim directory.  This is
   for the system administrator to overrule or add to the distributed
   defaults (rarely needed)
5. In the "after" directory in your home directory.  This is for
   personal preferences to overrule or add to the distributed defaults
   or system-wide settings (rarely needed).

More entries are added when using  packages .  If it gets very long
then `:set rtp` will be truncated, use `:echo &rtp` to see the full
string.

Note that, unlike 'path', no wildcards like "**" are allowed.  Normal
wildcards are allowed, but can significantly slow down searching for
runtime files.  For speed, use as few items as possible and avoid
wildcards.
See  :runtime .
Example:
        :set runtimepath=~/vimruntime,/mygroup/vim,$VIMRUNTIME
This will use the directory "~/vimruntime" first (containing your
personal Vim runtime files), then "/mygroup/vim" (shared between a
group of people) and finally "$VIMRUNTIME" (the distributed runtime
files).
You probably should always include $VIMRUNTIME somewhere, to use the
distributed runtime files.  You can put a directory before $VIMRUNTIME
to find files which replace a distributed runtime files.  You can put
a directory after $VIMRUNTIME to find files which add to distributed
runtime files.
When Vim is started with  --clean  the home directory entries are not
included.
This option cannot be set from a  modeline  or in the  sandbox , for
security reasons.

                                              'scroll'   'scr'
```

'scroll' 'scr'   number (default: half the window height)
                        local to window
        Number of lines to scroll with CTRL-U and CTRL-D commands. Will be
        set to half the number of lines in the window when the window size
        changes. If you give a count to the CTRL-U or CTRL-D command it will
        be used as the new value for 'scroll'. Reset to half the window
        height with ":set scroll=0".   {Vi is a bit different: 'scroll' gives
        the number of screen lines instead of file lines, makes a difference
        when lines wrap}

                                'scrollbind' 'scb' 'noscrollbind' 'noscb'
'scrollbind' 'scb'   boolean (default off)
                        local to window
                        {not in Vi}
        See also scroll-binding . When this option is set, the current
        window scrolls as other scrollbind windows (windows that also have
        this option set) scroll. This option is useful for viewing the
        differences between two versions of a file, see 'diff'.
        See 'scrollopt' for options that determine how this option should be
        interpreted.
        This option is mostly reset when splitting a window to edit another
        file. This means that ":split | edit file" results in two windows
        with scroll-binding, but ":split file" does not.

                                                'scrolljump' 'sj'
'scrolljump' 'sj'   number (default 1)
                        global
                        {not in Vi}
        Minimal number of lines to scroll when the cursor gets off the
        screen (e.g., with "j"). Not used for scroll commands (e.g., CTRL-E,
        CTRL-D). Useful if your terminal scrolls very slowly.
        When set to a negative number from -1 to -100 this is used as the
        percentage of the window height. Thus -50 scrolls half the window
        height.
        NOTE: This option is set to 1 when 'compatible' is set.

                                                'scrolloff' 'so'
'scrolloff' 'so'   number (default 0, set to 5 in defaults.vim)
                        global
                        {not in Vi}
        Minimal number of screen lines to keep above and below the cursor.
        This will make some context visible around where you are working. If
        you set it to a very large value (999) the cursor line will always be
        in the middle of the window (except at the start or end of the file or
        when long lines wrap).
        For scrolling horizontally see 'sidescrolloff'.
        NOTE: This option is set to 0 when 'compatible' is set.

                                                'scrollopt' 'sbo'
'scrollopt' 'sbo'   string (default "ver,jump")
                        global
                        {not in Vi}
        This is a comma-separated list of words that specifies how
        'scrollbind' windows should behave. 'sbo' stands for ScrollBind

Options.
The following words are available:
    ver   Bind vertical scrolling for 'scrollbind' windows
    hor   Bind horizontal scrolling for 'scrollbind' windows
    jump   Applies to the offset between two windows for vertical
                scrolling. This offset is the difference in the first
                displayed line of the bound windows. When moving
                around in a window, another 'scrollbind' window may
                reach a position before the start or after the end of
                the buffer. The offset is not changed though, when
                moving back the 'scrollbind' window will try to scroll
                to the desired position when possible.
                When now making that window the current one, two
                things can be done with the relative offset:
                1. When "jump" is not included, the relative offset is
                   adjusted for the scroll position in the new current
                   window. When going back to the other window, the
                   new relative offset will be used.
                2. When "jump" is included, the other windows are
                   scrolled to keep the same relative offset. When
                   going back to the other window, it still uses the
                   same relative offset.
Also see scroll-binding .
When 'diff' mode is active there always is vertical scroll binding,
even when "ver" isn't there.

                                                'sections'   'sect'
'sections' 'sect'   string (default "SHNHH HUnhsh")
                        global
Specifies the nroff macros that separate sections. These are pairs of
two letters (See object-motions). The default makes a section start
at the nroff macros ".SH", ".NH", ".H", ".HU", ".nh" and ".sh".

                                                'secure'   'nosecure'   E523
'secure'   boolean (default off)
                        global
                        {not in Vi}
When on, ":autocmd", shell and write commands are not allowed in
".vimrc" and ".exrc" in the current directory and map commands are
displayed. Switch it off only if you know that you will not run into
problems, or when the 'exrc' option is off. On Unix this option is
only used if the ".vimrc" or ".exrc" is not owned by you. This can be
dangerous if the systems allows users to do a "chown". You better set
'secure' at the end of your ~/.vimrc then.
This option cannot be set from a modeline or in the sandbox , for
security reasons.

                                                'selection'   'sel'
'selection' 'sel'   string (default "inclusive")
                        global
                        {not in Vi}
This option defines the behavior of the selection. It is only used
in Visual and Select mode.
Possible values:

```
            value        past line     inclusive
            old             no           yes
            inclusive       yes          yes
            exclusive       yes          no
         "past line" means that the cursor is allowed to be positioned one
         character past the line.
         "inclusive" means that the last character of the selection is included
         in an operation.  For example, when "x" is used to delete the
         selection.
         When "old" is used and 'virtualedit' allows the cursor to move past
         the end of line the line break still isn't included.
         Note that when "exclusive" is used and selecting from the end
         backwards, you cannot include the last character of a line, when
         starting in Normal mode and 'virtualedit' empty.

         The 'selection' option is set by the  :behave  command.

                                                  'selectmode'   'slm'
'selectmode' 'slm'      string  (default "")
                        global
                        {not in Vi}
         This is a comma separated list of words, which specifies when to start
         Select mode instead of Visual mode, when a selection is started.
         Possible values:
            mouse        when using the mouse
            key          when using shifted special keys
            cmd          when using "v", "V" or CTRL-V
         See  Select-mode .
         The 'selectmode' option is set by the  :behave  command.

                                                  'sessionoptions'   'ssop'
'sessionoptions' 'ssop' string  (default: "blank,buffers,curdir,folds,
                                        help,options,tabpages,winsize,terminal")
                        global
                        {not in Vi}
                        {not available when compiled without the  +mksession
                        feature}
         Changes the effect of the  :mksession  command.  It is a comma
         separated list of words.  Each word enables saving and restoring
         something:
            word         save and restore
            blank        empty windows
            buffers      hidden and unloaded buffers, not just those in windows
            curdir       the current directory
            folds        manually created folds, opened/closed folds and local
                         fold options
            globals      global variables that start with an uppercase letter
                         and contain at least one lowercase letter.  Only
                         String and Number types are stored.
            help         the help window
            localoptions options and mappings local to a window or buffer (not
                         global values for local options)
            options      all options and mappings (also global values for local
                         options)
```

```
            resize      size of the Vim window: 'lines' and 'columns'
            sesdir      the directory in which the session file is located
                        will become the current directory (useful with
                        projects accessed over a network from different
                        systems)
            slash       backslashes in file names replaced with forward
                        slashes
            tabpages    all tab pages; without this only the current tab page
                        is restored, so that you can make a session for each
                        tab page separately
            terminal    include terminal windows where the command can be restored
            unix        with Unix end-of-line format (single <NL>), even when
                        on Windows or DOS
            winpos      position of the whole Vim window
            winsize     window sizes

        Don't include both "curdir" and "sesdir".
        When neither "curdir" nor "sesdir" is included, file names are stored
        with absolute paths.
        "slash" and "unix" are useful on Windows when sharing session files
        with Unix.  The Unix version of Vim cannot source dos format scripts,
        but the Windows version of Vim can source unix format scripts.

                                                    'shell'   'sh'   E91
'shell' 'sh'            string  (default $SHELL or "sh",
                                 MS-DOS and Win32: "command.com" or
                                 "cmd.exe", OS/2: "cmd")
                        global
        Name of the shell to use for ! and :! commands.  When changing the
        value also check these options: 'shelltype', 'shellpipe', 'shellslash'
        'shellredir', 'shellquote', 'shellxquote' and 'shellcmdflag'.
        It is allowed to give an argument to the command, e.g.  "csh -f".
        See  option-backslash  about including spaces and backslashes.
        Environment variables are expanded  :set_env .

        If the name of the shell contains a space, you might need to enclose
        it in quotes or escape the space.  Example with quotes:
                :set shell=\"c:\program\ files\unix\sh.exe\"\ -f
      Note the backslash before each quote (to avoid starting a comment) and
        each space (to avoid ending the option value).  Also note that the
        "-f" is not inside the quotes, because it is not part of the command
        name.  Vim automagically recognizes the backslashes that are path
        separators.
        Example with escaped space (Vim will do this when initializing the
        option from $SHELL):
                :set shell=/bin/with\\\ space/sh
      The resulting value of 'shell' is  "/bin/with\ space/sh", two
        backslashes are consumed by `:set`.

        Under MS-Windows, when the executable ends in ".com" it must be
        included.  Thus setting the shell to "command.com" or "4dos.com"
        works, but "command" and "4dos" do not work for all commands (e.g.,
        filtering).
        For unknown reasons, when using "4dos.com" the current directory is
```

changed to "C:\". To avoid this set 'shell' like this:
		:set shell=command.com\ /c\ 4dos
	This option cannot be set from a modeline or in the sandbox , for
	security reasons.

'shellcmdflag' 'shcf'
'shellcmdflag' 'shcf'	string (default: "-c";
				 MS-DOS and Win32, when 'shell' does not
				 contain "sh" somewhere: "/c")
			global
			{not in Vi}
	Flag passed to the shell to execute "!" and ":!" commands; e.g.,
	"bash.exe -c ls" or "command.com /c dir". For the MS-DOS-like
	systems, the default is set according to the value of 'shell', to
	reduce the need to set this option by the user.
	On Unix it can have more than one flag. Each white space separated
	part is passed as an argument to the shell command.
	See option-backslash about including spaces and backslashes.
	Also see dos-shell for MS-DOS and MS-Windows.
	This option cannot be set from a modeline or in the sandbox , for
	security reasons.

'shellpipe' 'sp'
'shellpipe' 'sp'	string (default ">", "| tee", "|& tee" or "2>&1| tee")
			global
			{not in Vi}
			{not available when compiled without the +quickfix
			feature}
	String to be used to put the output of the ":make" command in the
	error file. See also :make_makeprg . See option-backslash about
	including spaces and backslashes.
	The name of the temporary file can be represented by "%s" if necessary
	(the file name is appended automatically if no %s appears in the value
	of this option).
	For the Amiga and MS-DOS the default is ">". The output is directly
	saved in a file and not echoed to the screen.
	For Unix the default it "| tee". The stdout of the compiler is saved
	in a file and echoed to the screen. If the 'shell' option is "csh" or
	"tcsh" after initializations, the default becomes "|& tee". If the
	'shell' option is "sh", "ksh", "mksh", "pdksh", "zsh" or "bash" the
	default becomes "2>&1| tee". This means that stderr is also included.
	Before using the 'shell' option a path is removed, thus "/bin/sh" uses
	"sh".
	The initialization of this option is done after reading the ".vimrc"
	and the other initializations, so that when the 'shell' option is set
	there, the 'shellpipe' option changes automatically, unless it was
	explicitly set before.
	When 'shellpipe' is set to an empty string, no redirection of the
	":make" output will be done. This is useful if you use a 'makeprg'
	that writes to 'makeef' by itself. If you want no piping, but do
	want to include the 'makeef', set 'shellpipe' to a single space.
	Don't forget to precede the space with a backslash: ":set sp=\ ".
	In the future pipes may be used for filtering and this option will
	become obsolete (at least for Unix).

This option cannot be set from a modeline or in the sandbox , for security reasons.

'shellquote' 'shq'
'shellquote' 'shq'	string (default: ""; MS-DOS and Win32, when 'shell' contains "sh" somewhere: "\"")
global
{not in Vi}

Quoting character(s), put around the command passed to the shell, for the "!" and ":!" commands. The redirection is kept outside of the quoting. See 'shellxquote' to include the redirection. It's probably not useful to set both options.
This is an empty string by default. Only known to be useful for third-party shells on MS-DOS-like systems, such as the MKS Korn Shell or bash, where it should be "\"". The default is adjusted according the value of 'shell', to reduce the need to set this option by the user. See dos-shell .
This option cannot be set from a modeline or in the sandbox , for security reasons.

'shellredir' 'srr'
'shellredir' 'srr'	string (default ">", ">&" or ">%s 2>&1")
global
{not in Vi}

String to be used to put the output of a filter command in a temporary file. See also :! . See option-backslash about including spaces and backslashes.
The name of the temporary file can be represented by "%s" if necessary (the file name is appended automatically if no %s appears in the value of this option).
The default is ">". For Unix, if the 'shell' option is "csh", "tcsh" or "zsh" during initializations, the default becomes ">&". If the 'shell' option is "sh", "ksh" or "bash" the default becomes ">%s 2>&1". This means that stderr is also included.
For Win32, the Unix checks are done and additionally "cmd" is checked for, which makes the default ">%s 2>&1". Also, the same names with ".exe" appended are checked for.
The initialization of this option is done after reading the ".vimrc" and the other initializations, so that when the 'shell' option is set there, the 'shellredir' option changes automatically unless it was explicitly set before.
In the future pipes may be used for filtering and this option will become obsolete (at least for Unix).
This option cannot be set from a modeline or in the sandbox , for security reasons.

'shellslash' 'ssl' 'noshellslash' 'nossl'
'shellslash' 'ssl'	boolean (default off)
global
{not in Vi} {only for MSDOS, MS-Windows and OS/2}

When set, a forward slash is used when expanding file names. This is useful when a Unix-like shell is used instead of command.com or cmd.exe. Backward slashes can still be typed, but they are changed to forward slashes by Vim.

Note that setting or resetting this option has no effect for some existing file names, thus this option needs to be set before opening any file for best results. This might change in the future. 'shellslash' only works when a backslash can be used as a path separator. To test if this is so use:
```
if exists('+shellslash')
```

'shelltemp' 'stmp' 'noshelltemp' 'nostmp'
'shelltemp' 'stmp' boolean (Vi default off, Vim default on)
global
{not in Vi}

When on, use temp files for shell commands. When off use a pipe. When using a pipe is not possible temp files are used anyway. Currently a pipe is only supported on Unix and MS-Windows 2K and later. You can check it with:
```
:if has("filterpipe")
```
The advantage of using a pipe is that nobody can read the temp file and the 'shell' command does not need to support redirection. The advantage of using a temp file is that the file type and encoding can be detected. The FilterReadPre, FilterReadPost and FilterWritePre, FilterWritePost autocommands event are not triggered when 'shelltemp' is off. The `system()` function does not respect this option and always uses temp files. NOTE: This option is set to the Vim default value when 'compatible' is reset.

'shelltype' 'st'
'shelltype' 'st' number (default 0)
global
{not in Vi} {only for the Amiga}

On the Amiga this option influences the way how the commands work which use a shell.
0 and 1: always use the shell
2 and 3: use the shell only to filter lines
4 and 5: use shell only for ':sh' command
When not using the shell, the command is executed directly.

0 and 2: use "shell 'shellcmdflag' cmd" to start external commands
1 and 3: use "shell cmd" to start external commands

'shellxescape' 'sxe'
'shellxescape' 'sxe' string (default: "";
for MS-DOS and MS-Windows: "\"&|<>()@^")
global
{not in Vi}

When 'shellxquote' is set to "(" then the characters listed in this option will be escaped with a '^' character. This makes it possible to execute most external commands with cmd.exe.

'shellxquote' 'sxq'
'shellxquote' 'sxq' string (default: "";
for Win32, when 'shell' is cmd.exe: "("

```
                                        for Win32, when 'shell' contains "sh"
                                        somewhere: "\""
                                        for Unix, when using system(): "\"")
                        global
                        {not in Vi}
        Quoting character(s), put around the command passed to the shell, for
        the "!" and ":!" commands.  Includes the redirection.  See
        'shellquote' to exclude the redirection.  It's probably not useful
        to set both options.
        When the value is '(' then ')' is appended. When the value is '"('
        then ')"' is appended.
        When the value is '(' then also see 'shellxescape'.
        This is an empty string by default on most systems, but is known to be
        useful for on Win32 version, either for cmd.exe which automatically
        strips off the first and last quote on a command, or 3rd-party shells
        such as the MKS Korn Shell or bash, where it should be "\"".  The
        default is adjusted according the value of 'shell', to reduce the need
        to set this option by the user.  See  dos-shell .
        This option cannot be set from a  modeline  or in the  sandbox , for
        security reasons.

                         'shiftround'   'sr'   'noshiftround'   'nosr'
'shiftround' 'sr'       boolean (default off)
                        global
                        {not in Vi}
        Round indent to multiple of 'shiftwidth'.  Applies to > and <
        commands.  CTRL-T and CTRL-D in Insert mode always round the indent to
        a multiple of 'shiftwidth' (this is Vi compatible).
        NOTE: This option is reset when 'compatible' is set.

                                                'shiftwidth'   'sw'
'shiftwidth' 'sw'       number  (default 8)
                        local to buffer
        Number of spaces to use for each step of (auto)indent.  Used for
         'cindent' ,  >> ,  << , etc.
        When zero the 'ts' value will be used.  Use the  shiftwidth()
        function to get the effective shiftwidth value.

                                                'shortmess'   'shm'
'shortmess' 'shm'       string  (Vim default "filnxtToO", Vi default: "",
                                                    POSIX default: "A")
                        global
                        {not in Vi}
        This option helps to avoid all the  hit-enter  prompts caused by file
        messages, for example  with CTRL-G, and to avoid some other messages.
        It is a list of flags:
         flag   meaning when present
          f     use "(3 of 5)" instead of "(file 3 of 5)"
          i     use "[noeol]" instead of "[Incomplete last line]"
          l     use "999L, 888C" instead of "999 lines, 888 characters"
          m     use "[+]" instead of "[Modified]"
          n     use "[New]" instead of "[New File]"
          r     use "[RO]" instead of "[readonly]"
          w     use "[w]" instead of "written" for file write message
```

```
            and "[a]" instead of "appended" for ':w >> file' command
      x     use "[dos]" instead of "[dos format]", "[unix]" instead of
            "[unix format]" and "[mac]" instead of "[mac format]".
      a     all of the above abbreviations

      o     overwrite message for writing a file with subsequent message
            for reading a file (useful for ":wn" or when 'autowrite' on)
      O     message for reading a file overwrites any previous message.
            Also for quickfix message (e.g., ":cn").
      s     don't give "search hit BOTTOM, continuing at TOP" or "search
            hit TOP, continuing at BOTTOM" messages
      t     truncate file message at the start if it is too long to fit
            on the command-line, "<" will appear in the left most column.
            Ignored in Ex mode.
      T     truncate other messages in the middle if they are too long to
            fit on the command line.  "..." will appear in the middle.
            Ignored in Ex mode.
      W     don't give "written" or "[w]" when writing a file
      A     don't give the "ATTENTION" message when an existing swap file
            is found.
      I     don't give the intro message when starting Vim  :intro .
      c     don't give  ins-completion-menu  messages.  For example,
            "-- XXX completion (YYY)", "match 1 of 2", "The only match",
            "Pattern not found", "Back at original", etc.
      q     use "recording" instead of "recording @a"
      F     don't give the file info when editing a file, like `:silent`
            was used for the command

    This gives you the opportunity to avoid that a change between buffers
    requires you to hit <Enter>, but still gives as useful a message as
    possible for the space available.  To get the whole message that you
    would have got with 'shm' empty, use ":file!"
    Useful values:
        shm=        No abbreviation of message.
        shm=a       Abbreviation, but no loss of information.
        shm=at      Abbreviation, and truncate message when necessary.

    NOTE: This option is set to the Vi default value when 'compatible' is
    set and to the Vim default value when 'compatible' is reset.

                                    'shortname'   'sn'   'noshortname'   'nosn'
'shortname' 'sn'        boolean (default off)
                        local to buffer
                        {not in Vi, not in MS-DOS versions}
    Filenames are assumed to be 8 characters plus one extension of 3
    characters.  Multiple dots in file names are not allowed.  When this
    option is on, dots in file names are replaced with underscores when
    adding an extension (".~" or ".swp").  This option is not available
    for MS-DOS, because then it would always be on.  This option is useful
    when editing files on an MS-DOS compatible filesystem, e.g., messydos
    or crossdos.  When running the Win32 GUI version under Win32s, this
    option is always on by default.

                                                'showbreak'   'sbr'   E595
```

'showbreak' 'sbr'	string (default "")
			global
			{not in Vi}
			{not available when compiled without the +linebreak
			feature}
	String to put at the start of lines that have been wrapped. Useful
	values are "> " or "+++ ":
		:set showbreak=>\
	Note the backslash to escape the trailing space. It's easier like
	this:
		:let &showbreak = '+++ '
	Only printable single-cell characters are allowed, excluding <Tab> and
	comma (in a future version the comma might be used to separate the
	part that is shown at the end and at the start of a line).
	The characters are highlighted according to the '@' flag in
	'highlight'.
	Note that tabs after the showbreak will be displayed differently.
	If you want the 'showbreak' to appear in between line numbers, add the
	"n" flag to 'cpoptions'.

					'showcmd' 'sc' 'noshowcmd' 'nosc'
'showcmd' 'sc'		boolean (Vim default: on, off for Unix,
					 Vi default: off, set in defaults.vim)
			global
			{not in Vi}
			{not available when compiled without the
			 +cmdline_info feature}
	Show (partial) command in the last line of the screen. Set this
	option off if your terminal is slow.
	In Visual mode the size of the selected area is shown:
	- When selecting characters within a line, the number of characters.
	  If the number of bytes is different it is also displayed: "2-6"
	  means two characters and six bytes.
	- When selecting more than one line, the number of lines.
	- When selecting a block, the size in screen characters:
	  {lines}x{columns}.
	NOTE: This option is set to the Vi default value when 'compatible' is
	set and to the Vim default value when 'compatible' is reset.

			'showfulltag' 'sft' 'noshowfulltag' 'nosft'
'showfulltag' 'sft'	boolean (default off)
			global
			{not in Vi}
	When completing a word in insert mode (see ins-completion) from the
	tags file, show both the tag name and a tidied-up form of the search
	pattern (if there is one) as possible matches. Thus, if you have
	matched a C function, you can see a template for what arguments are
	required (coding style permitting).
	Note that this doesn't work well together with having "longest" in
	'completeopt', because the completion from the search pattern may not
	match the typed text.

				'showmatch' 'sm' 'noshowmatch' 'nosm'
'showmatch' 'sm'	boolean (default off)

global
When a bracket is inserted, briefly jump to the matching one. The jump is only done if the match can be seen on the screen. The time to show the match can be set with 'matchtime'.
A Beep is given if there is no match (no matter if the match can be seen or not).
This option is reset when 'paste' is set and restored when 'paste' is reset.
When the 'm' flag is not included in 'cpoptions', typing a character will immediately move the cursor back to where it belongs.
See the "sm" field in 'guicursor' for setting the cursor shape and blinking when showing the match.
The 'matchpairs' option can be used to specify the characters to show matches for. 'rightleft' and 'revins' are used to look for opposite matches.
Also see the matchparen plugin for highlighting the match when moving around pi_paren.txt .
Note: Use of the short form is rated PG.

'showmode' 'smd' 'noshowmode' 'nosmd'
'showmode' 'smd' boolean (Vim default: on, Vi default: off)
global
If in Insert, Replace or Visual mode put a message on the last line. Use the 'M' flag in 'highlight' to set the type of highlighting for this message.
When XIM may be used the message will include "XIM". But this doesn't mean XIM is really active, especially when 'imactivatekey' is not set.
NOTE: This option is set to the Vi default value when 'compatible' is set and to the Vim default value when 'compatible' is reset.

'showtabline' 'stal'
'showtabline' 'stal' number (default 1)
global
{not in Vi}
{not available when compiled without the +windows feature}
The value of this option specifies when the line with tab page labels will be displayed:
0: never
1: only if there are at least two tab pages
2: always
This is both for the GUI and non-GUI implementation of the tab pages line.
See tab-page for more information about tab pages.

'sidescroll' 'ss'
'sidescroll' 'ss' number (default 0)
global
{not in Vi}
The minimal number of columns to scroll horizontally. Used only when the 'wrap' option is off and the cursor is moved off of the screen. When it is zero the cursor will be put in the middle of the screen. When using a slow terminal set it to a large number or 0. When using

a fast terminal use a small number or 1. Not used for "zh" and "zl" commands.

'sidescrolloff' 'siso'

'sidescrolloff' 'siso' number (default 0)
global
{not in Vi}

The minimal number of screen columns to keep to the left and to the right of the cursor if 'nowrap' is set. Setting this option to a value greater than 0 while having 'sidescroll' also at a non-zero value makes some context visible in the line you are scrolling in horizontally (except at beginning of the line). Setting this option to a large value (like 999) has the effect of keeping the cursor horizontally centered in the window, as long as one does not come too close to the beginning of the line.
NOTE: This option is set to 0 when 'compatible' is set.

Example: Try this together with 'sidescroll' and 'listchars' as in the following example to never allow the cursor to move onto the "extends" character:

```
:set nowrap sidescroll=1 listchars=extends:>,precedes:<
:set sidescrolloff=1
```

'signcolumn' 'scl'

'signcolumn' 'scl' string (default "auto")
local to window
{not in Vi}
{not available when compiled without the +signs feature}

Whether or not to draw the signcolumn. Valid values are:

"auto"	only when there is a sign to display
"no"	never
"yes"	always

'smartcase' 'scs' 'nosmartcase' 'noscs'

'smartcase' 'scs' boolean (default off)
global
{not in Vi}

Override the 'ignorecase' option if the search pattern contains upper case characters. Only used when the search pattern is typed and 'ignorecase' option is on. Used for the commands "/", "?", "n", "N", ":g" and ":s". Not used for "*", "#", "gd", tag search, etc. After "*" and "#" you can make 'smartcase' used by doing a "/" command, recalling the search pattern from history and hitting <Enter>.
NOTE: This option is reset when 'compatible' is set.

'smartindent' 'si' 'nosmartindent' 'nosi'

'smartindent' 'si' boolean (default off)
local to buffer
{not in Vi}
{not available when compiled without the +smartindent feature}

Do smart autoindenting when starting a new line. Works for C-like programs, but can also be used for other languages. 'cindent' does something like this, works better in most cases, but is more strict, see C-indenting . When 'cindent' is on or 'indentexpr' is set, setting 'si' has no effect. 'indentexpr' is a more advanced alternative.
Normally 'autoindent' should also be on when using 'smartindent'.
An indent is automatically inserted:
- After a line ending in '{'.
- After a line starting with a keyword from 'cinwords'.
- Before a line starting with '}' (only with the "O" command).
When typing '}' as the first character in a new line, that line is given the same indent as the matching '{'.
When typing '#' as the first character in a new line, the indent for that line is removed, the '#' is put in the first column. The indent is restored for the next line. If you don't want this, use this mapping: ":inoremap # X^H#", where ^H is entered with CTRL-V CTRL-H.
When using the ">>" command, lines starting with '#' are not shifted right.
NOTE: This option is reset when 'compatible' is set.
This option is reset when 'paste' is set and restored when 'paste' is reset.

'smarttab' 'sta' 'nosmarttab' 'nosta'

'smarttab' 'sta' boolean (default off)
global
{not in Vi}

When on, a <Tab> in front of a line inserts blanks according to 'shiftwidth'. 'tabstop' or 'softtabstop' is used in other places. A <BS> will delete a 'shiftwidth' worth of space at the start of the line.
When off, a <Tab> always inserts blanks according to 'tabstop' or 'softtabstop'. 'shiftwidth' is only used for shifting text left or right shift-left-right .
What gets inserted (a <Tab> or spaces) depends on the 'expandtab' option. Also see ins-expandtab . When 'expandtab' is not set, the number of spaces is minimized by using <Tab>s.
This option is reset when 'paste' is set and restored when 'paste' is reset.
NOTE: This option is reset when 'compatible' is set.

'softtabstop' 'sts'

'softtabstop' 'sts' number (default 0)
local to buffer
{not in Vi}

Number of spaces that a <Tab> counts for while performing editing operations, like inserting a <Tab> or using <BS>. It "feels" like <Tab>s are being inserted, while in fact a mix of spaces and <Tab>s is used. This is useful to keep the 'ts' setting at its standard value of 8, while being able to edit like it is set to 'sts'. However, commands like "x" still work on the actual characters.
When 'sts' is zero, this feature is off.
When 'sts' is negative, the value of 'shiftwidth' is used.
'softtabstop' is set to 0 when the 'paste' option is set and restored

when 'paste' is reset.
See also ins-expandtab . When 'expandtab' is not set, the number of spaces is minimized by using <Tab>s.
The 'L' flag in 'cpoptions' changes how tabs are used when 'list' is set.
NOTE: This option is set to 0 when 'compatible' is set.

If Vim is compiled with the +vartabs feature then the value of 'softtabstop' will be ignored if 'varsofttabstop' is set to anything other than an empty string.

'spell' 'nospell'
'spell' boolean (default off)
local to window
{not in Vi}
{not available when compiled without the +syntax feature}
When on spell checking will be done. See spell .
The languages are specified with 'spelllang'.

'spellcapcheck' 'spc'
'spellcapcheck' 'spc' string (default "[.?!]_[\])'" \t]\+")
local to buffer
{not in Vi}
{not available when compiled without the +syntax feature}
Pattern to locate the end of a sentence. The following word will be checked to start with a capital letter. If not then it is highlighted with SpellCap hl-SpellCap (unless the word is also badly spelled).
When this check is not wanted make this option empty.
Only used when 'spell' is set.
Be careful with special characters, see option-backslash about including spaces and backslashes.
To set this option automatically depending on the language, see set-spc-auto .

'spellfile' 'spf'
'spellfile' 'spf' string (default empty)
local to buffer
{not in Vi}
{not available when compiled without the +syntax feature}
Name of the word list file where words are added for the zg and zw commands. It must end in ".{encoding}.add". You need to include the path, otherwise the file is placed in the current directory.
E765
It may also be a comma separated list of names. A count before the zg and zw commands can be used to access each. This allows using a personal word list file and a project word list file.
When a word is added while this option is empty Vim will set it for you: Using the first directory in 'runtimepath' that is writable. If there is no "spell" directory yet it will be created. For the file name the first language name that appears in 'spelllang' is used, ignoring the region.

The resulting ".spl" file will be used for spell checking, it does not have to appear in 'spelllang'.
Normally one file is used for all regions, but you can add the region name if you want to. However, it will then only be used when 'spellfile' is set to it, for entries in 'spelllang' only files without region name will be found.
This option cannot be set from a modeline or in the sandbox , for security reasons.

'spelllang' 'spl'

'spelllang' 'spl' string (default "en")
local to buffer
{not in Vi}
{not available when compiled without the +syntax feature}

A comma separated list of word list names. When the 'spell' option is on spellchecking will be done for these languages. Example:

```
set spelllang=en_us,nl,medical
```

This means US English, Dutch and medical words are recognized. Words that are not recognized will be highlighted.
The word list name must not include a comma or dot. Using a dash is recommended to separate the two letter language name from a specification. Thus "en-rare" is used for rare English words.
A region name must come last and have the form "_xx", where "xx" is the two-letter, lower case region name. You can use more than one region by listing them: "en_us,en_ca" supports both US and Canadian English, but not words specific for Australia, New Zealand or Great Britain. (Note: currently en_au and en_nz dictionaries are older than en_ca, en_gb and en_us).
If the name "cjk" is included East Asian characters are excluded from spell checking. This is useful when editing text that also has Asian words.

E757

As a special case the name of a .spl file can be given as-is. The first "_xx" in the name is removed and used as the region name (_xx is an underscore, two letters and followed by a non-letter). This is mainly for testing purposes. You must make sure the correct encoding is used, Vim doesn't check it.
When 'encoding' is set the word lists are reloaded. Thus it's a good idea to set 'spelllang' after setting 'encoding' to avoid loading the files twice.
How the related spell files are found is explained here: spell-load .

If the spellfile.vim plugin is active and you use a language name for which Vim cannot find the .spl file in 'runtimepath' the plugin will ask you if you want to download the file.

After this option has been set successfully, Vim will source the files "spell/LANG.vim" in 'runtimepath'. "LANG" is the value of 'spelllang' up to the first comma, dot or underscore.
Also see set-spc-auto .

'spellsuggest' 'sps'

'spellsuggest' 'sps'	string (default "best")
global
{not in Vi}
{not available when compiled without the +syntax feature}

Methods used for spelling suggestions. Both for the z= command and the spellsuggest() function. This is a comma-separated list of items:

best	Internal method that works best for English. Finds changes like "fast" and uses a bit of sound-a-like scoring to improve the ordering.

double	Internal method that uses two methods and mixes the results. The first method is "fast", the other method computes how much the suggestion sounds like the bad word. That only works when the language specifies sound folding. Can be slow and doesn't always give better results.

fast	Internal method that only checks for simple changes: character inserts/deletes/swaps. Works well for simple typing mistakes.

{number}	The maximum number of suggestions listed for z= . Not used for spellsuggest() . The number of suggestions is never more than the value of 'lines' minus two.

file:{filename}	Read file {filename}, which must have two columns, separated by a slash. The first column contains the bad word, the second column the suggested good word. Example:

```
theribal/terrible
```

Use this for common mistakes that do not appear at the top of the suggestion list with the internal methods. Lines without a slash are ignored, use this for comments.
The word in the second column must be correct, otherwise it will not be used. Add the word to an ".add" file if it is currently flagged as a spelling mistake.
The file is used for all languages.

expr:{expr}	Evaluate expression {expr}. Use a function to avoid trouble with spaces. v:val holds the badly spelled word. The expression must evaluate to a List of Lists, each with a suggestion and a score.
Example:

```
[['the', 33], ['that', 44]]
```

Set 'verbose' and use z= to see the scores that the internal methods use. A lower score is better.
This may invoke spellsuggest() if you temporarily set 'spellsuggest' to exclude the "expr:" part.

Errors are silently ignored, unless you set the
'verbose' option to a non-zero value.

Only one of "best", "double" or "fast" may be used. The others may
appear several times in any order. Example:
:set sps=file:~/.vim/sugg,best,expr:MySuggest()

This option cannot be set from a modeline or in the sandbox , for
security reasons.

'splitbelow' 'sb' 'nosplitbelow' 'nosb'
'splitbelow' 'sb' boolean (default off)
global
{not in Vi}
{not available when compiled without the +windows
feature}
When on, splitting a window will put the new window below the current
one. :split

'splitright' 'spr' 'nosplitright' 'nospr'
'splitright' 'spr' boolean (default off)
global
{not in Vi}
{not available when compiled without the +vertsplit
feature}
When on, splitting a window will put the new window right of the
current one. :vsplit

'startofline' 'sol' 'nostartofline' 'nosol'
'startofline' 'sol' boolean (default on)
global
{not in Vi}
When "on" the commands listed below move the cursor to the first
non-blank of the line. When off the cursor is kept in the same column
(if possible). This applies to the commands: CTRL-D, CTRL-U, CTRL-B,
CTRL-F, "G", "H", "M", "L", gg, and to the commands "d", "<<" and ">>"
with a linewise operator, with "%" with a count and to buffer changing
commands (CTRL-^, :bnext, :bNext, etc.). Also for an Ex command that
only has a line number, e.g., ":25" or ":+".
In case of buffer changing commands the cursor is placed at the column
where it was the last time the buffer was edited.
NOTE: This option is set when 'compatible' is set.

'statusline' 'stl' E540 E542
'statusline' 'stl' string (default empty)
global or local to window global-local
{not in Vi}
{not available when compiled without the +statusline
feature}
When nonempty, this option determines the content of the status line.
Also see status-line .

The option consists of printf style '%' items interspersed with

normal text. Each status line item is of the form:
  %-0{minwid}.{maxwid}{item}
All fields except the {item} are optional. A single percent sign can
be given as "%%". Up to 80 items can be specified. E541

When the option starts with "%!" then it is used as an expression,
evaluated and the result is used as the option value. Example:
        :set statusline=%!MyStatusLine()
The result can contain %{} items that will be evaluated too.
Note that the "%!" expression is evaluated in the context of the
current window and buffer, while %{} items are evaluated in the
context of the window that the statusline belongs to.

When there is error while evaluating the option then it will be made
empty to avoid further errors. Otherwise screen updating would loop.

Note that the only effect of 'ruler' when this option is set (and
'laststatus' is 2) is controlling the output of CTRL-G .

field	meaning
-	Left justify the item. The default is right justified when minwid is larger than the length of the item.
0	Leading zeroes in numeric items. Overridden by '-'.
minwid	Minimum width of the item, padding as set by '-' & '0'. Value must be 50 or less.
maxwid	Maximum width of the item. Truncation occurs with a '<' on the left for text items. Numeric items will be shifted down to maxwid-2 digits followed by '>'number where number is the amount of missing digits, much like an exponential notation.
item	A one letter code as described below.

Following is a description of the possible statusline items. The
second character in "item" is the type:
        N for number
        S for string
        F for flags as described below
        - not applicable

item	meaning
f S	Path to the file in the buffer, as typed or relative to current directory.
F S	Full path to the file in the buffer.
t S	File name (tail) of file in the buffer.
m F	Modified flag, text is "[+]"; "[-]" if 'modifiable' is off.
M F	Modified flag, text is ",+" or ",-".
r F	Readonly flag, text is "[RO]".
R F	Readonly flag, text is ",RO".
h F	Help buffer flag, text is "[help]".
H F	Help buffer flag, text is ",HLP".
w F	Preview window flag, text is "[Preview]".
W F	Preview window flag, text is ",PRV".
y F	Type of file in the buffer, e.g., "[vim]". See 'filetype'.
Y F	Type of file in the buffer, e.g., ",VIM". See 'filetype'.

```
q S   "[Quickfix List]", "[Location List]" or empty.
k S   Value of "b:keymap_name" or 'keymap' when  :lmap  mappings are
      being used: "<keymap>"
n N   Buffer number.
b N   Value of character under cursor.
B N   As above, in hexadecimal.
o N   Byte number in file of byte under cursor, first byte is 1.
      Mnemonic: Offset from start of file (with one added)
      {not available when compiled without |+byte_offset| feature}
O N   As above, in hexadecimal.
N N   Printer page number.  (Only works in the 'printheader' option.)
l N   Line number.
L N   Number of lines in buffer.
c N   Column number.
v N   Virtual column number.
V N   Virtual column number as -{num}.  Not displayed if equal to 'c'.
p N   Percentage through file in lines as in  CTRL-G .
P S   Percentage through file of displayed window.  This is like the
      percentage described for 'ruler'.  Always 3 in length, unless
      translated.
a S   Argument list status as in default title.  ({current} of {max})
      Empty if the argument file count is zero or one.
{ NF  Evaluate expression between '%{' and '}' and substitute result.
      Note that there is no '%' before the closing '}'.  The
      expression cannot contain a '}' character, call a function to
      work around that.
( -   Start of item group.  Can be used for setting the width and
      alignment of a section.  Must be followed by %) somewhere.
) -   End of item group.  No width fields allowed.
T N   For 'tabline': start of tab page N label.  Use %T after the last
      label.  This information is used for mouse clicks.
X N   For 'tabline': start of close tab N label.  Use %X after the
      label, e.g.: %3Xclose%X.  Use %999X for a "close current tab"
      mark.  This information is used for mouse clicks.
< -   Where to truncate line if too long.  Default is at the start.
      No width fields allowed.
= -   Separation point between left and right aligned items.
      No width fields allowed.
# -   Set highlight group.  The name must follow and then a # again.
      Thus use %#HLname# for highlight group HLname.  The same
      highlighting is used, also for the statusline of non-current
      windows.
* -   Set highlight group to User{N}, where {N} is taken from the
      minwid field, e.g. %1*.  Restore normal highlight with %* or %0*.
      The difference between User{N} and StatusLine  will be applied
      to StatusLineNC for the statusline of non-current windows.
      The number N must be between 1 and 9.  See  hl-User1..9

When displaying a flag, Vim removes the leading comma, if any, when
that flag comes right after plaintext.  This will make a nice display
when flags are used like in the examples below.

When all items in a group becomes an empty string (i.e. flags that are
not set) and a minwid is not set for the group, the whole group will
```

become empty. This will make a group like the following disappear
completely from the statusline when none of the flags are set.
	:set statusline=...%(\ [%M%R%H]%)...
                                                    g:actual_curbuf
Beware that an expression is evaluated each and every time the status
line is displayed. The current buffer and current window will be set
temporarily to that of the window (and buffer) whose statusline is
currently being drawn. The expression will evaluate in this context.
The variable "actual_curbuf" is set to the 'bufnr()' number of the
real current buffer.

The 'statusline' option will be evaluated in the sandbox if set from
a modeline, see sandbox-option .

It is not allowed to change text or jump to another window while
evaluating 'statusline' textlock .

If the statusline is not updated when you want it (e.g., after setting
a variable that's used in an expression), you can force an update by
setting an option without changing its value. Example:
	:let &ro = &ro

A result of all digits is regarded a number for display purposes.
Otherwise the result is taken as flag text and applied to the rules
described above.

Watch out for errors in expressions. They may render Vim unusable!
If you are stuck, hold down ':' or 'Q' to get a prompt, then quit and
edit your .vimrc or whatever with "vim --clean" to get it right.

Examples:
Emulate standard status line with 'ruler' set
  :set statusline=%<%f\ %h%m%r%=%-14.(%l,%c%V%)\ %P
Similar, but add ASCII value of char under the cursor (like "ga")
  :set statusline=%<%f%h%m%r%=%b\ 0x%B\ \ %l,%c%V\ %P
Display byte count and byte value, modified flag in red.
  :set statusline=%<%f%=\ [%1*%M%*%n%R%H]\ %-19(%3l,%02c%03V%)%O'%02b'
  :hi User1 term=inverse,bold cterm=inverse,bold ctermfg=red
Display a ,GZ flag if a compressed file is loaded
  :set statusline=...%r%{VarExists('b:gzflag','\ [GZ]')}%h...
In the :autocmd 's:
  :let b:gzflag = 1
And:
  :unlet b:gzflag
And define this function:
  :function VarExists(var, val)
  :   if exists(a:var) | return a:val | else | return '' | endif
  :endfunction

                                                    'suffixes'   'su'
'suffixes' 'su'		string (default ".bak,~,.o,.h,.info,.swp,.obj")
			global
			{not in Vi}
Files with these suffixes get a lower priority when multiple files

match a wildcard. See suffixes . Commas can be used to separate the suffixes. Spaces after the comma are ignored. A dot is also seen as the start of a suffix. To avoid a dot or comma being recognized as a separator, precede it with a backslash (see option-backslash about including spaces and backslashes).
See 'wildignore' for completely ignoring files.
The use of :set+= and :set-= is preferred when adding or removing suffixes from the list. This avoids problems when a future version uses another default.

'suffixesadd' 'sua'

'suffixesadd' 'sua' string (default "")
local to buffer
{not in Vi}
{not available when compiled without the +file_in_path feature}
Comma separated list of suffixes, which are used when searching for a file for the "gf", "[I", etc. commands. Example:

```
:set suffixesadd=.java
```

'swapfile' 'swf' 'noswapfile' 'noswf'

'swapfile' 'swf' boolean (default on)
local to buffer
{not in Vi}
Use a swapfile for the buffer. This option can be reset when a swapfile is not wanted for a specific buffer. For example, with confidential information that even root must not be able to access.
Careful: All text will be in memory:
- Don't use this for big files.
- Recovery will be impossible!

A swapfile will only be present when 'updatecount' is non-zero and 'swapfile' is set.
When 'swapfile' is reset, the swap file for the current buffer is immediately deleted. When 'swapfile' is set, and 'updatecount' is non-zero, a swap file is immediately created.
Also see swap-file and 'swapsync' .
If you want to open a new buffer without creating a swap file for it, use the :noswapfile modifier.
See 'directory' for where the swap file is created.

This option is used together with 'bufhidden' and 'buftype' to specify special kinds of buffers. See special-buffers .

'swapsync' 'sws'

'swapsync' 'sws' string (default "fsync")
global
{not in Vi}
When this option is not empty a swap file is synced to disk after writing to it. This takes some time, especially on busy unix systems. When this option is empty parts of the swap file may be in memory and not written to disk. When the system crashes you may lose more work. On Unix the system does a sync now and then without Vim asking for it, so the disadvantage of setting this option off is small. On some systems the swap file will not be written at all. For a unix system

setting it to "sync" will use the sync() call instead of the default fsync(), which may work better on some systems.
The 'fsync' option is used for the actual file.

'switchbuf' 'swb' 'switchbuf' 'swb'
string (default "")
global
{not in Vi}
This option controls the behavior when switching between buffers. Possible values (comma separated list):
useopen If included, jump to the first open window that contains the specified buffer (if there is one). Otherwise: Do not examine other windows. This setting is checked with quickfix commands, when jumping to errors (":cc", ":cn", "cp", etc.). It is also used in all buffer related split commands, for example ":sbuffer", ":sbnext", or ":sbrewind".
usetab Like "useopen", but also consider windows in other tab pages.
split If included, split the current window before loading a buffer for a quickfix command that display errors. Otherwise: do not split, use current window.
vsplit Just like "split" but split vertically.
newtab Like "split", but open a new tab page. Overrules "split" when both are present.

'synmaxcol' 'smc' 'synmaxcol' 'smc'
number (default 3000)
local to buffer
{not in Vi}
{not available when compiled without the +syntax feature}
Maximum column in which to search for syntax items. In long lines the text after this column is not highlighted and following lines may not be highlighted correctly, because the syntax state is cleared. This helps to avoid very slow redrawing for an XML file that is one long line.
Set to zero to remove the limit.

'syntax' 'syn' 'syntax' 'syn'
string (default empty)
local to buffer
{not in Vi}
{not available when compiled without the +syntax feature}
When this option is set, the syntax with this name is loaded, unless syntax highlighting has been switched off with ":syntax off". Otherwise this option does not always reflect the current syntax (the b:current_syntax variable does).
This option is most useful in a modeline, for a file which syntax is not automatically recognized. Example, in an IDL file:

```
/* vim: set syntax=idl : */
```

When a dot appears in the value then this separates two filetype names. Example:

```
                /* vim: set syntax=c.doxygen : */
        This will use the "c" syntax first, then the "doxygen" syntax.
        Note that the second one must be prepared to be loaded as an addition,
        otherwise it will be skipped.  More than one dot may appear.
        To switch off syntax highlighting for the current file, use:
                :set syntax=OFF
       To switch syntax highlighting on according to the current value of the
        'filetype' option:
                :set syntax=ON
       What actually happens when setting the 'syntax' option is that the
        Syntax autocommand event is triggered with the value as argument.
        This option is not copied to another buffer, independent of the 's' or
        'S' flag in 'cpoptions'.
        Only normal file name characters can be used, "/\*?[|<>" are illegal.

                                                        'tabline'   'tal'
'tabline' 'tal'         string  (default empty)
                        global
                        {not in Vi}
                        {not available when compiled without the  +windows
                        feature}
        When nonempty, this option determines the content of the tab pages
        line at the top of the Vim window.  When empty Vim will use a default
        tab pages line.  See  setting-tabline  for more info.

        The tab pages line only appears as specified with the 'showtabline'
        option and only when there is no GUI tab line.  When 'e' is in
        'guioptions' and the GUI supports a tab line 'guitablabel' is used
        instead.  Note that the two tab pages lines are very different.

        The value is evaluated like with 'statusline'.  You can use
         tabpagenr() ,  tabpagewinnr()  and  tabpagebuflist()  to figure out
        the text to be displayed.  Use "%1T" for the first label, "%2T" for
        the second one, etc.  Use "%X" items for closing labels.

        Keep in mind that only one of the tab pages is the current one, others
        are invisible and you can't jump to their windows.

                                                        'tabpagemax'   'tpm'
'tabpagemax' 'tpm'      number  (default 10)
                        global
                        {not in Vi}
                        {not available when compiled without the  +windows
                        feature}
        Maximum number of tab pages to be opened by the  -p  command line
        argument or the ":tab all" command.  tabpage

                                                        'tabstop'   'ts'
'tabstop' 'ts'          number  (default 8)
                        local to buffer
        Number of spaces that a <Tab> in the file counts for.  Also see
         :retab  command, and 'softtabstop' option.
```

Note: Setting 'tabstop' to any other value than 8 can make your file
appear wrong in many places (e.g., when printing it).

There are four main ways to use tabs in Vim:
1. Always keep 'tabstop' at 8, set 'softtabstop' and 'shiftwidth' to 4
   (or 3 or whatever you prefer) and use 'noexpandtab'. Then Vim
   will use a mix of tabs and spaces, but typing <Tab> and <BS> will
   behave like a tab appears every 4 (or 3) characters.
2. Set 'tabstop' and 'shiftwidth' to whatever you prefer and use
   'expandtab'. This way you will always insert spaces. The
   formatting will never be messed up when 'tabstop' is changed.
3. Set 'tabstop' and 'shiftwidth' to whatever you prefer and use a
   modeline to set these values when editing the file again. Only
   works when using Vim to edit the file.
4. Always set 'tabstop' and 'shiftwidth' to the same value, and
   'noexpandtab'. This should then work (for initial indents only)
   for any tabstop setting that people use. It might be nice to have
   tabs after the first non-blank inserted as spaces if you do this
   though. Otherwise aligned comments will be wrong when 'tabstop' is
   changed.

If Vim is compiled with the +vartabs feature then the value of
'tabstop' will be ignored if 'vartabstop' is set to anything other
than an empty string.

'tagbsearch' 'tbs' 'notagbsearch' 'notbs'
'tagbsearch' 'tbs' boolean (default on)
global
{not in Vi}
When searching for a tag (e.g., for the :ta command), Vim can either
use a binary search or a linear search in a tags file. Binary
searching makes searching for a tag a LOT faster, but a linear search
will find more tags if the tags file wasn't properly sorted.
Vim normally assumes that your tags files are sorted, or indicate that
they are not sorted. Only when this is not the case does the
'tagbsearch' option need to be switched off.

When 'tagbsearch' is on, binary searching is first used in the tags
files. In certain situations, Vim will do a linear search instead for
certain files, or retry all files with a linear search. When
'tagbsearch' is off, only a linear search is done.

Linear searching is done anyway, for one file, when Vim finds a line
at the start of the file indicating that it's not sorted:
!_TAG_FILE_SORTED 0 /some comment/
[The whitespace before and after the '0' must be a single <Tab>]

When a binary search was done and no match was found in any of the
files listed in 'tags', and case is ignored or a pattern is used
instead of a normal tag name, a retry is done with a linear search.
Tags in unsorted tags files, and matches with different case will only
be found in the retry.

If a tag file indicates that it is case-fold sorted, the second,
linear search can be avoided when case is ignored. Use a value of '2'
in the "!_TAG_FILE_SORTED" line for this. A tag file can be case-fold
sorted with the -f switch to "sort" in most unices, as in the command:
"sort -f -o tags tags". For "Exuberant ctags" version 5.x or higher
(at least 5.5) the --sort=foldcase switch can be used for this as
well. Note that case must be folded to uppercase for this to work.

By default, tag searches are case-sensitive. Case is ignored when
'ignorecase' is set and 'tagcase' is "followic", or when 'tagcase' is
"ignore".
Also when 'tagcase' is "followscs" and 'smartcase' is set, or
'tagcase' is "smart", and the pattern contains only lowercase
characters.

When 'tagbsearch' is off, tags searching is slower when a full match
exists, but faster when no full match exists. Tags in unsorted tags
files may only be found with 'tagbsearch' off.
When the tags file is not sorted, or sorted in a wrong way (not on
ASCII byte value), 'tagbsearch' should be off, or the line given above
must be included in the tags file.
This option doesn't affect commands that find all matching tags (e.g.,
command-line completion and ":help").
{Vi: always uses binary search in some versions}

                                                    'tagcase' 'tc'
'tagcase' 'tc'   string (default "followic")
                        global or local to buffer global-local
                        {not in Vi}
This option specifies how case is handled when searching the tags
file:
   followic   Follow the 'ignorecase' option
   followscs   Follow the 'smartcase' and 'ignorecase' options
   ignore   Ignore case
   match   Match case
   smart   Ignore case unless an upper case letter is used
NOTE: This option is set to the Vi default value when 'compatible' is
set and to the Vim default value when 'compatible' is reset.

                                                'taglength' 'tl'
'taglength' 'tl'   number (default 0)
                        global
If non-zero, tags are significant up to this number of characters.

                         'tagrelative' 'tr' 'notagrelative' 'notr'
'tagrelative' 'tr'   boolean (Vim default: on, Vi default: off)
                        global
                        {not in Vi}
If on and using a tags file in another directory, file names in that
tags file are relative to the directory where the tags file is.
NOTE: This option is set to the Vi default value when 'compatible' is
set and to the Vim default value when 'compatible' is reset.

                                                'tags' 'tag' E433

'tags' 'tag'		string	(default "./tags,tags", when compiled with
				+emacs_tags : "./tags,./TAGS,tags,TAGS")
			global or local to buffer	global-local
	Filenames for the tag command, separated by spaces or commas. To
	include a space or comma in a file name, precede it with a backslash
	(see option-backslash about including spaces and backslashes).
	When a file name starts with "./", the '.' is replaced with the path
	of the current file. But only when the 'd' flag is not included in
	'cpoptions'. Environment variables are expanded :set_env . Also see
	tags-option .
	"*", "**" and other wildcards can be used to search for tags files in
	a directory tree. See file-searching . E.g., "/lib/**/tags" will
	find all files named "tags" below "/lib". The filename itself cannot
	contain wildcards, it is used as-is. E.g., "/lib/**/tags?" will find
	files called "tags?". {not available when compiled without the
	+path_extra feature}
	The tagfiles() function can be used to get a list of the file names
	actually used.
	If Vim was compiled with the +emacs_tags feature, Emacs-style tag
	files are also supported. They are automatically recognized. The
	default value becomes "./tags,./TAGS,tags,TAGS", unless case
	differences are ignored (MS-Windows). emacs-tags
	The use of :set+= and :set-= is preferred when adding or removing
	file names from the list. This avoids problems when a future version
	uses another default.
	{Vi: default is "tags /usr/lib/tags"}

'tagstack' 'tgst'		'tagstack' 'tgst' 'notagstack' 'notgst'
			boolean (default on)
			global
			{not in all versions of Vi}
	When on, the tagstack is used normally. When off, a ":tag" or
	":tselect" command with an argument will not push the tag onto the
	tagstack. A following ":tag" without an argument, a ":pop" command or
	any other command that uses the tagstack will use the unmodified
	tagstack, but does change the pointer to the active entry.
	Resetting this option is useful when using a ":tag" command in a
	mapping which should not change the tagstack.

'tcldll'		'tcldll'
			string	(default depends on the build)
			global
			{not in Vi}
			{only available when compiled with the +tcl/dyn
			feature}
	Specifies the name of the Tcl shared library. The default is
	DYNAMIC_TCL_DLL, which was specified at compile time.
	Environment variables are expanded :set_env .
	This option cannot be set from a modeline or in the sandbox , for
	security reasons.

'term'		'term' E529 E530 E531
			string	(default is $TERM, if that fails:
				in the GUI: "builtin_gui"

```
                                        on Amiga: "amiga"
                                         on BeOS: "beos-ansi"
                                          on Mac: "mac-ansi"
                                         on MiNT: "vt52"
                                       on MS-DOS: "pcterm"
                                         on OS/2: "os2ansi"
                                         on Unix: "ansi"
                                          on VMS: "ansi"
                                       on Win 32: "win32")
                        global
        Name of the terminal.  Used for choosing the terminal control
        characters.  Environment variables are expanded  :set_env .
        For example:
                :set term=$TERM
      See  termcap .

                                                  'termbidi'   'tbidi'
                                                  'notermbidi'   'notbidi'
'termbidi' 'tbidi'      boolean (default off, on for "mlterm")
                        global
                        {not in Vi}
                        {only available when compiled with the  +arabic
                        feature}
        The terminal is in charge of Bi-directionality of text (as specified
        by Unicode).  The terminal is also expected to do the required shaping
        that some languages (such as Arabic) require.
        Setting this option implies that 'rightleft' will not be set when
        'arabic' is set and the value of 'arabicshape' will be ignored.
        Note that setting 'termbidi' has the immediate effect that
        'arabicshape' is ignored, but 'rightleft' isn't changed automatically.
        This option is reset when the GUI is started.
        For further details see  arabic.txt .

                                          'termencoding'   'tenc'
'termencoding' 'tenc'   string  (default ""; with GTK+ GUI: "utf-8"; with
                                                Macintosh GUI: "macroman")
                        global
                        {only available when compiled with the  +multi_byte
                        feature}
                        {not in Vi}
        Encoding used for the terminal.  This specifies what character
        encoding the keyboard produces and the display will understand.  For
        the GUI it only applies to the keyboard ('encoding' is used for the
        display).  Except for the Mac when 'macatsui' is off, then
        'termencoding' should be "macroman".
                                                                  E617
        Note: This does not apply to the GTK+ GUI.  After the GUI has been
        successfully initialized, 'termencoding' is forcibly set to "utf-8".
        Any attempts to set a different value will be rejected, and an error
        message is shown.
        For the Win32 GUI and console versions 'termencoding' is not used,
        because the Win32 system always passes Unicode characters.
        When empty, the same encoding is used as for the 'encoding' option.
        This is the normal value.
```

Not all combinations for 'termencoding' and 'encoding' are valid. See encoding-table .
The value for this option must be supported by internal conversions or iconv(). When this is not possible no conversion will be done and you will probably experience problems with non-ASCII characters.
Example: You are working with the locale set to euc-jp (Japanese) and want to edit a UTF-8 file:

```
:let &termencoding = &encoding
:set encoding=utf-8
```

You need to do this when your system has no locale support for UTF-8.

'termguicolors' 'tgc' E954

'termguicolors' 'tgc' boolean (default off)
global
{not in Vi}
{not available when compiled without the +termguicolors feature}

When on, uses highlight-guifg and highlight-guibg attributes in the terminal (thus using 24-bit color).

Requires a ISO-8613-3 compatible terminal. If setting this option does not work (produces a colorless UI) reading xterm-true-color might help.

For Win32 console, Windows 10 version 1703 (Creators Update) or later is required. Use this check to find out:

```
if has('vcon')
```

This requires Vim to be built with the +vtp feature.

Note that the "cterm" attributes are still used, not the "gui" ones.
NOTE: This option is reset when 'compatible' is set.

'termwinscroll' 'twsl'

'termwinscroll' 'twsl' number (default 10000)
local to buffer
{not in Vi}
{not available when compiled without the +terminal feature}

Number of scrollback lines to keep. When going over this limit the first 10% of the scrollback lines are deleted. This is just to reduce the memory usage. See Terminal-Normal .

'termwinkey' 'twk'

'termwinkey' 'twk' string (default "")
local to window
{not in Vi}

The key that starts a CTRL-W command in a terminal window. Other keys are sent to the job running in the window.
The <> notation can be used, e.g.:

```
:set termwinkey=<C-L>
```

The string must be one key stroke but can be multiple bytes.
When not set CTRL-W is used, so that CTRL-W : gets you to the command line. If 'termwinkey' is set to CTRL-L then CTRL-L : gets you to the command line.

'termwinsize' 'tws'

'termwinsize' 'tws'	string (default "")
			local to window
			{not in Vi}
	Size of the terminal window. Format: {rows}x{columns} or
	{rows}*{columns}.
	- When empty the terminal gets the size from the window.
	- When set with a "x" (e.g., "24x80") the terminal size is not
	  adjusted to the window size. If the window is smaller only the
	  top-left part is displayed.
	- When set with a "*" (e.g., "10*50") the terminal size follows the
	  window size, but will not be smaller than the specified rows and/or
	  columns.
	- When rows is zero then use the height of the window.
	- When columns is zero then use the width of the window.
	- Using "0x0" or "0*0" is the same as empty.

	Examples:
	  "30x0" uses 30 rows and the current window width.
	  "20*0" uses at least 20 rows and the current window width.
	  "0*40" uses the current window height and at least 40 columns.
	Note that the command running in the terminal window may still change
	the size of the terminal. In that case the Vim window will be
	adjusted to that size, if possible.

'terse' 'noterse'

'terse'			boolean (default off)
			global
	When set: Add 's' flag to 'shortmess' option (this makes the message
	for a search that hits the start or end of the file not being
	displayed). When reset: Remove 's' flag from 'shortmess' option. {Vi
	shortens a lot of messages}

'textauto' 'ta' 'notextauto' 'nota'

'textauto' 'ta'		boolean (Vim default: on, Vi default: off)
			global
			{not in Vi}
	This option is obsolete. Use 'fileformats'.
	For backwards compatibility, when 'textauto' is set, 'fileformats' is
	set to the default value for the current system. When 'textauto' is
	reset, 'fileformats' is made empty.
	NOTE: This option is set to the Vi default value when 'compatible' is
	set and to the Vim default value when 'compatible' is reset.

'textmode' 'tx' 'notextmode' 'notx'

'textmode' 'tx'		boolean (MS-DOS, Win32 and OS/2: default on,
				 others: default off)
			local to buffer
			{not in Vi}
	This option is obsolete. Use 'fileformat'.
	For backwards compatibility, when 'textmode' is set, 'fileformat' is
	set to "dos". When 'textmode' is reset, 'fileformat' is set to
	"unix".

'textwidth' 'tw'

'textwidth' 'tw' number (default 0)
local to buffer
{not in Vi}

Maximum width of text that is being inserted. A longer line will be broken after white space to get this width. A zero value disables this.
'textwidth' is set to 0 when the 'paste' option is set and restored when 'paste' is reset.
When 'textwidth' is zero, 'wrapmargin' may be used. See also 'formatoptions' and ins-textwidth .
When 'formatexpr' is set it will be used to break the line.
NOTE: This option is set to 0 when 'compatible' is set.

'thesaurus' 'tsr'

'thesaurus' 'tsr' string (default "")
global or local to buffer global-local
{not in Vi}

List of file names, separated by commas, that are used to lookup words for thesaurus completion commands i_CTRL-X_CTRL-T . Each line in the file should contain words with similar meaning, separated by non-keyword characters (white space is preferred). Maximum line length is 510 bytes.
To obtain a file to be used here, check out this ftp site:
[Sorry this link doesn't work anymore, do you know the right one?]
ftp://ftp.ox.ac.uk/pub/wordlists/ First get the README file.
To include a comma in a file name precede it with a backslash. Spaces after a comma are ignored, otherwise spaces are included in the file name. See option-backslash about using backslashes.
The use of :set+= and :set-= is preferred when adding or removing directories from the list. This avoids problems when a future version uses another default.
Backticks cannot be used in this option for security reasons.

'tildeop' 'top' 'notildeop' 'notop'

'tildeop' 'top' boolean (default off)
global
{not in Vi}

When on: The tilde command "~" behaves like an operator.
NOTE: This option is reset when 'compatible' is set.

'timeout' 'to' 'notimeout' 'noto'

'timeout' 'to' boolean (default on)
global

'ttimeout' 'nottimeout'

'ttimeout' boolean (default off, set in defaults.vim)
global
{not in Vi}

These two options together determine the behavior when part of a mapped key sequence or keyboard code has been received:

'timeout'	'ttimeout'	action
off	off	do not time out

```
   on          on or off       time out on :mappings and key codes
   off         on              time out on key codes
```

If both options are off, Vim will wait until either the complete mapping or key sequence has been received, or it is clear that there is no mapping or key sequence for the received characters. For example: if you have mapped "vl" and Vim has received 'v', the next character is needed to see if the 'v' is followed by an 'l'.
When one of the options is on, Vim will wait for about 1 second for the next character to arrive. After that the already received characters are interpreted as single characters. The waiting time can be changed with the 'timeoutlen' option.
On slow terminals or very busy systems timing out may cause malfunctioning cursor keys. If both options are off, Vim waits forever after an entered <Esc> if there are key codes that start with <Esc>. You will have to type <Esc> twice. If you do not have problems with key codes, but would like to have :mapped key sequences not timing out in 1 second, set the 'ttimeout' option and reset the 'timeout' option.

NOTE: 'ttimeout' is reset when 'compatible' is set.

```
                                                    'timeoutlen'   'tm'
'timeoutlen' 'tm'       number  (default 1000)
                        global
                        {not in all versions of Vi}
                                                    'ttimeoutlen'   'ttm'
'ttimeoutlen' 'ttm'     number  (default -1, set to 100 in  defaults.vim )
                        global
                        {not in Vi}
```

The time in milliseconds that is waited for a key code or mapped key sequence to complete. Also used for CTRL-\ CTRL-N and CTRL-\ CTRL-G when part of a command has been typed.
Normally only 'timeoutlen' is used and 'ttimeoutlen' is -1. When a different timeout value for key codes is desired set 'ttimeoutlen' to a non-negative number.

```
            ttimeoutlen     mapping delay      key code delay
               < 0          'timeoutlen'       'timeoutlen'
              >= 0          'timeoutlen'       'ttimeoutlen'
```

The timeout only happens when the 'timeout' and 'ttimeout' options tell so. A useful setting would be
```
        :set timeout timeoutlen=3000 ttimeoutlen=100
```
(time out on mapping after three seconds, time out on key codes after a tenth of a second).

```
                                                    'title'   'notitle'
'title'                 boolean (default off, on when title can be restored)
                        global
                        {not in Vi}
                        {not available when compiled without the  +title
                        feature}
```

When on, the title of the window will be set to the value of

'titlestring' (if it is not empty), or to:
        filename [+=-] (path) - VIM
Where:
        filename   the name of the file being edited
        -               indicates the file cannot be modified, 'ma' off
        +   indicates the file was modified
        =   indicates the file is read-only
        =+   indicates the file is read-only and modified
        (path)   is the path of the file being edited
        - VIM   the server name v:servername or "VIM"
Only works if the terminal supports setting window titles
(currently Amiga console, Win32 console, all GUI versions and
terminals with a non- empty 't_ts' option - these are Unix xterm and
iris-ansi by default, where 't_ts' is taken from the builtin termcap).
                                                        X11
When Vim was compiled with HAVE_X11 defined, the original title will
be restored if possible. The output of ":version" will include "+X11"
when HAVE_X11 was defined, otherwise it will be "-X11". This also
works for the icon name 'icon' .
But: When Vim was started with the -X argument, restoring the title
will not work (except in the GUI).
If the title cannot be restored, it is set to the value of 'titleold'.
You might want to restore the title outside of Vim then.
When using an xterm from a remote machine you can use this command:
    rsh machine_name xterm -display $DISPLAY &
then the WINDOWID environment variable should be inherited and the
title of the window should change back to what it should be after
exiting Vim.

                                                        'titlelen'
'titlelen'   number (default 85)
                        global
                        {not in Vi}
                        {not available when compiled without the +title
                        feature}
Gives the percentage of 'columns' to use for the length of the window
title. When the title is longer, only the end of the path name is
shown. A '<' character before the path name is used to indicate this.
Using a percentage makes this adapt to the width of the window. But
it won't work perfectly, because the actual number of characters
available also depends on the font used and other things in the title
bar. When 'titlelen' is zero the full path is used. Otherwise,
values from 1 to 30000 percent can be used.
'titlelen' is also used for the 'titlestring' option.

                                                    'titleold'
'titleold'   string (default "Thanks for flying Vim")
                        global
                        {not in Vi}
                        {only available when compiled with the +title
                        feature}
This option will be used for the window title when exiting Vim if the
original title cannot be restored. Only happens if 'title' is on or
'titlestring' is not empty.

This option cannot be set from a modeline or in the sandbox, for security reasons.

'titlestring'

'titlestring' string (default "")
global
{not in Vi}
{not available when compiled without the +title feature}

When this option is not empty, it will be used for the title of the window. This happens only when the 'title' option is on.
Only works if the terminal supports setting window titles (currently Amiga console, Win32 console, all GUI versions and terminals with a non-empty 't_ts' option).
When Vim was compiled with HAVE_X11 defined, the original title will be restored if possible, see X11.
When this option contains printf-style '%' items, they will be expanded according to the rules used for 'statusline'.
Example:

```
:auto BufEnter * let &titlestring = hostname() . "/" . expand("%:p")
:set title titlestring=%<%F%=%l/%L-%P titlelen=70
```

The value of 'titlelen' is used to align items in the middle or right of the available space.
Some people prefer to have the file name first:

```
:set titlestring=%t%(\ %M%)%(\ (%{expand(\"%:~:.:h\")})%)%(\ %a%)
```

Note the use of "%{ }" and an expression to get the path of the file, without the file name. The "%(%)" constructs are used to add a separating space only when needed.
NOTE: Use of special characters in 'titlestring' may cause the display to be garbled (e.g., when it contains a CR or NL character).
{not available when compiled without the |+statusline| feature}

'toolbar' 'tb'

'toolbar' 'tb' string (default "icons,tooltips")
global
{only for +GUI_GTK, +GUI_Athena, +GUI_Motif and +GUI_Photon}

The contents of this option controls various toolbar settings. The possible values are:

icons	Toolbar buttons are shown with icons.
text	Toolbar buttons shown with text.
horiz	Icon and text of a toolbar button are horizontally arranged. {only in GTK+ 2 GUI}
tooltips	Tooltips are active for toolbar buttons.

Tooltips refer to the popup help text which appears after the mouse cursor is placed over a toolbar button for a brief moment.

If you want the toolbar to be shown with icons as well as text, do the following:

```
:set tb=icons,text
```

Motif and Athena cannot display icons and text at the same time. They will show icons if both are requested.

If none of the strings specified in 'toolbar' are valid or if 'toolbar' is empty, this option is ignored. If you want to disable

the toolbar, you need to set the 'guioptions' option. For example:
```
:set guioptions-=T
```
Also see gui-toolbar .

'toolbariconsize' 'tbis'
'toolbariconsize' 'tbis' string (default "small")
global
{not in Vi}
{only in the GTK+ GUI}

Controls the size of toolbar icons. The possible values are:

tiny	Use tiny icons.
small	Use small icons (default).
medium	Use medium-sized icons.
large	Use large icons.
huge	Use even larger icons.
giant	Use very big icons.

The exact dimensions in pixels of the various icon sizes depend on the current theme. Common dimensions are giant=48x48, huge=32x32, large=24x24, medium=24x24, small=20x20 and tiny=16x16.

If 'toolbariconsize' is empty, the global default size as determined by user preferences or the current theme is used.

'ttybuiltin' 'tbi' 'nottybuiltin' 'notbi'
'ttybuiltin' 'tbi' boolean (default on)
global
{not in Vi}

When on, the builtin termcaps are searched before the external ones. When off the builtin termcaps are searched after the external ones. When this option is changed, you should set the 'term' option next for the change to take effect, for example:
```
:set notbi term=$TERM
```
See also termcap .
Rationale: The default for this option is "on", because the builtin termcap entries are generally better (many systems contain faulty xterm entries...).

'ttyfast' 'tf' 'nottyfast' 'notf'
'ttyfast' 'tf' boolean (default off, on when 'term' is xterm, hpterm, sun-cmd, screen, rxvt, dtterm or iris-ansi; also on when running Vim in a DOS console)
global
{not in Vi}

Indicates a fast terminal connection. More characters will be sent to the screen for redrawing, instead of using insert/delete line commands. Improves smoothness of redrawing when there are multiple windows and the terminal does not support a scrolling region.
Also enables the extra writing of characters at the end of each screen line for lines that wrap. This helps when using copy/paste with the mouse in an xterm and other terminals.

'ttymouse' 'ttym'
'ttymouse' 'ttym' string (default depends on 'term')

global
{not in Vi}
{only in Unix and VMS, doesn't work in the GUI; not
available when compiled without +mouse }
Name of the terminal type for which mouse codes are to be recognized.
Currently these strings are valid:

xterm-mouse

xterm — xterm-like mouse handling. The mouse generates "<Esc>[Mscr", where "scr" is three bytes:
"s" = button state
"c" = column plus 33
"r" = row plus 33
This only works up to 223 columns! See "dec", "urxvt", and "sgr" for solutions.

xterm2 — Works like "xterm", but with the xterm reporting the mouse position while the mouse is dragged. This works much faster and more precise. Your xterm must at least at patchlevel 88 / XFree 3.3.3 for this to work. See below for how Vim detects this automatically.

netterm-mouse

netterm — NetTerm mouse handling. The mouse generates "<Esc>}r,c<CR>", where "r,c" are two decimal numbers for the row and column.

dec-mouse

dec — DEC terminal mouse handling. The mouse generates a rather complex sequence, starting with "<Esc>[". This is also available for an Xterm, if it was configured with "--enable-dec-locator".

jsbterm-mouse

jsbterm — JSB term mouse handling.

pterm-mouse

pterm — QNX pterm mouse handling.

urxvt-mouse

urxvt — Mouse handling for the urxvt (rxvt-unicode) terminal. The mouse works only if the terminal supports this encoding style, but it does not have 223 columns limit unlike "xterm" or "xterm2".

sgr-mouse

sgr — Mouse handling for the terminal that emits SGR-styled mouse reporting. The mouse works even in columns beyond 223. This option is backward compatible with "xterm2" because it can also decode "xterm2" style mouse codes.

The mouse handling must be enabled at compile time +mouse_xterm +mouse_dec +mouse_netterm +mouse_jsbterm +mouse_urxvt +mouse_sgr .
Only "xterm"(2) is really recognized. NetTerm mouse codes are always recognized, if enabled at compile time. DEC terminal mouse codes are recognized if enabled at compile time, and 'ttymouse' is not "xterm", "xterm2", "urxvt" or "sgr" (because dec mouse codes conflict with them).
This option is automatically set to "xterm", when the 'term' option is

set to a name that starts with "xterm", "mlterm", "screen", "tmux", "st" (full match only), "st-" or "stterm", and 'ttymouse' is not set already.
Additionally, if vim is compiled with the +termresponse feature and t_RV is set to the escape sequence to request the xterm version number, more intelligent detection process runs.
The "xterm2" value will be set if the xterm version is reported to be from 95 to 276. The "sgr" value will be set if the xterm version is 277 or higher and when Vim detects Mac Terminal.app or iTerm2.
If you do not want 'ttymouse' to be set to "xterm2" or "sgr" automatically, set t_RV to an empty string:

```
:set t_RV=
```

'ttyscroll' 'tsl'

'ttyscroll' 'tsl' number (default 999)
global
Maximum number of lines to scroll the screen. If there are more lines to scroll the window is redrawn. For terminals where scrolling is very slow and redrawing is not slow this can be set to a small number, e.g., 3, to speed up displaying.

'ttytype' 'tty'

'ttytype' 'tty' string (default from $TERM)
global
Alias for 'term', see above.

'undodir' 'udir'

'undodir' 'udir' string (default ".")
global
{not in Vi}
{only when compiled with the |+persistent_undo| feature}
List of directory names for undo files, separated with commas.
See 'backupdir' for details of the format.
"." means using the directory of the file. The undo file name for "file.txt" is ".file.txt.un~".
For other directories the file name is the full path of the edited file, with path separators replaced with "%".
When writing: The first directory that exists is used. "." always works, no directories after "." will be used for writing.
When reading all entries are tried to find an undo file. The first undo file that exists is used. When it cannot be read an error is given, no further entry is used.
See undo-persistence .

'undofile' 'noundofile' 'udf' 'noudf'

'undofile' 'udf' boolean (default off)
local to buffer
{not in Vi}
{only when compiled with the |+persistent_undo| feature}
When on, Vim automatically saves undo history to an undo file when writing a buffer to a file, and restores undo history from the same file on buffer read.
The directory where the undo file is stored is specified by 'undodir'.
For more information about this feature see undo-persistence .

The undo file is not read when 'undoreload' causes the buffer from
before a reload to be saved for undo.
When 'undofile' is turned off the undo file is NOT deleted.
NOTE: This option is reset when 'compatible' is set.

'undolevels' 'ul'

'undolevels' 'ul'	number (default 100, 1000 for Unix, VMS,
Win32 and OS/2)
global or local to buffer global-local
{not in Vi}
Maximum number of changes that can be undone. Since undo information
is kept in memory, higher numbers will cause more memory to be used
(nevertheless, a single change can use an unlimited amount of memory).
Set to 0 for Vi compatibility: One level of undo and "u" undoes
itself:
set ul=0
But you can also get Vi compatibility by including the 'u' flag in
'cpoptions', and still be able to use CTRL-R to repeat undo.
Also see undo-two-ways .
Set to -1 for no undo at all. You might want to do this only for the
current buffer:
setlocal ul=-1
This helps when you run out of memory for a single change.

The local value is set to -123456 when the global value is to be used.

Also see clear-undo .

'undoreload' 'ur'

'undoreload' 'ur'	number (default 10000)
global
{not in Vi}
Save the whole buffer for undo when reloading it. This applies to the
":e!" command and reloading for when the buffer changed outside of
Vim. FileChangedShell
The save only happens when this option is negative or when the number
of lines is smaller than the value of this option.
Set this option to zero to disable undo for a reload.

When saving undo for a reload, any undo file is not read.

Note that this causes the whole buffer to be stored in memory. Set
this option to a lower value if you run out of memory.

'updatecount' 'uc'

'updatecount' 'uc'	number (default: 200)
global
{not in Vi}
After typing this many characters the swap file will be written to
disk. When zero, no swap file will be created at all (see chapter on
recovery crash-recovery). 'updatecount' is set to zero by starting
Vim with the "-n" option, see startup . When editing in readonly
mode this option will be initialized to 10000.
The swapfile can be disabled per buffer with 'swapfile' .

When 'updatecount' is set from zero to non-zero, swap files are created for all buffers that have 'swapfile' set. When 'updatecount' is set to zero, existing swap files are not deleted.
Also see 'swapsync' .
This option has no meaning in buffers where 'buftype' is "nofile" or "nowrite".

'updatetime' 'ut'

'updatetime' 'ut' number (default 4000)
global
{not in Vi}

If this many milliseconds nothing is typed the swap file will be written to disk (see crash-recovery). Also used for the CursorHold autocommand event.

'varsofttabstop' 'vsts'

'varsofttabstop' 'vsts' string (default "")
local to buffer
{only available when compiled with the +vartabs feature}
{not in Vi}

A list of the number of spaces that a <Tab> counts for while editing, such as inserting a <Tab> or using <BS>. It "feels" like variable-width <Tab>s are being inserted, while in fact a mixture of spaces and <Tab>s is used. Tab widths are separated with commas, with the final value applying to all subsequent tabs.

For example, when editing assembly language files where statements start in the 9th column and comments in the 41st, it may be useful to use the following:

```
:set varsofttabstop=8,32,8
```

This will set soft tabstops with 8 and 8 + 32 spaces, and 8 more for every column thereafter.

Note that the value of 'softtabstop' will be ignored while 'varsofttabstop' is set.

'vartabstop' 'vts'

'vartabstop' 'vts' string (default "")
local to buffer
{only available when compiled with the +vartabs feature}
{not in Vi}

A list of the number of spaces that a <Tab> in the file counts for, separated by commas. Each value corresponds to one tab, with the final value applying to all subsequent tabs. For example:

```
:set vartabstop=4,20,10,8
```

This will make the first tab 4 spaces wide, the second 20 spaces, the third 10 spaces, and all following tabs 8 spaces.

Note that the value of 'tabstop' will be ignored while 'vartabstop' is set.

'verbose' 'vbs'

```
'verbose' 'vbs'         number  (default 0)
                        global
                        {not in Vi, although some versions have a boolean
                        verbose option}
        When bigger than zero, Vim will give messages about what it is doing.
        Currently, these messages are given:
        >= 1    When the viminfo file is read or written.
        >= 2    When a file is ":source"'ed.
        >= 5    Every searched tags file and include file.
        >= 8    Files for which a group of autocommands is executed.
        >= 9    Every executed autocommand.
        >= 12   Every executed function.
        >= 13   When an exception is thrown, caught, finished, or discarded.
        >= 14   Anything pending in a ":finally" clause.
        >= 15   Every executed Ex command (truncated at 200 characters).

        This option can also be set with the "-V" argument.  See  -V .
        This option is also set by the  :verbose  command.

        When the 'verbosefile' option is set then the verbose messages are not
        displayed.

                                                    'verbosefile'   'vfile'
'verbosefile' 'vfile'   string  (default empty)
                        global
                        {not in Vi}
        When not empty all messages are written in a file with this name.
        When the file exists messages are appended.
        Writing to the file ends when Vim exits or when 'verbosefile' is made
        empty.  Writes are buffered, thus may not show up for some time.
        Setting 'verbosefile' to a new value is like making it empty first.
        The difference with  :redir  is that verbose messages are not
        displayed when 'verbosefile' is set.

                                                    'viewdir'   'vdir'
'viewdir' 'vdir'        string  (default for Amiga, MS-DOS, OS/2 and Win32:
                                                        "$VIM/vimfiles/view",
                                 for Unix: "~/.vim/view",
                                 for Macintosh: "$VIM:vimfiles:view"
                                 for VMS: "sys$login:vimfiles/view"
                                 for RiscOS: "Choices:vimfiles/view")
                        global
                        {not in Vi}
                        {not available when compiled without the  +mksession
                        feature}
        Name of the directory where to store files for  :mkview .
        This option cannot be set from a  modeline  or in the  sandbox , for
        security reasons.

                                                    'viewoptions'   'vop'
'viewoptions' 'vop'     string  (default: "folds,options,cursor,curdir")
                        global
                        {not in Vi}
                        {not available when compiled without the  +mksession
```

feature}
Changes the effect of the :mkview command. It is a comma separated list of words. Each word enables saving and restoring something:

word	save and restore
cursor	cursor position in file and in window
folds	manually created folds, opened/closed folds and local fold options
options	options and mappings local to a window or buffer (not global values for local options)
localoptions	same as "options"
slash	backslashes in file names replaced with forward slashes
unix	with Unix end-of-line format (single <NL>), even when on Windows or DOS
curdir	the window-local directory, if set with `:lcd`

"slash" and "unix" are useful on Windows when sharing view files with Unix. The Unix version of Vim cannot source dos format scripts, but the Windows version of Vim can source unix format scripts.

'viminfo' 'vi' E526 E527 E528

'viminfo' 'vi' string (Vi default: "", Vim default for MS-DOS, Windows and OS/2: '100,<50,s10,h,rA:,rB:, for Amiga: '100,<50,s10,h,rdf0:,rdf1:,rdf2: for others: '100,<50,s10,h)
global
{not in Vi}
{not available when compiled without the +viminfo feature}
When non-empty, the viminfo file is read upon startup and written when exiting Vim (see viminfo-file). Except when 'viminfofile' is "NONE".
The string should be a comma separated list of parameters, each consisting of a single character identifying the particular parameter, followed by a number or string which specifies the value of that parameter. If a particular character is left out, then the default value is used for that parameter. The following is a list of the identifying characters and the effect of their value.

CHAR	VALUE
	viminfo-!
!	When included, save and restore global variables that start with an uppercase letter, and don't contain a lowercase letter. Thus "KEEPTHIS and "K_L_M" are stored, but "KeepThis" and "_K_L_M" are not. Nested List and Dict items may not be read back correctly, you end up with an empty item.
	viminfo-quote
"	Maximum number of lines saved for each register. Old name of the '<' item, with the disadvantage that you need to put a backslash before the ", otherwise it will be recognized as the start of a comment!
	viminfo-%
%	When included, save and restore the buffer list. If Vim is started with a file name argument, the buffer list is not restored. If Vim is started without a file name argument, the

buffer list is restored from the viminfo file. Quickfix
('buftype'), unlisted ('buflisted'), unnamed and buffers on
removable media (viminfo-r) are not saved.
When followed by a number, the number specifies the maximum
number of buffers that are stored. Without a number all
buffers are stored.

viminfo-'

' Maximum number of previously edited files for which the marks
are remembered. This parameter must always be included when
'viminfo' is non-empty.
Including this item also means that the jumplist and the
 changelist are stored in the viminfo file.

viminfo-/

/ Maximum number of items in the search pattern history to be
saved. If non-zero, then the previous search and substitute
patterns are also saved. When not included, the value of
'history' is used.

viminfo-:

: Maximum number of items in the command-line history to be
saved. When not included, the value of 'history' is used.

viminfo-<

< Maximum number of lines saved for each register. If zero then
registers are not saved. When not included, all lines are
saved. '"' is the old name for this item.
Also see the 's' item below: limit specified in Kbyte.

viminfo-@

@ Maximum number of items in the input-line history to be
saved. When not included, the value of 'history' is used.

viminfo-c

c When included, convert the text in the viminfo file from the
'encoding' used when writing the file to the current
'encoding'. See viminfo-encoding .

viminfo-f

f Whether file marks need to be stored. If zero, file marks ('0
to '9, 'A to 'Z) are not stored. When not present or when
non-zero, they are all stored. '0 is used for the current
cursor position (when exiting or when doing ":wviminfo").

viminfo-h

h Disable the effect of 'hlsearch' when loading the viminfo
file. When not included, it depends on whether ":nohlsearch"
has been used since the last search command.

viminfo-n

n Name of the viminfo file. The name must immediately follow
the 'n'. Must be at the end of the option! If the
'viminfofile' option is set, that file name overrides the one
given here with 'viminfo'. Environment variables are
expanded when opening the file, not when setting the option.

viminfo-r

r Removable media. The argument is a string (up to the next
','). This parameter can be given several times. Each
specifies the start of a path for which no marks will be
stored. This is to avoid removable media. For MS-DOS you
could use "ra:,rb:", for Amiga "rdf0:,rdf1:,rdf2:". You can
also use it for temp files, e.g., for Unix: "r/tmp". Case is

ignored. Maximum length of each 'r' argument is 50 characters.

viminfo-s

s Maximum size of an item in Kbyte. If zero then registers are not saved. Currently only applies to registers. The default "s10" will exclude registers with more than 10 Kbyte of text. Also see the '<' item above: line count limit.

Example:

```
:set viminfo='50,<1000,s100,:0,n~/vim/viminfo
```

'50	Marks will be remembered for the last 50 files you edited.
<1000	Contents of registers (up to 1000 lines each) will be remembered.
s100	Registers with more than 100 Kbyte text are skipped.
:0	Command-line history will not be saved.
n~/vim/viminfo	The name of the file to use is "~/vim/viminfo".
no /	Since '/' is not specified, the default will be used, that is, save all of the search history, and also the previous search and substitute patterns.
no %	The buffer list will not be saved nor read back.
no h	'hlsearch' highlighting will be restored.

When setting 'viminfo' from an empty value you can use :rviminfo to load the contents of the file, this is not done automatically.

This option cannot be set from a modeline or in the sandbox, for security reasons.

NOTE: This option is set to the Vim default value when 'compatible' is reset.

'viminfofile' 'vif'

'viminfofile' 'vif' string (default: "")
global
{not in Vi}
{not available when compiled without the +viminfo feature}

When non-empty, overrides the file name used for viminfo.
When equal to "NONE" no viminfo file will be read or written.
This option can be set with the -i command line flag. The --clean command line flag sets it to "NONE".

'virtualedit' 've'

'virtualedit' 've' string (default "")
global
{not in Vi}
{not available when compiled without the +virtualedit feature}

A comma separated list of these words:

block	Allow virtual editing in Visual block mode.
insert	Allow virtual editing in Insert mode.
all	Allow virtual editing in all modes.
onemore	Allow the cursor to move just past the end of the line

Virtual editing means that the cursor can be positioned where there is no actual character. This can be halfway into a tab or beyond the end of the line. Useful for selecting a rectangle in Visual mode and editing a table.
"onemore" is not the same, it will only allow moving the cursor just after the last character of the line. This makes some commands more consistent. Previously the cursor was always past the end of the line if the line was empty. But it is far from Vi compatible. It may also break some plugins or Vim scripts. For example because `l` can move the cursor after the last character. Use with care!
Using the `$` command will move to the last character in the line, not past it. This may actually move the cursor to the left!
The `g$` command will move to the end of the screen line.
It doesn't make sense to combine "all" with "onemore", but you will not get a warning for it.
NOTE: This option is set to "" when 'compatible' is set.

'visualbell' 'vb' 'novisualbell' 'novb' beep
'visualbell' 'vb' boolean (default off)
global
{not in Vi}

Use a visual bell instead of beeping. The terminal code to display the visual bell is given with 't_vb'. When no beep or flash is wanted, use:

```
:set vb t_vb=
```

If you want a short flash, you can use this on many terminals:

```
:set vb t_vb=?[?5h$<100>?[?5l
```

Here $<100> specifies the time, you can use a smaller or bigger value to get a shorter or longer flash.

Note: Vim will limit the bell to once per half a second. This avoids having to wait for the flashing to finish when there are lots of bells, e.g. on key repeat. This also happens without 'visualbell' set.

In the GUI, 't_vb' defaults to "<Esc>|f", which inverts the display for 20 msec. If you want to use a different time, use "<Esc>|40f", where 40 is the time in msec.

Note: When the GUI starts, 't_vb' is reset to its default value. You might want to set it again in your `gvimrc` .

Does not work on the Amiga, you always get a screen flash.
Also see 'errorbells'.

'warn' 'nowarn'
'warn' boolean (default on)
global

Give a warning message when a shell command is used while the buffer has been changed.

'weirdinvert' 'wiv' 'noweirdinvert' 'nowiv'
'weirdinvert' 'wiv' boolean (default off)

```
                        global
                        {not in Vi}
        This option has the same effect as the 't_xs' terminal option.
        It is provided for backwards compatibility with version 4.x.
        Setting 'weirdinvert' has the effect of making 't_xs' non-empty, and
        vice versa.  Has no effect when the GUI is running.

                                                    'whichwrap'   'ww'
'whichwrap' 'ww'        string  (Vim default: "b,s", Vi default: "")
                        global
                        {not in Vi}
        Allow specified keys that move the cursor left/right to move to the
        previous/next line when the cursor is on the first/last character in
        the line.  Concatenate characters to allow this for these keys:
                char   key        mode
                 b    <BS>       Normal and Visual
                 s    <Space>    Normal and Visual
                 h    "h"        Normal and Visual (not recommended)
                 l    "l"        Normal and Visual (not recommended)
                 <    <Left>     Normal and Visual
                 >    <Right>    Normal and Visual
                 ~    "~"        Normal
                 [    <Left>     Insert and Replace
                 ]    <Right>    Insert and Replace
        For example:
                :set ww=<,>,[,]
       allows wrap only when cursor keys are used.
        When the movement keys are used in combination with a delete or change
        operator, the <EOL> also counts for a character.  This makes "3h"
        different from "3dh" when the cursor crosses the end of a line.  This
        is also true for "x" and "X", because they do the same as "dl" and
        "dh".  If you use this, you may also want to use the mapping
        ":map <BS> X" to make backspace delete the character in front of the
        cursor.
        When 'l' is included and it is used after an operator at the end of a
        line then it will not move to the next line.  This makes "dl", "cl",
        "yl" etc. work normally.
        NOTE: This option is set to the Vi default value when 'compatible' is
        set and to the Vim default value when 'compatible' is reset.

                                                    'wildchar'   'wc'
'wildchar' 'wc'         number  (Vim default: <Tab>, Vi default: CTRL-E)
                        global
                        {not in Vi}
        Character you have to type to start wildcard expansion in the
        command-line, as specified with 'wildmode'.
        More info here:  cmdline-completion .
        The character is not recognized when used inside a macro.  See
        'wildcharm' for that.
        Although 'wc' is a number option, you can set it to a special key:
                :set wc=<Esc>
       NOTE: This option is set to the Vi default value when 'compatible' is
        set and to the Vim default value when 'compatible' is reset.
```

'wildcharm' 'wcm'
'wildcharm' 'wcm'	number (default: none (0))
global
{not in Vi}
'wildcharm' works exactly like 'wildchar', except that it is recognized when used inside a macro. You can find "spare" command-line keys suitable for this option by looking at ex-edit-index . Normally you'll never actually type 'wildcharm', just use it in mappings that automatically invoke completion mode, e.g.:
:set wcm=<C-Z>
:cnoremap ss so $vim/sessions/*.vim<C-Z>
Then after typing :ss you can use CTRL-P & CTRL-N.

'wildignore' 'wig'
'wildignore' 'wig'	string (default "")
global
{not in Vi}
{not available when compiled without the +wildignore feature}
A list of file patterns. A file that matches with one of these patterns is ignored when expanding wildcards , completing file or directory names, and influences the result of expand() , glob() and globpath() unless a flag is passed to disable this.
The pattern is used like with :autocmd , see autocmd-patterns .
Also see 'suffixes'.
Example:
:set wildignore=*.o,*.obj
The use of :set+= and :set-= is preferred when adding or removing a pattern from the list. This avoids problems when a future version uses another default.

'wildignorecase' 'wic' 'nowildignorecase' 'nowic'
'wildignorecase' 'wic'	boolean (default off)
global
{not in Vi}
When set case is ignored when completing file names and directories.
Has no effect when 'fileignorecase' is set.
Does not apply when the shell is used to expand wildcards, which happens when there are special characters.

'wildmenu' 'wmnu' 'nowildmenu' 'nowmnu'
'wildmenu' 'wmnu'	boolean (default off, set in defaults.vim)
global
{not in Vi}
{not available if compiled without the +wildmenu feature}
When 'wildmenu' is on, command-line completion operates in an enhanced mode. On pressing 'wildchar' (usually <Tab>) to invoke completion, the possible matches are shown just above the command line, with the first match highlighted (overwriting the status line, if there is one). Keys that show the previous/next match, such as <Tab> or CTRL-P/CTRL-N, cause the highlight to move to the appropriate match.

When 'wildmode' is used, "wildmenu" mode is used where "full" is
specified. "longest" and "list" do not start "wildmenu" mode.
You can check the current mode with wildmenumode() .
If there are more matches than can fit in the line, a ">" is shown on
the right and/or a "<" is shown on the left. The status line scrolls
as needed.
The "wildmenu" mode is abandoned when a key is hit that is not used
for selecting a completion.
While the "wildmenu" is active the following keys have special
meanings:

<Left> <Right> - select previous/next match (like CTRL-P/CTRL-N)
<Down>   - in filename/menu name completion: move into a
                  subdirectory or submenu.
<CR>   - in menu completion, when the cursor is just after a
                  dot: move into a submenu.
<Up>   - in filename/menu name completion: move up into
                  parent directory or parent menu.

This makes the menus accessible from the console console-menus .

If you prefer the <Left> and <Right> keys to move the cursor instead
of selecting a different match, use this:
        :cnoremap <Left> <Space><BS><Left>
        :cnoremap <Right> <Space><BS><Right>

The "WildMenu" highlighting is used for displaying the current match
 hl-WildMenu .

                                                'wildmode'   'wim'
'wildmode' 'wim'   string (Vim default: "full")
                        global
                        {not in Vi}
Completion mode that is used for the character specified with
'wildchar'. It is a comma separated list of up to four parts. Each
part specifies what to do for each consecutive use of 'wildchar'. The
first part specifies the behavior for the first use of 'wildchar',
The second part for the second use, etc.
These are the possible values for each part:
""   Complete only the first match.
"full"   Complete the next full match. After the last match,
                the original string is used and then the first match
                again.
"longest"   Complete till longest common string. If this doesn't
                result in a longer string, use the next part.
"longest:full" Like "longest", but also start 'wildmenu' if it is
                enabled.
"list"   When more than one match, list all matches.
"list:full"   When more than one match, list all matches and
                complete first match.
"list:longest" When more than one match, list all matches and
                complete till longest common string.
When there is only a single match, it is fully completed in all cases.

```
        Examples:
                :set wildmode=full
        Complete first full match, next match, etc.  (the default)
                :set wildmode=longest,full
        Complete longest common string, then each full match
                :set wildmode=list:full
        List all matches and complete each full match
                :set wildmode=list,full
        List all matches without completing, then each full match
                :set wildmode=longest,list
        Complete longest common string, then list alternatives.
        More info here:  cmdline-completion .

                                                    'wildoptions'   'wop'
'wildoptions' 'wop'     string  (default "")
                        global
                        {not in Vi}
                        {not available when compiled without the  +wildignore
                        feature}
        A list of words that change how command line completion is done.
        Currently only one word is allowed:
          tagfile       When using CTRL-D to list matching tags, the kind of
                        tag and the file of the tag is listed.  Only one match
                        is displayed per line.  Often used tag kinds are:
                                d       #define
                                f       function
        Also see  cmdline-completion .

                                                    'winaltkeys'   'wak'
'winaltkeys' 'wak'      string  (default "menu")
                        global
                        {not in Vi}
                        {only used in Win32, Motif, GTK and Photon GUI}
        Some GUI versions allow the access to menu entries by using the ALT
        key in combination with a character that appears underlined in the
        menu.  This conflicts with the use of the ALT key for mappings and
        entering special characters.  This option tells what to do:
          no    Don't use ALT keys for menus.  ALT key combinations can be
                mapped, but there is no automatic handling.  This can then be
                done with the  :simalt  command.
          yes   ALT key handling is done by the windowing system.  ALT key
                combinations cannot be mapped.
          menu  Using ALT in combination with a character that is a menu
                shortcut key, will be handled by the windowing system.  Other
                keys can be mapped.
        If the menu is disabled by excluding 'm' from 'guioptions', the ALT
        key is never used for the menu.
        This option is not used for <F10>; on Win32 and with GTK <F10> will
        select the menu, unless it has been mapped.

                                                    'window'   'wi'
'window' 'wi'           number  (default screen height - 1)
                        global
        Window height.  Do not confuse this with the height of the Vim window,
```

use 'lines' for that.
Used for CTRL-F and CTRL-B when there is only one window and the value is smaller than 'lines' minus one. The screen will scroll 'window' minus two lines, with a minimum of one.
When 'window' is equal to 'lines' minus one CTRL-F and CTRL-B scroll in a much smarter way, taking care of wrapping lines.
When resizing the Vim window, the value is smaller than 1 or more than or equal to 'lines' it will be set to 'lines' minus 1.
{Vi also uses the option to specify the number of displayed lines}

'winheight' 'wh' E591
'winheight' 'wh' number (default 1)
global
{not in Vi}
{not available when compiled without the +windows feature}
Minimal number of lines for the current window. This is not a hard minimum, Vim will use fewer lines if there is not enough room. If the focus goes to a window that is smaller, its size is increased, at the cost of the height of other windows.
Set 'winheight' to a small number for normal editing.
Set it to 999 to make the current window fill most of the screen.
Other windows will be only 'winminheight' high. This has the drawback that ":all" will create only two windows. To avoid "vim -o 1 2 3 4" to create only two windows, set the option after startup is done, using the VimEnter event:

```
au VimEnter * set winheight=999
```

Minimum value is 1.
The height is not adjusted after one of the commands that change the height of the current window.
'winheight' applies to the current window. Use 'winminheight' to set the minimal height for other windows.

'winfixheight' 'wfh' 'nowinfixheight' 'nowfh'
'winfixheight' 'wfh' boolean (default off)
local to window
{not in Vi}
{not available when compiled without the +windows feature}
Keep the window height when windows are opened or closed and 'equalalways' is set. Also for CTRL-W_= . Set by default for the preview-window and quickfix-window .
The height may be changed anyway when running out of room.

'winfixwidth' 'wfw' 'nowinfixwidth' 'nowfw'
'winfixwidth' 'wfw' boolean (default off)
local to window
{not in Vi}
{not available when compiled without the +windows feature}
Keep the window width when windows are opened or closed and 'equalalways' is set. Also for CTRL-W_= .
The width may be changed anyway when running out of room.

'winminheight' 'wmh'
'winminheight' 'wmh' number (default 1)
global
{not in Vi}
{not available when compiled without the +windows
feature}
The minimal height of a window, when it's not the current window.
This is a hard minimum, windows will never become smaller.
When set to zero, windows may be "squashed" to zero lines (i.e. just a
status bar) if necessary. They will return to at least one line when
they become active (since the cursor has to have somewhere to go.)
Use 'winheight' to set the minimal height of the current window.
This option is only checked when making a window smaller. Don't use a
large number, it will cause errors when opening more than a few
windows. A value of 0 to 3 is reasonable.

'winminwidth' 'wmw'
'winminwidth' 'wmw' number (default 1)
global
{not in Vi}
{not available when compiled without the +vertsplit
feature}
The minimal width of a window, when it's not the current window.
This is a hard minimum, windows will never become smaller.
When set to zero, windows may be "squashed" to zero columns (i.e. just
a vertical separator) if necessary. They will return to at least one
line when they become active (since the cursor has to have somewhere
to go.)
Use 'winwidth' to set the minimal width of the current window.
This option is only checked when making a window smaller. Don't use a
large number, it will cause errors when opening more than a few
windows. A value of 0 to 12 is reasonable.

'winptydll'
'winptydll' string (default "winpty32.dll" or "winpty64.dll")
global
{not in Vi}
{only available when compiled with the terminal
feature on MS-Windows}
Specifies the name of the winpty shared library, used for the
:terminal command. The default depends on whether was build as a
32-bit or 64-bit executable. If not found, "winpty.dll" is tried as
a fallback.
Environment variables are expanded :set_env .
This option cannot be set from a modeline or in the sandbox , for
security reasons.

'winwidth' 'wiw' E592
'winwidth' 'wiw' number (default 20)
global
{not in Vi}
{not available when compiled without the +vertsplit
feature}
Minimal number of columns for the current window. This is not a hard

minimum, Vim will use fewer columns if there is not enough room. If the current window is smaller, its size is increased, at the cost of the width of other windows. Set it to 999 to make the current window always fill the screen. Set it to a small number for normal editing. The width is not adjusted after one of the commands to change the width of the current window.
'winwidth' applies to the current window. Use 'winminwidth' to set the minimal width for other windows.

'wrap' 'nowrap'

'wrap' boolean (default on)
local to window
{not in Vi}
This option changes how text is displayed. It doesn't change the text in the buffer, see 'textwidth' for that.
When on, lines longer than the width of the window will wrap and displaying continues on the next line. When off lines will not wrap and only part of long lines will be displayed. When the cursor is moved to a part that is not shown, the screen will scroll horizontally.
The line will be broken in the middle of a word if necessary. See 'linebreak' to get the break at a word boundary.
To make scrolling horizontally a bit more useful, try this:

```
:set sidescroll=5
:set listchars+=precedes:<,extends:>
```

See 'sidescroll', 'listchars' and wrap-off .
This option can't be set from a modeline when the 'diff' option is on.

'wrapmargin' 'wm'

'wrapmargin' 'wm' number (default 0)
local to buffer
Number of characters from the right window border where wrapping starts. When typing text beyond this limit, an <EOL> will be inserted and inserting continues on the next line.
Options that add a margin, such as 'number' and 'foldcolumn', cause the text width to be further reduced. This is Vi compatible.
When 'textwidth' is non-zero, this option is not used.
This option is set to 0 when 'paste' is set and restored when 'paste' is reset.
See also 'formatoptions' and ins-textwidth . {Vi: works differently and less usefully}

'wrapscan' 'ws' 'nowrapscan' 'nows'

'wrapscan' 'ws' boolean (default on) E384 E385
global
Searches wrap around the end of the file. Also applies to]s and [s , searching for spelling mistakes.

'write' 'nowrite'

'write' boolean (default on)
global
{not in Vi}
Allows writing files. When not set, writing a file is not allowed.

Can be used for a view-only mode, where modifications to the text are still allowed. Can be reset with the -m or -M command line argument. Filtering text is still possible, even though this requires writing a temporary file.

'writeany' 'wa' 'nowriteany' 'nowa'
'writeany' 'wa' boolean (default off)
global
Allows writing to any file with no need for "!" override.

'writebackup' 'wb' 'nowritebackup' 'nowb'
'writebackup' 'wb' boolean (default on with +writebackup feature, off otherwise)
global
{not in Vi}
Make a backup before overwriting a file. The backup is removed after the file was successfully written, unless the 'backup' option is also on.
WARNING: Switching this option off means that when Vim fails to write your buffer correctly and then, for whatever reason, Vim exits, you lose both the original file and what you were writing. Only reset this option if your file system is almost full and it makes the write fail (and make sure not to exit Vim until the write was successful). See backup-table for another explanation.
When the 'backupskip' pattern matches, a backup is not made anyway.
NOTE: This option is set to the default value when 'compatible' is set.

'writedelay' 'wd'
'writedelay' 'wd' number (default 0)
global
{not in Vi}
The number of milliseconds to wait for each character sent to the screen. When non-zero, characters are sent to the terminal one by one. For MS-DOS pcterm this does not work. For debugging purposes.

vim:tw=78:ts=8:noet:ft=help:norl:

pattern.txt For Vim version 8.1. Last change: 2018 Mar 13

VIM REFERENCE MANUAL by Bram Moolenaar

Patterns and search commands pattern-searches

The very basics can be found in section 03.9 of the user manual. A few more explanations are in chapter 27 usr_27.txt .

==========

1. Search commands search-commands

/

/{pattern}[/]<CR> Search forward for the [count]'th occurrence of {pattern} exclusive .

/{pattern}/{offset}<CR> Search forward for the [count]'th occurrence of {pattern} and go {offset} lines up or down. linewise .

/<CR>

/<CR> Search forward for the [count]'th occurrence of the latest used pattern last-pattern with latest used {offset} .

//{offset}<CR> Search forward for the [count]'th occurrence of the latest used pattern last-pattern with new {offset} . If {offset} is empty no offset is used.

?

?{pattern}[?]<CR> Search backward for the [count]'th previous occurrence of {pattern} exclusive .

?{pattern}?{offset}<CR> Search backward for the [count]'th previous occurrence of {pattern} and go {offset} lines up or down linewise .

?<CR>

?<CR> Search backward for the [count]'th occurrence of the latest used pattern last-pattern with latest used {offset} .

??{offset}<CR>		Search backward for the [count]'th occurrence of the
latest used pattern last-pattern with new
 {offset} . If {offset} is empty no offset is used.

n

n		Repeat the latest "/" or "?" [count] times.
If the cursor doesn't move the search is repeated with
count + 1.
 last-pattern {Vi: no count}

N

N		Repeat the latest "/" or "?" [count] times in
opposite direction. last-pattern {Vi: no count}

star E348 E349

*		Search forward for the [count]'th occurrence of the
word nearest to the cursor. The word used for the
search is the first of:
	1. the keyword under the cursor 'iskeyword'
	2. the first keyword after the cursor, in the
	   current line
	3. the non-blank word under the cursor
	4. the first non-blank word after the cursor,
	   in the current line
Only whole keywords are searched for, like with the
command "/\<keyword\>". exclusive {not in Vi}
'ignorecase' is used, 'smartcase' is not.

#

#		Same as "*", but search backward. The pound sign
(character 163) also works. If the "#" key works as
backspace, try using "stty erase <BS>" before starting
Vim (<BS> is CTRL-H or a real backspace). {not in Vi}

gstar

g*		Like "*", but don't put "\<" and "\>" around the word.
This makes the search also find matches that are not a
whole word. {not in Vi}

g#

g#		Like "#", but don't put "\<" and "\>" around the word.
This makes the search also find matches that are not a
whole word. {not in Vi}

gd

gd		Goto local Declaration. When the cursor is on a local
variable, this command will jump to its declaration.
First Vim searches for the start of the current
function, just like "[[". If it is not found the
search stops in line 1. If it is found, Vim goes back
until a blank line is found. From this position Vim
searches for the keyword under the cursor, like with
"*", but lines that look like a comment are ignored

(see 'comments' option).
Note that this is not guaranteed to work, Vim does not really check the syntax, it only searches for a match with the keyword. If included files also need to be searched use the commands listed in include-search .
After this command n searches forward for the next match (not backward).
{not in Vi}

gD

gD Goto global Declaration. When the cursor is on a global variable that is defined in the file, this command will jump to its declaration. This works just like "gd", except that the search for the keyword always starts in line 1. {not in Vi}

1gd

1gd Like "gd", but ignore matches inside a {} block that ends before the cursor position. {not in Vi}

1gD

1gD Like "gD", but ignore matches inside a {} block that ends before the cursor position. {not in Vi}

CTRL-C

CTRL-C Interrupt current (search) command. Use CTRL-Break on MS-DOS dos-CTRL-Break .
In Normal mode, any pending command is aborted.

:noh :nohlsearch

:noh[lsearch] Stop the highlighting for the 'hlsearch' option. It is automatically turned back on when using a search command, or setting the 'hlsearch' option.
This command doesn't work in an autocommand, because the highlighting state is saved and restored when executing autocommands autocmd-searchpat .
Same thing for when invoking a user function.

While typing the search pattern the current match will be shown if the 'incsearch' option is on. Remember that you still have to finish the search command with <CR> to actually position the cursor at the displayed match. Or use <Esc> to abandon the search.

All matches for the last used search pattern will be highlighted if you set the 'hlsearch' option. This can be suspended with the :nohlsearch command.

When no match is found you get the error: E486 Pattern not found
Note that for the :global command this behaves like a normal message, for Vi compatibility. For the :s command the "e" flag can be used to avoid the error message :s_flags .

search-offset {offset}

These commands search for the specified pattern. With "/" and "?" an additional offset may be given. There are two types of offsets: line offsets

and character offsets. {the character offsets are not in Vi}

The offset gives the cursor position relative to the found match:
```
    [num]       [num] lines downwards, in column 1
    +[num]      [num] lines downwards, in column 1
    -[num]      [num] lines upwards, in column 1
    e[+num]     [num] characters to the right of the end of the match
    e[-num]     [num] characters to the left of the end of the match
    s[+num]     [num] characters to the right of the start of the match
    s[-num]     [num] characters to the left of the start of the match
    b[+num]     [num] identical to s[+num] above (mnemonic: begin)
    b[-num]     [num] identical to s[-num] above (mnemonic: begin)
    ;{pattern}  perform another search, see  //;
```

If a '-' or '+' is given but [num] is omitted, a count of one will be used.
When including an offset with 'e', the search becomes inclusive (the
character the cursor lands on is included in operations).

Examples:

```
pattern                 cursor position
/test/+1                one line below "test", in column 1
/test/e                 on the last t of "test"
/test/s+2               on the 's' of "test"
/test/b-3               three characters before "test"
```

If one of these commands is used after an operator, the characters between
the cursor position before and after the search is affected. However, if a
line offset is given, the whole lines between the two cursor positions are
affected.

An example of how to search for matches with a pattern and change the match
with another word:
```
        /foo<CR>        find "foo"
        c//e<CR>        change until end of match
        bar<Esc>        type replacement
        //<CR>          go to start of next match
        c//e<CR>        change until end of match
        beep<Esc>       type another replacement
                        etc.
```

                                                                //;   E386
A very special offset is ';' followed by another search command. For example:

```
   /test 1/;/test
   /test.*/+1;?ing?
```

The first one first finds the next occurrence of "test 1", and then the first
occurrence of "test" after that.

This is like executing two search commands after each other, except that:
- It can be used as a single motion command after an operator.
- The direction for a following "n" or "N" command comes from the first
  search command.

- When an error occurs the cursor is not moved at all.

last-pattern

The last used pattern and offset are remembered. They can be used to repeat the search, possibly in another direction or with another count. Note that two patterns are remembered: One for 'normal' search commands and one for the substitute command ":s". Each time an empty pattern is given, the previously used pattern is used. However, if there is no previous search command, a previous substitute pattern is used, if possible.

The 'magic' option sticks with the last used pattern. If you change 'magic', this will not change how the last used pattern will be interpreted.
The 'ignorecase' option does not do this. When 'ignorecase' is changed, it will result in the pattern to match other text.

All matches for the last used search pattern will be highlighted if you set the 'hlsearch' option.

To clear the last used search pattern:
```
:let @/ = ""
```
This will not set the pattern to an empty string, because that would match everywhere. The pattern is really cleared, like when starting Vim.

The search usually skips matches that don't move the cursor. Whether the next match is found at the next character or after the skipped match depends on the 'c' flag in 'cpoptions'. See cpo-c .
```
          with 'c' flag:   "/..." advances 1 to 3 characters
       without 'c' flag:   "/..." advances 1 character
```
The unpredictability with the 'c' flag is caused by starting the search in the first column, skipping matches until one is found past the cursor position.

When searching backwards, searching starts at the start of the line, using the 'c' flag in 'cpoptions' as described above. Then the last match before the cursor position is used.

In Vi the ":tag" command sets the last search pattern when the tag is searched for. In Vim this is not done, the previous search pattern is still remembered, unless the 't' flag is present in 'cpoptions'. The search pattern is always put in the search history.

If the 'wrapscan' option is on (which is the default), searches wrap around the end of the buffer. If 'wrapscan' is not set, the backward search stops at the beginning and the forward search stops at the end of the buffer. If 'wrapscan' is set and the pattern was not found the error message "pattern not found" is given, and the cursor will not be moved. If 'wrapscan' is not set the message becomes "search hit BOTTOM without match" when searching forward, or "search hit TOP without match" when searching backward. If wrapscan is set and the search wraps around the end of the file the message "search hit TOP, continuing at BOTTOM" or "search hit BOTTOM, continuing at TOP" is given when searching backwards or forwards respectively. This can be switched off by setting the 's' flag in the 'shortmess' option. The highlight method 'w' is used for this message (default: standout).

search-range

You can limit the search command "/" to a certain range of lines by including
\%>l items. For example, to match the word "limit" below line 199 and above
line 300:
        /\%>199l\%<300llimit
Also see /\%>l .

Another way is to use the ":substitute" command with the 'c' flag. Example:
   :.,300s/Pattern//gc
This command will search from the cursor position until line 300 for
"Pattern". At the match, you will be asked to type a character. Type 'q' to
stop at this match, type 'n' to find the next match.

The "*", "#", "g*" and "g#" commands look for a word near the cursor in this
order, the first one that is found is used:
- The keyword currently under the cursor.
- The first keyword to the right of the cursor, in the same line.
- The WORD currently under the cursor.
- The first WORD to the right of the cursor, in the same line.
The keyword may only contain letters and characters in 'iskeyword'.
The WORD may contain any non-blanks (<Tab>s and/or <Space>s).
Note that if you type with ten fingers, the characters are easy to remember:
the "#" is under your left hand middle finger (search to the left and up) and
the "*" is under your right hand middle finger (search to the right and down).
(this depends on your keyboard layout though).

                                                                        E956
In very rare cases a regular expression is used recursively. This can happen
when executing a pattern takes a long time and when checkig for messages on
channels a callback is invoked that also uses a pattern or an autocommand is
triggered. In most cases this should be fine, but if a pattern is in use when
it's used again it fails. Usually this means there is something wrong with
the pattern.

==
2. The definition of a pattern   search-pattern   pattern   [pattern]
                                        regular-expression   regexp   Pattern
                                        E76   E383   E476

For starters, read chapter 27 of the user manual usr_27.txt .

                                                    /bar   /\bar   /pattern
1. A pattern is one or more branches, separated by "\|". It matches anything
   that matches one of the branches. Example: "foo\|beep" matches "foo" and
   matches "beep". If more than one branch matches, the first one is used.

   pattern ::=   branch
               or   branch \| branch
               or   branch \| branch \| branch
               etc.

                                                    /branch   /\&
2. A branch is one or more concats, separated by "\&". It matches the last
   concat, but only if all the preceding concats also match at the same
   position. Examples:

"foobeep\&..." matches "foo" in "foobeep".
".*Peter\&.*Bob" matches in a line containing both "Peter" and "Bob"

```
branch ::=      concat
            or  concat \& concat
            or  concat \& concat \& concat
            etc.
```

/concat

3. A concat is one or more pieces, concatenated. It matches a match for the first piece, followed by a match for the second piece, etc. Example: "f[0-9]b", first matches "f", then a digit and then "b".

```
concat  ::=     piece
            or  piece piece
            or  piece piece piece
            etc.
```

/piece

4. A piece is an atom, possibly followed by a multi, an indication of how many times the atom can be matched. Example: "a*" matches any sequence of "a" characters: "", "a", "aa", etc. See /multi .

```
piece   ::=     atom
            or  atom  multi
```

/atom

5. An atom can be one of a long list of items. Many atoms match one character in the text. It is often an ordinary character or a character class. Braces can be used to make a pattern into an atom. The "\z(\)" construct is only for syntax highlighting.

```
atom    ::=     ordinary-atom               /ordinary-atom
            or  \( pattern \)               /\(
            or  \%( pattern \)              /\%(
            or  \z( pattern \)              /\z(
```

/\%#= two-engines NFA

Vim includes two regexp engines:
1. An old, backtracking engine that supports everything.
2. A new, NFA engine that works much faster on some patterns, possibly slower on some patterns.

Vim will automatically select the right engine for you. However, if you run into a problem or want to specifically select one engine or the other, you can prepend one of the following to the pattern:

```
\%#=0   Force automatic selection.  Only has an effect when
        'regexpengine' has been set to a non-zero value.
\%#=1   Force using the old engine.
\%#=2   Force using the NFA engine.
```

You can also use the 'regexpengine' option to change the default.

E864 E868 E874 E875 E876 E877 E878
If selecting the NFA engine and it runs into something that is not implemented the pattern will not match. This is only useful when debugging Vim.

==========
3. Magic /magic

Some characters in the pattern are taken literally. They match with the same character in the text. When preceded with a backslash however, these characters get a special meaning.

Other characters have a special meaning without a backslash. They need to be preceded with a backslash to match literally.

If a character is taken literally or not depends on the 'magic' option and the items mentioned next.
/\m /\M
Use of "\m" makes the pattern after it be interpreted as if 'magic' is set, ignoring the actual value of the 'magic' option.
Use of "\M" makes the pattern after it be interpreted as if 'nomagic' is used.
/\v /\V
Use of "\v" means that in the pattern after it all ASCII characters except '0'-'9', 'a'-'z', 'A'-'Z' and '_' have a special meaning. "very magic"

Use of "\V" means that in the pattern after it only the backslash and the terminating character (/ or ?) has a special meaning. "very nomagic"

Examples:

after:	\v	\m 'magic'	\M 'nomagic'	\V	matches
	$	$	$	\$	matches end-of-line
	.	.	\.	\.	matches any character
	*	*	*	*	any number of the previous atom
	~	~	\~	\~	latest substitute string
	()	\(\)	\(\)	\(\)	grouping into an atom
	|	|	|	|	separating alternatives
	\a	\a	\a	\a	alphabetic character
	\\	\\	\\	\\	literal backslash
	\.	\.	.	.	literal dot
	\{	{	{	{	literal '{'
	a	a	a	a	literal 'a'

{only Vim supports \m, \M, \v and \V}

It is recommended to always keep the 'magic' option at the default setting, which is 'magic'. This avoids portability problems. To make a pattern immune to the 'magic' option being set or not, put "\m" or "\M" at the start of the pattern.

          ...
 /\9     \9       \9       Like "\1", but uses ninth \(\)
                                                              E68
 /\z1    \z1      \z1      only for syntax highlighting, see  :syn-ext-match
          ...
 /\z1    \z9      \z9      only for syntax highlighting, see  :syn-ext-match

        x        x        a character with no special meaning matches itself
```

```
 /[]    []      \[]     any character specified inside the []
 /\%[]  \%[]    \%[]    a sequence of optionally matched atoms

 /\c    \c      \c      ignore case, do not use the 'ignorecase' option
 /\C    \C      \C      match case, do not use the 'ignorecase' option
 /\Z    \Z      \Z      ignore differences in Unicode "combining characters".
                        Useful when searching voweled Hebrew or Arabic text.

      magic   nomagic   matches
 /\m    \m      \m      'magic' on for the following chars in the pattern
 /\M    \M      \M      'magic' off for the following chars in the pattern
 /\v    \v      \v      the following chars in the pattern are "very magic"
 /\V    \V      \V      the following chars in the pattern are "very nomagic"
 /\%#=    \%#=1   \%#=1   select regexp engine  /zero-width

 /\%d   \%d     \%d     match specified decimal character (eg \%d123)
 /\%x   \%x     \%x     match specified hex character (eg \%x2a)
 /\%o   \%o     \%o     match specified octal character (eg \%o040)
 /\%u   \%u     \%u     match specified multibyte character (eg \%u20ac)
 /\%U   \%U     \%U     match specified large multibyte character (eg
                        \%U12345678)
 /\%C   \%C     \%C     match any composing characters

Example                 matches
\<\I\i*         or
\<\h\w*
\<[a-zA-Z_][a-zA-Z0-9_]*
                        An identifier (e.g., in a C program).

\(\.$\|\. \)            A period followed by <EOL> or a space.

[.!?][])"']*\($\|[ ]\)  A search pattern that finds the end of a sentence,
                        with almost the same definition as the ")" command.

cat\Z                   Both "cat" and "càt" ("a" followed by 0x0300)
                        Does not match "càt" (character 0x00e0), even
                        though it may look the same.

==============================================================================
5. Multi items                                          pattern-multi-items

An atom can be followed by an indication of how many times the atom can be
matched and in what way.  This is called a multi.  See  /multi  for an
overview.

                                                        /star   /\star
*       (use \* when 'magic' is not set)
        Matches 0 or more of the preceding atom, as many as possible.
        Example  'nomagic'      matches
        a*          a\*         "", "a", "aa", "aaa", etc.
        .*          \.\*        anything, also an empty string, no end-of-line
        \_.*        \_.\*       everything up to the end of the buffer
        \_.*END     \_.\*END    everything up to and including the last "END"
```

in the buffer

Exception: When "*" is used at the start of the pattern or just after "^" it matches the star character.

Be aware that repeating "_." can match a lot of text and take a long time. For example, "_.*END" matches all text from the current position to the last occurrence of "END" in the file. Since the "*" will match as many as possible, this first skips over all lines until the end of the file and then tries matching "END", backing up one character at a time.

/\+

\+ Matches 1 or more of the preceding atom, as many as possible. {not in Vi}

Example	matches
^.\+$	any non-empty line
\s\+	white space of at least one character

/\=

\= Matches 0 or 1 of the preceding atom, as many as possible. {not in Vi}

Example	matches
foo\=	"fo" and "foo"

/\?

\? Just like \=. Cannot be used when searching backwards with the "?" command. {not in Vi}

/\{ E60 E554 E870

\{n,m} Matches n to m of the preceding atom, as many as possible
\{n} Matches n of the preceding atom
\{n,} Matches at least n of the preceding atom, as many as possible
\{,m} Matches 0 to m of the preceding atom, as many as possible
\{} Matches 0 or more of the preceding atom, as many as possible (like *)

/\{-

\{-n,m} matches n to m of the preceding atom, as few as possible
\{-n} matches n of the preceding atom
\{-n,} matches at least n of the preceding atom, as few as possible
\{-,m} matches 0 to m of the preceding atom, as few as possible
\{-} matches 0 or more of the preceding atom, as few as possible
{Vi does not have any of these}

n and m are positive decimal numbers or zero

non-greedy

If a "-" appears immediately after the "{", then a shortest match first algorithm is used (see example below). In particular, "\{-}" is the same as "*" but uses the shortest match first algorithm. BUT: A match that starts earlier is preferred over a shorter match: "a\{-}b" matches "aaab" in "xaaab".

Example	matches
ab\{2,3}c	"abbc" or "abbbc"
a\{5}	"aaaaa"
ab\{2,}c	"abbc", "abbbc", "abbbbc", etc.

```
ab\{,3}c                "ac", "abc", "abbc" or "abbbc"
a[bc]\{3}d              "abbbd", "abbcd", "acbcd", "acccd", etc.
a\(bc\)\{1,2}d          "abcd" or "abcbcd"
a[bc]\{-}[cd]           "abc" in "abcd"
a[bc]*[cd]              "abcd" in "abcd"
```

The } may optionally be preceded with a backslash: \{n,m\}.

/\@=

\@= Matches the preceding atom with zero width. {not in Vi}
Like "(?=pattern)" in Perl.

```
Example                 matches
foo\(bar\)\@=           "foo" in "foobar"
foo\(bar\)\@=foo        nothing
```

/zero-width

When using "\@=" (or "^", "$", "\<", "\>") no characters are included in the match. These items are only used to check if a match can be made. This can be tricky, because a match with following items will be done in the same position. The last example above will not match "foobarfoo", because it tries match "foo" in the same position where "bar" matched.

Note that using "\&" works the same as using "\@=": "foo\&.." is the same as "\(foo\)\@=..". But using "\&" is easier, you don't need the braces.

/\@!

\@! Matches with zero width if the preceding atom does NOT match at the current position. /zero-width {not in Vi}
Like "(?!pattern)" in Perl.

```
Example                 matches
foo\(bar\)\@!           any "foo" not followed by "bar"
a.\{-}p\@!              "a", "ap", "app", "appp", etc. not immediately
                        followed by a "p"
if \(\(then\)\@!.\)*$   "if " not followed by "then"
```

Using "\@!" is tricky, because there are many places where a pattern does not match. "a.*p\@!" will match from an "a" to the end of the line, because ".*" can match all characters in the line and the "p" doesn't match at the end of the line. "a.\{-}p\@!" will match any "a", "ap", "app", etc. that isn't followed by a "p", because the "." can match a "p" and "p\@!" doesn't match after that.

You can't use "\@!" to look for a non-match before the matching position: "\(foo\)\@!bar" will match "bar" in "foobar", because at the position where "bar" matches, "foo" does not match. To avoid matching "foobar" you could use "\(foo\)\@!...bar", but that doesn't match a bar at the start of a line. Use "\(foo\)\@<!bar".

Useful example: to find "foo" in a line that does not contain "bar":

```
/^\%(.*bar\)\@!.*\zsfoo
```

This pattern first checks that there is not a single position in the line where "bar" matches. If ".*bar" matches somewhere the \@! will

reject the pattern. When there is no match any "foo" will be found.
The "\zs" is to have the match start just before "foo".

/\@<=

\@<=	Matches with zero width if the preceding atom matches just before what
follows. /zero-width {not in Vi}
Like "(?<=pattern)" in Perl, but Vim allows non-fixed-width patterns.
Example matches
\(an_s\+\)\@<=file "file" after "an" and white space or an
end-of-line
For speed it's often much better to avoid this multi. Try using "\zs"
instead /\zs . To match the same as the above example:
an_s\+\zsfile
At least set a limit for the look-behind, see below.

"\@<=" and "\@<!" check for matches just before what follows.
Theoretically these matches could start anywhere before this position.
But to limit the time needed, only the line where what follows matches
is searched, and one line before that (if there is one). This should
be sufficient to match most things and not be too slow.

In the old regexp engine the part of the pattern after "\@<=" and
"\@<!" are checked for a match first, thus things like "\1" don't work
to reference \(\) inside the preceding atom. It does work the other
way around:
Bad example matches
\%#=1\1\@<=,\([a-z]\+\) ",abc" in "abc,abc"

However, the new regexp engine works differently, it is better to not
rely on this behavior, do not use \@<= if it can be avoided:
Example matches
\([a-z]\+\)\zs,\1 ",abc" in "abc,abc"

\@123<=
Like "\@<=" but only look back 123 bytes. This avoids trying lots
of matches that are known to fail and make executing the pattern very
slow. Example, check if there is a "<" just before "span":
/<\@1<=span
This will try matching "<" only one byte before "span", which is the
only place that works anyway.
After crossing a line boundary, the limit is relative to the end of
the line. Thus the characters at the start of the line with the match
are not counted (this is just to keep it simple).
The number zero is the same as no limit.

/\@<!

\@<!	Matches with zero width if the preceding atom does NOT match just
before what follows. Thus this matches if there is no position in the
current or previous line where the atom matches such that it ends just
before what follows. /zero-width {not in Vi}
Like "(?<!pattern)" in Perl, but Vim allows non-fixed-width patterns.
The match with the preceding atom is made to end just before the match
with what follows, thus an atom that ends in ".*" will work.
Warning: This can be slow (because many positions need to be checked

for a match). Use a limit if you can, see below.

Example	matches
\(foo\)\@<!bar	any "bar" that's not in "foobar"
\(\/\/.*\)\@<!in	"in" which is not after "//"

\@123<!
Like "\@<!" but only look back 123 bytes. This avoids trying lots of matches that are known to fail and make executing the pattern very slow.

/\@>
\@> Matches the preceding atom like matching a whole pattern. {not in Vi} Like "(?>pattern)" in Perl.

Example	matches
\(a*\)\@>a	nothing (the "a*" takes all the "a"'s, there can't be another one following)

This matches the preceding atom as if it was a pattern by itself. If it doesn't match, there is no retry with shorter sub-matches or anything. Observe this difference: "a*b" and "a*ab" both match "aaab", but in the second case the "a*" matches only the first two "a"s. "\(a*\)\@>ab" will not match "aaab", because the "a*" matches the "aaa" (as many "a"s as possible), thus the "ab" can't match.

==========

6. Ordinary atoms pattern-atoms

An ordinary atom can be:

/^
^ At beginning of pattern or after "\|", "\(", "\%(" or "\n": matches start-of-line; at other positions, matches literal '^'. /zero-width

Example	matches
^beep(	the start of the C function "beep" (probably).

/\^
\^ Matches literal '^'. Can be used at any position in the pattern.

/_^
_^ Matches start-of-line. /zero-width Can be used at any position in the pattern.

Example	matches
_s*_^foo	white space and blank lines and then "foo" at start-of-line

/$
$ At end of pattern or in front of "\|", "\)" or "\n" ('magic' on): matches end-of-line <EOL>; at other positions, matches literal '$'. /zero-width

/\$
\$ Matches literal '$'. Can be used at any position in the pattern.

/_$

$ Matches end-of-line. /zero-width Can be used at any position in the pattern. Note that "a$b" never matches, since "b" cannot match an end-of-line. Use "a\nb" instead /\n .
Example matches
foo_$_s* "foo" at end-of-line and following white space and blank lines

. (with 'nomagic': \.) /. /\.
Matches any single character, but not an end-of-line.

/_.

_. Matches any single character or end-of-line.
Careful: "_.*" matches all text to the end of the buffer!

/\<

\< Matches the beginning of a word: The next char is the first char of a word. The 'iskeyword' option specifies what is a word character.
/zero-width

/\>

\> Matches the end of a word: The previous char is the last char of a word. The 'iskeyword' option specifies what is a word character.
/zero-width

/\zs

\zs Matches at any position, and sets the start of the match there: The next char is the first char of the whole match. /zero-width
Example:
/^\s*\zsif
matches an "if" at the start of a line, ignoring white space.
Can be used multiple times, the last one encountered in a matching branch is used. Example:
/\(.\{-}\zsFab\)\{3}
Finds the third occurrence of "Fab".
This cannot be followed by a multi. E888
{not in Vi} {not available when compiled without the |+syntax| feature}

/\ze

\ze Matches at any position, and sets the end of the match there: The previous char is the last char of the whole match. /zero-width
Can be used multiple times, the last one encountered in a matching branch is used.
Example: "end\ze\(if\|for\)" matches the "end" in "endif" and "endfor".
This cannot be followed by a multi. E888
{not in Vi} {not available when compiled without the |+syntax| feature}

/\%^ start-of-file

\%^ Matches start of the file. When matching with a string, matches the start of the string. {not in Vi}
For example, to find the first "VIM" in a file:
/\%^_.\{-}\zsVIM

/\%$ end-of-file

\%$	Matches end of the file. When matching with a string, matches the
	end of the string. {not in Vi}
	Note that this does NOT find the last "VIM" in a file:
		/VIM_.\{-}\%$
	It will find the next VIM, because the part after it will always
	match. This one will find the last "VIM" in the file:
		/VIM\ze\(\(VIM\)\@!_.\)*\%$
	This uses /\@! to ascertain that "VIM" does NOT match in any
	position after the first "VIM".
	Searching from the end of the file backwards is easier!

/\%V
\%V	Match inside the Visual area. When Visual mode has already been
	stopped match in the area that gv would reselect.
	This is a /zero-width match. To make sure the whole pattern is
	inside the Visual area put it at the start and just before the end of
	the pattern, e.g.:
		/\%Vfoo.*ba\%Vr
	This also works if only "foo bar" was Visually selected. This:
		/\%Vfoo.*bar\%V
	would match "foo bar" if the Visual selection continues after the "r".
	Only works for the current buffer.

/\%# cursor-position
\%#	Matches with the cursor position. Only works when matching in a
	buffer displayed in a window. {not in Vi}
	WARNING: When the cursor is moved after the pattern was used, the
	result becomes invalid. Vim doesn't automatically update the matches.
	This is especially relevant for syntax highlighting and 'hlsearch'.
	In other words: When the cursor moves the display isn't updated for
	this change. An update is done for lines which are changed (the whole
	line is updated) or when using the CTRL-L command (the whole screen
	is updated). Example, to highlight the word under the cursor:
		/\k*\%#\k*
	When 'hlsearch' is set and you move the cursor around and make changes
	this will clearly show when the match is updated or not.

/\%'m /\%<'m /\%>'m
\%'m	Matches with the position of mark m.
\%<'m	Matches before the position of mark m.
\%>'m	Matches after the position of mark m.
	Example, to highlight the text from mark 's to 'e:
		/.\%>'s.*\%<'e..
	Note that two dots are required to include mark 'e in the match. That
	is because "\%<'e" matches at the character before the 'e mark, and
	since it's a /zero-width match it doesn't include that character.
	{not in Vi}
	WARNING: When the mark is moved after the pattern was used, the result
	becomes invalid. Vim doesn't automatically update the matches.
	Similar to moving the cursor for "\%#" /\%# .

/\%l /\%>l /\%<l E951
\%23l	Matches in a specific line.
\%<23l	Matches above a specific line (lower line number).

\%>23l Matches below a specific line (higher line number).
        These three can be used to match specific lines in a buffer. The "23"
        can be any line number. The first line is 1. {not in Vi}
        WARNING: When inserting or deleting lines Vim does not automatically
        update the matches. This means Syntax highlighting quickly becomes
        wrong.
        Example, to highlight the line where the cursor currently is:
                :exe '/\%' . line(".") . 'l.*'
       When 'hlsearch' is set and you move the cursor around and make changes
        this will clearly show when the match is updated or not.

                                                /\%c   /\%>c   /\%<c
\%23c   Matches in a specific column.
\%<23c Matches before a specific column.
\%>23c Matches after a specific column.
        These three can be used to match specific columns in a buffer or
        string. The "23" can be any column number. The first column is 1.
        Actually, the column is the byte number (thus it's not exactly right
        for multi-byte characters). {not in Vi}
        WARNING: When inserting or deleting text Vim does not automatically
        update the matches. This means Syntax highlighting quickly becomes
        wrong.
        Example, to highlight the column where the cursor currently is:
                :exe '/\%' . col(".") . 'c'
       When 'hlsearch' is set and you move the cursor around and make changes
        this will clearly show when the match is updated or not.
        Example for matching a single byte in column 44:
                /\%>43c.\%<46c
       Note that "\%<46c" matches in column 45 when the "." matches a byte in
        column 44.
                                                /\%v   /\%>v   /\%<v
\%23v   Matches in a specific virtual column.
\%<23v Matches before a specific virtual column.
\%>23v Matches after a specific virtual column.
        These three can be used to match specific virtual columns in a buffer
        or string. When not matching with a buffer in a window, the option
        values of the current window are used (e.g., 'tabstop').
        The "23" can be any column number. The first column is 1.
        Note that some virtual column positions will never match, because they
        are halfway through a tab or other character that occupies more than
        one screen character. {not in Vi}
        WARNING: When inserting or deleting text Vim does not automatically
        update highlighted matches. This means Syntax highlighting quickly
        becomes wrong.
        Example, to highlight all the characters after virtual column 72:
                /\%>72v.*
       When 'hlsearch' is set and you move the cursor around and make changes
        this will clearly show when the match is updated or not.
        To match the text up to column 17:
                /^.*\%17v
       Column 17 is not included, because this is a /zero-width match. To
        include the column use:
                /^.*\%17v.
       This command does the same thing, but also matches when there is no

```
        character in column 17:
                /^.*\%<18v.
       Note that without the "^" to anchor the match in the first column,
        this will also highlight column 17:
                /.*\%17v
       Column 17 is highlighted by 'hlsearch' because there is another match
        where ".*" matches zero characters.
<

Character classes: {not in Vi}
\i      identifier character (see 'isident' option)      /\i
\I      like "\i", but excluding digits                  /\I
\k      keyword character (see 'iskeyword' option)       /\k
\K      like "\k", but excluding digits                  /\K
\f      file name character (see 'isfname' option)       /\f
\F      like "\f", but excluding digits                  /\F
\p      printable character (see 'isprint' option)       /\p
\P      like "\p", but excluding digits                  /\P

NOTE: the above also work for multi-byte characters.  The ones below only
match ASCII characters, as indicated by the range.

                                                 whitespace   white-space
\s      whitespace character: <Space> and <Tab>          /\s
\S      non-whitespace character; opposite of \s         /\S
\d      digit:                              [0-9]        /\d
\D      non-digit:                          [^0-9]       /\D
\x      hex digit:                          [0-9A-Fa-f]  /\x
\X      non-hex digit:                      [^0-9A-Fa-f] /\X
\o      octal digit:                        [0-7]        /\o
\O      non-octal digit:                    [^0-7]       /\O
\w      word character:                     [0-9A-Za-z_] /\w
\W      non-word character:                 [^0-9A-Za-z_] /\W
\h      head of word character:             [A-Za-z_]    /\h
\H      non-head of word character:         [^A-Za-z_]   /\H
\a      alphabetic character:               [A-Za-z]     /\a
\A      non-alphabetic character:           [^A-Za-z]    /\A
\l      lowercase character:                [a-z]        /\l
\L      non-lowercase character:            [^a-z]       /\L
\u      uppercase character:                [A-Z]        /\u
\U      non-uppercase character:            [^A-Z]       /\U

        NOTE: Using the atom is faster than the [] form.

        NOTE: 'ignorecase', "\c" and "\C" are not used by character classes.

                        /\_   E63   /\_i   /\_I   /\_k   /\_K   /\_f   /\_F
                        /\_p   /\_P   /\_s   /\_S   /\_d   /\_D   /\_x   /\_X
                        /\_o   /\_O   /\_w   /\_W   /\_h   /\_H   /\_a   /\_A
                        /\_l   /\_L   /\_u   /\_U
\_x     Where "x" is any of the characters above: The character class with
        end-of-line added
(end of character classes)
```

```
\e      matches <Esc>                                           /\e
\t      matches <Tab>                                           /\t
\r      matches <CR>                                            /\r
\b      matches <BS>                                            /\b
\n      matches an end-of-line                                  /\n
        When matching in a string instead of buffer text a literal newline
        character is matched.

~       matches the last given substitute string        /~   /\~

\(\)    A pattern enclosed by escaped parentheses.      /\(   /\(\)   /\)
        E.g., "\(^a\)" matches 'a' at the start of a line.
         E51   E54   E55   E872   E873

\1      Matches the same string that was matched by     /\1   E65
        the first sub-expression in \( and \). {not in Vi}
        Example: "\([a-z]\).\1" matches "ata", "ehe", "tot", etc.
\2      Like "\1", but uses second sub-expression,      /\2
   ...                                                  /\3
\9      Like "\1", but uses ninth sub-expression.       /\9
        Note: The numbering of groups is done based on which "\(" comes first
        in the pattern (going left to right), NOT based on what is matched
        first.

\%(\)   A pattern enclosed by escaped parentheses.      /\%(\)   /\%(   E53
        Just like \(\), but without counting it as a sub-expression.  This
        allows using more groups and it's a little bit faster.
        {not in Vi}

x       A single character, with no special meaning, matches itself

                                                        /\   /\\
\x      A backslash followed by a single character, with no special meaning,
        is reserved for future expansions

[]      (with 'nomagic': \[])           /[]   /\[]   /\_[]   /collection
\_[]
        A collection.  This is a sequence of characters enclosed in brackets.
        It matches any single character in the collection.
        Example         matches
        [xyz]           any 'x', 'y' or 'z'
        [a-zA-Z]$       any alphabetic character at the end of a line
        \c[a-z]$        same
        [A-яЁё]         Russian alphabet (with utf-8 and cp1251)

                                                                /[\n]
        With "\_" prepended the collection also includes the end-of-line.
        The same can be done by including "\n" in the collection.  The
        end-of-line is also matched when the collection starts with "^"!  Thus
        "\_[^ab]" matches the end-of-line and any character but "a" and "b".
        This makes it Vi compatible: Without the "\_" or "\n" the collection
        does not match an end-of-line.
                                                                E769
        When the ']' is not there Vim will not give an error message but
```

assume no collection is used. Useful to search for '['. However, you do get E769 for internal searching. And be aware that in a `:substitute` command the whole command becomes the pattern. E.g. ":s/[/x/" searches for "[/x" and replaces it with nothing. It does not search for "[" and replaces it with "x"!

E944 E945

If the sequence begins with "^", it matches any single character NOT in the collection: "[^xyz]" matches anything but 'x', 'y' and 'z'.

- If two characters in the sequence are separated by '-', this is shorthand for the full list of ASCII characters between them. E.g., "[0-9]" matches any decimal digit. If the starting character exceeds the ending character, e.g. [c-a], E944 occurs. Non-ASCII characters can be used, but the character values must not be more than 256 apart in the old regexp engine. For example, searching by [\u3000-\u4000] after setting re=1 emits a E945 error. Prepending \%#=2 will fix it.
- A character class expression is evaluated to the set of characters belonging to that character class. The following character classes are supported:

Name	Func	Contents
[:alnum:]	isalnum	ASCII letters and digits
[:alpha:]	isalpha	ASCII letters
[:blank:]		space and tab
[:cntrl:]	iscntrl	ASCII control characters
[:digit:]		decimal digits '0' to '9'
[:graph:]	isgraph	ASCII printable characters excluding space
[:lower:]	(1)	lowercase letters (all letters when 'ignorecase' is used)
[:print:]	(2)	printable characters including space
[:punct:]	ispunct	ASCII punctuation characters
[:space:]		whitespace characters: space, tab, CR, NL, vertical tab, form feed
[:upper:]	(3)	uppercase letters (all letters when 'ignorecase' is used)
[:xdigit:]		hexadecimal digits: 0-9, a-f, A-F
[:return:]		the <CR> character
[:tab:]		the <Tab> character
[:escape:]		the <Esc> character
[:backspace:]		the <BS> character

The brackets in character class expressions are additional to the brackets delimiting a collection. For example, the following is a plausible pattern for a UNIX filename: "[-./[:alnum:]_~]\+" That is, a list of at least one character, each of which is either '-', '.', '/', alphabetic, numeric, '_' or '~'.
These items only work for 8-bit characters, except [:lower:] and [:upper:] also work for multi-byte characters when using the new regexp engine. See two-engines . In the future these items may work for multi-byte characters. For now, to get all "alpha" characters you can use: [[:lower:][:upper:]].

The "Func" column shows what library function is used. The implementation depends on the system. Otherwise:
(1) Uses islower() for ASCII and Vim builtin rules for other

characters when built with the +multi_byte feature.
(2) Uses Vim builtin rules
(3) As with (1) but using isupper()

/[[= [==]

- An equivalence class. This means that characters are matched that have almost the same meaning, e.g., when ignoring accents. This only works for Unicode, latin1 and latin9. The form is:
  [=a=]

/[[. [..]

- A collation element. This currently simply accepts a single character in the form:
  [.a.]

/\]

- To include a literal ']', '^', '-' or '\' in the collection, put a backslash before it: "[xyz\]]", "[\^xyz]", "[xy\-z]" and "[xyz\\]". (Note: POSIX does not support the use of a backslash this way). For ']' you can also make it the first character (following a possible "^"): "[]xyz]" or "[^]xyz]" {not in Vi}.
  For '-' you can also make it the first or last character: "[-xyz]", "[^-xyz]" or "[xyz-]". For '\' you can also let it be followed by any character that's not in "^]-\bdertnoUux". "[\xyz]" matches '\', 'x', 'y' and 'z'. It's better to use "\\" though, future expansions may use other characters after '\'.
- Omitting the trailing] is not considered an error. "[]" works like "[]]", it matches the ']' character.
- The following translations are accepted when the 'l' flag is not included in 'cpoptions' {not in Vi}:

\e	<Esc>	
\t	<Tab>	
\r	<CR>	(NOT end-of-line!)
\b	<BS>	
\n	line break, see above	/[\n]
\d123	decimal number of character	
\o40	octal number of character up to 0377	
\x20	hexadecimal number of character up to 0xff	
\u20AC	hex. number of multibyte character up to 0xffff	
\U1234	hex. number of multibyte character up to 0xffffffff	

  NOTE: The other backslash codes mentioned above do not work inside []!
- Matching with a collection can be slow, because each character in the text has to be compared with each character in the collection. Use one of the other atoms above when possible. Example: "\d" is much faster than "[0-9]" and matches the same characters. However, the new NFA regexp engine deals with this better than the old one.

/\%[] E69 E70 E369

\%[] A sequence of optionally matched atoms. This always matches.
It matches as much of the list of atoms it contains as possible. Thus it stops at the first atom that doesn't match. For example:

```
/r\%[ead]
```

matches "r", "re", "rea" or "read". The longest that matches is used.
To match the Ex command "function", where "fu" is required and "nction" is optional, this would work:

```
/\<fu\%[nction]\>
```

The end-of-word atom "\>" is used to avoid matching "fu" in "full".
It gets more complicated when the atoms are not ordinary characters.
You don't often have to use it, but it is possible. Example:

```
/\<r\%[[eo]ad]\>
```

Matches the words "r", "re", "ro", "rea", "roa", "read" and "road".
There can be no \(\), \%(\) or \z(\) items inside the [] and \%[] does not nest.
To include a "[" use "[[]" and for "]" use []]", e.g.,:

```
/index\%[[[]0[]]]
```

matches "index" "index[", "index[0" and "index[0]".
{not available when compiled without the |+syntax| feature}

/\%d /\%x /\%o /\%u /\%U E678

\%d123 Matches the character specified with a decimal number. Must be followed by a non-digit.
\%o40 Matches the character specified with an octal number up to 0377. Numbers below 040 must be followed by a non-octal digit or a non-digit.
\%x2a Matches the character specified with up to two hexadecimal characters.
\%u20AC Matches the character specified with up to four hexadecimal characters.
\%U1234abcd Matches the character specified with up to eight hexadecimal characters.

==========

7. Ignoring case in a pattern /ignorecase

If the 'ignorecase' option is on, the case of normal letters is ignored.
'smartcase' can be set to ignore case when the pattern contains lowercase letters only.

/\c /\C

When "\c" appears anywhere in the pattern, the whole pattern is handled like 'ignorecase' is on. The actual value of 'ignorecase' and 'smartcase' is ignored. "\C" does the opposite: Force matching case for the whole pattern.
{only Vim supports \c and \C}
Note that 'ignorecase', "\c" and "\C" are not used for the character classes.

Examples:

pattern	'ignorecase'	'smartcase'	matches
foo	off	-	foo
foo	on	-	foo Foo FOO
Foo	on	off	foo Foo FOO
Foo	on	on	Foo
\cfoo	-	-	foo Foo FOO
foo\C	-	-	foo

Technical detail: NL-used-for-Nul
<Nul> characters in the file are stored as <NL> in memory. In the display they are shown as "^@". The translation is done when reading and writing files. To match a <Nul> with a search pattern you can just enter CTRL-@ or "CTRL-V 000". This is probably just what you expect. Internally the character is replaced with a <NL> in the search pattern. What is unusual is that typing CTRL-V CTRL-J also inserts a <NL>, thus also searches for a <Nul> in the file. {Vi cannot handle <Nul> characters in the file at all}

CR-used-for-NL

When 'fileformat' is "mac", <NL> characters in the file are stored as <CR> characters internally. In the text they are shown as "^J". Otherwise this works similar to the usage of <NL> for a <Nul>.

When working with expression evaluation, a <NL> character in the pattern matches a <NL> in the string. The use of "\n" (backslash n) to match a <NL> doesn't work there, it only works to match text in the buffer.

pattern-multi-byte

Patterns will also work with multi-byte characters, mostly as you would expect. But invalid bytes may cause trouble, a pattern with an invalid byte will probably never match.

==

8. Composing characters patterns-composing

/\Z

When "\Z" appears anywhere in the pattern, all composing characters are ignored. Thus only the base characters need to match, the composing characters may be different and the number of composing characters may differ. Only relevant when 'encoding' is "utf-8".
Exception: If the pattern starts with one or more composing characters, these must match.

/\%C

Use "\%C" to skip any composing characters. For example, the pattern "a" does not match in "càt" (where the a has the composing character 0x0300), but "a\%C" does. Note that this does not match "cát" (where the á is character 0xe1, it does not have a compositing character). It does match "cat" (where the a is just an a).

When a composing character appears at the start of the pattern of after an item that doesn't include the composing character, a match is found at any character that includes this composing character.

When using a dot and a composing character, this works the same as the composing character by itself, except that it doesn't matter what comes before this.

The order of composing characters does not matter. Also, the text may have more composing characters than the pattern, it still matches. But all composing characters in the pattern must be found in the text.

Suppose B is a base character and x and y are composing characters:

pattern	text	match
Bxy	Bxy	yes (perfect match)
Bxy	Byx	yes (order ignored)
Bxy	By	no (x missing)
Bxy	Bx	no (y missing)
Bx	Bx	yes (perfect match)
Bx	By	no (x missing)
Bx	Bxy	yes (extra y ignored)
Bx	Byx	yes (extra y ignored)

==
9. Compare with Perl patterns   perl-patterns

Vim's regexes are most similar to Perl's, in terms of what you can do. The
difference between them is mostly just notation; here's a summary of where
they differ:

Capability	in Vimspeak	in Perlspeak
force case insensitivity	\c	(?i)
force case sensitivity	\C	(?-i)
backref-less grouping	\%(atom\)	(?:atom)
conservative quantifiers	\{-n,m}	*?, +?, ??, {}?
0-width match	atom\@=	(?=atom)
0-width non-match	atom\@!	(?!atom)
0-width preceding match	atom\@<=	(?<=atom)
0-width preceding non-match	atom\@<!	(?<!atom)
match without retry	atom\@>	(?>atom)

Vim and Perl handle newline characters inside a string a bit differently:

In Perl, ^ and $ only match at the very beginning and end of the text,
by default, but you can set the 'm' flag, which lets them match at
embedded newlines as well. You can also set the 's' flag, which causes
a . to match newlines as well. (Both these flags can be changed inside
a pattern using the same syntax used for the i flag above, BTW.)

On the other hand, Vim's ^ and $ always match at embedded newlines, and
you get two separate atoms, \%^ and \%$, which only match at the very
start and end of the text, respectively. Vim solves the second problem
by giving you the _ "modifier": put it in front of a . or a character
class, and they will match newlines as well.

Finally, these constructs are unique to Perl:
- execution of arbitrary code in the regex: (?{perl code})
- conditional expressions: (?(condition)true-expr|false-expr)

...and these are unique to Vim:
- changing the magic-ness of a pattern: \v \V \m \M
   (very useful for avoiding backslashitis)
- sequence of optionally matching atoms: \%[atoms]
- \& (which is to \| what "and" is to "or"; it forces several branches
   to match at one spot)
- matching lines/columns by number: \%5l \%5c \%5v
- setting the start and end of the match: \zs \ze

==
10. Highlighting matches   match-highlight

                                                           :mat   :match
:mat[ch] {group} /{pattern}/
                Define a pattern to highlight in the current window. It will
                be highlighted with {group}. Example:

```
                :highlight MyGroup ctermbg=green guibg=green
                :match MyGroup /TODO/
            Instead of // any character can be used to mark the start and
            end of the {pattern}.  Watch out for using special characters,
            such as '"' and '|'.

            {group} must exist at the moment this command is executed.

            The {group} highlighting still applies when a character is
            to be highlighted for 'hlsearch', as the highlighting for
            matches is given higher priority than that of 'hlsearch'.
            Syntax highlighting (see 'syntax') is also overruled by
            matches.

            Note that highlighting the last used search pattern with
            'hlsearch' is used in all windows, while the pattern defined
            with ":match" only exists in the current window.  It is kept
            when switching to another buffer.

            'ignorecase' does not apply, use  /\c  in the pattern to
            ignore case.  Otherwise case is not ignored.

            'redrawtime' defines the maximum time searched for pattern
            matches.

            When matching end-of-line and Vim redraws only part of the
            display you may get unexpected results.  That is because Vim
            looks for a match in the line where redrawing starts.

            Also see  matcharg()  and  getmatches() . The former returns
            the highlight group and pattern of a previous  :match
            command.  The latter returns a list with highlight groups and
            patterns defined by both  matchadd()  and  :match .

            Highlighting matches using  :match  are limited to three
            matches (aside from  :match ,  :2match  and  :3match  are
            available).  matchadd()  does not have this limitation and in
            addition makes it possible to prioritize matches.

            Another example, which highlights all characters in virtual
            column 72 and more:
                :highlight rightMargin term=bold ctermfg=blue guifg=blue
                :match rightMargin /.\%>72v/
            To highlight all character that are in virtual column 7:
                :highlight col8 ctermbg=grey guibg=grey
                :match col8 /\%<8v.\%>7v/
            Note the use of two items to also match a character that
            occupies more than one virtual column, such as a TAB.

:mat[ch]
:mat[ch] none
            Clear a previously defined match pattern.
```

:2mat[ch] {group} /{pattern}/ :2match
:2mat[ch]
:2mat[ch] none
:3mat[ch] {group} /{pattern}/ :3match
:3mat[ch]
:3mat[ch] none

Just like :match above, but set a separate match. Thus there can be three matches active at the same time. The match with the lowest number has priority if several match at the same position.
The ":3match" command is used by the matchparen plugin. You are suggested to use ":match" for manual matching and ":2match" for another plugin.

vim:tw=78:ts=8:noet:ft=help:norl:

map.txt For Vim version 8.1. Last change: 2018 May 13

VIM REFERENCE MANUAL by Bram Moolenaar

Key mapping, abbreviations and user-defined commands.

This subject is introduced in sections 05.3 , 24.7 and 40.1 of the user manual.

==========

1. Key mapping key-mapping mapping macro

Key mapping is used to change the meaning of typed keys. The most common use is to define a sequence of commands for a function key. Example:

```
:map <F2> a<C-R>=strftime("%c")<CR><Esc>
```

This appends the current date and time after the cursor (in <> notation <>).

1.1 MAP COMMANDS :map-commands

There are commands to enter new mappings, remove mappings and list mappings. See map-overview for the various forms of "map" and their relationships with modes.

{lhs} means left-hand-side {lhs}
{rhs} means right-hand-side {rhs}

:map	{lhs} {rhs}	mapmode-nvo	:map
:nm[ap]	{lhs} {rhs}	mapmode-n	:nm :nmap
:vm[ap]	{lhs} {rhs}	mapmode-v	:vm :vmap
:xm[ap]	{lhs} {rhs}	mapmode-x	:xm :xmap
:smap	{lhs} {rhs}	mapmode-s	:smap
:om[ap]	{lhs} {rhs}	mapmode-o	:om :omap
:map!	{lhs} {rhs}	mapmode-ic	:map!

:im[ap] {lhs} {rhs} mapmode-i :im :imap
:lm[ap] {lhs} {rhs} mapmode-l :lm :lmap
:cm[ap] {lhs} {rhs} mapmode-c :cm :cmap
:tma[p] {lhs} {rhs} mapmode-t :tma :tmap

Map the key sequence {lhs} to {rhs} for the modes where the map command applies. The result, including {rhs}, is then further scanned for mapping. This allows for nested and recursive use of mappings.

:nore :norem
:no[remap] {lhs} {rhs} mapmode-nvo :no :noremap :nor
:nn[oremap] {lhs} {rhs} mapmode-n :nn :nnoremap
:vn[oremap] {lhs} {rhs} mapmode-v :vn :vnoremap
:xn[oremap] {lhs} {rhs} mapmode-x :xn :xnoremap
:snor[emap] {lhs} {rhs} mapmode-s :snor :snoremap
:ono[remap] {lhs} {rhs} mapmode-o :ono :onoremap
:no[remap]! {lhs} {rhs} mapmode-ic :no! :noremap!
:ino[remap] {lhs} {rhs} mapmode-i :ino :inoremap
:ln[oremap] {lhs} {rhs} mapmode-l :ln :lnoremap
:cno[remap] {lhs} {rhs} mapmode-c :cno :cnoremap
:tno[remap] {lhs} {rhs} mapmode-t :tno :tnoremap

Map the key sequence {lhs} to {rhs} for the modes where the map command applies. Disallow mapping of {rhs}, to avoid nested and recursive mappings. Often used to redefine a command. {not in Vi}

:unm[ap] {lhs} mapmode-nvo :unm :unmap
:nun[map] {lhs} mapmode-n :nun :nunmap
:vu[nmap] {lhs} mapmode-v :vu :vunmap
:xu[nmap] {lhs} mapmode-x :xu :xunmap
:sunm[ap] {lhs} mapmode-s :sunm :sunmap
:ou[nmap] {lhs} mapmode-o :ou :ounmap
:unm[ap]! {lhs} mapmode-ic :unm! :unmap!
:iu[nmap] {lhs} mapmode-i :iu :iunmap
:lu[nmap] {lhs} mapmode-l :lu :lunmap
:cu[nmap] {lhs} mapmode-c :cu :cunmap
:tunma[p] {lhs} mapmode-t :tunma :tunmap

Remove the mapping of {lhs} for the modes where the map command applies. The mapping may remain defined for other modes where it applies.
Note: Trailing spaces are included in the {lhs}. This unmap does NOT work:

```
:map @@ foo
:unmap @@ | print
```

:mapc[lear] mapmode-nvo :mapc :mapclear
:nmapc[lear] mapmode-n :nmapc :nmapclear
:vmapc[lear] mapmode-v :vmapc :vmapclear
:xmapc[lear] mapmode-x :xmapc :xmapclear
:smapc[lear] mapmode-s :smapc :smapclear
:omapc[lear] mapmode-o :omapc :omapclear
:mapc[lear]! mapmode-ic :mapc! :mapclear!
:imapc[lear] mapmode-i :imapc :imapclear

:lmapc[lear]		mapmode-l		:lmapc	:lmapclear
:cmapc[lear]		mapmode-c		:cmapc	:cmapclear
:tmapc[lear]		mapmode-t		:tmapc	:tmapclear
		Remove ALL mappings for the modes where the map
		command applies. {not in Vi}
		Use the <buffer> argument to remove buffer-local
		mappings :map-<buffer>
		Warning: This also removes the default mappings.

:map			mapmode-nvo
:nm[ap]			mapmode-n
:vm[ap]			mapmode-v
:xm[ap]			mapmode-x
:sm[ap]			mapmode-s
:om[ap]			mapmode-o
:map!			mapmode-ic
:im[ap]			mapmode-i
:lm[ap]			mapmode-l
:cm[ap]			mapmode-c
:tma[p]			mapmode-t
		List all key mappings for the modes where the map
		command applies. Note that ":map" and ":map!" are
		used most often, because they include the other modes.

:map {lhs}		mapmode-nvo		:map_l
:nm[ap] {lhs}		mapmode-n		:nmap_l
:vm[ap] {lhs}		mapmode-v		:vmap_l
:xm[ap] {lhs}		mapmode-x		:xmap_l
:sm[ap] {lhs}		mapmode-s		:smap_l
:om[ap] {lhs}		mapmode-o		:omap_l
:map! {lhs}		mapmode-ic		:map_l!
:im[ap] {lhs}		mapmode-i		:imap_l
:lm[ap] {lhs}		mapmode-l		:lmap_l
:cm[ap] {lhs}		mapmode-c		:cmap_l
:tma[p] {lhs}		mapmode-t		:tmap_l
		List the key mappings for the key sequences starting
		with {lhs} in the modes where the map command applies.
		{not in Vi}

These commands are used to map a key or key sequence to a string of
characters. You can use this to put command sequences under function keys,
translate one key into another, etc. See :mkexrc for how to save and
restore the current mappings.

map-ambiguous
When two mappings start with the same sequence of characters, they are
ambiguous. Example:
	:imap aa foo
	:imap aaa bar
When Vim has read "aa", it will need to get another character to be able to
decide if "aa" or "aaa" should be mapped. This means that after typing "aa"
that mapping won't get expanded yet, Vim is waiting for another character.
If you type a space, then "foo" will get inserted, plus the space. If you
type "a", then "bar" will get inserted.

{Vi does not allow ambiguous mappings}

1.2 SPECIAL ARGUMENTS :map-arguments

"<buffer>", "<nowait>", "<silent>", "<special>", "<script>", "<expr>" and "<unique>" can be used in any order. They must appear right after the command, before any other arguments.

:map-local :map-<buffer> E224 E225

If the first argument to one of these commands is "<buffer>" the mapping will be effective in the current buffer only. Example:

```
:map <buffer>  ,w  /[.,;]<CR>
```

Then you can map ",w" to something else in another buffer:

```
:map <buffer>  ,w  /[#&!]<CR>
```

The local buffer mappings are used before the global ones. See <nowait> below to make a short local mapping not taking effect when a longer global one exists.

The "<buffer>" argument can also be used to clear mappings:

```
:unmap <buffer> ,w
:mapclear <buffer>
```

Local mappings are also cleared when a buffer is deleted, but not when it is unloaded. Just like local option values.

Also see map-precedence .

:map-<nowait> :map-nowait

When defining a buffer-local mapping for "," there may be a global mapping that starts with ",". Then you need to type another character for Vim to know whether to use the "," mapping or the longer one. To avoid this add the <nowait> argument. Then the mapping will be used when it matches, Vim does not wait for more characters to be typed. However, if the characters were already typed they are used.

:map-<silent> :map-silent

To define a mapping which will not be echoed on the command line, add "<silent>" as the first argument. Example:

```
:map <silent> ,h /Header<CR>
```

The search string will not be echoed when using this mapping. Messages from the executed command are still given though. To shut them up too, add a ":silent" in the executed command:

```
:map <silent> ,h :exe ":silent normal /Header\r"<CR>
```

Prompts will still be given, e.g., for inputdialog().

Using "<silent>" for an abbreviation is possible, but will cause redrawing of the command line to fail.

:map-<special> :map-special

Define a mapping with <> notation for special keys, even though the "<" flag may appear in 'cpoptions'. This is useful if the side effect of setting 'cpoptions' is not desired. Example:

```
:map <special> <F12> /Header<CR>
```

:map-<script> :map-script

If the first argument to one of these commands is "<script>" and it is used to define a new mapping or abbreviation, the mapping will only remap characters

in the {rhs} using mappings that were defined local to a script, starting with "<SID>". This can be used to avoid that mappings from outside a script interfere (e.g., when CTRL-V is remapped in mswin.vim), but do use other mappings defined in the script.
Note: ":map <script>" and ":noremap <script>" do the same thing. The "<script>" overrules the command name. Using ":noremap <script>" is preferred, because it's clearer that remapping is (mostly) disabled.

:map-<unique> E226 E227
If the first argument to one of these commands is "<unique>" and it is used to define a new mapping or abbreviation, the command will fail if the mapping or abbreviation already exists. Example:
```
:map <unique> ,w /[#&!]<CR>
```
When defining a local mapping, there will also be a check if a global map already exists which is equal.
Example of what will fail:
```
:map ,w /[#&!]<CR>
:map <buffer> <unique> ,w /[.,;]<CR>
```
If you want to map a key and then have it do what it was originally mapped to, have a look at maparg() .

:map-<expr> :map-expression
If the first argument to one of these commands is "<expr>" and it is used to define a new mapping or abbreviation, the argument is an expression. The expression is evaluated to obtain the {rhs} that is used. Example:
```
:inoremap <expr> . InsertDot()
```
The result of the InsertDot() function will be inserted. It could check the text before the cursor and start omni completion when some condition is met.

For abbreviations v:char is set to the character that was typed to trigger the abbreviation. You can use this to decide how to expand the {lhs}. You should not either insert or change the v:char.

Be very careful about side effects! The expression is evaluated while obtaining characters, you may very well make the command dysfunctional.
For this reason the following is blocked:
- Changing the buffer text textlock .
- Editing another buffer.
- The :normal command.
- Moving the cursor is allowed, but it is restored afterwards.

If you want the mapping to do any of these let the returned characters do that.

You can use getchar(), it consumes typeahead if there is any. E.g., if you have these mappings:
```
inoremap <expr> <C-L> nr2char(getchar())
inoremap <expr> <C-L>x "foo"
```
If you now type CTRL-L nothing happens yet, Vim needs the next character to decide what mapping to use. If you type 'x' the second mapping is used and "foo" is inserted. If you type any other key the first mapping is used, getchar() gets the typed key and returns it.

Here is an example that inserts a list number that increases:
```
let counter = 0
```

```
        inoremap <expr> <C-L> ListItem()
        inoremap <expr> <C-R> ListReset()

        func ListItem()
          let g:counter += 1
          return g:counter . '. '
        endfunc

        func ListReset()
          let g:counter = 0
          return ''
        endfunc
```

CTRL-L inserts the next number, CTRL-R resets the count. CTRL-R returns an empty string, so that nothing is inserted.

Note that there are some tricks to make special keys work and escape CSI bytes in the text. The :map command also does this, thus you must avoid that it is done twice. This does not work:

```
        :imap <expr> <F3> "<Char-0x611B>"
```

Because the <Char- sequence is escaped for being a :imap argument and then again for using <expr>. This does work:

```
        :imap <expr> <F3> "\u611B"
```

Using 0x80 as a single byte before other text does not work, it will be seen as a special key.

1.3 MAPPING AND MODES

:map-modes
mapmode-nvo mapmode-n mapmode-v mapmode-o

There are six sets of mappings
- For Normal mode: When typing commands.
- For Visual mode: When typing commands while the Visual area is highlighted.
- For Select mode: like Visual mode but typing text replaces the selection.
- For Operator-pending mode: When an operator is pending (after "d", "y", "c", etc.). See below: omap-info .
- For Insert mode. These are also used in Replace mode.
- For Command-line mode: When entering a ":" or "/" command.

Special case: While typing a count for a command in Normal mode, mapping zero is disabled. This makes it possible to map zero without making it impossible to type a count with a zero.

map-overview map-modes

Overview of which map command works in which mode. More details below.

COMMANDS			MODES
:map	:noremap	:unmap	Normal, Visual, Select, Operator-pending
:nmap	:nnoremap	:nunmap	Normal
:vmap	:vnoremap	:vunmap	Visual and Select
:smap	:snoremap	:sunmap	Select
:xmap	:xnoremap	:xunmap	Visual
:omap	:onoremap	:ounmap	Operator-pending
:map!	:noremap!	:unmap!	Insert and Command-line
:imap	:inoremap	:iunmap	Insert

```
:lmap  :lnoremap :lunmap    Insert, Command-line, Lang-Arg
:cmap  :cnoremap :cunmap    Command-line
:tmap  :tnoremap :tunmap    Terminal-Job
```

COMMANDS				MODES		
				Normal	Visual+Select	Operator-pending
:map	:noremap	:unmap	:mapclear	yes	yes	yes
:nmap	:nnoremap	:nunmap	:nmapclear	yes	-	-
:vmap	:vnoremap	:vunmap	:vmapclear	-	yes	-
:omap	:onoremap	:ounmap	:omapclear	-	-	yes

:nunmap can also be used outside of a monastery.

mapmode-x mapmode-s

Some commands work both in Visual and Select mode, some in only one. Note that quite often "Visual" is mentioned where both Visual and Select mode apply. Select-mode-mapping

NOTE: Mapping a printable character in Select mode may confuse the user. It's better to explicitly use :xmap and :smap for printable characters. Or use :sunmap after defining the mapping.

COMMANDS				MODES	
				Visual	Select
:vmap	:vnoremap	:vunmap	:vmapclear	yes	yes
:xmap	:xnoremap	:xunmap	:xmapclear	yes	-
:smap	:snoremap	:sunmap	:smapclear	-	yes

mapmode-ic mapmode-i mapmode-c mapmode-l

Some commands work both in Insert mode and Command-line mode, some not:

COMMANDS				MODES		
				Insert	Command-line	Lang-Arg
:map!	:noremap!	:unmap!	:mapclear!	yes	yes	-
:imap	:inoremap	:iunmap	:imapclear	yes	-	-
:cmap	:cnoremap	:cunmap	:cmapclear	-	yes	-
:lmap	:lnoremap	:lunmap	:lmapclear	yes*	yes*	yes*

The original Vi did not have separate mappings for Normal/Visual/Operator-pending mode and for Insert/Command-line mode. Therefore the ":map" and ":map!" commands enter and display mappings for several modes. In Vim you can use the ":nmap", ":vmap", ":omap", ":cmap" and ":imap" commands to enter mappings for each mode separately.

mapmode-t

The terminal mappings are used in a terminal window, when typing keys for the job running in the terminal. See terminal-typing .

omap-info

Operator-pending mappings can be used to define a movement command that can be used with any operator. Simple example: ":omap { w" makes "y{" work like "yw" and "d{" like "dw".

To ignore the starting cursor position and select different text, you can have the omap start Visual mode to select the text to be operated upon. Example

that operates on a function name in the current line:
```
        onoremap <silent> F :<C-U>normal! 0f(hviw<CR>
```
The CTRL-U (<C-U>) is used to remove the range that Vim may insert. The Normal mode commands find the first '(' character and select the first word before it. That usually is the function name.

To enter a mapping for Normal and Visual mode, but not Operator-pending mode, first define it for all three modes, then unmap it for Operator-pending mode:
```
        :map    xx something-difficult
        :ounmap xx
```
Likewise for a mapping for Visual and Operator-pending mode or Normal and Operator-pending mode.

language-mapping

":lmap" defines a mapping that applies to:
- Insert mode
- Command-line mode
- when entering a search pattern
- the argument of the commands that accept a text character, such as "r" and "f"
- for the input() line

Generally: Whenever a character is to be typed that is part of the text in the buffer, not a Vim command character. "Lang-Arg" isn't really another mode, it's just used here for this situation.

The simplest way to load a set of related language mappings is by using the 'keymap' option. See 45.5 .

In Insert mode and in Command-line mode the mappings can be disabled with the CTRL-^ command i_CTRL-^ c_CTRL-^ . These commands change the value of the 'iminsert' option. When starting to enter a normal command line (not a search pattern) the mappings are disabled until a CTRL-^ is typed. The state last used is remembered for Insert mode and Search patterns separately. The state for Insert mode is also used when typing a character as an argument to command like "f" or "t".

Language mappings will never be applied to already mapped characters. They are only used for typed characters. This assumes that the language mapping was already done when typing the mapping.

1.4 LISTING MAPPINGS map-listing

When listing mappings the characters in the first two columns are:

CHAR	MODE
<Space>	Normal, Visual, Select and Operator-pending
n	Normal
v	Visual and Select
s	Select
x	Visual
o	Operator-pending
!	Insert and Command-line
i	Insert
l	":lmap" mappings for Insert, Command-line and Lang-Arg
c	Command-line
t	Terminal-Job

Just before the {rhs} a special character can appear:
        *   indicates that it is not remappable
        &   indicates that only script-local mappings are remappable
        @   indicates a buffer-local mapping

Everything from the first non-blank after {lhs} up to the end of the line
(or '|') is considered to be part of {rhs}. This allows the {rhs} to end
with a space.

Note: When using mappings for Visual mode, you can use the "'<" mark, which
is the start of the last selected Visual area in the current buffer '< .

The :filter command can be used to select what mappings to list. The
pattern is matched against the {lhs} and {rhs} in the raw form.

                                                              :map-verbose
When 'verbose' is non-zero, listing a key map will also display where it was
last defined. Example:

        :verbose map <C-W>*
        n <C-W>*   * <C-W><C-S>*
                Last set from /home/abcd/.vimrc

See :verbose-cmd for more information.

1.5 MAPPING SPECIAL KEYS   :map-special-keys

There are three ways to map a special key:
1. The Vi-compatible method: Map the key code. Often this is a sequence that
   starts with <Esc>. To enter a mapping like this you type ":map " and then
   you have to type CTRL-V before hitting the function key. Note that when
   the key code for the key is in the termcap (the t_ options), it will
   automatically be translated into the internal code and become the second
   way of mapping (unless the 'k' flag is included in 'cpoptions').
2. The second method is to use the internal code for the function key. To
   enter such a mapping type CTRL-K and then hit the function key, or use
   the form "#1", "#2", .. "#9", "#0", "<Up>", "<S-Down>", "<S-F7>", etc.
   (see table of keys key-notation , all keys from <Up> can be used). The
   first ten function keys can be defined in two ways: Just the number, like
   "#2", and with "<F>", like "<F2>". Both stand for function key 2. "#0"
   refers to function key 10, defined with option 't_f10', which may be
   function key zero on some keyboards. The <> form cannot be used when
   'cpoptions' includes the '<' flag.
3. Use the termcap entry, with the form <t_xx>, where "xx" is the name of the
   termcap entry. Any string entry can be used. For example:
     :map <t_F3> G
  Maps function key 13 to "G". This does not work if 'cpoptions' includes
   the '<' flag.

The advantage of the second and third method is that the mapping will work on
different terminals without modification (the function key will be
translated into the same internal code or the actual key code, no matter what

terminal you are using. The termcap must be correct for this to work, and you must use the same mappings).

DETAIL: Vim first checks if a sequence from the keyboard is mapped. If it isn't the terminal key codes are tried (see terminal-options). If a terminal code is found it is replaced with the internal code. Then the check for a mapping is done again (so you can map an internal code to something else). What is written into the script file depends on what is recognized. If the terminal key code was recognized as a mapping the key code itself is written to the script file. If it was recognized as a terminal code the internal code is written to the script file.

1.6 SPECIAL CHARACTERS :map-special-chars

map_backslash map-backslash

Note that only CTRL-V is mentioned here as a special character for mappings and abbreviations. When 'cpoptions' does not contain 'B', a backslash can also be used like CTRL-V. The <> notation can be fully used then <> . But you cannot use "<C-V>" like CTRL-V to escape the special meaning of what follows.

To map a backslash, or use a backslash literally in the {rhs}, the special sequence "<Bslash>" can be used. This avoids the need to double backslashes when using nested mappings.

map_CTRL-C map-CTRL-C

Using CTRL-C in the {lhs} is possible, but it will only work when Vim is waiting for a key, not when Vim is busy with something. When Vim is busy CTRL-C interrupts/breaks the command.
When using the GUI version on MS-Windows CTRL-C can be mapped to allow a Copy command to the clipboard. Use CTRL-Break to interrupt Vim.

map_space_in_lhs map-space_in_lhs

To include a space in {lhs} precede it with a CTRL-V (type two CTRL-Vs for each space).

map_space_in_rhs map-space_in_rhs

If you want a {rhs} that starts with a space, use "<Space>". To be fully Vi compatible (but unreadable) don't use the <> notation, precede {rhs} with a single CTRL-V (you have to type CTRL-V two times).

map_empty_rhs map-empty-rhs

You can create an empty {rhs} by typing nothing after a single CTRL-V (you have to type CTRL-V two times). Unfortunately, you cannot do this in a vimrc file.

<Nop>

An easier way to get a mapping that doesn't produce anything, is to use "<Nop>" for the {rhs}. This only works when the <> notation is enabled. For example, to make sure that function key 8 does nothing at all:

```
:map  <F8>  <Nop>
:map! <F8>  <Nop>
```

map-multibyte

It is possible to map multibyte characters, but only the whole character. You cannot map the first byte only. This was done to prevent problems in this scenario:

```
        :set encoding=latin1
        :imap <M-C> foo
        :set encoding=utf-8
```
The mapping for <M-C> is defined with the latin1 encoding, resulting in a 0xc3 byte. If you type the character á (0xe1 <M-a>) in UTF-8 encoding this is the two bytes 0xc3 0xa1. You don't want the 0xc3 byte to be mapped then or otherwise it would be impossible to type the á character.

<Leader> mapleader

To define a mapping which uses the "mapleader" variable, the special string "<Leader>" can be used. It is replaced with the string value of "mapleader". If "mapleader" is not set or empty, a backslash is used instead. Example:
```
        :map <Leader>A  oanother line<Esc>
```
Works like:
```
        :map \A  oanother line<Esc>
```
But after:
```
        :let mapleader = ","
```
It works like:
```
        :map ,A  oanother line<Esc>
```

Note that the value of "mapleader" is used at the moment the mapping is defined. Changing "mapleader" after that has no effect for already defined mappings.

<LocalLeader> maplocalleader

<LocalLeader> is just like <Leader>, except that it uses "maplocalleader" instead of "mapleader". <LocalLeader> is to be used for mappings which are local to a buffer. Example:
```
      :map <buffer> <LocalLeader>A  oanother line<Esc>
```

In a global plugin <Leader> should be used and in a filetype plugin <LocalLeader>. "mapleader" and "maplocalleader" can be equal. Although, if you make them different, there is a smaller chance of mappings from global plugins to clash with mappings for filetype plugins. For example, you could keep "mapleader" at the default backslash, and set "maplocalleader" to an underscore.

map-<SID>

In a script the special key name "<SID>" can be used to define a mapping that's local to the script. See <SID> for details.

<Plug>

The special key name "<Plug>" can be used for an internal mapping, which is not to be matched with any key sequence. This is useful in plugins using-<Plug> .

<Char> <Char->

To map a character by its decimal, octal or hexadecimal number the <Char> construct can be used:
```
        <Char-123>      character 123
        <Char-033>      character 27
        <Char-0x7f>     character 127
        <S-Char-114>    character 114 ('r') shifted ('R')
```
This is useful to specify a (multi-byte) character in a 'keymap' file.

Upper and lowercase differences are ignored.

map-comments
It is not possible to put a comment after these commands, because the '"'
character is considered to be part of the {lhs} or {rhs}. However, one can
use |", since this starts a new, empty command with a comment.

map_bar map-bar
Since the '|' character is used to separate a map command from the next
command, you will have to do something special to include a '|' in {rhs}.
There are three methods:

use	works when	example
<Bar>	'<' is not in 'cpoptions'	:map _l :!ls <Bar> more^M
|	'b' is not in 'cpoptions'	:map _l :!ls | more^M
^V|	always, in Vim and Vi	:map _l :!ls ^V| more^M

(here ^V stands for CTRL-V; to get one CTRL-V you have to type it twice; you
cannot use the <> notation "<C-V>" here).

All three work when you use the default setting for 'cpoptions'.

When 'b' is present in 'cpoptions', "\|" will be recognized as a mapping
ending in a '\' and then another command. This is Vi compatible, but
illogical when compared to other commands.

map_return map-return
When you have a mapping that contains an Ex command, you need to put a line
terminator after it to have it executed. The use of <CR> is recommended for
this (see <>). Example:

```
:map  _ls  :!ls -l %:S<CR>:echo "the end"<CR>
```

To avoid mapping of the characters you type in insert or Command-line mode,
type a CTRL-V first. The mapping in Insert mode is disabled if the 'paste'
option is on.

map-error
Note that when an error is encountered (that causes an error message or beep)
the rest of the mapping is not executed. This is Vi-compatible.

Note that the second character (argument) of the commands @zZtTfF[]rm'`"v
and CTRL-X is not mapped. This was done to be able to use all the named
registers and marks, even when the command with the same name has been
mapped.

1.7 WHAT KEYS TO MAP map-which-keys

If you are going to map something, you will need to choose which key(s) to use
for the {lhs}. You will have to avoid keys that are used for Vim commands,
otherwise you would not be able to use those commands anymore. Here are a few
suggestions:
- Function keys <F2>, <F3>, etc.. Also the shifted function keys <S-F1>,
  <S-F2>, etc. Note that <F1> is already used for the help command.
- Meta-keys (with the ALT key pressed). Depending on your keyboard accented
  characters may be used as well. :map-alt-keys

- Use the '_' or ',' character and then any other character. The "_" and "," commands do exist in Vim (see _ and ,), but you probably never use them.
- Use a key that is a synonym for another command. For example: CTRL-P and CTRL-N. Use an extra character to allow more mappings.
- The key defined by <Leader> and one or more other keys. This is especially useful in scripts. mapleader

See the file "index" for keys that are not used and thus can be mapped without losing any builtin function. You can also use ":help {key}^D" to find out if a key is used for some command. ({key} is the specific key you want to find out about, ^D is CTRL-D).

1.8 EXAMPLES map-examples

A few examples (given as you type them, for "<CR>" you type four characters; the '<' flag must not be present in 'cpoptions' for this to work).

```
:map <F3>  o#include
:map <M-g> /foo<CR>cwbar<Esc>
:map _x    d/END/e<CR>
:map! qq   quadrillion questions
```

Multiplying a count

When you type a count before triggering a mapping, it's like the count was typed before the {lhs}. For example, with this mapping:

```
:map <F4>  3w
```

Typing 2<F4> will result in "23w". Thus not moving 2 * 3 words but 23 words. If you want to multiply counts use the expression register:

```
:map <F4>  @='3w'<CR>
```

The part between quotes is the expression being executed. @=

1.9 USING MAPPINGS map-typing

Vim will compare what you type with the start of a mapped sequence. If there is an incomplete match, it will get more characters until there either is a complete match or until there is no match at all. Example: If you map! "qq", the first 'q' will not appear on the screen until you type another character. This is because Vim cannot know if the next character will be a 'q' or not. If the 'timeout' option is on (which is the default) Vim will only wait for one second (or as long as specified with the 'timeoutlen' option). After that it assumes that the 'q' is to be interpreted as such. If you type slowly, or your system is slow, reset the 'timeout' option. Then you might want to set the 'ttimeout' option.

map-precedence

Buffer-local mappings (defined using :map-<buffer>) take precedence over global mappings. When a buffer-local mapping is the same as a global mapping, Vim will use the buffer-local mapping. In addition, Vim will use a complete mapping immediately if it was defined with <nowait>, even if a longer mapping has the same prefix. For example, given the following two mappings:

```
    :map <buffer> <nowait> \a   :echo "Local \a"<CR>
    :map                   \abc :echo "Global \abc"<CR>
```
When typing \a the buffer-local mapping will be used immediately. Vim will
not wait for more characters to see if the user might be typing \abc.

map-keys-fails
There are situations where key codes might not be recognized:
- Vim can only read part of the key code. Mostly this is only the first
  character. This happens on some Unix versions in an xterm.
- The key code is after character(s) that are mapped. E.g., "<F1><F1>" or
  "g<F1>".

The result is that the key code is not recognized in this situation, and the
mapping fails. There are two actions needed to avoid this problem:

- Remove the 'K' flag from 'cpoptions'. This will make Vim wait for the rest
  of the characters of the function key.
- When using <F1> to <F4> the actual key code generated may correspond to
  <xF1> to <xF4>. There are mappings from <xF1> to <F1>, <xF2> to <F2>, etc.,
  but these are not recognized after another half a mapping. Make sure the
  key codes for <F1> to <F4> are correct:
```
        :set <F1>=<type CTRL-V><type F1>
```
 Type the <F1> as four characters. The part after the "=" must be done with
  the actual keys, not the literal text.
Another solution is to use the actual key code in the mapping for the second
special key:
```
        :map <F1><Esc>OP :echo "yes"<CR>
```
Don't type a real <Esc>, Vim will recognize the key code and replace it with
<F1> anyway.

Another problem may be that when keeping ALT or Meta pressed the terminal
prepends ESC instead of setting the 8th bit. See :map-alt-keys .

recursive_mapping
If you include the {lhs} in the {rhs} you have a recursive mapping. When
{lhs} is typed, it will be replaced with {rhs}. When the {lhs} which is
included in {rhs} is encountered it will be replaced with {rhs}, and so on.
This makes it possible to repeat a command an infinite number of times. The
only problem is that the only way to stop this is by causing an error. The
macros to solve a maze uses this, look there for an example. There is one
exception: If the {rhs} starts with {lhs}, the first character is not mapped
again (this is Vi compatible).
For example:
```
   :map ab abcd
```
will execute the "a" command and insert "bcd" in the text. The "ab" in the
{rhs} will not be mapped again.

If you want to exchange the meaning of two keys you should use the :noremap
command. For example:
```
   :noremap k j
   :noremap j k
```
This will exchange the cursor up and down commands.

With the normal :map command, when the 'remap' option is on, mapping takes

place until the text is found not to be a part of a {lhs}. For example, if you use:

```
:map x y
:map y x
```

Vim will replace x with y, and then y with x, etc. When this has happened 'maxmapdepth' times (default 1000), Vim will give the error message "recursive mapping".

:map-undo

If you include an undo command inside a mapped sequence, this will bring the text back in the state before executing the macro. This is compatible with the original Vi, as long as there is only one undo command in the mapped sequence (having two undo commands in a mapped sequence did not make sense in the original Vi, you would get back the text before the first undo).

1.10 MAPPING ALT-KEYS :map-alt-keys

In the GUI Vim handles the Alt key itself, thus mapping keys with ALT should always work. But in a terminal Vim gets a sequence of bytes and has to figure out whether ALT was pressed or not.

By default Vim assumes that pressing the ALT key sets the 8th bit of a typed character. Most decent terminals can work that way, such as xterm, aterm and rxvt. If your <A-k> mappings don't work it might be that the terminal is prefixing the character with an ESC character. But you can just as well type ESC before a character, thus Vim doesn't know what happened (except for checking the delay between characters, which is not reliable).

As of this writing, some mainstream terminals like gnome-terminal and konsole use the ESC prefix. There doesn't appear a way to have them use the 8th bit instead. Xterm should work well by default. Aterm and rxvt should work well when started with the "--meta8" argument. You can also tweak resources like "metaSendsEscape", "eightBitInput" and "eightBitOutput".

On the Linux console, this behavior can be toggled with the "setmetamode" command. Bear in mind that not using an ESC prefix could get you in trouble with other programs. You should make sure that bash has the "convert-meta" option set to "on" in order for your Meta keybindings to still work on it (it's the default readline behavior, unless changed by specific system configuration). For that, you can add the line:

```
set convert-meta on
```

to your ~/.inputrc file. If you're creating the file, you might want to use:

```
$include /etc/inputrc
```

as the first line, if that file exists on your system, to keep global options. This may cause a problem for entering special characters, such as the umlaut. Then you should use CTRL-V before that character.

Bear in mind that convert-meta has been reported to have troubles when used in UTF-8 locales. On terminals like xterm, the "metaSendsEscape" resource can be

toggled on the fly through the "Main Options" menu, by pressing Ctrl-LeftClick on the terminal; that's a good last resource in case you want to send ESC when using other applications but not when inside Vim.

1.11 MAPPING AN OPERATOR :map-operator

An operator is used before a {motion} command. To define your own operator you must create mapping that first sets the 'operatorfunc' option and then invoke the g@ operator. After the user types the {motion} command the specified function will be called.

g@ E774 E775

g@{motion} Call the function set by the 'operatorfunc' option.
The '[mark is positioned at the start of the text moved over by {motion}, the '] mark on the last character of the text.
The function is called with one String argument:
"line" {motion} was linewise
"char" {motion} was characterwise
"block" {motion} was blockwise-visual
Although "block" would rarely appear, since it can only result from Visual mode where "g@" is not useful.
{not available when compiled without the +eval feature}

Here is an example that counts the number of spaces with <F4>:

```
nmap <silent> <F4> :set opfunc=CountSpaces<CR>g@
vmap <silent> <F4> :<C-U>call CountSpaces(visualmode(), 1)<CR>

function! CountSpaces(type, ...)
  let sel_save = &selection
  let &selection = "inclusive"
  let reg_save = @@

  if a:0  " Invoked from Visual mode, use gv command.
    silent exe "normal! gvy"
  elseif a:type == 'line'
    silent exe "normal! '[V']y"
  else
    silent exe "normal! `[v`]y"
  endif

  echomsg strlen(substitute(@@, '[^ ]', '', 'g'))

  let &selection = sel_save
  let @@ = reg_save
endfunction
```

Note that the 'selection' option is temporarily set to "inclusive" to be able to yank exactly the right text by using Visual mode from the '[to the '] mark.

Also note that there is a separate mapping for Visual mode. It removes the "'<,'>" range that ":" inserts in Visual mode and invokes the function with visualmode() and an extra argument.

==
2. Abbreviations   abbreviations   Abbreviations

Abbreviations are used in Insert mode, Replace mode and Command-line mode.
If you enter a word that is an abbreviation, it is replaced with the word it
stands for. This can be used to save typing for often used long words. And
you can use it to automatically correct obvious spelling errors.
Examples:

```
        :iab ms Microsoft
        :iab tihs this
```

There are three types of abbreviations:

full-id   The "full-id" type consists entirely of keyword characters (letters
          and characters from 'iskeyword' option). This is the most common
          abbreviation.

          Examples: "foo", "g3", "-1"

end-id   The "end-id" type ends in a keyword character, but all the other
          characters are not keyword characters.

          Examples: "#i", "..f", "$/7"

non-id   The "non-id" type ends in a non-keyword character, the other
          characters may be of any type, excluding space and tab. {this type
          is not supported by Vi}

          Examples: "def#", "4/7$"

Examples of strings that cannot be abbreviations: "a.b", "#def", "a b", "_$r"

An abbreviation is only recognized when you type a non-keyword character.
This can also be the <Esc> that ends insert mode or the <CR> that ends a
command. The non-keyword character which ends the abbreviation is inserted
after the expanded abbreviation. An exception to this is the character <C-]>,
which is used to expand an abbreviation without inserting any extra
characters.

Example:
```
   :ab hh       hello
           "hh<Space>" is expanded to "hello<Space>"
            "hh<C-]>" is expanded to "hello"
```

The characters before the cursor must match the abbreviation. Each type has
an additional rule:

full-id   In front of the match is a non-keyword character, or this is where
          the line or insertion starts. Exception: When the abbreviation is

```
          only one character, it is not recognized if there is a non-keyword
          character in front of it, other than a space or a tab. However, for
          the command line "'<,'>" (or any other marks) is ignored, as if the
          command line starts after it.

end-id    In front of the match is a keyword character, or a space or a tab,
          or this is where the line or insertion starts.

non-id    In front of the match is a space, tab or the start of the line or
          the insertion.

Examples: ({CURSOR} is where you type a non-keyword character)
   :ab foo   four old otters
               " foo{CURSOR}"    is expanded to " four old otters"
                " foobar{CURSOR}" is not expanded
                "barfoo{CURSOR}"  is not expanded

   :ab #i #include
              "#i{CURSOR}"      is expanded to "#include"
               ">#i{CURSOR}"     is not expanded

   :ab ;; <endofline>
              "test;;"          is not expanded
               "test ;;"         is expanded to "test <endofline>"

To avoid the abbreviation in Insert mode: Type CTRL-V before the character
that would trigger the abbreviation.  E.g. CTRL-V <Space>.  Or type part of
the abbreviation, exit insert mode with <Esc>, re-enter insert mode with "a"
and type the rest.

To avoid the abbreviation in Command-line mode: Type CTRL-V twice somewhere in
the abbreviation to avoid it to be replaced.  A CTRL-V in front of a normal
character is mostly ignored otherwise.

It is possible to move the cursor after an abbreviation:
   :iab if if ()<Left>
This does not work if 'cpoptions' includes the '<' flag.  <>

You can even do more complicated things.  For example, to consume the space
typed after an abbreviation:
   func Eatchar(pat)
      let c = nr2char(getchar(0))
      return (c =~ a:pat) ? '' : c
   endfunc
   iabbr <silent> if if ()<Left><C-R>=Eatchar('\s')<CR>

There are no default abbreviations.

Abbreviations are never recursive.  You can use ":ab f f-o-o" without any
problem.  But abbreviations can be mapped.  {some versions of Vi support
recursive abbreviations, for no apparent reason}

Abbreviations are disabled if the 'paste' option is on.
```

:abbreviate-local :abbreviate-<buffer>
Just like mappings, abbreviations can be local to a buffer. This is mostly used in a filetype-plugin file. Example for a C plugin file:

```
:abb <buffer> FF  for (i = 0; i < ; ++i)
```

:ab :abbreviate
:ab[breviate] list all abbreviations. The character in the first column indicates the mode where the abbreviation is used: 'i' for insert mode, 'c' for Command-line mode, '!' for both. These are the same as for mappings, see map-listing .

:abbreviate-verbose
When 'verbose' is non-zero, listing an abbreviation will also display where it was last defined. Example:

```
:verbose abbreviate
!  teh           the
        Last set from /home/abcd/vim/abbr.vim
```

See :verbose-cmd for more information.

:ab[breviate] {lhs} list the abbreviations that start with {lhs}
You may need to insert a CTRL-V (type it twice) to avoid that a typed {lhs} is expanded, since command-line abbreviations apply here.

:ab[breviate] [<expr>] [<buffer>] {lhs} {rhs}
add abbreviation for {lhs} to {rhs}. If {lhs} already existed it is replaced with the new {rhs}. {rhs} may contain spaces.
See :map-<expr> for the optional <expr> argument.
See :map-<buffer> for the optional <buffer> argument.

:una :unabbreviate
:una[bbreviate] {lhs} Remove abbreviation for {lhs} from the list. If none is found, remove abbreviations in which {lhs} matches with the {rhs}. This is done so that you can even remove abbreviations after expansion. To avoid expansion insert a CTRL-V (type it twice).

:norea :noreabbrev
:norea[bbrev] [<expr>] [<buffer>] [lhs] [rhs]
same as ":ab", but no remapping for this {rhs} {not in Vi}

:ca :cabbrev
:ca[bbrev] [<expr>] [<buffer>] [lhs] [rhs]
same as ":ab", but for Command-line mode only. {not in Vi}

:cuna :cunabbrev
:cuna[bbrev] {lhs} same as ":una", but for Command-line mode only. {not in Vi}

:cnorea :cnoreabbrev
:cnorea[bbrev] [<expr>] [<buffer>] [lhs] [rhs]
                        same as ":ab", but for Command-line mode only and no
                        remapping for this {rhs} {not in Vi}

:ia :iabbrev
:ia[bbrev] [<expr>] [<buffer>] [lhs] [rhs]
                        same as ":ab", but for Insert mode only. {not in Vi}

:iuna :iunabbrev
:iuna[bbrev] {lhs}   same as ":una", but for insert mode only. {not in
                        Vi}

:inorea :inoreabbrev
:inorea[bbrev] [<expr>] [<buffer>] [lhs] [rhs]
                        same as ":ab", but for Insert mode only and no
                        remapping for this {rhs} {not in Vi}

:abc :abclear
:abc[lear] [<buffer>]   Remove all abbreviations. {not in Vi}

:iabc :iabclear
:iabc[lear] [<buffer>] Remove all abbreviations for Insert mode. {not in Vi}

:cabc :cabclear
:cabc[lear] [<buffer>] Remove all abbreviations for Command-line mode. {not
                        in Vi}

using_CTRL-V
It is possible to use special characters in the rhs of an abbreviation.
CTRL-V has to be used to avoid the special meaning of most non printable
characters. How many CTRL-Vs need to be typed depends on how you enter the
abbreviation. This also applies to mappings. Let's use an example here.

Suppose you want to abbreviate "esc" to enter an <Esc> character. When you
type the ":ab" command in Vim, you have to enter this: (here ^V is a CTRL-V
and ^[is <Esc>)

You type: ab esc ^V^V^V^V^V^[

        All keyboard input is subjected to ^V quote interpretation, so
        the first, third, and fifth ^V characters simply allow the second,
        and fourth ^Vs, and the ^[, to be entered into the command-line.

You see: ab esc ^V^V^[

        The command-line contains two actual ^Vs before the ^[. This is
        how it should appear in your .exrc file, if you choose to go that
        route. The first ^V is there to quote the second ^V; the :ab
        command uses ^V as its own quote character, so you can include quoted
        whitespace or the | character in the abbreviation. The :ab command
        doesn't do anything special with the ^[character, so it doesn't need
        to be quoted. (Although quoting isn't harmful; that's why typing 7

[but not 8!] ^Vs works.)

Stored as: esc   ^V^[

After parsing, the abbreviation's short form ("esc") and long form (the two characters "^V^[") are stored in the abbreviation table. If you give the :ab command with no arguments, this is how the abbreviation will be displayed.

Later, when the abbreviation is expanded because the user typed in the word "esc", the long form is subjected to the same type of ^V interpretation as keyboard input. So the ^V protects the ^[character from being interpreted as the "exit Insert mode" character. Instead, the ^[is inserted into the text.

Expands to: ^[

[example given by Steve Kirkendall]

==
3. Local mappings and functions   script-local

When using several Vim script files, there is the danger that mappings and functions used in one script use the same name as in other scripts. To avoid this, they can be made local to the script.

                                                    <SID> <SNR> E81
The string "<SID>" can be used in a mapping or menu. This requires that the '<' flag is not present in 'cpoptions'.
   When executing the map command, Vim will replace "<SID>" with the special key code <SNR>, followed by a number that's unique for the script, and an underscore. Example:

```
:map <SID>Add
```

could define a mapping "<SNR>23_Add".

When defining a function in a script, "s:" can be prepended to the name to make it local to the script. But when a mapping is executed from outside of the script, it doesn't know in which script the function was defined. To avoid this problem, use "<SID>" instead of "s:". The same translation is done as for mappings. This makes it possible to define a call to the function in a mapping.

When a local function is executed, it runs in the context of the script it was defined in. This means that new functions and mappings it defines can also use "s:" or "<SID>" and it will use the same unique number as when the function itself was defined. Also, the "s:var" local script variables can be used.

When executing an autocommand or a user command, it will run in the context of the script it was defined in. This makes it possible that the command calls a local function or uses a local mapping.

Otherwise, using "<SID>" outside of a script context is an error.

If you need to get the script number to use in a complicated script, you can use this function:

```
function s:SID()
  return matchstr(expand('<sfile>'), '<SNR>\zs\d\+\ze_SID$')
endfun
```

The "<SNR>" will be shown when listing functions and mappings. This is useful to find out what they are defined to.

The :scriptnames command can be used to see which scripts have been sourced and what their <SNR> number is.

This is all {not in Vi} and {not available when compiled without the +eval feature}.

==
4. User-defined commands user-commands

It is possible to define your own Ex commands. A user-defined command can act just like a built-in command (it can have a range or arguments, arguments can be completed as filenames or buffer names, etc), except that when the command is executed, it is transformed into a normal Ex command and then executed.

For starters: See section 40.2 in the user manual.

E183 E841 user-cmd-ambiguous

All user defined commands must start with an uppercase letter, to avoid confusion with builtin commands. Exceptions are these builtin commands:

```
:Next
:X
```

They cannot be used for a user defined command. ":Print" is also an existing command, but it is deprecated and can be overruled.

The other characters of the user command can be uppercase letters, lowercase letters or digits. When using digits, note that other commands that take a numeric argument may become ambiguous. For example, the command ":Cc2" could be the user command ":Cc2" without an argument, or the command ":Cc" with argument "2". It is advised to put a space between the command name and the argument to avoid these problems.

When using a user-defined command, the command can be abbreviated. However, if an abbreviation is not unique, an error will be issued. Furthermore, a built-in command will always take precedence.

Example:

```
:command Rename ...
:command Renumber ...
:Rena                          " Means "Rename"
:Renu                          " Means "Renumber"
:Ren                           " Error - ambiguous
:command Paste ...
:P                             " The built-in :Print
```

It is recommended that full names for user-defined commands are used in

scripts.

:com[mand]   :com   :command
                        List all user-defined commands. When listing commands,
                        the characters in the first two columns are
                            !   Command has the -bang attribute
                            "   Command has the -register attribute
                            b   Command is local to current buffer
                        (see below for details on attributes)
                        The list can be filtered on command name with
                         :filter , e.g., to list all commands with "Pyth" in
                        the name:
                                filter Pyth command

:com[mand] {cmd}   List the user-defined commands that start with {cmd}

                                                              :command-verbose
When 'verbose' is non-zero, listing a command will also display where it was
last defined. Example:

    :verbose command TOhtml
       Name   Args Range Complete Definition
        TOhtml   0   %   :call Convert2HTML(<line1>, <line2>)
            Last set from /usr/share/vim/vim-7.0/plugin/tohtml.vim

See :verbose-cmd for more information.

                                                              E174   E182
:com[mand][!] [{attr}...] {cmd} {rep}
                        Define a user command. The name of the command is
                        {cmd} and its replacement text is {rep}. The command's
                        attributes (see below) are {attr}. If the command
                        already exists, an error is reported, unless a ! is
                        specified, in which case the command is redefined.

:delc[ommand] {cmd}   :delc   :delcommand   E184
                        Delete the user-defined command {cmd}.

:comc[lear]   :comc   :comclear
                        Delete all user-defined commands.

Command attributes

User-defined commands are treated by Vim just like any other Ex commands. They
can have arguments, or have a range specified. Arguments are subject to
completion as filenames, buffers, etc. Exactly how this works depends upon the
command's attributes, which are specified when the command is defined.

There are a number of attributes, split into four categories: argument
handling, completion behavior, range handling, and special cases. The
attributes are described below, by category.

Argument handling   E175   E176   :command-nargs

By default, a user defined command will take no arguments (and an error is reported if any are supplied). However, it is possible to specify that the command can take arguments, using the -nargs attribute. Valid cases are:

```
        -nargs=0    No arguments are allowed (the default)
        -nargs=1    Exactly one argument is required, it includes spaces
        -nargs=*    Any number of arguments are allowed (0, 1, or many),
                    separated by white space
        -nargs=?    0 or 1 arguments are allowed
        -nargs=+    Arguments must be supplied, but any number are allowed
```

Arguments are considered to be separated by (unescaped) spaces or tabs in this context, except when there is one argument, then the white space is part of the argument.

Note that arguments are used as text, not as expressions. Specifically, "s:var" will use the script-local variable in the script where the command was defined, not where it is invoked! Example:

```
    script1.vim:
        :let s:error = "None"
        :command -nargs=1 Error echoerr <args>
   script2.vim:
        :source script1.vim
        :let s:error = "Wrong!"
        :Error s:error
```

Executing script2.vim will result in "None" being echoed. Not what you intended! Calling a function may be an alternative.

Completion behavior :command-completion E179 E180 E181 :command-complete

By default, the arguments of user defined commands do not undergo completion. However, by specifying one or the other of the following attributes, argument completion can be enabled:

```
        -complete=arglist       file names in argument list
        -complete=augroup       autocmd groups
        -complete=buffer        buffer names
        -complete=behave        :behave suboptions
        -complete=color         color schemes
        -complete=command       Ex command (and arguments)
        -complete=compiler      compilers
        -complete=cscope         :cscope  suboptions
        -complete=dir           directory names
        -complete=environment   environment variable names
        -complete=event         autocommand events
        -complete=expression    Vim expression
        -complete=file          file and directory names
        -complete=file_in_path  file and directory names in  'path'
        -complete=filetype      filetype names  'filetype'
        -complete=function      function name
        -complete=help          help subjects
        -complete=highlight     highlight groups
        -complete=history       :history suboptions
        -complete=locale        locale names (as output of locale -a)
```

```
        -complete=mapclear      buffer argument
        -complete=mapping       mapping name
        -complete=menu          menus
        -complete=messages       :messages  suboptions
        -complete=option        options
        -complete=packadd       optional package  pack-add  names
        -complete=shellcmd      Shell command
        -complete=sign           :sign  suboptions
        -complete=syntax        syntax file names  'syntax'
        -complete=syntime        :syntime  suboptions
        -complete=tag           tags
        -complete=tag_listfiles tags, file names are shown when CTRL-D is hit
        -complete=user          user names
        -complete=var           user variables
        -complete=custom,{func} custom completion, defined via {func}
        -complete=customlist,{func} custom completion, defined via {func}
```

Note: That some completion methods might expand environment variables.

Custom completion :command-completion-custom
:command-completion-customlist
E467 E468

It is possible to define customized completion schemes via the "custom,{func}" or the "customlist,{func}" completion argument. The {func} part should be a function with the following signature:

```
        :function {func}(ArgLead, CmdLine, CursorPos)
```

The function need not use all these arguments. The function should provide the completion candidates as the return value.

For the "custom" argument, the function should return the completion candidates one per line in a newline separated string.

For the "customlist" argument, the function should return the completion candidates as a Vim List. Non-string items in the list are ignored.

The function arguments are:

```
        ArgLead         the leading portion of the argument currently being
                        completed on
        CmdLine         the entire command line
        CursorPos       the cursor position in it (byte index)
```

The function may use these for determining context. For the "custom" argument, it is not necessary to filter candidates against the (implicit pattern in) ArgLead. Vim will filter the candidates with its regexp engine after function return, and this is probably more efficient in most cases. For the "customlist" argument, Vim will not filter the returned completion candidates and the user supplied function should filter the candidates.

The following example lists user names to a Finger command

```
    :com -complete=custom,ListUsers -nargs=1 Finger !finger <args>
    :fun ListUsers(A,L,P)
    :    return system("cut -d: -f1 /etc/passwd")
```

```
    :endfun
```

The following example completes filenames from the directories specified in the 'path' option:

```
    :com -nargs=1 -bang -complete=customlist,EditFileComplete
                        \ EditFile edit<bang> <args>
    :fun EditFileComplete(A,L,P)
    :    return split(globpath(&path, a:A), "\n")
    :endfun
```

This example does not work for file names with spaces!

Range handling E177 E178 :command-range :command-count

By default, user-defined commands do not accept a line number range. However, it is possible to specify that the command does take a range (the -range attribute), or that it takes an arbitrary count value, either in the line number position (-range=N, like the :split command) or as a "count" argument (-count=N, like the :Next command). The count will then be available in the argument with <count> .

Possible attributes are:

-range	Range allowed, default is current line
-range=%	Range allowed, default is whole file (1,$)
-range=N	A count (default N) which is specified in the line number position (like :split); allows for zero line number.
-count=N	A count (default N) which is specified either in the line number position, or as an initial argument (like :Next). Specifying -count (without a default) acts like -count=0

Note that -range=N and -count=N are mutually exclusive - only one should be specified.

:command-addr

It is possible that the special characters in the range like ., $ or % which by default correspond to the current line, last line and the whole buffer, relate to arguments, (loaded) buffers, windows or tab pages.

Possible values are:

-addr=lines	Range of lines (this is the default)
-addr=arguments	Range for arguments
-addr=buffers	Range for buffers (also not loaded buffers)
-addr=loaded_buffers	Range for loaded buffers
-addr=windows	Range for windows
-addr=tabs	Range for tab pages

Special cases :command-bang :command-bar :command-register :command-buffer

There are some special cases as well:

-bang	The command can take a ! modifier (like :q or :w)

```
        -bar        The command can be followed by a "|" and another command.
                    A "|" inside the command argument is not allowed then.
                    Also checks for a " to start a comment.
        -register   The first argument to the command can be an optional
                    register name (like :del, :put, :yank).
        -buffer     The command will only be available in the current buffer.

In the cases of the -count and -register attributes, if the optional argument
is supplied, it is removed from the argument list and is available to the
replacement text separately.
Note that these arguments can be abbreviated, but that is a deprecated
feature.  Use the full name for new scripts.

Replacement text

The replacement text for a user defined command is scanned for special escape
sequences, using <...> notation.  Escape sequences are replaced with values
from the entered command line, and all other text is copied unchanged.  The
resulting string is executed as an Ex command.  To avoid the replacement use
<lt> in place of the initial <.  Thus to include "<bang>" literally use
"<lt>bang>".

The valid escape sequences are

                                                    <line1>
        <line1> The starting line of the command range.
                                                    <line2>
        <line2> The final line of the command range.
                                                    <range>
        <range> The number of items in the command range: 0, 1 or 2
                                                    <count>
        <count> Any count supplied (as described for the '-range'
                and '-count' attributes).
                                                    <bang>
        <bang>  (See the '-bang' attribute) Expands to a ! if the
                command was executed with a ! modifier, otherwise
                expands to nothing.
                                                    <mods>
        <mods>  The command modifiers, if specified. Otherwise, expands to
                nothing. Supported modifiers are  :aboveleft ,  :belowright ,
                 :botright ,  :browse ,  :confirm ,  :hide ,  :keepalt ,
                 :keepjumps ,  :keepmarks ,  :keeppatterns ,  :leftabove ,
                 :lockmarks ,  :noswapfile   :rightbelow ,  :silent ,  :tab ,
                 :topleft ,  :verbose , and  :vertical .
                Note that these are not yet supported:  :noautocmd ,
                 :sandbox  and  :unsilent .
                Examples:
                    command! -nargs=+ -complete=file MyEdit
                                \ for f in expand(<q-args>, 0, 1) |
                                \ exe '<mods> split ' . f |
                                \ endfor

                    function! SpecialEdit(files, mods)
                        for f in expand(a:files, 0, 1)
```

```
                    exe a:mods . ' split ' . f
                endfor
            endfunction
            command! -nargs=+ -complete=file Sedit
                        \ call SpecialEdit(<q-args>, <q-mods>)
```

<reg> <register>

<reg> (See the '-register' attribute) The optional register, if specified. Otherwise, expands to nothing. <register> is a synonym for this.

<args>

<args> The command arguments, exactly as supplied (but as noted above, any count or register can consume some of the arguments, which are then not part of <args>).

<lt> A single '<' (Less-Than) character. This is needed if you want to get a literal copy of one of these escape sequences into the expansion - for example, to get <bang>, use <lt>bang>.

<q-args>

If the first two characters of an escape sequence are "q-" (for example, <q-args>) then the value is quoted in such a way as to make it a valid value for use in an expression. This uses the argument as one single value. When there is no argument <q-args> is an empty string.

<f-args>

To allow commands to pass their arguments on to a user-defined function, there is a special form <f-args> ("function args"). This splits the command arguments at spaces and tabs, quotes each argument individually, and the <f-args> sequence is replaced by the comma-separated list of quoted arguments. See the Mycmd example below. If no arguments are given <f-args> is removed.

To embed whitespace into an argument of <f-args>, prepend a backslash. <f-args> replaces every pair of backslashes (\\) with one backslash. A backslash followed by a character other than white space or a backslash remains unmodified. Overview:

```
command             <f-args>
XX ab               'ab'
XX a\b              'a\b'
XX a\ b             'a b'
XX a\  b            'a ', 'b'
XX a\\b             'a\b'
XX a\\ b            'a\', 'b'
XX a\\\b            'a\\b'
XX a\\\ b           'a\ b'
XX a\\\\b           'a\\b'
XX a\\\\ b          'a\\', 'b'
```

Examples

```
" Delete everything after here to the end
:com Ddel +,$d

" Rename the current buffer
:com -nargs=1 -bang -complete=file Ren f <args>|w<bang>
```

```
   " Replace a range with the contents of a file
   " (Enter this all as one line)
   :com -range -nargs=1 -complete=file
         Replace <line1>-pu_|<line1>,<line2>d|r <args>|<line1>d

   " Count the number of lines in the range
   :com! -range -nargs=0 Lines  echo <line2> - <line1> + 1 "lines"

   " Call a user function (example of <f-args>)
   :com -nargs=* Mycmd call Myfunc(<f-args>)
```

When executed as:

```
        :Mycmd arg1 arg2
```

This will invoke:

```
        :call Myfunc("arg1","arg2")
```

```
   :" A more substantial example
   :function Allargs(command)
   :   let i = 0
   :   while i < argc()
   :      if filereadable(argv(i))
   :         execute "e " . argv(i)
   :         execute a:command
   :      endif
   :      let i = i + 1
   :   endwhile
   :endfunction
   :command -nargs=+ -complete=command Allargs call Allargs(<q-args>)
```

The command Allargs takes any Vim command(s) as argument and executes it on all files in the argument list. Usage example (note use of the "e" flag to ignore errors and the "update" command to write modified buffers):

```
        :Allargs %s/foo/bar/ge|update
```

This will invoke:

```
        :call Allargs("%s/foo/bar/ge|update")
```

When defining a user command in a script, it will be able to call functions local to the script and use mappings local to the script. When the user invokes the user command, it will run in the context of the script it was defined in. This matters if <SID> is used in a command.

vim:tw=78:ts=8:noet:ft=help:norl:

tagsrch.txt For Vim version 8.1. Last change: 2018 May 04

VIM REFERENCE MANUAL by Bram Moolenaar

Tags and special searches tags-and-searches

See section 29.1 of the user manual for an introduction.

==
1. Jump to a tag tag-commands

tag tags
A tag is an identifier that appears in a "tags" file. It is a sort of label that can be jumped to. For example: In C programs each function name can be used as a tag. The "tags" file has to be generated by a program like ctags, before the tag commands can be used.

With the ":tag" command the cursor will be positioned on the tag. With the CTRL-] command, the keyword on which the cursor is standing is used as the tag. If the cursor is not on a keyword, the first keyword to the right of the cursor is used.

The ":tag" command works very well for C programs. If you see a call to a function and wonder what that function does, position the cursor inside of the function name and hit CTRL-]. This will bring you to the function definition. An easy way back is with the CTRL-T command. Also read about the tag stack below.

:ta :tag E426 E429
:[count]ta[g][!] {name}
Jump to the definition of {name}, using the information in the tags file(s). Put {name} in the tag stack. See tag-! for [!].
{name} can be a regexp pattern, see tag-regexp .
When there are several matching tags for {name}, jump to the [count] one. When [count] is omitted the first one is jumped to. See tag-matchlist for jumping to other matching tags.

g<LeftMouse> g<LeftMouse>
<C-LeftMouse> <C-LeftMouse> CTRL-]
CTRL-]
Jump to the definition of the keyword under the cursor. Same as ":tag {name}", where {name} is the keyword under or after cursor.
When there are several matching tags for {name}, jump

to the [count] one. When no [count] is given the first one is jumped to. See tag-matchlist for jumping to other matching tags.
{Vi: identifier after the cursor}

v_CTRL-]
{Visual}CTRL-] Same as ":tag {name}", where {name} is the text that is highlighted. {not in Vi}

telnet-CTRL-]
CTRL-] is the default telnet escape key. When you type CTRL-] to jump to a tag, you will get the telnet prompt instead. Most versions of telnet allow changing or disabling the default escape key. See the telnet man page. You can 'telnet -E {Hostname}' to disable the escape character, or 'telnet -e {EscapeCharacter} {Hostname}' to specify another escape character. If possible, try to use "ssh" instead of "telnet" to avoid this problem.

tag-priority
When there are multiple matches for a tag, this priority is used:
1. "FSC" A full matching static tag for the current file.
2. "F C" A full matching global tag for the current file.
3. "F " A full matching global tag for another file.
4. "FS " A full matching static tag for another file.
5. " SC" An ignore-case matching static tag for the current file.
6. " C" An ignore-case matching global tag for the current file.
7. " " An ignore-case matching global tag for another file.
8. " S " An ignore-case matching static tag for another file.

Note that when the current file changes, the priority list is mostly not changed, to avoid confusion when using ":tnext". It is changed when using ":tag {name}".

The ignore-case matches are not found for a ":tag" command when:
- the 'ignorecase' option is off and 'tagcase' is "followic"
- 'tagcase' is "match"
- 'tagcase' is "smart" and the pattern contains an upper case character.
- 'tagcase' is "followscs" and 'smartcase' option is on and the pattern contains an upper case character.

The ignore-case matches are found when:
- a pattern is used (starting with a "/")
- for ":tselect"
- when 'tagcase' is "followic" and 'ignorecase' is off
- when 'tagcase' is "match"
- when 'tagcase' is "followscs" and the 'smartcase' option is off

Note that using ignore-case tag searching disables binary searching in the tags file, which causes a slowdown. This can be avoided by fold-case sorting the tag file. See the 'tagbsearch' option for an explanation.

==
2. Tag stack tag-stack tagstack E425

On the tag stack is remembered which tags you jumped to, and from where.

Tags are only pushed onto the stack when the 'tagstack' option is set.

g<RightMouse> g<RightMouse>
<C-RightMouse> <C-RightMouse> CTRL-T
CTRL-T Jump to [count] older entry in the tag stack
(default 1). {not in Vi}

:po :pop E555 E556
:[count]po[p][!] Jump to [count] older entry in tag stack (default 1).
See tag-! for [!]. {not in Vi}

:[count]ta[g][!] Jump to [count] newer entry in tag stack (default 1).
See tag-! for [!]. {not in Vi}

:tags
:tags Show the contents of the tag stack. The active
entry is marked with a '>'. {not in Vi}

The output of ":tags" looks like this:

```
   # TO tag      FROM line  in file/text
   1  1 main            1  harddisk2:text/vim/test
 > 2  2 FuncA           58  i = FuncA(10);
   3  1 FuncC          357  harddisk2:text/vim/src/amiga.c
```

This list shows the tags that you jumped to and the cursor position before
that jump. The older tags are at the top, the newer at the bottom.

The '>' points to the active entry. This is the tag that will be used by the
next ":tag" command. The CTRL-T and ":pop" command will use the position
above the active entry.

Below the "TO" is the number of the current match in the match list. Note
that this doesn't change when using ":pop" or ":tag".

The line number and file name are remembered to be able to get back to where
you were before the tag command. The line number will be correct, also when
deleting/inserting lines, unless this was done by another program (e.g.
another instance of Vim).

For the current file, the "file/text" column shows the text at the position.
An indent is removed and a long line is truncated to fit in the window.

You can jump to previously used tags with several commands. Some examples:

```
":pop" or CTRL-T        to position before previous tag
{count}CTRL-T           to position before {count} older tag
":tag"                  to newer tag
":0tag"                 to last used tag
```

The most obvious way to use this is while browsing through the call graph of
a program. Consider the following call graph:

```
main  --->  FuncA  --->  FuncC
```

```
              --->  FuncB
```

(Explanation: main calls FuncA and FuncB; FuncA calls FuncC).
You can get from main to FuncA by using CTRL-] on the call to FuncA. Then you can CTRL-] to get to FuncC. If you now want to go back to main you can use CTRL-T twice. Then you can CTRL-] to FuncB.

If you issue a ":ta {name}" or CTRL-] command, this tag is inserted at the current position in the stack. If the stack was full (it can hold up to 20 entries), the oldest entry is deleted and the older entries shift one position up (their index number is decremented by one). If the last used entry was not at the bottom, the entries below the last used one are deleted. This means that an old branch in the call graph is lost. After the commands explained above the tag stack will look like this:

```
   # TO tag     FROM line  in file/text
   1  1 main           1  harddisk2:text/vim/test
   2  1 FuncB         59  harddisk2:text/vim/src/main.c
```

E73

When you try to use the tag stack while it doesn't contain anything you will get an error message.

==========

3. Tag match list tag-matchlist E427 E428

When there are several matching tags, these commands can be used to jump between them. Note that these commands don't change the tag stack, they keep the same entry.

:ts :tselect

:ts[elect][!] [name] List the tags that match [name], using the information in the tags file(s).
When [name] is not given, the last tag name from the tag stack is used.
See tag-! for [!].
With a '>' in the first column is indicated which is the current position in the list (if there is one).
[name] can be a regexp pattern, see tag-regexp .
See tag-priority for the priorities used in the listing. {not in Vi}
Example output:

```
  nr pri kind tag               file
   1 F   f    mch_delay         os_amiga.c
                 mch_delay(msec, ignoreinput)
 > 2 F   f    mch_delay         os_msdos.c
                 mch_delay(msec, ignoreinput)
   3 F   f    mch_delay         os_unix.c
                 mch_delay(msec, ignoreinput)
 Enter nr of choice (<CR> to abort):
```

See tag-priority for the "pri" column. Note that

this depends on the current file, thus using
":tselect xxx" can produce different results.
The "kind" column gives the kind of tag, if this was
included in the tags file.
The "info" column shows information that could be
found in the tags file. It depends on the program
that produced the tags file.
When the list is long, you may get the more-prompt .
If you already see the tag you want to use, you can
type 'q' and enter the number.

:sts :stselect

:sts[elect][!] [name] Does ":tselect[!] [name]" and splits the window for the selected tag. {not in Vi}

g]

g] Like CTRL-], but use ":tselect" instead of ":tag".
{not in Vi}

v_g]

{Visual}g] Same as "g]", but use the highlighted text as the identifier. {not in Vi}

:tj :tjump

:tj[ump][!] [name] Like ":tselect", but jump to the tag directly when there is only one match. {not in Vi}

:stj :stjump

:stj[ump][!] [name] Does ":tjump[!] [name]" and splits the window for the selected tag. {not in Vi}

g_CTRL-]

g CTRL-] Like CTRL-], but use ":tjump" instead of ":tag".
{not in Vi}

v_g_CTRL-]

{Visual}g CTRL-] Same as "g CTRL-]", but use the highlighted text as the identifier. {not in Vi}

:tn :tnext

:[count]tn[ext][!] Jump to [count] next matching tag (default 1). See tag-! for [!]. {not in Vi}

:tp :tprevious

:[count]tp[revious][!] Jump to [count] previous matching tag (default 1).
See tag-! for [!]. {not in Vi}

:tN :tNext

:[count]tN[ext][!] Same as ":tprevious". {not in Vi}

:tr :trewind

:[count]tr[ewind][!] Jump to first matching tag. If [count] is given, jump to [count]th matching tag. See tag-! for [!]. {not in Vi}

:tf :tfirst

:[count]tf[irst][!] Same as ":trewind". {not in Vi}

:tl :tlast

:tl[ast][!] Jump to last matching tag. See tag-! for [!]. {not in Vi}

:lt :ltag

:lt[ag][!] [name] Jump to tag [name] and add the matching tags to a new location list for the current window. [name] can be a regexp pattern, see tag-regexp . When [name] is not given, the last tag name from the tag stack is used. The search pattern to locate the tag line is prefixed with "\V" to escape all the special characters (very nomagic). The location list showing the matching tags is independent of the tag stack. See tag-! for [!].
{not in Vi}

When there is no other message, Vim shows which matching tag has been jumped to, and the number of matching tags:

```
tag 1 of 3 or more
```

The " or more" is used to indicate that Vim didn't try all the tags files yet. When using ":tnext" a few times, or with ":tlast", more matches may be found.

When you didn't see this message because of some other message, or you just want to know where you are, this command will show it again (and jump to the same tag as last time):

```
:0tn
```

tag-skip-file

When a matching tag is found for which the file doesn't exist, this match is skipped and the next matching tag is used. Vim reports this, to notify you of missing files. When the end of the list of matches has been reached, an error message is given.

tag-preview

The tag match list can also be used in the preview window. The commands are the same as above, with a "p" prepended.
{not available when compiled without the |+quickfix| feature}

:pts :ptselect

:pts[elect][!] [name] Does ":tselect[!] [name]" and shows the new tag in a "Preview" window. See :ptag for more info.
{not in Vi}

:ptj :ptjump

:ptj[ump][!] [name] Does ":tjump[!] [name]" and shows the new tag in a "Preview" window. See :ptag for more info.
{not in Vi}

:ptn :ptnext

:[count]ptn[ext][!] ":tnext" in the preview window. See :ptag .

{not in Vi}

:ptp :ptprevious
:[count]ptp[revious][!] ":tprevious" in the preview window. See :ptag .
{not in Vi}

:ptN :ptNext
:[count]ptN[ext][!] Same as ":ptprevious". {not in Vi}

:ptr :ptrewind
:[count]ptr[ewind][!] ":trewind" in the preview window. See :ptag .
{not in Vi}

:ptf :ptfirst
:[count]ptf[irst][!] Same as ":ptrewind". {not in Vi}

:ptl :ptlast
:ptl[ast][!] ":tlast" in the preview window. See :ptag .
{not in Vi}

==
4. Tags details tag-details

static-tag
A static tag is a tag that is defined for a specific file. In a C program
this could be a static function.

In Vi jumping to a tag sets the current search pattern. This means that
the "n" command after jumping to a tag does not search for the same pattern
that it did before jumping to the tag. Vim does not do this as we consider it
to be a bug. You can still find the tag search pattern in the search history.
If you really want the old Vi behavior, set the 't' flag in 'cpoptions'.

tag-binary-search
Vim uses binary searching in the tags file to find the desired tag quickly
(when enabled at compile time +tag_binary). But this only works if the
tags file was sorted on ASCII byte value. Therefore, if no match was found,
another try is done with a linear search. If you only want the linear search,
reset the 'tagbsearch' option. Or better: Sort the tags file!

Note that the binary searching is disabled when not looking for a tag with a
specific name. This happens when ignoring case and when a regular expression
is used that doesn't start with a fixed string. Tag searching can be a lot
slower then. The former can be avoided by case-fold sorting the tags file.
See 'tagbsearch' for details.

tag-regexp
The ":tag" and ":tselect" commands accept a regular expression argument. See
pattern for the special characters that can be used.
When the argument starts with '/', it is used as a pattern. If the argument
does not start with '/', it is taken literally, as a full tag name.
Examples:
:tag main
jumps to the tag "main" that has the highest priority.

    :tag /^get
       jumps to the tag that starts with "get" and has the highest priority.
    :tag /norm
       lists all the tags that contain "norm", including "id_norm".
When the argument both exists literally, and match when used as a regexp, a literal match has a higher priority. For example, ":tag /open" matches "open" before "open_file" and "file_open".
When using a pattern case is ignored. If you want to match case use "\C" in the pattern.

                                                                tag-!
If the tag is in the current file this will always work. Otherwise the performed actions depend on whether the current file was changed, whether a ! is added to the command and on the 'autowrite' option:

tag in current file	file changed	!	autowrite option	action
yes	x	x	x	goto tag
no	no	x	x	read other file, goto tag
no	yes	yes	x	abandon current file, read other file, goto tag
no	yes	no	on	write current file, read other file, goto tag
no	yes	no	off	fail

- If the tag is in the current file, the command will always work.
- If the tag is in another file and the current file was not changed, the other file will be made the current file and read into the buffer.
- If the tag is in another file, the current file was changed and a ! is added to the command, the changes to the current file are lost, the other file will be made the current file and read into the buffer.
- If the tag is in another file, the current file was changed and the 'autowrite' option is on, the current file will be written, the other file will be made the current file and read into the buffer.
- If the tag is in another file, the current file was changed and the 'autowrite' option is off, the command will fail. If you want to save the changes, use the ":w" command and then use ":tag" without an argument. This works because the tag is put on the stack anyway. If you want to lose the changes you can use the ":tag!" command.

                                                        tag-security
Note that Vim forbids some commands, for security reasons. This works like using the 'secure' option for exrc/vimrc files in the current directory. See trojan-horse and sandbox .
When the {tagaddress} changes a buffer, you will get a warning message:
        "WARNING: tag command changed a buffer!!!"
In a future version changing the buffer will be impossible. All this for security reasons: Somebody might hide a nasty command in the tags file, which would otherwise go unnoticed. Example:
        :$d|/tag-function-name/
{this security prevention is not present in Vi}

In Vi the ":tag" command sets the last search pattern when the tag is searched for. In Vim this is not done, the previous search pattern is still remembered, unless the 't' flag is present in 'cpoptions'. The search pattern is always put in the search history, so you can modify it if searching fails.

emacs-tags emacs_tags E430

Emacs style tag files are only supported if Vim was compiled with the +emacs_tags feature enabled. Sorry, there is no explanation about Emacs tag files here, it is only supported for backwards compatibility :-).

Lines in Emacs tags files can be very long. Vim only deals with lines of up to about 510 bytes. To see whether lines are ignored set 'verbose' to 5 or higher.

tags-option

The 'tags' option is a list of file names. Each of these files is searched for the tag. This can be used to use a different tags file than the default file "tags". It can also be used to access a common tags file.

The next file in the list is not used when:
- A matching static tag for the current buffer has been found.
- A matching global tag has been found.

This also depends on whether case is ignored. Case is ignored when:
- 'tagcase' is "followic" and 'ignorecase' is set
- 'tagcase' is "ignore"
- 'tagcase' is "smart" and the pattern only contains lower case characters.
- 'tagcase' is "followscs" and 'smartcase' is set and the pattern only contains lower case characters.

If case is not ignored, and the tags file only has a match without matching case, the next tags file is searched for a match with matching case. If no tag with matching case is found, the first match without matching case is used. If case is ignored, and a matching global tag with or without matching case is found, this one is used, no further tags files are searched.

When a tag file name starts with "./", the '.' is replaced with the path of the current file. This makes it possible to use a tags file in the directory where the current file is (no matter what the current directory is). The idea of using "./" is that you can define which tag file is searched first: In the current directory ("tags,./tags") or in the directory of the current file ("./tags,tags").

For example:

```
:set tags=./tags,tags,/home/user/commontags
```

In this example the tag will first be searched for in the file "tags" in the directory where the current file is. Next the "tags" file in the current directory. If it is not found there, then the file "/home/user/commontags" will be searched for the tag.

This can be switched off by including the 'd' flag in 'cpoptions', to make it Vi compatible. "./tags" will then be the tags file in the current directory, instead of the tags file in the directory where the current file is.

Instead of the comma a space may be used. Then a backslash is required for the space to be included in the string option:
	:set tags=tags\ /home/user/commontags

To include a space in a file name use three backslashes. To include a comma in a file name use two backslashes. For example, use:
	:set tags=tag\\\ file,/home/user/common\\,tags

for the files "tag file" and "/home/user/common,tags". The 'tags' option will have the value "tag\ file,/home/user/common\,tags".

If the 'tagrelative' option is on (which is the default) and using a tag file in another directory, file names in that tag file are relative to the directory where the tag file is.

==
5. Tags file format   tags-file-format   E431

                                                       ctags   jtags
A tags file can be created with an external command, for example "ctags". It will contain a tag for each function. Some versions of "ctags" will also make a tag for each "#defined" macro, typedefs, enums, etc.

Some programs that generate tags files:
ctags   As found on most Unix systems. Only supports C. Only does the basic work.
                                                                Exuberant_ctags
exuberant ctags   This a very good one. It works for C, C++, Java, Fortran, Eiffel and others. It can generate tags for many items. See http://ctags.sourceforge.net.
etags   Connected to Emacs. Supports many languages.
JTags   For Java, in Java. It can be found at http://www.fleiner.com/jtags/.
ptags.py   For Python, in Python. Found in your Python source directory at Tools/scripts/ptags.py.
ptags   For Perl, in Perl. It can be found at http://www.eleves.ens.fr:8080/home/nthiery/Tags/.
gnatxref   For Ada. See http://www.gnuada.org/. gnatxref is part of the gnat package.

The lines in the tags file must have one of these three formats:

1. {tagname}   {TAB} {tagfile} {TAB} {tagaddress}
2. {tagfile}:{tagname} {TAB} {tagfile} {TAB} {tagaddress}
3. {tagname}   {TAB} {tagfile} {TAB} {tagaddress} {term} {field} ..

The first is a normal tag, which is completely compatible with Vi. It is the only format produced by traditional ctags implementations. This is often used for functions that are global, also referenced in other files.

The lines in the tags file can end in <LF> or <CR><LF>. On the Macintosh <CR> also works. The <CR> and <NL> characters can never appear inside a line.

tag-old-static

The second format is for a static tag only. It is obsolete now, replaced by the third format. It is only supported by Elvis 1.x and Vim and a few versions of ctags. A static tag is often used for functions that are local, only referenced in the file {tagfile}. Note that for the static tag, the two occurrences of {tagfile} must be exactly the same. Also see tags-option below, for how static tags are used.

The third format is new. It includes additional information in optional fields at the end of each line. It is backwards compatible with Vi. It is only supported by new versions of ctags (such as Exuberant ctags).

{tagname} The identifier. Normally the name of a function, but it can be any identifier. It cannot contain a <Tab>.

{TAB} One <Tab> character. Note: previous versions allowed any white space here. This has been abandoned to allow spaces in {tagfile}. It can be re-enabled by including the +tag_any_white feature at compile time. tag-any-white

{tagfile} The file that contains the definition of {tagname}. It can have an absolute or relative path. It may contain environment variables and wildcards (although the use of wildcards is doubtful). It cannot contain a <Tab>.

{tagaddress} The Ex command that positions the cursor on the tag. It can be any Ex command, although restrictions apply (see tag-security). Posix only allows line numbers and search commands, which are mostly used.

{term} ;" The two characters semicolon and double quote. This is interpreted by Vi as the start of a comment, which makes the following be ignored. This is for backwards compatibility with Vi, it ignores the following fields.

{field} .. A list of optional fields. Each field has the form:

<Tab>{fieldname}:{value}

The {fieldname} identifies the field, and can only contain alphabetical characters [a-zA-Z].
The {value} is any string, but cannot contain a <Tab>.
These characters are special:
"\t" stands for a <Tab>
"\r" stands for a <CR>
"\n" stands for a <NL>
"\\" stands for a single '\' character

There is one field that doesn't have a ':'. This is the kind of the tag. It is handled like it was preceded with "kind:". See the documentation of ctags for the kinds it produces.

The only other field currently recognized by Vim is "file:" (with an empty value). It is used for a static tag.

The first lines in the tags file can contain lines that start with
!_TAG_
These are sorted to the first lines, only rare tags that start with "!" can

sort to before them. Vim recognizes two items. The first one is the line
that indicates if the file was sorted. When this line is found, Vim uses
binary searching for the tags file:
	!_TAG_FILE_SORTED<Tab>1<Tab>{anything}

A tag file may be case-fold sorted to avoid a linear search when case is
ignored. (Case is ignored when 'ignorecase' is set and 'tagcase' is
"followic", or when 'tagcase' is "ignore".) See 'tagbsearch' for details.
The value '2' should be used then:
	!_TAG_FILE_SORTED<Tab>2<Tab>{anything}

The other tag that Vim recognizes, but only when compiled with the
 +multi_byte feature, is the encoding of the tags file:
	!_TAG_FILE_ENCODING<Tab>utf-8<Tab>{anything}
Here "utf-8" is the encoding used for the tags. Vim will then convert the tag
being searched for from 'encoding' to the encoding of the tags file. And when
listing tags the reverse happens. When the conversion fails the unconverted
tag is used.

                                                              tag-search
The command can be any Ex command, but often it is a search command.
Examples:
	tag1	file1	/^main(argc, argv)/
	tag2	file2	108

The command is always executed with 'magic' not set. The only special
characters in a search pattern are "^" (begin-of-line) and "$" (<EOL>).
See pattern . Note that you must put a backslash before each backslash in
the search text. This is for backwards compatibility with Vi.

                                                          E434 E435
If the command is a normal search command (it starts and ends with "/" or
"?"), some special handling is done:
- Searching starts on line 1 of the file.
  The direction of the search is forward for "/", backward for "?".
  Note that 'wrapscan' does not matter, the whole file is always searched. (Vi
  does use 'wrapscan', which caused tags sometimes not be found.) {Vi starts
  searching in line 2 of another file. It does not find a tag in line 1 of
  another file when 'wrapscan' is not set}
- If the search fails, another try is done ignoring case. If that fails too,
  a search is done for:
	"^tagname[\t]*("
  (the tag with '^' prepended and "[\t]*(" appended). When using function
  names, this will find the function name when it is in column 0. This will
  help when the arguments to the function have changed since the tags file was
  made. If this search also fails another search is done with:
	"^[#a-zA-Z_].*\<tagname[\t]*("
  This means: A line starting with '#' or an identifier and containing the tag
  followed by white space and a '('. This will find macro names and function
  names with a type prepended. {the extra searches are not in Vi}

==
6. Include file searches   include-search definition-search
                                                        E387 E388 E389

These commands look for a string in the current file and in all encountered included files (recursively). This can be used to find the definition of a variable, function or macro. If you only want to search in the current buffer, use the commands listed at pattern-searches .

These commands are not available when the +find_in_path feature was disabled at compile time.

When a line is encountered that includes another file, that file is searched before continuing in the current buffer. Files included by included files are also searched. When an include file could not be found it is silently ignored. Use the :checkpath command to discover which files could not be found, possibly your 'path' option is not set up correctly. Note: the included file is searched, not a buffer that may be editing that file. Only for the current file the lines in the buffer are used.

The string can be any keyword or a defined macro. For the keyword any match will be found. For defined macros only lines that match with the 'define' option will be found. The default is "^#\s*define", which is for C programs. For other languages you probably want to change this. See 'define' for an example for C++. The string cannot contain an end-of-line, only matches within a line are found.

When a match is found for a defined macro, the displaying of lines continues with the next line when a line ends in a backslash.

The commands that start with "[" start searching from the start of the current file. The commands that start with "]" start at the current cursor position.

The 'include' option is used to define a line that includes another file. The default is "\^#\s*include", which is for C programs. Note: Vim does not recognize C syntax, if the 'include' option matches a line inside "#ifdef/#endif" or inside a comment, it is searched anyway. The 'isfname' option is used to recognize the file name that comes after the matched pattern.

The 'path' option is used to find the directory for the include files that do not have an absolute path.

The 'comments' option is used for the commands that display a single line or jump to a line. It defines patterns that may start a comment. Those lines are ignored for the search, unless [!] is used. One exception: When the line matches the pattern "^# *define" it is not considered to be a comment.

If you want to list matches, and then select one to jump to, you could use a mapping to do that for you. Here is an example:

```
:map <F4> [I:let nr = input("Which one: ")<Bar>exe "normal " . nr ."[\t"<CR>
```

[i

[i Display the first line that contains the keyword under the cursor. The search starts at the beginning of the file. Lines that look like a comment are

ignored (see 'comments' option). If a count is given, the count'th matching line is displayed, and comment lines are not ignored. {not in Vi}

]i

]i like "[i", but start at the current cursor position. {not in Vi}

:is :isearch

:[range]is[earch][!] [count] [/]pattern[/]
Like "[i" and "]i", but search in [range] lines (default: whole file).
See :search-args for [/] and [!]. {not in Vi}

[I

[I Display all lines that contain the keyword under the cursor. Filenames and line numbers are displayed for the found lines. The search starts at the beginning of the file. {not in Vi}

]I

]I like "[I", but start at the current cursor position. {not in Vi}

:il :ilist

:[range]il[ist][!] [/]pattern[/]
Like "[I" and "]I", but search in [range] lines (default: whole file).
See :search-args for [/] and [!]. {not in Vi}

[_CTRL-I

[CTRL-I Jump to the first line that contains the keyword under the cursor. The search starts at the beginning of the file. Lines that look like a comment are ignored (see 'comments' option). If a count is given, the count'th matching line is jumped to, and comment lines are not ignored. {not in Vi}

]_CTRL-I

] CTRL-I like "[CTRL-I", but start at the current cursor position. {not in Vi}

:ij :ijump

:[range]ij[ump][!] [count] [/]pattern[/]
Like "[CTRL-I" and "] CTRL-I", but search in [range] lines (default: whole file).
See :search-args for [/] and [!]. {not in Vi}

CTRL-W CTRL-I CTRL-W_CTRL-I CTRL-W_i

CTRL-W i Open a new window, with the cursor on the first line that contains the keyword under the cursor. The search starts at the beginning of the file. Lines that look like a comment line are ignored (see 'comments' option). If a count is given, the count'th

matching line is jumped to, and comment lines are not ignored. {not in Vi}

:isp :isplit
:[range]isp[lit][!] [count] [/]pattern[/]
Like "CTRL-W i" and "CTRL-W i", but search in [range] lines (default: whole file).
See :search-args for [/] and [!]. {not in Vi}

[d
[d Display the first macro definition that contains the macro under the cursor. The search starts from the beginning of the file. If a count is given, the count'th matching line is displayed. {not in Vi}

]d
]d like "[d", but start at the current cursor position. {not in Vi}

:ds :dsearch
:[range]ds[earch][!] [count] [/]string[/]
Like "[d" and "]d", but search in [range] lines (default: whole file).
See :search-args for [/] and [!]. {not in Vi}

[D
[D Display all macro definitions that contain the macro under the cursor. Filenames and line numbers are displayed for the found lines. The search starts from the beginning of the file. {not in Vi}

]D
]D like "[D", but start at the current cursor position. {not in Vi}

:dli :dlist
:[range]dli[st][!] [/]string[/]
Like `[D` and `]D`, but search in [range] lines (default: whole file).
See :search-args for [/] and [!]. {not in Vi}
Note that `:dl` works like `:delete` with the "l" flag, not `:dlist`.

[_CTRL-D
[CTRL-D Jump to the first macro definition that contains the keyword under the cursor. The search starts from the beginning of the file. If a count is given, the count'th matching line is jumped to. {not in Vi}

]_CTRL-D
] CTRL-D like "[CTRL-D", but start at the current cursor position. {not in Vi}

:dj :djump

```
:[range]dj[ump][!] [count] [/]string[/]
                        Like "[ CTRL-D"  and "] CTRL-D", but search  in
                        [range] lines (default: whole file).
                        See  :search-args  for [/] and [!].  {not in Vi}

CTRL-W CTRL-D                                       CTRL-W_CTRL-D   CTRL-W_d
CTRL-W d                Open a new window, with the cursor on the first
                        macro definition line that contains the keyword
                        under the cursor.  The search starts from the
                        beginning of the file.  If a count is given, the
                        count'th matching line is jumped to.  {not in Vi}

                                                                :dsp   :dsplit
:[range]dsp[lit][!] [count] [/]string[/]
                        Like "CTRL-W d", but search in [range] lines
                        (default: whole file).
                        See  :search-args  for [/] and [!].  {not in Vi}

                                                                :che   :checkpath
:che[ckpath]            List all the included files that could not be found.
                        {not in Vi}

:che[ckpath]!           List all the included files.  {not in Vi}

                                                                    :search-args
Common arguments for the commands above:
[!]     When included, find matches in lines that are recognized as comments.
        When excluded, a match is ignored when the line is recognized as a
        comment (according to 'comments'), or the match is in a C comment
        (after "//" or inside /* */).  Note that a match may be missed if a
        line is recognized as a comment, but the comment ends halfway the line.
        And if the line is a comment, but it is not recognized (according to
        'comments') a match may be found in it anyway.  Example:
                /* comment
                   foobar */
       A match for "foobar" is found, because this line is not recognized as
        a comment (even though syntax highlighting does recognize it).
        Note: Since a macro definition mostly doesn't look like a comment, the
        [!] makes no difference for ":dlist", ":dsearch" and ":djump".
[/]     A pattern can be surrounded by '/'.  Without '/' only whole words are
        matched, using the pattern "\<pattern\>".  Only after the second '/' a
        next command can be appended with '|'.  Example:
        :isearch /string/ | echo "the last one"
       For a ":djump", ":dsplit", ":dlist" and ":dsearch" command the pattern
        is used as a literal string, not as a search pattern.

 vim:tw=78:ts=8:noet:ft=help:norl:
```

quickfix.txt For Vim version 8.1. Last change: 2018 May 01

VIM REFERENCE MANUAL by Bram Moolenaar

This subject is introduced in section 30.1 of the user manual.

{Vi does not have any of these commands}

The quickfix commands are not available when the +quickfix feature was disabled at compile time.

==
1. Using QuickFix commands quickfix Quickfix E42

Vim has a special mode to speedup the edit-compile-edit cycle. This is inspired by the quickfix option of the Manx's Aztec C compiler on the Amiga. The idea is to save the error messages from the compiler in a file and use Vim to jump to the errors one by one. You can examine each problem and fix it, without having to remember all the error messages.

In Vim the quickfix commands are used more generally to find a list of positions in files. For example, :vimgrep finds pattern matches. You can use the positions in a script with the getqflist() function. Thus you can do a lot more than the edit/compile/fix cycle!

If you have the error messages in a file you can start Vim with:

```
vim -q filename
```

From inside Vim an easy way to run a command and handle the output is with the :make command (see below).

The 'errorformat' option should be set to match the error messages from your compiler (see errorformat below).

quickfix-ID

Each quickfix list has a unique identifier called the quickfix ID and this number will not change within a Vim session. The getqflist() function can be used to get the identifier assigned to a list. There is also a quickfix list number which may change whenever more than ten lists are added to a quickfix stack.

location-list E776

A location list is a window-local quickfix list. You get one after commands like `:lvimgrep`, `:lgrep`, `:lhelpgrep`, `:lmake`, etc., which create a location list instead of a quickfix list as the corresponding `:vimgrep`, `:grep`, `:helpgrep`, `:make` do.
A location list is associated with a window and each window can have a separate location list. A location list can be associated with only one window. The location list is independent of the quickfix list.

When a window with a location list is split, the new window gets a copy of the location list. When there are no longer any references to a location list, the location list is destroyed.

quickfix-changedtick
Every quickfix and location list has a read-only changedtick variable that tracks the total number of changes made to the list. Every time the quickfix list is modified, this count is incremented. This can be used to perform an action only when the list has changed. The getqflist() and getloclist() functions can be used to query the current value of changedtick. You cannot change the changedtick variable.

The following quickfix commands can be used. The location list commands are similar to the quickfix commands, replacing the 'c' prefix in the quickfix command with 'l'.

E924
If the current window was closed by an autocommand while processing a location list command, it will be aborted.

E925 E926
If the current quickfix or location list was changed by an autocommand while processing a quickfix or location list command, it will be aborted.

:cc
:cc[!] [nr] Display error [nr]. If [nr] is omitted, the same error is displayed again. Without [!] this doesn't work when jumping to another buffer, the current buffer has been changed, there is the only window for the buffer and both 'hidden' and 'autowrite' are off.
When jumping to another buffer with [!] any changes to the current buffer are lost, unless 'hidden' is set or there is another window for this buffer.
The 'switchbuf' settings are respected when jumping to a buffer.

:ll
:ll[!] [nr] Same as ":cc", except the location list for the current window is used instead of the quickfix list.

:cn :cnext E553
:[count]cn[ext][!] Display the [count] next error in the list that includes a file name. If there are no file names at all, go to the [count] next error. See :cc for [!] and 'switchbuf'.

:lne :lnext
:[count]lne[xt][!] Same as ":cnext", except the location list for the current window is used instead of the quickfix list.

:[count]cN[ext][!] :cp :cprevious :cN :cNext
:[count]cp[revious][!] Display the [count] previous error in the list that includes a file name. If there are no file names at all, go to the [count] previous error. See :cc for [!] and 'switchbuf'.

:[count]lN[ext][!] :lp :lprevious :lN :lNext
:[count]lp[revious][!] Same as ":cNext" and ":cprevious", except the location list for the current window is used instead of the quickfix list.

:cnf :cnfile
:[count]cnf[ile][!] Display the first error in the [count] next file in the list that includes a file name. If there are no file names at all or if there is no next file, go to the [count] next error. See :cc for [!] and 'switchbuf'.

:lnf :lnfile
:[count]lnf[ile][!] Same as ":cnfile", except the location list for the current window is used instead of the quickfix list.

:[count]cNf[ile][!] :cpf :cpfile :cNf :cNfile
:[count]cpf[ile][!] Display the last error in the [count] previous file in the list that includes a file name. If there are no file names at all or if there is no next file, go to the [count] previous error. See :cc for [!] and 'switchbuf'.

:[count]lNf[ile][!] :lpf :lpfile :lNf :lNfile
:[count]lpf[ile][!] Same as ":cNfile" and ":cpfile", except the location list for the current window is used instead of the quickfix list.

:crewind :cr
:cr[ewind][!] [nr] Display error [nr]. If [nr] is omitted, the FIRST error is displayed. See :cc .

:lrewind :lr
:lr[ewind][!] [nr] Same as ":crewind", except the location list for the current window is used instead of the quickfix list.

:cfirst :cfir
:cfir[st][!] [nr] Same as ":crewind".

:lfirst :lfir
:lfir[st][!] [nr] Same as ":lrewind".

:cla[st][!] [nr] Display error [nr]. If [nr] is omitted, the LAST error is displayed. See :cc .

:clast :cla

:lla[st][!] [nr] Same as ":clast", except the location list for the current window is used instead of the quickfix list.

:llast :lla

:cq[uit][!] Quit Vim with an error code, so that the compiler will not compile the same file again.
WARNING: All changes in files are lost! Also when the [!] is not used. It works like ":qall!" :qall , except that Vim returns a non-zero exit code.

:cq :cquit

:cf[ile][!] [errorfile] Read the error file and jump to the first error.
This is done automatically when Vim is started with the -q option. You can use this command when you keep Vim running while compiling. If you give the name of the errorfile, the 'errorfile' option will be set to [errorfile]. See :cc for [!].
If the encoding of the error file differs from the 'encoding' option, you can use the 'makeencoding' option to specify the encoding.

:cf :cfile

:lf[ile][!] [errorfile] Same as ":cfile", except the location list for the current window is used instead of the quickfix list.
You can not use the -q command-line option to set the location list.

:lf :lfile

:cg[etfile] [errorfile] Read the error file. Just like ":cfile" but don't jump to the first error.
If the encoding of the error file differs from the 'encoding' option, you can use the 'makeencoding' option to specify the encoding.

:cg :cgetfile

:lg[etfile] [errorfile] Same as ":cgetfile", except the location list for the current window is used instead of the quickfix list.

:lg :lgetfile

:caddf[ile] [errorfile] Read the error file and add the errors from the errorfile to the current quickfix list. If a quickfix list is not present, then a new list is created.
If the encoding of the error file differs from the 'encoding' option, you can use the 'makeencoding' option to specify the encoding.

:caddf :caddfile

:laddf :laddfile

:laddf[ile] [errorfile] Same as ":caddfile", except the location list for the current window is used instead of the quickfix list.

:cb :cbuffer E681

:cb[uffer][!] [bufnr] Read the error list from the current buffer. When [bufnr] is given it must be the number of a loaded buffer. That buffer will then be used instead of the current buffer.
A range can be specified for the lines to be used. Otherwise all lines in the buffer are used.
See :cc for [!].

:lb :lbuffer

:lb[uffer][!] [bufnr] Same as ":cbuffer", except the location list for the current window is used instead of the quickfix list.

:cgetb :cgetbuffer

:cgetb[uffer] [bufnr] Read the error list from the current buffer. Just like ":cbuffer" but don't jump to the first error.

:lgetb :lgetbuffer

:lgetb[uffer] [bufnr] Same as ":cgetbuffer", except the location list for the current window is used instead of the quickfix list.

:cad :caddbuffer

:cad[dbuffer] [bufnr] Read the error list from the current buffer and add the errors to the current quickfix list. If a quickfix list is not present, then a new list is created. Otherwise, same as ":cbuffer".

:laddb :laddbuffer

:laddb[uffer] [bufnr] Same as ":caddbuffer", except the location list for the current window is used instead of the quickfix list.

:cex :cexpr E777

:cex[pr][!] {expr} Create a quickfix list using the result of {expr} and jump to the first error.
If {expr} is a String, then each new-line terminated line in the String is processed using the global value of 'errorformat' and the result is added to the quickfix list.
If {expr} is a List, then each String item in the list is processed and added to the quickfix list. Non String items in the List are ignored.
See :cc for [!].
Examples:

```
:cexpr system('grep -n xyz *')
:cexpr getline(1, '$')
```

:lex :lexpr

:lex[pr][!] {expr} Same as :cexpr , except the location list for the current window is used instead of the quickfix list.

:cgete[xpr] {expr} :cgete :cgetexpr
Create a quickfix list using the result of {expr}. Just like :cexpr , but don't jump to the first error.

:lgete[xpr] {expr} :lgete :lgetexpr
Same as :cgetexpr , except the location list for the current window is used instead of the quickfix list.

:cadde[xpr] {expr} :cadde :caddexpr
Evaluate {expr} and add the resulting lines to the current quickfix list. If a quickfix list is not present, then a new list is created. The current cursor position will not be changed. See :cexpr for more information.
Example:

```
:g/mypattern/caddexpr expand("%") . ":" . line(".") .  ":" . getline(".")
```

:lad[dexpr] {expr} :lad :laddexpr
Same as ":caddexpr", except the location list for the current window is used instead of the quickfix list.

:cl[ist] [from] [, [to]] :cl :clist
List all errors that are valid quickfix-valid . If numbers [from] and/or [to] are given, the respective range of errors is listed. A negative number counts from the last error backwards, -1 being the last error. The 'switchbuf' settings are respected when jumping to a buffer.
The :filter command can be used to display only the quickfix entries matching a supplied pattern. The pattern is matched against the filename, module name, pattern and text of the entry.

:cl[ist] +{count}
List the current and next {count} valid errors. This is similar to ":clist from from+count", where "from" is the current error position.

:cl[ist]! [from] [, [to]]
List all errors.

:cl[ist]! +{count}
List the current and next {count} error lines. This is useful to see unrecognized lines after the current one. For example, if ":clist" shows:

```
8384 testje.java:252: error: cannot find symbol
```

Then using ":cl! +3" shows the reason:

```
8384 testje.java:252: error: cannot find symbol
8385:   ZexitCode = Fmainx();
8386:               ^
8387:   symbol:   method Fmainx()
```

:lli[st] [from] [, [to]] :lli :llist
Same as ":clist", except the location list for the

current window is used instead of the quickfix list.

:lli[st]! [from] [, [to]]
List all the entries in the location list for the current window.

If you insert or delete lines, mostly the correct error location is still found because hidden marks are used. Sometimes, when the mark has been deleted for some reason, the message "line changed" is shown to warn you that the error location may not be correct. If you quit Vim and start again the marks are lost and the error locations may not be correct anymore.

Two autocommands are available for running commands before and after a quickfix command (':make', ':grep' and so on) is executed. See QuickFixCmdPre and QuickFixCmdPost for details.

QuickFixCmdPost-example
When 'encoding' differs from the locale, the error messages may have a different encoding from what Vim is using. To convert the messages you can use this code:

```
function QfMakeConv()
   let qflist = getqflist()
   for i in qflist
      let i.text = iconv(i.text, "cp936", "utf-8")
   endfor
   call setqflist(qflist)
endfunction

au QuickfixCmdPost make call QfMakeConv()
```

Another option is using 'makeencoding'.

quickfix-title
Every quickfix and location list has a title. By default the title is set to the command that created the list. The getqflist() and getloclist() functions can be used to get the title of a quickfix and a location list respectively. The setqflist() and setloclist() functions can be used to modify the title of a quickfix and location list respectively. Examples:

```
call setqflist([], 'a', {'title' : 'Cmd output'})
echo getqflist({'title' : 1})
call setloclist(3, [], 'a', {'title' : 'Cmd output'})
echo getloclist(3, {'title' : 1})
```

quickfix-size
You can get the number of entries (size) in a quickfix and a location list using the getqflist() and getloclist() functions respectively. Examples:

```
echo getqflist({'size' : 1})
echo getloclist(5, {'size' : 1})
```

quickfix-context
Any Vim type can be associated as a context with a quickfix or location list. The setqflist() and the setloclist() functions can be used to associate a context with a quickfix and a location list respectively. The getqflist() and the getloclist() functions can be used to retrieve the context of a quickfix and a location list respectively. This is useful for a Vim plugin

dealing with multiple quickfix/location lists.
Examples:

```
	let somectx = {'name' : 'Vim', 'type' : 'Editor'}
	call setqflist([], 'a', {'context' : somectx})
	echo getqflist({'context' : 1})

	let newctx = ['red', 'green', 'blue']
	call setloclist(2, [], 'a', {'id' : qfid, 'context' : newctx})
	echo getloclist(2, {'id' : qfid, 'context' : 1})
```

quickfix-parse
You can parse a list of lines using 'errorformat' without creating or
modifying a quickfix list using the getqflist() function. Examples:

```
	echo getqflist({'lines' : ["F1:10:Line10", "F2:20:Line20"]})
	echo getqflist({'lines' : systemlist('grep -Hn quickfix *')})
```

This returns a dictionary where the 'items' key contains the list of quickfix
entries parsed from lines. The following shows how to use a custom
'errorformat' to parse the lines without modifying the 'errorformat' option:

```
	echo getqflist({'efm' : '%f#%l#%m', 'lines' : ['F1#10#Line']})
```

EXECUTE A COMMAND IN ALL THE BUFFERS IN QUICKFIX OR LOCATION LIST:
:cdo
:cdo[!] {cmd} Execute {cmd} in each valid entry in the quickfix list.
It works like doing this:

```
	:cfirst
	:{cmd}
	:cnext
	:{cmd}
	etc.
```

When the current file can't be abandon ed and the [!]
is not present, the command fails.
When an error is detected execution stops.
The last buffer (or where an error occurred) becomes
the current buffer.
{cmd} can contain '|' to concatenate several commands.

Only valid entries in the quickfix list are used.
A range can be used to select entries, e.g.:

```
	:10,$cdo cmd
```

To skip entries 1 to 9.

Note: While this command is executing, the Syntax
autocommand event is disabled by adding it to
'eventignore'. This considerably speeds up editing
each buffer.
{not in Vi}
Also see :bufdo , :tabdo , :argdo , :windo ,
:ldo , :cfdo and :lfdo .

:cfdo
:cfdo[!] {cmd} Execute {cmd} in each file in the quickfix list.
It works like doing this:

:cfirst
:{cmd}
:cnfile
:{cmd}
etc.
Otherwise it works the same as `:cdo`.
{not in Vi}

:ldo
:ld[o][!] {cmd} Execute {cmd} in each valid entry in the location list
for the current window.
It works like doing this:
:lfirst
:{cmd}
:lnext
:{cmd}
etc.
Only valid entries in the location list are used.
Otherwise it works the same as `:cdo`.
{not in Vi}

:lfdo
:lfdo[!] {cmd} Execute {cmd} in each file in the location list for
the current window.
It works like doing this:
:lfirst
:{cmd}
:lnfile
:{cmd}
etc.
Otherwise it works the same as `:ldo`.
{not in Vi}

==
2. The error window quickfix-window

:cope :copen w:quickfix_title
:cope[n] [height] Open a window to show the current list of errors.

When [height] is given, the window becomes that high
(if there is room). When [height] is omitted the
window is made ten lines high.

If there already is a quickfix window, it will be made
the current window. It is not possible to open a
second quickfix window. If [height] is given the
existing window will be resized to it.

The window will contain a special buffer, with
'buftype' equal to "quickfix". Don't change this!
The window will have the w:quickfix_title variable set
which will indicate the command that produced the
quickfix list. This can be used to compose a custom
status line if the value of 'statusline' is adjusted

properly. Whenever this buffer is modified by a quickfix command or function, the b:changedtick variable is incremented.

:lop[en] [height] — :lop :lopen
Open a window to show the location list for the current window. Works only when the location list for the current window is present. You can have more than one location window opened at a time. Otherwise, it acts the same as ":copen".

:ccl[ose] — :ccl :cclose
Close the quickfix window.

:lcl[ose] — :lcl :lclose
Close the window showing the location list for the current window.

:cw[indow] [height] — :cw :cwindow
Open the quickfix window when there are recognized errors. If the window is already open and there are no recognized errors, close the window.

:lw[indow] [height] — :lw :lwindow
Same as ":cwindow", except use the window showing the location list for the current window.

:cbo[ttom] — :cbo :cbottom
Put the cursor in the last line of the quickfix window and scroll to make it visible. This is useful for when errors are added by an asynchronous callback. Only call it once in a while if there are many updates to avoid a lot of redrawing.

:lbo[ttom] — :lbo :lbottom
Same as ":cbottom", except use the window showing the location list for the current window.

Normally the quickfix window is at the bottom of the screen. If there are vertical splits, it's at the bottom of the rightmost column of windows. To make it always occupy the full width:

```
:botright cwindow
```

You can move the window around with window-moving commands.
For example, to move it to the top: CTRL-W K
The 'winfixheight' option will be set, which means that the window will mostly keep its height, ignoring 'winheight' and 'equalalways'. You can change the height manually (e.g., by dragging the status line above it with the mouse).

In the quickfix window, each line is one error. The line number is equal to the error number. The current entry is highlighted with the QuickFixLine highlighting. You can change it to your liking, e.g.:

```
:hi QuickFixLine ctermbg=Yellow guibg=Yellow
```

You can use ":.cc" to jump to the error under the cursor.

Hitting the <Enter> key or double-clicking the mouse on a line has the same effect. The file containing the error is opened in the window above the quickfix window. If there already is a window for that file, it is used instead. If the buffer in the used window has changed, and the error is in another file, jumping to the error will fail. You will first have to make sure the window contains a buffer which can be abandoned.
CTRL-W_<Enter> CTRL-W_<CR>
You can use CTRL-W <Enter> to open a new window and jump to the error there.

When the quickfix window has been filled, two autocommand events are triggered. First the 'filetype' option is set to "qf", which triggers the FileType event. Then the BufReadPost event is triggered, using "quickfix" for the buffer name. This can be used to perform some action on the listed errors. Example:

```
au BufReadPost quickfix  setlocal modifiable
        \ | silent exe 'g/^/s//\=line(".")." "/'
        \ | setlocal nomodifiable
```

This prepends the line number to each line. Note the use of "\=" in the substitute string of the ":s" command, which is used to evaluate an expression.
The BufWinEnter event is also triggered, again using "quickfix" for the buffer name.

Note: When adding to an existing quickfix list the autocommand are not triggered.

Note: Making changes in the quickfix window has no effect on the list of errors. 'modifiable' is off to avoid making changes. If you delete or insert lines anyway, the relation between the text and the error number is messed up. If you really want to do this, you could write the contents of the quickfix window to a file and use ":cfile" to have it parsed and used as the new error list.

location-list-window
The location list window displays the entries in a location list. When you open a location list window, it is created below the current window and displays the location list for the current window. The location list window is similar to the quickfix window, except that you can have more than one location list window open at a time. When you use a location list command in this window, the displayed location list is used.

When you select a file from the location list window, the following steps are used to find a window to edit the file:

1. If a window with the location list displayed in the location list window is present, then the file is opened in that window.
2. If the above step fails and if the file is already opened in another window, then that window is used.
3. If the above step fails then an existing window showing a buffer with 'buftype' not set is used.
4. If the above step fails, then the file is edited in a new window.

In all of the above cases, if the location list for the selected window is not yet set, then it is set to the location list displayed in the location list

window.

quickfix-window-ID

You can use the getqflist() and getloclist() functions to obtain the window ID of the quickfix window and location list window respectively (if present). Examples:

```
echo getqflist({'winid' : 1}).winid
echo getloclist(2, {'winid' : 1}).winid
```

getqflist-examples

The getqflist() and getloclist() functions can be used to get the various attributes of a quickfix and location list respectively. Some examples for using these functions are below:

```
" get the title of the current quickfix list
:echo getqflist({'title' : 0}).title

" get the identifier of the current quickfix list
:let qfid = getqflist({'id' : 0}).id

" get the identifier of the fourth quickfix list in the stack
:let qfid = getqflist({'nr' : 4, 'id' : 0}).id

" check whether a quickfix list with a specific identifier exists
:if getqflist({'id' : qfid}).id == qfid

" get the index of the current quickfix list in the stack
:let qfnum = getqflist({'nr' : 0}).nr

" get the items of a quickfix list specified by an identifier
:echo getqflist({'id' : qfid, 'items' : 0}).items

" get the number of entries in a quickfix list specified by an id
:echo getqflist({'id' : qfid, 'size' : 0}).size

" get the context of the third quickfix list in the stack
:echo getqflist({'nr' : 3, 'context' : 0}).context

" get the number of quickfix lists in the stack
:echo getqflist({'nr' : '$'}).nr

" get the number of times the current quickfix list is changed
:echo getqflist({'changedtick' : 0}).changedtick

" get the current entry in a quickfix list specified by an identifier
:echo getqflist({'id' : qfid, 'idx' : 0}).idx

" get all the quickfix list attributes using an identifier
:echo getqflist({'id' : qfid, 'all' : 0})

" parse text from a List of lines and return a quickfix list
:let myList = ["a.java:10:L10", "b.java:20:L20"]
:echo getqflist({'lines' : myList}).items
```

```
    " parse text using a custom 'efm' and return a quickfix list
    :echo getqflist({'lines' : ['a.c#10#Line 10'], 'efm':'%f#%l#%m'}).items

    " get the quickfix list window id
    :echo getqflist({'winid' : 0}).winid

    " get the context of the current location list
    :echo getloclist(0, {'context' : 0}).context

    " get the location list window id of the third window
    :echo getloclist(3, {'winid' : 0}).winid
```

setqflist-examples

The setqflist() and setloclist() functions can be used to set the various attributes of a quickfix and location list respectively. Some examples for using these functions are below:

```
    " create an empty quickfix list with a title and a context
    :let t = 'Search results'
    :let c = {'cmd' : 'grep'}
    :call setqflist([], ' ', {'title' : t, 'context' : c})

    " set the title of the current quickfix list
    :call setqflist([], 'a', {'title' : 'Mytitle'})

    " set the context of a quickfix list specified by an identifier
    :call setqflist([], 'a', {'id' : qfid, 'context' : {'val' : 100}})

    " create a new quickfix list from a command output
    :call setqflist([], ' ', {'lines' : systemlist('grep -Hn main *.c')})

    " parse text using a custom efm and add to a particular quickfix list
    :call setqflist([], 'a', {'id' : qfid,
                \ 'lines' : ["a.c#10#L10", "b.c#20#L20"], 'efm':'%f#%l#%m'})

    " add items to the quickfix list specified by an identifier
    :let newItems = [{'filename' : 'a.txt', 'lnum' : 10, 'text' : "Apple"},
                    \ {'filename' : 'b.txt', 'lnum' : 20, 'text' : "Orange"}]
    :call setqflist([], 'a', {'id' : qfid, 'items' : newItems})

    " empty a quickfix list specified by an identifier
    :call setqflist([], 'r', {'id' : qfid, 'items' : []})

    " free all the quickfix lists in the stack
    :call setqflist([], 'f')

    " set the title of the fourth quickfix list
    :call setqflist([], 'a', {'nr' : 4, 'title' : 'SomeTitle'})

    " create a new quickfix list at the end of the stack
    :call setqflist([], ' ', {'nr' : '$',
                        \ 'lines' : systemlist('grep -Hn class *.java')})

    " create a new location list from a command output
```

```
    :call setloclist(0, [], ' ', {'lines' : systemlist('grep -Hn main *.c')})

    " replace the location list entries for the third window
    :call setloclist(3, [], 'r', {'items' : newItems})
```

==
3. Using more than one list of errors   quickfix-error-lists

So far has been assumed that there is only one list of errors. Actually the
ten last used lists are remembered. When starting a new list, the previous
ones are automatically kept. Two commands can be used to access older error
lists. They set one of the existing error lists as the current one.

                                                    :colder   :col   E380
:col[der] [count]   Go to older error list. When [count] is given, do
                        this [count] times. When already at the oldest error
                        list, an error message is given.

                                                    :lolder   :lol
:lol[der] [count]   Same as `:colder`, except use the location list for
                        the current window instead of the quickfix list.

                                                    :cnewer   :cnew   E381
:cnew[er] [count]   Go to newer error list. When [count] is given, do
                        this [count] times. When already at the newest error
                        list, an error message is given.

                                                    :lnewer   :lnew
:lnew[er] [count]   Same as `:cnewer`, except use the location list for
                        the current window instead of the quickfix list.

                                                    :chistory   :chi
:chi[story]   Show the list of error lists. The current list is
                        marked with ">". The output looks like:
                                  error list 1 of 3; 43 errors
                                > error list 2 of 3; 0 errors
                                  error list 3 of 3; 15 errors

                                                    :lhistory   :lhi
:lhi[story]   Show the list of location lists, otherwise like
                        `:chistory`.

When adding a new error list, it becomes the current list.

When ":colder" has been used and ":make" or ":grep" is used to add a new error
list, one newer list is overwritten. This is especially useful if you are
browsing with ":grep" `grep .`. If you want to keep the more recent error
lists, use ":cnewer 99" first.

To get the number of lists in the quickfix and location list stack, you can
use the `getqflist()` and `getloclist()` functions respectively with the list
number set to the special value '$'. Examples:
```
        echo getqflist({'nr' : '$'}).nr
        echo getloclist(3, {'nr' : '$'}).nr
```

To get the number of the current list in the stack:
	echo getqflist({'nr' : 0}).nr

==
4. Using :make   :make_makeprg

                                                                :mak   :make
:mak[e][!] [arguments] 1. All relevant QuickFixCmdPre autocommands are
                           executed.
                        2. If the 'autowrite' option is on, write any changed
                           buffers
                        3. An errorfile name is made from 'makeef'. If
                           'makeef' doesn't contain "##", and a file with this
                           name already exists, it is deleted.
                        4. The program given with the 'makeprg' option is
                           started (default "make") with the optional
                           [arguments] and the output is saved in the
                           errorfile (for Unix it is also echoed on the
                           screen).
                        5. The errorfile is read using 'errorformat'.
                        6. All relevant QuickFixCmdPost autocommands are
                           executed. See example below.
                        7. If [!] is not given the first error is jumped to.
                        8. The errorfile is deleted.
                        9. You can now move through the errors with commands
                           like :cnext and :cprevious , see above.
                        This command does not accept a comment, any "
                        characters are considered part of the arguments.
                        If the encoding of the program output differs from the
                        'encoding' option, you can use the 'makeencoding'
                        option to specify the encoding.

                                                                :lmak   :lmake
:lmak[e][!] [arguments]
                        Same as ":make", except the location list for the
                        current window is used instead of the quickfix list.

The ":make" command executes the command given with the 'makeprg' option.
This is done by passing the command to the shell given with the 'shell'
option. This works almost like typing

	":!{makeprg} [arguments] {shellpipe} {errorfile}".

{makeprg} is the string given with the 'makeprg' option. Any command can be
used, not just "make". Characters '%' and '#' are expanded as usual on a
command-line. You can use "%<" to insert the current file name without
extension, or "#<" to insert the alternate file name without extension, for
example:
   :set makeprg=make\ #<.o

[arguments] is anything that is typed after ":make".
{shellpipe} is the 'shellpipe' option.
{errorfile} is the 'makeef' option, with ## replaced to make it unique.

The placeholder "$*" can be used for the argument list in {makeprg} if the command needs some additional characters after its arguments. The $* is replaced then by all arguments. Example:

```
   :set makeprg=latex\ \\\\nonstopmode\ \\\\input\\{$*}
```

or simpler

```
   :let &mp = 'latex \\nonstopmode \\input\{$*}'
```

"$*" can be given multiple times, for example:

```
   :set makeprg=gcc\ -o\ $*\ $*
```

The 'shellpipe' option defaults to ">" for the Amiga, MS-DOS and Win32. This means that the output of the compiler is saved in a file and not shown on the screen directly. For Unix "| tee" is used. The compiler output is shown on the screen and saved in a file the same time. Depending on the shell used "|& tee" or "2>&1| tee" is the default, so stderr output will be included.

If 'shellpipe' is empty, the {errorfile} part will be omitted. This is useful for compilers that write to an errorfile themselves (e.g., Manx's Amiga C).

Using QuickFixCmdPost to fix the encoding

It may be that 'encoding' is set to an encoding that differs from the messages your build program produces. This example shows how to fix this after Vim has read the error messages:

```
        function QfMakeConv()
           let qflist = getqflist()
           for i in qflist
              let i.text = iconv(i.text, "cp936", "utf-8")
           endfor
           call setqflist(qflist)
        endfunction

        au QuickfixCmdPost make call QfMakeConv()
```

(Example by Faque Cheng)
Another option is using 'makeencoding'.

==
5. Using :vimgrep and :grep grep lid

Vim has two ways to find matches for a pattern: Internal and external. The advantage of the internal grep is that it works on all systems and uses the powerful Vim search patterns. An external grep program can be used when the Vim grep does not do what you want.

The internal method will be slower, because files are read into memory. The advantages are:
- Line separators and encoding are automatically recognized, as if a file is being edited.
- Uses Vim search patterns. Multi-line patterns can be used.
- When plugins are enabled: compressed and remote files can be searched.
  gzip netrw

To be able to do this Vim loads each file as if it is being edited. When there is no match in the file the associated buffer is wiped out again. The 'hidden' option is ignored here to avoid running out of memory or file descriptors when searching many files. However, when the :hide command modifier is used the buffers are kept loaded. This makes following searches in the same files a lot faster.

Note that :copen (or :lopen for :lgrep) may be used to open a buffer containing the search results in linked form. The :silent command may be used to suppress the default full screen grep output. The ":grep!" form of the :grep command doesn't jump to the first match automatically. These commands can be combined to create a NewGrep command:

```
command! -nargs=+ NewGrep execute 'silent grep! <args>' | copen 42
```

5.1 using Vim's internal grep

:vim :vimgrep E682 E683

:vim[grep][!] /{pattern}/[g][j] {file} ...
Search for {pattern} in the files {file} ... and set the error list to the matches. Files matching 'wildignore' are ignored; files in 'suffixes' are searched last.
Without the 'g' flag each line is added only once.
With 'g' every match is added.

{pattern} is a Vim search pattern. Instead of enclosing it in / any non-ID character (see 'isident') can be used, so long as it does not appear in {pattern}.
'ignorecase' applies. To overrule it put /\c in the pattern to ignore case or /\C to match case.
'smartcase' is not used.
If {pattern} is empty (e.g. // is specified), the last used search pattern is used. last-pattern

When a number is put before the command this is used as the maximum number of matches to find. Use ":1vimgrep pattern file" to find only the first. Useful if you only want to check if there is a match and quit quickly when it's found.

Without the 'j' flag Vim jumps to the first match.
With 'j' only the quickfix list is updated.
With the [!] any changes in the current buffer are abandoned.

Every second or so the searched file name is displayed to give you an idea of the progress made.
Examples:

```
:vimgrep /an error/ *.c
:vimgrep /\<FileName\>/ *.h include/*
:vimgrep /myfunc/ **/*.c
```

For the use of "**" see starstar-wildcard .

:vim[grep][!] {pattern} {file} ...
Like above, but instead of enclosing the pattern in a non-ID character use a white-separated pattern. The pattern must start with an ID character.
Example:
```
:vimgrep Error *.c
```

:lv :lvimgrep
:lv[imgrep][!] /{pattern}/[g][j] {file} ...
:lv[imgrep][!] {pattern} {file} ...
Same as ":vimgrep", except the location list for the current window is used instead of the quickfix list.

:vimgrepa :vimgrepadd
:vimgrepa[dd][!] /{pattern}/[g][j] {file} ...
:vimgrepa[dd][!] {pattern} {file} ...
Just like ":vimgrep", but instead of making a new list of errors the matches are appended to the current list.

:lvimgrepa :lvimgrepadd
:lvimgrepa[dd][!] /{pattern}/[g][j] {file} ...
:lvimgrepa[dd][!] {pattern} {file} ...
Same as ":vimgrepadd", except the location list for the current window is used instead of the quickfix list.

5.2 External grep

Vim can interface with "grep" and grep-like programs (such as the GNU id-utils) in a similar way to its compiler integration (see :make above).

[Unix trivia: The name for the Unix "grep" command comes from ":g/re/p", where "re" stands for Regular Expression.]

:gr :grep
:gr[ep][!] [arguments] Just like ":make", but use 'grepprg' instead of 'makeprg' and 'grepformat' instead of 'errorformat'.
When 'grepprg' is "internal" this works like :vimgrep . Note that the pattern needs to be enclosed in separator characters then.
If the encoding of the program output differs from the 'encoding' option, you can use the 'makeencoding' option to specify the encoding.

:lgr :lgrep
:lgr[ep][!] [arguments] Same as ":grep", except the location list for the current window is used instead of the quickfix list.

:grepa :grepadd
:grepa[dd][!] [arguments]
Just like ":grep", but instead of making a new list of

errors the matches are appended to the current list.
Example:

```
:call setqflist([])
:bufdo grepadd! something %
```

The first command makes a new error list which is empty. The second command executes "grepadd" for each listed buffer. Note the use of ! to avoid that ":grepadd" jumps to the first error, which is not allowed with :bufdo .
An example that uses the argument list and avoids errors for files without matches:

```
:silent argdo try
  \ | grepadd! something %
  \ | catch /E480:/
  \ | endtry"
```

If the encoding of the program output differs from the 'encoding' option, you can use the 'makeencoding' option to specify the encoding.

:lgrepa :lgrepadd

:lgrepa[dd][!] [arguments]
Same as ":grepadd", except the location list for the current window is used instead of the quickfix list.

5.3 Setting up external grep

If you have a standard "grep" program installed, the :grep command may work well with the defaults. The syntax is very similar to the standard command:

```
:grep foo *.c
```

Will search all files with the .c extension for the substring "foo". The arguments to :grep are passed straight to the "grep" program, so you can use whatever options your "grep" supports.

By default, :grep invokes grep with the -n option (show file and line numbers). You can change this with the 'grepprg' option. You will need to set 'grepprg' if:

a) You are using a program that isn't called "grep"
b) You have to call grep with a full path
c) You want to pass other options automatically (e.g. case insensitive search.)

Once "grep" has executed, Vim parses the results using the 'grepformat' option. This option works in the same way as the 'errorformat' option - see that for details. You may need to change 'grepformat' from the default if your grep outputs in a non-standard format, or you are using some other program with a special format.

Once the results are parsed, Vim loads the first file containing a match and jumps to the appropriate line, in the same way that it jumps to a compiler error in quickfix mode. You can then use the :cnext , :clist , etc.

commands to see the other matches.

5.4 Using :grep with id-utils

You can set up :grep to work with the GNU id-utils like this:

```
:set grepprg=lid\ -Rgrep\ -s
:set grepformat=%f:%l:%m
```

then

```
:grep (regexp)
```

works just as you'd expect.
(provided you remembered to mkid first :)

5.5 Browsing source code with :vimgrep or :grep

Using the stack of error lists that Vim keeps, you can browse your files to look for functions and the functions they call. For example, suppose that you have to add an argument to the read_file() function. You enter this command:

```
:vimgrep /\<read_file\>/ *.c
```

You use ":cn" to go along the list of matches and add the argument. At one place you have to get the new argument from a higher level function msg(), and need to change that one too. Thus you use:

```
:vimgrep /\<msg\>/ *.c
```

While changing the msg() functions, you find another function that needs to get the argument from a higher level. You can again use ":vimgrep" to find these functions. Once you are finished with one function, you can use

```
:colder
```

to go back to the previous one.

This works like browsing a tree: ":vimgrep" goes one level deeper, creating a list of branches. ":colder" goes back to the previous level. You can mix this use of ":vimgrep" and "colder" to browse all the locations in a tree-like way. If you do this consistently, you will find all locations without the need to write down a "todo" list.

==
6. Selecting a compiler compiler-select

:comp :compiler E666

:comp[iler][!] {name} Set options to work with compiler {name}.
Without the "!" options are set for the current buffer. With "!" global options are set.
If you use ":compiler foo" in "file.foo" and

then ":compiler! bar" in another buffer, Vim
will keep on using "foo" in "file.foo".
{not available when compiled without the
+eval feature}

The Vim plugins in the "compiler" directory will set options to use the selected compiler. For `:compiler` local options are set, for `:compiler!` global options.

current_compiler

To support older Vim versions, the plugins always use "current_compiler" and not "b:current_compiler". What the command actually does is the following:

- Delete the "current_compiler" and "b:current_compiler" variables.
- Define the "CompilerSet" user command. With "!" it does ":set", without "!" it does ":setlocal".
- Execute ":runtime! compiler/{name}.vim". The plugins are expected to set options with "CompilerSet" and set the "current_compiler" variable to the name of the compiler.
- Delete the "CompilerSet" user command.
- Set "b:current_compiler" to the value of "current_compiler".
- Without "!" the old value of "current_compiler" is restored.

For writing a compiler plugin, see write-compiler-plugin .

GCC

quickfix-gcc compiler-gcc

There's one variable you can set for the GCC compiler:

g:compiler_gcc_ignore_unmatched_lines
Ignore lines that don't match any patterns defined for GCC. Useful if output from commands run from make are generating false positives.

MANX AZTEC C

quickfix-manx compiler-manx

To use Vim with Manx's Aztec C compiler on the Amiga you should do the following:
- Set the CCEDIT environment variable with the command:
  mset "CCEDIT=vim -q"
- Compile with the -qf option. If the compiler finds any errors, Vim is started and the cursor is positioned on the first error. The error message will be displayed on the last line. You can go to other errors with the commands mentioned above. You can fix the errors and write the file(s).
- If you exit Vim normally the compiler will re-compile the same file. If you exit with the :cq command, the compiler will terminate. Do this if you cannot fix the error, or if another file needs to be compiled first.

There are some restrictions to the Quickfix mode on the Amiga. The compiler only writes the first 25 errors to the errorfile (Manx's

documentation does not say how to get more). If you want to find the others, you will have to fix a few errors and exit the editor. After recompiling, up to 25 remaining errors will be found.

If Vim was started from the compiler, the :sh and some :! commands will not work, because Vim is then running in the same process as the compiler and stdin (standard input) will not be interactive.

PERL quickfix-perl compiler-perl

The Perl compiler plugin doesn't actually compile, but invokes Perl's internal syntax checking feature and parses the output for possible errors so you can correct them in quick-fix mode.

Warnings are forced regardless of "no warnings" or "$^W = 0" within the file being checked. To disable this set g:perl_compiler_force_warnings to a zero value. For example:

```
let g:perl_compiler_force_warnings = 0
```

PYUNIT COMPILER compiler-pyunit

This is not actually a compiler, but a unit testing framework for the Python language. It is included into standard Python distribution starting from version 2.0. For older versions, you can get it from http://pyunit.sourceforge.net.

When you run your tests with the help of the framework, possible errors are parsed by Vim and presented for you in quick-fix mode.

Unfortunately, there is no standard way to run the tests.
The alltests.py script seems to be used quite often, that's all.
Useful values for the 'makeprg' options therefore are:

```
 setlocal makeprg=./alltests.py " Run a testsuite
 setlocal makeprg=python\ %:S   " Run a single testcase
```

Also see http://vim.sourceforge.net/tip_view.php?tip_id=280.

TEX COMPILER compiler-tex

Included in the distribution compiler for TeX ($VIMRUNTIME/compiler/tex.vim) uses make command if possible. If the compiler finds a file named "Makefile" or "makefile" in the current directory, it supposes that you want to process your *TeX files with make, and the makefile does the right work. In this case compiler sets 'errorformat' for *TeX output and leaves 'makeprg' untouched. If neither "Makefile" nor "makefile" is found, the compiler will not use make. You can force the compiler to ignore makefiles by defining b:tex_ignore_makefile or g:tex_ignore_makefile variable (they are checked for existence only).

If the compiler chose not to use make, it need to choose a right program for processing your input. If b:tex_flavor or g:tex_flavor (in this precedence)

variable exists, it defines TeX flavor for :make (actually, this is the name of executed command), and if both variables do not exist, it defaults to "latex". For example, while editing chapter2.tex \input-ed from mypaper.tex written in AMS-TeX:

```
:let b:tex_flavor = 'amstex'
:compiler tex
[editing...]
:make mypaper
```

Note that you must specify a name of the file to process as an argument (to process the right file when editing \input-ed or \include-ed file; portable solution for substituting % for no arguments is welcome). This is not in the semantics of make, where you specify a target, not source, but you may specify filename without extension ".tex" and mean this as "make filename.dvi or filename.pdf or filename.some_result_extension according to compiler".

Note: tex command line syntax is set to usable both for MikTeX (suggestion by Srinath Avadhanula) and teTeX (checked by Artem Chuprina). Suggestion from errorformat-LaTeX is too complex to keep it working for different shells and OSes and also does not allow to use other available TeX options, if any. If your TeX doesn't support "-interaction=nonstopmode", please report it with different means to express \nonstopmode from the command line.

==
7. The error format error-file-format

errorformat E372 E373 E374 E375 E376 E377 E378

The 'errorformat' option specifies a list of formats that are recognized. The first format that matches with an error message is used. You can add several formats for different messages your compiler produces, or even entries for multiple compilers. See efm-entries .

Each entry in 'errorformat' is a scanf-like string that describes the format. First, you need to know how scanf works. Look in the documentation of your C compiler. Below you find the % items that Vim understands. Others are invalid.

Special characters in 'errorformat' are comma and backslash. See efm-entries for how to deal with them. Note that a literal "%" is matched by "%%", thus it is not escaped with a backslash.
Keep in mind that in the `:make` and `:grep` output all NUL characters are replaced with SOH (0x01).

Note: By default the difference between upper and lowercase is ignored. If you want to match case, add "\C" to the pattern /\C .

Basic items

```
%f              file name (finds a string)
%o              module name (finds a string)
%l              line number (finds a number)
```

```
        %c              column number (finds a number representing character
                        column of the error, (1 <tab> == 1 character column))
        %v              virtual column number (finds a number representing
                        screen column of the error (1 <tab> == 8 screen
                        columns))
        %t              error type (finds a single character)
        %n              error number (finds a number)
        %m              error message (finds a string)
        %r              matches the "rest" of a single-line file message %O/P/Q
        %p              pointer line (finds a sequence of '-', '.', ' ' or
                        tabs and uses the length for the column number)
        %*{conv}        any scanf non-assignable conversion
        %%              the single '%' character
        %s              search text (finds a string)
```

The "%f" conversion may depend on the current 'isfname' setting. "~/" is expanded to the home directory and environment variables are expanded.

The "%f" and "%m" conversions have to detect the end of the string. This normally happens by matching following characters and items. When nothing is following the rest of the line is matched. If "%f" is followed by a '%' or a backslash, it will look for a sequence of 'isfname' characters.

On MS-DOS, MS-Windows and OS/2 a leading "C:" will be included in "%f", even when using "%f:". This means that a file name which is a single alphabetical letter will not be detected.

The "%p" conversion is normally followed by a "^". It's used for compilers that output a line like:

```
          ^
```

or

```
   ---------^
```

to indicate the column of the error. This is to be used in a multi-line error message. See errorformat-javac for a useful example.

The "%s" conversion specifies the text to search for, to locate the error line. The text is used as a literal string. The anchors "^" and "$" are added to the text to locate the error line exactly matching the search text and the text is prefixed with the "\V" atom to make it "very nomagic". The "%s" conversion can be used to locate lines without a line number in the error output. Like the output of the "grep" shell command.
When the pattern is present the line number will not be used.

The "%o" conversion specifies the module name in quickfix entry. If present it will be used in quickfix error window instead of the filename. The module name is used only for displaying purposes, the file name is used when jumping to the file.

Changing directory

The following uppercase conversion characters specify the type of special format strings. At most one of them may be given as a prefix at the beginning of a single comma-separated format pattern.
Some compilers produce messages that consist of directory names that have to

be prepended to each file name read by %f (example: GNU make). The following codes can be used to scan these directory names; they will be stored in an internal directory stack. E379

```
        %D              "enter directory" format string; expects a following
                          %f that finds the directory name
        %X              "leave directory" format string; expects following %f
```

When defining an "enter directory" or "leave directory" format, the "%D" or "%X" has to be given at the start of that substring. Vim tracks the directory changes and prepends the current directory to each erroneous file found with a relative path. See quickfix-directory-stack for details, tips and limitations.

Multi-line messages errorformat-multi-line

It is possible to read the output of programs that produce multi-line messages, i.e. error strings that consume more than one line. Possible prefixes are:

```
        %E              start of a multi-line error message
        %W              start of a multi-line warning message
        %I              start of a multi-line informational message
        %A              start of a multi-line message (unspecified type)
        %>              for next line start with current pattern again  efm-%>
        %C              continuation of a multi-line message
        %Z              end of a multi-line message
```

These can be used with '+' and '-', see efm-ignore below.

Using "\n" in the pattern won't work to match multi-line messages.

Example: Your compiler happens to write out errors in the following format (leading line numbers not being part of the actual output):

```
     1  Error 275
     2  line 42
     3  column 3
     4  ' ' expected after '--'
```

The appropriate error format string has to look like this:

```
   :set efm=%EError\ %n,%Cline\ %l,%Ccolumn\ %c,%Z%m
```

And the :clist error message generated for this error is:

```
 1:42 col 3 error 275:  ' ' expected after '--'
```

Another example: Think of a Python interpreter that produces the following error message (line numbers are not part of the actual output):

```
     1  ======================================================================
     2  FAIL: testGetTypeIdCachesResult (dbfacadeTest.DjsDBFacadeTest)
     3  ----------------------------------------------------------------------
     4  Traceback (most recent call last):
     5    File "unittests/dbfacadeTest.py", line 89, in testFoo
     6      self.assertEquals(34, dtid)
```

```
 7    File "/usr/lib/python2.2/unittest.py", line 286, in
 8   failUnlessEqual
 9      raise self.failureException, \
10  AssertionError: 34 != 33
11
12  ----------------------------------------------------------------------
13  Ran 27 tests in 0.063s
```

Say you want :clist write the relevant information of this message only,
namely:
```
 5 unittests/dbfacadeTest.py:89:  AssertionError: 34 != 33
```

Then the error format string could be defined as follows:
```
  :set efm=%C\ %.%#,%A\ \ File\ \"%f\"\\,\ line\ %l%.%#,%Z%[%^\ ]%\\@=%m
```

Note that the %C string is given before the %A here: since the expression
' %.%#' (which stands for the regular expression ' .*') matches every line
starting with a space, followed by any characters to the end of the line,
it also hides line 7 which would trigger a separate error message otherwise.
Error format strings are always parsed pattern by pattern until the first
match occurs.

                                                              efm-%>

The %> item can be used to avoid trying patterns that appear earlier in
'errorformat'. This is useful for patterns that match just about anything.
For example, if the error looks like this:

```
        Error in line 123 of foo.c:
        unknown variable "i"
```

This can be found with:
```
        :set efm=xxx,%E%>Error in line %l of %f:,%Z%m
```
Where "xxx" has a pattern that would also match the second line.

Important: There is no memory of what part of the errorformat matched before;
every line in the error file gets a complete new run through the error format
lines. For example, if one has:
```
  setlocal efm=aa,bb,cc,dd,ee
```
Where aa, bb, etc. are error format strings. Each line of the error file will
be matched to the pattern aa, then bb, then cc, etc. Just because cc matched
the previous error line does _not_ mean that dd will be tried first on the
current line, even if cc and dd are multi-line errorformat strings.

Separate file name   errorformat-separate-filename

These prefixes are useful if the file name is given once and multiple messages
follow that refer to this file name.

%O	single-line file message: overread the matched part
%P	single-line file message: push file %f onto the stack
%Q	single-line file message: pop the last file from stack

Example: Given a compiler that produces the following error logfile (without
leading line numbers):

```
 1  [a1.tt]
 2  (1,17)  error: ';' missing
 3  (21,2)  warning: variable 'z' not defined
 4  (67,3)  error: end of file found before string ended
 5
 6  [a2.tt]
 7
 8  [a3.tt]
 9  NEW compiler v1.1
10  (2,2)   warning: variable 'x' not defined
11  (67,3)  warning: 's' already defined
```

This logfile lists several messages for each file enclosed in [...] which are
properly parsed by an error format like this:

```
:set efm=%+P[%f],(%l\\,%c)%*[\ ]%t%*[^:]:\ %m,%-Q
```

A call of :clist writes them accordingly with their correct filenames:

```
2 a1.tt:1 col 17 error: ';' missing
3 a1.tt:21 col 2 warning: variable 'z' not defined
4 a1.tt:67 col 3 error: end of file found before string ended
8 a3.tt:2 col 2 warning: variable 'x' not defined
9 a3.tt:67 col 3 warning: 's' already defined
```

Unlike the other prefixes that all match against whole lines, %P, %Q and %O
can be used to match several patterns in the same line. Thus it is possible
to parse even nested files like in the following line:

```
{"file1" {"file2" error1} error2 {"file3" error3 {"file4" error4 error5}}}
```

The %O then parses over strings that do not contain any push/pop file name
information. See errorformat-LaTeX for an extended example.

Ignoring and using whole messages efm-ignore

The codes '+' or '-' can be combined with the uppercase codes above; in that
case they have to precede the letter, e.g. '%+A' or '%-G':

%-	do not include the matching multi-line in any output
%+	include the whole matching line in the %m error string

One prefix is only useful in combination with '+' or '-', namely %G. It parses
over lines containing general information like compiler version strings or
other headers that can be skipped.

%-G	ignore this message
%+G	general message

Pattern matching

The scanf()-like "%*[]" notation is supported for backward-compatibility
with previous versions of Vim. However, it is also possible to specify
(nearly) any Vim supported regular expression in format strings.
Since meta characters of the regular expression language can be part of
ordinary matching strings or file names (and therefore internally have to

be escaped), meta symbols have to be written with leading '%':
	%\		The single '\' character. Note that this has to be
			escaped ("%\\") in ":set errorformat=" definitions.
	%.		The single '.' character.
	%#		The single '*'(!) character.
	%^		The single '^' character. Note that this is not
			useful, the pattern already matches start of line.
	%$		The single '$' character. Note that this is not
			useful, the pattern already matches end of line.
	%[		The single '[' character for a [] character range.
	%~		The single '~' character.
When using character classes in expressions (see /\i for an overview),
terms containing the "\+" quantifier can be written in the scanf() "%*"
notation. Example: "%\\d%\\+" ("\d\+", "any number") is equivalent to "%*\\d".
Important note: The \(...\) grouping of sub-matches can not be used in format
specifications because it is reserved for internal conversions.

Multiple entries in 'errorformat'		efm-entries

To be able to detect output from several compilers, several format patterns
may be put in 'errorformat', separated by commas (note: blanks after the comma
are ignored). The first pattern that has a complete match is used. If no
match is found, matching parts from the last one will be used, although the
file name is removed and the error message is set to the whole message. If
there is a pattern that may match output from several compilers (but not in a
right way), put it after one that is more restrictive.

To include a comma in a pattern precede it with a backslash (you have to type
two in a ":set" command). To include a backslash itself give two backslashes
(you have to type four in a ":set" command). You also need to put a backslash
before a space for ":set".

Valid matches		quickfix-valid

If a line does not completely match one of the entries in 'errorformat', the
whole line is put in the error message and the entry is marked "not valid"
These lines are skipped with the ":cn" and ":cp" commands (unless there is
no valid line at all). You can use ":cl!" to display all the error messages.

If the error format does not contain a file name Vim cannot switch to the
correct file. You will have to do this by hand.

Examples

The format of the file from the Amiga Aztec compiler is:

	filename>linenumber:columnnumber:errortype:errornumber:errormessage

	filename	name of the file in which the error was detected
	linenumber	line number where the error was detected
	columnnumber	column number where the error was detected

```
        errortype       type of the error, normally a single 'E' or 'W'
        errornumber     number of the error (for lookup in the manual)
        errormessage    description of the error

This can be matched with this 'errorformat' entry:
        %f>%l:%c:%t:%n:%m

Some examples for C compilers that produce single-line error outputs:
%f:%l:\ %t%*[^0123456789]%n:\ %m        for Manx/Aztec C error messages
                                        (scanf() doesn't understand [0-9])
%f\ %l\ %t%*[^0-9]%n:\ %m               for SAS C
\"%f\"\\,%*[^0-9]%l:\ %m                for generic C compilers
%f:%l:\ %m                              for GCC
%f:%l:\ %m,%Dgmake[%*\\d]:\ Entering\ directory\ `%f',
%Dgmake[%*\\d]:\ Leaving\ directory\ `%f'
                                        for GCC with gmake (concat the lines!)
%f(%l)\ :\ %*[^:]:\ %m                  old SCO C compiler (pre-OS5)
%f(%l)\ :\ %t%*[^0-9]%n:\ %m            idem, with error type and number
%f:%l:\ %m,In\ file\ included\ from\ %f:%l:,\^I\^Ifrom\ %f:%l%m
                                        for GCC, with some extras

Extended examples for the handling of multi-line messages are given below,
see  errorformat-Jikes  and  errorformat-LaTeX .

Note the backslash in front of a space and double quote.  It is required for
the :set command.  There are two backslashes in front of a comma, one for the
:set command and one to avoid recognizing the comma as a separator of error
formats.

Filtering messages

If you have a compiler that produces error messages that do not fit in the
format string, you could write a program that translates the error messages
into this format.  You can use this program with the ":make" command by
changing the 'makeprg' option.  For example:
   :set mp=make\ \\\|&\ error_filter
The backslashes before the pipe character are required to avoid it to be
recognized as a command separator.  The backslash before each space is
required for the set command.

==============================================================================
8. The directory stack                          quickfix-directory-stack

Quickfix maintains a stack for saving all used directories parsed from the
make output.  For GNU-make this is rather simple, as it always prints the
absolute path of all directories it enters and leaves.  Regardless if this is
done via a 'cd' command in the makefile or with the parameter "-C dir" (change
to directory before reading the makefile).  It may be useful to use the switch
"-w" to force GNU-make to print out the working directory before and after
processing.

Maintaining the correct directory is more complicated if you don't use
GNU-make.  AIX-make for example doesn't print any information about its
```

working directory. Then you need to enhance the makefile. In the makefile of LessTif there is a command which echoes "Making {target} in {dir}". The special problem here is that it doesn't print information on leaving the directory and that it doesn't print the absolute path.

To solve the problem with relative paths and missing "leave directory" messages Vim uses following algorithm:

1) Check if the given directory is a subdirectory of the current directory.
   If this is true, store it as the current directory.
2) If it is not a subdir of the current directory, try if this is a
   subdirectory of one of the upper directories.
3) If the directory still isn't found, it is assumed to be a subdirectory
   of Vim's current directory.

Additionally it is checked for every file, if it really exists in the identified directory. If not, it is searched in all other directories of the directory stack (NOT the directory subtree!). If it is still not found, it is assumed that it is in Vim's current directory.

There are limitations in this algorithm. These examples assume that make just prints information about entering a directory in the form "Making all in dir".

1) Assume you have following directories and files:
   ./dir1
   ./dir1/file1.c
   ./file1.c

   If make processes the directory "./dir1" before the current directory and there is an error in the file "./file1.c", you will end up with the file "./dir1/file.c" loaded by Vim.

   This can only be solved with a "leave directory" message.

2) Assume you have following directories and files:
   ./dir1
   ./dir1/dir2
   ./dir2

   You get the following:

Make output	Directory interpreted by Vim
Making all in dir1	./dir1
Making all in dir2	./dir1/dir2
Making all in dir2	./dir1/dir2

   This can be solved by printing absolute directories in the "enter directory" message or by printing "leave directory" messages.

To avoid this problem, ensure to print absolute directory names and "leave directory" messages.

Examples for Makefiles:

```
Unix:
    libs:
            for dn in $(LIBDIRS); do                                \
                (cd $$dn; echo "Entering dir '$$(pwd)'"; make); \
                echo "Leaving dir";                                 \
            done

Add
    %DEntering\ dir\ '%f',%XLeaving\ dir
to your 'errorformat' to handle the above output.

Note that Vim doesn't check if the directory name in a "leave directory"
messages is the current directory.  This is why you could just use the message
"Leaving dir".

==============================================================================
9. Specific error file formats                  errorformats

                                                errorformat-Jikes
Jikes(TM), a source-to-bytecode Java compiler published by IBM Research,
produces simple multi-line error messages.

An 'errorformat' string matching the produced messages is shown below.
The following lines can be placed in the user's  vimrc  to overwrite Vim's
recognized default formats, or see  :set+=  how to install this format
additionally to the default.

  :set efm=%A%f:%l:%c:%*\\d:%*\\d:,
        \%C%*\\s%trror:%m,
        \%+C%*[^:]%trror:%m,
        \%C%*\\s%tarning:%m,
        \%C%m

Jikes(TM) produces a single-line error message when invoked with the option
"+E", and can be matched with the following:

  :setl efm=%f:%l:%v:%*\\d:%*\\d:%*\\s%m

                                                errorformat-javac
This 'errorformat' has been reported to work well for javac, which outputs a
line with "^" to indicate the column of the error:
  :setl efm=%A%f:%l:\ %m,%-Z%p^,%-C%.%#
or:
  :setl efm=%A%f:%l:\ %m,%+Z%p^,%+C%.%#,%-G%.%#

Here is an alternative from Michael F. Lamb for Unix that filters the errors
first:
  :setl errorformat=%Z%f:%l:\ %m,%A%p^,%-G%*[^sl]%.%#
  :setl makeprg=javac\ %:S\ 2>&1\ \\\|\ vim-javac-filter

You need to put the following in "vim-javac-filter" somewhere in your path
(e.g., in ~/bin) and make it executable:
   #!/bin/sed -f
```

```
   /\^$/s/\t/\ /g;/:[0-9]\+:/{h;d};/^[ \t]*\^/G;
```

In English, that sed script:
- Changes single tabs to single spaces and
- Moves the line with the filename, line number, error message to just after
  the pointer line. That way, the unused error text between doesn't break
  vim's notion of a "multi-line message" and also doesn't force us to include
  it as a "continuation of a multi-line message."

errorformat-ant

For ant (http://jakarta.apache.org/) the above errorformat has to be modified
to honour the leading [javac] in front of each javac output line:
```
  :set efm=%A\ %#[javac]\ %f:%l:\ %m,%-Z\ %#[javac]\ %p^,%-C%.%#
```

The 'errorformat' can also be configured to handle ant together with either
javac or jikes. If you're using jikes, you should tell ant to use jikes' +E
command line switch which forces jikes to generate one-line error messages.
This is what the second line (of a build.xml file) below does:
```
  <property name = "build.compiler"       value = "jikes"/>
  <property name = "build.compiler.emacs" value = "true"/>
```

The 'errorformat' which handles ant with both javac and jikes is:
```
  :set efm=\ %#[javac]\ %#%f:%l:%c:%*\\d:%*\\d:\ %t%[%^:]%#:%m,
           \%A\ %#[javac]\ %f:%l:\ %m,%-Z\ %#[javac]\ %p^,%-C%.%#
```

errorformat-jade

parsing jade (see http://www.jclark.com/) errors is simple:
```
  :set efm=jade:%f:%l:%c:%t:%m
```

errorformat-LaTeX

The following is an example how an 'errorformat' string can be specified
for the (La)TeX typesetting system which displays error messages over
multiple lines. The output of ":clist" and ":cc" etc. commands displays
multi-lines in a single line, leading white space is removed.
It should be easy to adopt the above LaTeX errorformat to any compiler output
consisting of multi-line errors.

The commands can be placed in a vimrc file or some other Vim script file,
e.g. a script containing LaTeX related stuff which is loaded only when editing
LaTeX sources.
Make sure to copy all lines of the example (in the given order), afterwards
remove the comment lines. For the '\' notation at the start of some lines see
 line-continuation .

```
               First prepare 'makeprg' such that LaTeX will report multiple
               errors; do not stop when the first error has occurred:
 :set makeprg=latex\ \\\\nonstopmode\ \\\\input\\{$*}

               Start of multi-line error messages:
 :set efm=%E!\ LaTeX\ %trror:\ %m,
        \%E!\ %m,
              Start of multi-line warning messages; the first two also
               include the line number.  Meaning of some regular expressions:
                 - "%.%#"  (".*")   matches a (possibly empty) string
```

```
          - "%*\\d" ("\d\+") matches a number
\%+WLaTeX\ %.%#Warning:\ %.%#line\ %l%.%#,
\%+W%.%#\ at\ lines\ %l--%*\\d,
\%WLaTeX\ %.%#Warning:\ %m,
       Possible continuations of error/warning messages; the first
        one also includes the line number:
\%Cl.%l\ %m,
\%+C\ \ %m.,
\%+C%.%#-%.%#,
\%+C%.%#[]%.%#,
\%+C[]%.%#,
\%+C%.%#%[{}\\]%.%#,
\%+C<%.%#>%.%#,
\%C\ \ %m,
       Lines that match the following patterns do not contain any
        important information; do not include them in messages:
\%-GSee\ the\ LaTeX%m,
\%-GType\ \ H\ <return>%m,
\%-G\ ...%.%#,
\%-G%.%#\ (C)\ %.%#,
\%-G(see\ the\ transcript%.%#),
       Generally exclude any empty or whitespace-only line from
        being displayed:
\%-G\\s%#,
       The LaTeX output log does not specify the names of erroneous
        source files per line; rather they are given globally,
        enclosed in parentheses.
        The following patterns try to match these names and store
        them in an internal stack.  The patterns possibly scan over
        the same input line (one after another), the trailing "%r"
        conversion indicates the "rest" of the line that will be
        parsed in the next go until the end of line is reached.

        Overread a file name enclosed in '('...')'; do not push it
        on a stack since the file apparently does not contain any
        error:
\%+O(%f)%r,
       Push a file name onto the stack.  The name is given after '(':
\%+P(%f%r,
\%+P\ %\\=(%f%r,
\%+P%*[^()](%f%r,
\%+P[%\\d%[^()]%#(%f%r,
       Pop the last stored file name when a ')' is scanned:
\%+Q)%r,
\%+Q%*[^()])%r,
\%+Q[%\\d%*[^()])%r
```

Note that in some cases file names in the LaTeX output log cannot be parsed properly. The parser might have been messed up by unbalanced parentheses then. The above example tries to catch the most relevant cases only.
You can customize the given setting to suit your own purposes, for example, all the annoying "Overfull ..." warnings could be excluded from being recognized as an error.
Alternatively to filtering the LaTeX compiler output, it is also possible

to directly read the *.log file that is produced by the [La]TeX compiler.
This contains even more useful information about possible error causes.
However, to properly parse such a complex file, an external filter should
be used. See the description further above how to make such a filter known
by Vim.

errorformat-Perl

In $VIMRUNTIME/tools you can find the efm_perl.pl script, which filters Perl
error messages into a format that quickfix mode will understand. See the
start of the file about how to use it. (This script is deprecated, see
compiler-perl .)

vim:tw=78:ts=8:noet:ft=help:norl:

windows.txt For Vim version 8.1. Last change: 2018 Apr 24

VIM REFERENCE MANUAL by Bram Moolenaar

Editing with multiple windows and buffers. windows buffers

The commands which have been added to use multiple windows and buffers are explained here. Additionally, there are explanations for commands that work differently when used in combination with more than one window.

The basics are explained in chapter 7 and 8 of the user manual usr_07.txt usr_08.txt .

{Vi does not have any of these commands}
{not able to use multiple windows when the +windows feature was disabled at compile time}
{not able to use vertically split windows when the +vertsplit feature was disabled at compile time}

==========

1. Introduction windows-intro window

Summary:
   A buffer is the in-memory text of a file.
   A window is a viewport on a buffer.
   A tab page is a collection of windows.

A window is a viewport onto a buffer. You can use multiple windows on one buffer, or several windows on different buffers.

A buffer is a file loaded into memory for editing. The original file remains unchanged until you write the buffer to the file.

A buffer can be in one of three states:

active-buffer

active: The buffer is displayed in a window. If there is a file for this buffer, it has been read into the buffer. The buffer may have been modified since then and thus be different from the file.

hidden-buffer
hidden: The buffer is not displayed. If there is a file for this buffer, it has been read into the buffer. Otherwise it's the same as an active buffer, you just can't see it.

inactive-buffer
inactive: The buffer is not displayed and does not contain anything. Options for the buffer are remembered if the file was once loaded. It can contain marks from the viminfo file. But the buffer doesn't contain text.

In a table:

state	displayed in window	loaded	":buffers" shows
active	yes	yes	'a'
hidden	no	yes	'h'
inactive	no	no	' '

Note: All CTRL-W commands can also be executed with :wincmd , for those places where a Normal mode command can't be used or is inconvenient.

The main Vim window can hold several split windows. There are also tab pages tab-page , each of which can hold multiple windows.

window-ID winid windowid
Each window has a unique identifier called the window ID. This identifier will not change within a Vim session. The win_getid() and win_id2tabwin() functions can be used to convert between the window/tab number and the identifier. There is also the window number, which may change whenever windows are opened or closed, see winnr() .

Each buffer has a unique number and the number will not change within a Vim session. The bufnr() and bufname() functions can be used to convert between a buffer name and the buffer number.

==
2. Starting Vim windows-starting

By default, Vim starts with one window, just like Vi.

The "-o" and "-O" arguments to Vim can be used to open a window for each file in the argument list. The "-o" argument will split the windows horizontally; the "-O" argument will split the windows vertically. If both "-o" and "-O" are given, the last one encountered will be used to determine the split orientation. For example, this will open three windows, split horizontally:

```
vim -o file1 file2 file3
```

"-oN", where N is a decimal number, opens N windows split horizontally. If there are more file names than windows, only N windows are opened and some files do not get a window. If there are more windows than file names, the last few windows will be editing empty buffers. Similarly, "-ON" opens N windows split vertically, with the same restrictions.

If there are many file names, the windows will become very small. You might want to set the 'winheight' and/or 'winwidth' options to create a workable

situation.

Buf/Win Enter/Leave autocommand s are not executed when opening the new
windows and reading the files, that's only done when they are really entered.

                                                              status-line
A status line will be used to separate windows. The 'laststatus' option tells
when the last window also has a status line:
        'laststatus' = 0   never a status line
        'laststatus' = 1   status line if there is more than one window
        'laststatus' = 2   always a status line

You can change the contents of the status line with the 'statusline' option.
This option can be local to the window, so that you can have a different
status line in each window.

Normally, inversion is used to display the status line. This can be changed
with the 's' character in the 'highlight' option. For example, "sb" sets it to
bold characters. If no highlighting is used for the status line ("sn"), the
'^' character is used for the current window, and '=' for other windows. If
the mouse is supported and enabled with the 'mouse' option, a status line can
be dragged to resize windows.

Note: If you expect your status line to be in reverse video and it isn't,
check if the 'highlight' option contains "si". In version 3.0, this meant to
invert the status line. Now it should be "sr", reverse the status line, as
"si" now stands for italic! If italic is not available on your terminal, the
status line is inverted anyway; you will only see this problem on terminals
that have termcap codes for italics.

==
3. Opening and closing a window   opening-window   E36

CTRL-W s   CTRL-W_s
CTRL-W S   CTRL-W_S
CTRL-W CTRL-S   CTRL-W_CTRL-S
:[N]sp[lit] [++opt] [+cmd] [file]   :sp   :split
                Split current window in two. The result is two viewports on
                the same file.

                Make the new window N high (default is to use half the height
                of the current window). Reduces the current window height to
                create room (and others, if the 'equalalways' option is set,
                'eadirection' isn't "hor", and one of them is higher than the
                current or the new window).

                If [file] is given it will be edited in the new window. If it
                is not loaded in any buffer, it will be read. Else the new
                window will use the already loaded buffer.

                Note: CTRL-S does not work on all terminals and might block
                further input, use CTRL-Q to get going again.
                Also see ++opt and +cmd .

CTRL-W CTRL-V   CTRL-W_CTRL-V
CTRL-W v   CTRL-W_v
:[N]vs[plit] [++opt] [+cmd] [file]   :vs   :vsplit
Like :split , but split vertically. The windows will be spread out horizontally if
1. a width was not specified,
2. 'equalalways' is set,
3. 'eadirection' isn't "ver", and
4. one of the other windows is wider than the current or new window.
Note: In other places CTRL-Q does the same as CTRL-V, but here it doesn't!

CTRL-W n   CTRL-W_n
CTRL-W CTRL_N   CTRL-W_CTRL-N
:[N]new [++opt] [+cmd]   :new
Create a new window and start editing an empty file in it. Make new window N high (default is to use half the existing height). Reduces the current window height to create room (and others, if the 'equalalways' option is set and 'eadirection' isn't "hor").
Also see ++opt and +cmd .
If 'fileformats' is not empty, the first format given will be used for the new buffer. If 'fileformats' is empty, the 'fileformat' of the current buffer is used. This can be overridden with the ++opt argument.
Autocommands are executed in this order:
1. WinLeave for the current window
2. WinEnter for the new window
3. BufLeave for the current buffer
4. BufEnter for the new buffer
This behaves like a ":split" first, and then an ":enew" command.

:[N]vne[w] [++opt] [+cmd] [file]   :vne   :vnew
Like :new , but split vertically. If 'equalalways' is set and 'eadirection' isn't "ver" the windows will be spread out horizontally, unless a width was specified.

:[N]new [++opt] [+cmd] {file}
:[N]sp[lit] [++opt] [+cmd] {file}   :split_f
Create a new window and start editing file {file} in it. This behaves like a ":split" first, and then an ":e" command.
If [+cmd] is given, execute the command when the file has been loaded +cmd .
Also see ++opt .
Make new window N high (default is to use half the existing height). Reduces the current window height to create room (and others, if the 'equalalways' option is set).

:[N]sv[iew] [++opt] [+cmd] {file}   :sv   :sview   splitview
Same as ":split", but set 'readonly' option for this buffer.

:[N]sf[ind] [++opt] [+cmd] {file}   :sf   :sfind   splitfind

Same as ":split", but search for {file} in 'path' like in
:find . Doesn't split if {file} is not found.

CTRL-W CTRL-^ CTRL-W_CTRL-^ CTRL-W_^
CTRL-W ^ Does ":split #", split window in two and edit alternate file.
When a count is given, it becomes ":split #N", split window
and edit buffer N.

CTRL-W_:
CTRL-W : Does the same as typing : - enter a command line. Useful in a
terminal window, where all Vim commands must be preceded with
CTRL-W or 'termwinkey'.

Note that the 'splitbelow' and 'splitright' options influence where a new
window will appear.

:vert :vertical
:vert[ical] {cmd}
Execute {cmd}. If it contains a command that splits a window,
it will be split vertically.
Doesn't work for :execute and :normal .

:lefta[bove] {cmd} :lefta :leftabove
:abo[veleft] {cmd} :abo :aboveleft
Execute {cmd}. If it contains a command that splits a window,
it will be opened left (vertical split) or above (horizontal
split) the current window. Overrules 'splitbelow' and
'splitright'.
Doesn't work for :execute and :normal .

:rightb[elow] {cmd} :rightb :rightbelow
:bel[owright] {cmd} :bel :belowright
Execute {cmd}. If it contains a command that splits a window,
it will be opened right (vertical split) or below (horizontal
split) the current window. Overrules 'splitbelow' and
'splitright'.
Doesn't work for :execute and :normal .

:topleft E442
:to[pleft] {cmd}
Execute {cmd}. If it contains a command that splits a window,
it will appear at the top and occupy the full width of the Vim
window. When the split is vertical the window appears at the
far left and occupies the full height of the Vim window.
Doesn't work for :execute and :normal .

:bo :botright
:bo[tright] {cmd}
Execute {cmd}. If it contains a command that splits a window,
it will appear at the bottom and occupy the full width of the
Vim window. When the split is vertical the window appears at
the far right and occupies the full height of the Vim window.
Doesn't work for :execute and :normal .

These command modifiers can be combined to make a vertically split window
occupy the full height. Example:
        :vertical topleft split tags
Opens a vertically split, full-height window on the "tags" file at the far
left of the Vim window.

Closing a window

:q[uit]
:{count}q[uit]
CTRL-W q   CTRL-W_q
CTRL-W CTRL-Q   CTRL-W_CTRL-Q
                Without {count}: Quit the current window. If {count} is
                given quit the {count} window.

                When quitting the last window (not counting a help window),
                exit Vim.

                When 'hidden' is set, and there is only one window for the
                current buffer, it becomes hidden. When 'hidden' is not set,
                and there is only one window for the current buffer, and the
                buffer was changed, the command fails.

                (Note: CTRL-Q does not work on all terminals).

                If [count] is greater than the last window number the last
                window will be closed:
                    :1quit " quit the first window
                    :$quit " quit the last window
                    :9quit " quit the last window
                            " if there are fewer than 9 windows opened
                    :-quit " quit the previous window
                    :+quit " quit the next window
                    :+2quit " quit the second next window

:q[uit]!
:{count}q[uit]!
                Without {count}: Quit the current window. If {count} is
                given quit the {count} window.

                If this was the last window for a buffer, any changes to that
                buffer are lost. When quitting the last window (not counting
                help windows), exit Vim. The contents of the buffer are lost,
                even when 'hidden' is set.

:clo[se][!]
:{count}clo[se][!]
CTRL-W c   CTRL-W_c   :clo   :close
                Without {count}: Close the current window. If {count} is
                given close the {count} window.

                When the 'hidden' option is set, or when the buffer was

changed and the [!] is used, the buffer becomes hidden (unless there is another window editing it).

When there is only one window in the current tab page and there is another tab page, this closes the current tab page. tab-page .

This command fails when: E444
- There is only one window on the screen.
- When 'hidden' is not set, [!] is not used, the buffer has changes, and there is no other window on this buffer.
Changes to the buffer are not written and won't get lost, so this is a "safe" command.

CTRL-W CTRL-C CTRL-W_CTRL-C
You might have expected that CTRL-W CTRL-C closes the current window, but that does not work, because the CTRL-C cancels the command.

:hide

:hid[e]
:{count}hid[e]
Without {count}: Quit the current window, unless it is the last window on the screen.
If {count} is given quit the {count} window.

The buffer becomes hidden (unless there is another window editing it or 'bufhidden' is "unload", "delete" or "wipe"). If the window is the last one in the current tab page the tab page is closed. tab-page

The value of 'hidden' is irrelevant for this command. Changes to the buffer are not written and won't get lost, so this is a "safe" command.

:hid[e] {cmd} Execute {cmd} with 'hidden' is set. The previous value of 'hidden' is restored after {cmd} has been executed.
Example:
```
:hide edit Makefile
```
This will edit "Makefile", and hide the current buffer if it has any changes.

:on[ly][!]
:{count}on[ly][!]
CTRL-W o CTRL-W_o E445
CTRL-W CTRL-O CTRL-W_CTRL-O :on :only
Make the current window the only one on the screen. All other windows are closed. For {count} see :quit command.

When the 'hidden' option is set, all buffers in closed windows become hidden.

When 'hidden' is not set, and the 'autowrite' option is set, modified buffers are written. Otherwise, windows that have

buffers that are modified are not removed, unless the [!] is given, then they become hidden. But modified buffers are never abandoned, so changes cannot get lost.

==========

4. Moving cursor to other windows window-move-cursor

CTRL-W <Down> CTRL-W_<Down>
CTRL-W CTRL-J CTRL-W_CTRL-J CTRL-W_j
CTRL-W j Move cursor to Nth window below current one. Uses the cursor position to select between alternatives.

CTRL-W <Up> CTRL-W_<Up>
CTRL-W CTRL-K CTRL-W_CTRL-K CTRL-W_k
CTRL-W k Move cursor to Nth window above current one. Uses the cursor position to select between alternatives.

CTRL-W <Left> CTRL-W_<Left>
CTRL-W CTRL-H CTRL-W_CTRL-H
CTRL-W <BS> CTRL-W_<BS> CTRL-W_h
CTRL-W h Move cursor to Nth window left of current one. Uses the cursor position to select between alternatives.

CTRL-W <Right> CTRL-W_<Right>
CTRL-W CTRL-L CTRL-W_CTRL-L CTRL-W_l
CTRL-W l Move cursor to Nth window right of current one. Uses the cursor position to select between alternatives.

CTRL-W w CTRL-W_w CTRL-W_CTRL-W
CTRL-W CTRL-W Without count: move cursor to window below/right of the current one. If there is no window below or right, go to top-left window.
With count: go to Nth window (windows are numbered from top-left to bottom-right). To obtain the window number see bufwinnr() and winnr() . When N is larger than the number of windows go to the last window.

CTRL-W_W
CTRL-W W Without count: move cursor to window above/left of current one. If there is no window above or left, go to bottom-right window. With count: go to Nth window, like with CTRL-W w.

CTRL-W t CTRL-W_t CTRL-W_CTRL-T
CTRL-W CTRL-T Move cursor to top-left window.

CTRL-W b CTRL-W_b CTRL-W_CTRL-B
CTRL-W CTRL-B Move cursor to bottom-right window.

CTRL-W p CTRL-W_p CTRL-W_CTRL-P
CTRL-W CTRL-P Go to previous (last accessed) window.

CTRL-W_P E441
CTRL-W P Go to preview window. When there is no preview window this is an error.

{not available when compiled without the |+quickfix| feature}

If Visual mode is active and the new window is not for the same buffer, the Visual mode is ended. If the window is on the same buffer, the cursor position is set to keep the same Visual area selected.

:winc :wincmd
These commands can also be executed with ":wincmd":

:[count]winc[md] {arg}
Like executing CTRL-W [count] {arg}. Example:
:wincmd j
Moves to the window below the current one.
This command is useful when a Normal mode cannot be used (for the CursorHold autocommand event). Or when a Normal mode command is inconvenient.
The count can also be a window number. Example:
:exe nr . "wincmd w"
This goes to window "nr".

==========
5. Moving windows around window-moving

CTRL-W r CTRL-W_r CTRL-W_CTRL-R E443
CTRL-W CTRL-R Rotate windows downwards/rightwards. The first window becomes the second one, the second one becomes the third one, etc. The last window becomes the first window. The cursor remains in the same window.
This only works within the row or column of windows that the current window is in.

CTRL-W_R
CTRL-W R Rotate windows upwards/leftwards. The second window becomes the first one, the third one becomes the second one, etc. The first window becomes the last window. The cursor remains in the same window.
This only works within the row or column of windows that the current window is in.

CTRL-W x CTRL-W_x CTRL-W_CTRL-X
CTRL-W CTRL-X Without count: Exchange current window with next one. If there is no next window, exchange with previous window.
With count: Exchange current window with Nth window (first window is 1). The cursor is put in the other window.
When vertical and horizontal window splits are mixed, the exchange is only done in the row or column of windows that the current window is in.

The following commands can be used to change the window layout. For example, when there are two vertically split windows, CTRL-W K will change that in horizontally split windows. CTRL-W H does it the other way around.

CTRL-W_K
CTRL-W K Move the current window to be at the very top, using the full

width of the screen. This works like closing the current
window and then creating another one with ":topleft split",
except that the current window contents is used for the new
window.

CTRL-W_J
CTRL-W J	Move the current window to be at the very bottom, using the
full width of the screen. This works like closing the current
window and then creating another one with ":botright split",
except that the current window contents is used for the new
window.

CTRL-W_H
CTRL-W H	Move the current window to be at the far left, using the
full height of the screen. This works like closing the
current window and then creating another one with
":vert topleft split", except that the current window contents
is used for the new window.
{not available when compiled without the |+vertsplit| feature}

CTRL-W_L
CTRL-W L	Move the current window to be at the far right, using the full
height of the screen. This works like closing the
current window and then creating another one with
":vert botright split", except that the current window
contents is used for the new window.
{not available when compiled without the |+vertsplit| feature}

CTRL-W_T
CTRL-W T	Move the current window to a new tab page. This fails if
there is only one window in the current tab page.
When a count is specified the new tab page will be opened
before the tab page with this index. Otherwise it comes after
the current tab page.

==
6. Window resizing   window-resize

CTRL-W_=
CTRL-W =	Make all windows (almost) equally high and wide, but use
'winheight' and 'winwidth' for the current window.
Windows with 'winfixheight' set keep their height and windows
with 'winfixwidth' set keep their width.

:res[ize] -N   :res   :resize   CTRL-W_-
CTRL-W -	Decrease current window height by N (default 1).
If used after :vertical : decrease width by N.

:res[ize] +N   CTRL-W_+
CTRL-W +	Increase current window height by N (default 1).
If used after :vertical : increase width by N.

:res[ize] [N]
CTRL-W CTRL-_   CTRL-W_CTRL-_   CTRL-W__

CTRL-W _   Set current window height to N (default: highest possible).

z{nr}<CR>   Set current window height to {nr}.

                                                CTRL-W_<
CTRL-W <   Decrease current window width by N (default 1).

                                                CTRL-W_>
CTRL-W >   Increase current window width by N (default 1).

:vertical res[ize] [N]   :vertical-resize   CTRL-W_bar
CTRL-W | Set current window width to N (default: widest possible).

You can also resize a window by dragging a status line up or down with the mouse. Or by dragging a vertical separator line left or right. This only works if the version of Vim that is being used supports the mouse and the 'mouse' option has been set to enable it.

The option 'winheight' ('wh') is used to set the minimal window height of the current window. This option is used each time another window becomes the current window. If the option is '0', it is disabled. Set 'winheight' to a very large value, e.g., '9999', to make the current window always fill all available space. Set it to a reasonable value, e.g., '10', to make editing in the current window comfortable.

The equivalent 'winwidth' ('wiw') option is used to set the minimal width of the current window.

When the option 'equalalways' ('ea') is set, all the windows are automatically made the same size after splitting or closing a window. If you don't set this option, splitting a window will reduce the size of the current window and leave the other windows the same. When closing a window, the extra lines are given to the window above it.

The 'eadirection' option limits the direction in which the 'equalalways' option is applied. The default "both" resizes in both directions. When the value is "ver" only the heights of windows are equalized. Use this when you have manually resized a vertically split window and want to keep this width. Likewise, "hor" causes only the widths of windows to be equalized.

The option 'cmdheight' ('ch') is used to set the height of the command-line. If you are annoyed by the hit-enter prompt for long messages, set this option to 2 or 3.

If there is only one window, resizing that window will also change the command line height. If there are several windows, resizing the current window will also change the height of the window below it (and sometimes the window above it).

The minimal height and width of a window is set with 'winminheight' and 'winminwidth'. These are hard values, a window will never become smaller.

==
7. Argument and buffer list commands   buffer-list

	args list	buffer list	meaning
1.	:[N]argument [N]	11. :[N]buffer [N]	to arg/buf N
2.	:[N]next [file ..]	12. :[N]bnext [N]	to Nth next arg/buf
3.	:[N]Next [N]	13. :[N]bNext [N]	to Nth previous arg/buf
4.	:[N]previous [N]	14. :[N]bprevious [N]	to Nth previous arg/buf
5.	:rewind / :first	15. :brewind / :bfirst	to first arg/buf
6.	:last	16. :blast	to last arg/buf
7.	:all	17. :ball	edit all args/buffers
		18. :unhide	edit all loaded buffers
		19. :[N]bmod [N]	to Nth modified buf

	split & args list	split & buffer list	meaning
21.	:[N]sargument [N]	31. :[N]sbuffer [N]	split + to arg/buf N
22.	:[N]snext [file ..]	32. :[N]sbnext [N]	split + to Nth next arg/buf
23.	:[N]sNext [N]	33. :[N]sbNext [N]	split + to Nth previous arg/buf
24.	:[N]sprevious [N]	34. :[N]sbprevious [N]	split + to Nth previous arg/buf
25.	:srewind / :sfirst	35. :sbrewind / :sbfirst	split + to first arg/buf
26.	:slast	36. :sblast	split + to last arg/buf
27.	:sall	37. :sball	edit all args/buffers
		38. :sunhide	edit all loaded buffers
		39. :[N]sbmod [N]	split + to Nth modified buf

40.	:args	list of arguments
41.	:buffers	list of buffers

The meaning of [N] depends on the command:
 [N] is the number of buffers to go forward/backward on 2/12/22/32,
     3/13/23/33, and 4/14/24/34
 [N] is an argument number, defaulting to current argument, for 1 and 21
 [N] is a buffer number, defaulting to current buffer, for 11 and 31
 [N] is a count for 19 and 39

Note: ":next" is an exception, because it must accept a list of file names
for compatibility with Vi.

The argument list and multiple windows

The current position in the argument list can be different for each window.
Remember that when doing ":e file", the position in the argument list stays
the same, but you are not editing the file at that position. To indicate
this, the file message (and the title, if you have one) shows
"(file (N) of M)", where "(N)" is the current position in the file list, and
"M" the number of files in the file list.

All the entries in the argument list are added to the buffer list. Thus, you
can also get to them with the buffer list commands, like ":bnext".

:[N]al[l][!] [N] :al :all :sal :sall
:[N]sal[l][!] [N]
Rearrange the screen to open one window for each argument.
All other windows are closed. When a count is given, this is

the maximum number of windows to open.
With the :tab modifier open a tab page for each argument.
When there are more arguments than 'tabpagemax' further ones become split windows in the last tab page.
When the 'hidden' option is set, all buffers in closed windows become hidden.
When 'hidden' is not set, and the 'autowrite' option is set, modified buffers are written. Otherwise, windows that have buffers that are modified are not removed, unless the [!] is given, then they become hidden. But modified buffers are never abandoned, so changes cannot get lost.
[N] is the maximum number of windows to open. 'winheight' also limits the number of windows opened ('winwidth' if :vertical was prepended).
Buf/Win Enter/Leave autocommands are not executed for the new windows here, that's only done when they are really entered.

:[N]sa[rgument][!] [++opt] [+cmd] [N] :sa :sargument
Short for ":split | argument [N]": split window and go to Nth argument. But when there is no such argument, the window is not split. Also see ++opt and +cmd .

:[N]sn[ext][!] [++opt] [+cmd] [file ..] :sn :snext
Short for ":split | [N]next": split window and go to Nth next argument. But when there is no next file, the window is not split. Also see ++opt and +cmd .

:[N]spr[evious][!] [++opt] [+cmd] [N] :spr :sprevious
:[N]sN[ext][!] [++opt] [+cmd] [N] :sN :sNext
Short for ":split | [N]Next": split window and go to Nth previous argument. But when there is no previous file, the window is not split. Also see ++opt and +cmd .

:sre :srewind
:sre[wind][!] [++opt] [+cmd]
Short for ":split | rewind": split window and go to first argument. But when there is no argument list, the window is not split. Also see ++opt and +cmd .

:sfir :sfirst
:sfir[st] [++opt] [+cmd]
Same as ":srewind".

:sla :slast
:sla[st][!] [++opt] [+cmd]
Short for ":split | last": split window and go to last argument. But when there is no argument list, the window is not split. Also see ++opt and +cmd .

:dr :drop
:dr[op] [++opt] [+cmd] {file} ..
Edit the first {file} in a window.
- If the file is already open in a window change to that window.

- If the file is not open in a window edit the file in the
  current window. If the current buffer can't be abandon ed,
  the window is split first.
- Windows that are not in the argument list or are not full
  width will be closed if possible.

The argument-list is set, like with the :next command.
The purpose of this command is that it can be used from a
program that wants Vim to edit another file, e.g., a debugger.
When using the :tab modifier each argument is opened in a
tab page. The last window is used if it's empty.
Also see ++opt and +cmd .

==
8. Do a command in all buffers or windows   list-repeat

                                                                :windo
:[range]windo {cmd}   Execute {cmd} in each window or if [range] is given
                        only in windows for which the window number lies in
                        the [range]. It works like doing this:
                                CTRL-W t
                                :{cmd}
                                CTRL-W w
                                :{cmd}
                                etc.
                       This only operates in the current tab page.
                        When an error is detected on one window, further
                        windows will not be visited.
                        The last window (or where an error occurred) becomes
                        the current window.
                        {cmd} can contain '|' to concatenate several commands.
                        {cmd} must not open or close windows or reorder them.
                        {not in Vi}
                        Also see :tabdo , :argdo , :bufdo , :cdo , :ldo ,
                         :cfdo and :lfdo

                                                                :bufdo
:[range]bufdo[!] {cmd} Execute {cmd} in each buffer in the buffer list or if
                        [range] is given only for buffers for which their
                        buffer number is in the [range]. It works like doing
                        this:
                                :bfirst
                                :{cmd}
                                :bnext
                                :{cmd}
                                etc.
                       When the current file can't be abandon ed and the [!]
                        is not present, the command fails.
                        When an error is detected on one buffer, further
                        buffers will not be visited.
                        Unlisted buffers are skipped.
                        The last buffer (or where an error occurred) becomes
                        the current buffer.
                        {cmd} can contain '|' to concatenate several commands.
                        {cmd} must not delete buffers or add buffers to the

buffer list.
Note: While this command is executing, the Syntax autocommand event is disabled by adding it to 'eventignore'. This considerably speeds up editing each buffer.
{not in Vi}
Also see :tabdo , :argdo , :windo , :cdo , :ldo , :cfdo and :lfdo

Examples:

```
:windo set nolist nofoldcolumn | normal zn
```

This resets the 'list' option and disables folding in all windows.

```
:bufdo set fileencoding= | update
```

This resets the 'fileencoding' in each buffer and writes it if this changed the buffer. The result is that all buffers will use the 'encoding' encoding (if conversion works properly).

==
9. Tag or file name under the cursor window-tag

:sta :stag

:sta[g][!] [tagname]
Does ":tag[!] [tagname]" and splits the window for the found tag. See also :tag .

CTRL-W] CTRL-W_] CTRL-W_CTRL-]
CTRL-W CTRL-] Split current window in two. Use identifier under cursor as a tag and jump to it in the new upper window.
In Visual mode uses the Visually selected text as a tag.
Make new window N high.

CTRL-W_g]
CTRL-W g] Split current window in two. Use identifier under cursor as a tag and perform ":tselect" on it in the new upper window.
In Visual mode uses the Visually selected text as a tag.
Make new window N high.

CTRL-W_g_CTRL-]
CTRL-W g CTRL-] Split current window in two. Use identifier under cursor as a tag and perform ":tjump" on it in the new upper window.
In Visual mode uses the Visually selected text as a tag.
Make new window N high.

CTRL-W f CTRL-W_f CTRL-W_CTRL-F
CTRL-W CTRL-F Split current window in two. Edit file name under cursor.
Like ":split gf", but window isn't split if the file does not exist.
Uses the 'path' variable as a list of directory names where to look for the file. Also the path for current file is used to search for the file name.

If the name is a hypertext link that looks like
"type://machine/path", only "/path" is used.
If a count is given, the count'th matching file is edited.
{not available when the +file_in_path feature was disabled
at compile time}

CTRL-W F CTRL-W_F
Split current window in two. Edit file name under cursor and
jump to the line number following the file name. See gF for
details on how the line number is obtained.
{not available when the +file_in_path feature was disabled
at compile time}

CTRL-W gf CTRL-W_gf
Open a new tab page and edit the file name under the cursor.
Like "tab split" and "gf", but the new tab page isn't created
if the file does not exist.
{not available when the +file_in_path feature was disabled
at compile time}

CTRL-W gF CTRL-W_gF
Open a new tab page and edit the file name under the cursor
and jump to the line number following the file name. Like
"tab split" and "gF", but the new tab page isn't created if
the file does not exist.
{not available when the +file_in_path feature was disabled
at compile time}

Also see CTRL-W_CTRL-I : open window for an included file that includes
the keyword under the cursor.

==
10. The preview window preview-window

The preview window is a special window to show (preview) another file. It is
normally a small window used to show an include file or definition of a
function.
{not available when compiled without the |+quickfix| feature}

There can be only one preview window (per tab page). It is created with one
of the commands below. The 'previewheight' option can be set to specify the
height of the preview window when it's opened. The 'previewwindow' option is
set in the preview window to be able to recognize it. The 'winfixheight'
option is set to have it keep the same height when opening/closing other
windows.

:pta :ptag
:pta[g][!] [tagname]
Does ":tag[!] [tagname]" and shows the found tag in a
"Preview" window without changing the current buffer or cursor
position. If a "Preview" window already exists, it is re-used
(like a help window is). If a new one is opened,
'previewheight' is used for the height of the window. See
also :tag .

See below for an example. CursorHold-example
Small difference from :tag : When [tagname] is equal to the already displayed tag, the position in the matching tag list is not reset. This makes the CursorHold example work after a :ptnext .

CTRL-W z CTRL-W_z
CTRL-W CTRL-Z CTRL-W_CTRL-Z :pc :pclose
:pc[lose][!] Close any "Preview" window currently open. When the 'hidden' option is set, or when the buffer was changed and the [!] is used, the buffer becomes hidden (unless there is another window editing it). The command fails if any "Preview" buffer cannot be closed. See also :close .

:pp :ppop
:[count]pp[op][!]
Does ":[count]pop[!]" in the preview window. See :pop and :ptag . {not in Vi}

CTRL-W } CTRL-W_}
Use identifier under cursor as a tag and perform a :ptag on it. Make the new Preview window (if required) N high. If N is not given, 'previewheight' is used.

CTRL-W g } CTRL-W_g}
Use identifier under cursor as a tag and perform a :ptjump on it. Make the new Preview window (if required) N high. If N is not given, 'previewheight' is used.

:ped :pedit
:ped[it][!] [++opt] [+cmd] {file}
Edit {file} in the preview window. The preview window is opened like with :ptag . The current window and cursor position isn't changed. Useful example:

```
:pedit +/fputc /usr/include/stdio.h
```

:ps :psearch
:[range]ps[earch][!] [count] [/]pattern[/]
Works like :ijump but shows the found match in the preview window. The preview window is opened like with :ptag . The current window and cursor position isn't changed. Useful example:

```
:psearch popen
```

Like with the :ptag command, you can use this to automatically show information about the word under the cursor. This is less clever than using :ptag , but you don't need a tags file and it will also find matches in system include files. Example:

```
:au! CursorHold *.[ch] nested exe "silent! psearch " . expand("<cword>")
```

Warning: This can be slow.

Example CursorHold-example

```
:au! CursorHold *.[ch] nested exe "silent! ptag " . expand("<cword>")
```

This will cause a ":ptag" to be executed for the keyword under the cursor, when the cursor hasn't moved for the time set with 'updatetime'. The "nested" makes other autocommands be executed, so that syntax highlighting works in the preview window. The "silent!" avoids an error message when the tag could not be found. Also see CursorHold . To disable this again:

```
:au! CursorHold
```

A nice addition is to highlight the found tag, avoid the ":ptag" when there is no word under the cursor, and a few other things:

```
:au! CursorHold *.[ch] nested call PreviewWord()
:func PreviewWord()
:  if &previewwindow                  " don't do this in the preview window
:    return
:  endif
:  let w = expand("<cword>")          " get the word under cursor
:  if w =~ '\a'                       " if the word contains a letter
:
:    " Delete any existing highlight before showing another tag
:    silent! wincmd P                 " jump to preview window
:    if &previewwindow                       " if we really get there...
:      match none                     " delete existing highlight
:      wincmd p                       " back to old window
:    endif
:
:    " Try displaying a matching tag for the word under the cursor
:    try
:       exe "ptag " . w
:    catch
:      return
:    endtry
:
:    silent! wincmd P                 " jump to preview window
:    if &previewwindow                " if we really get there...
:      if has("folding")
:        silent! .foldopen            " don't want a closed fold
:      endif
:      call search("$", "b")          " to end of previous line
:      let w = substitute(w, '\\', '\\\\', "")
:      call search('\<\V' . w . '\>') " position cursor on match
:      " Add a match highlight to the word at this position
:      hi previewWord term=bold ctermbg=green guibg=green
:      exe 'match previewWord "\%' . line(".") . 'l\%' . col(".") . 'c\k*"'
:      wincmd p                       " back to old window
:    endif
:  endif
:endfun
```

==========

11. Using hidden buffers buffer-hidden

A hidden buffer is not displayed in a window, but is still loaded into memory.

This makes it possible to jump from file to file, without the need to read or write the file every time you get another buffer in a window.

:buffer-!

If the option 'hidden' ('hid') is set, abandoned buffers are kept for all commands that start editing another file: ":edit", ":next", ":tag", etc. The commands that move through the buffer list sometimes make the current buffer hidden although the 'hidden' option is not set. This happens when a buffer is modified, but is forced (with '!') to be removed from a window, and 'autowrite' is off or the buffer can't be written.

You can make a hidden buffer not hidden by starting to edit it with any command. Or by deleting it with the ":bdelete" command.

The 'hidden' is global, it is used for all buffers. The 'bufhidden' option can be used to make an exception for a specific buffer. It can take these values:

<empty>	Use the value of 'hidden'.
hide	Hide this buffer, also when 'hidden' is not set.
unload	Don't hide but unload this buffer, also when 'hidden' is set.
delete	Delete the buffer.

hidden-quit

When you try to quit Vim while there is a hidden, modified buffer, you will get an error message and Vim will make that buffer the current buffer. You can then decide to write this buffer (":wq") or quit without writing (":q!"). Be careful: there may be more hidden, modified buffers!

A buffer can also be unlisted. This means it exists, but it is not in the list of buffers. unlisted-buffer

:files[!] [flags] :files
:buffers[!] [flags] :buffers :ls
:ls[!] [flags]

Show all buffers. Example:

```
1 #h   "/test/text"          line 1
2u     "asdf"                line 0
3 %a + "version.c"           line 1
```

When the [!] is included the list will show unlisted buffers (the term "unlisted" is a bit confusing then...).

Each buffer has a unique number. That number will not change, thus you can always go to a specific buffer with ":buffer N" or "N CTRL-^", where N is the buffer number.

Indicators (chars in the same column are mutually exclusive):

u	an unlisted buffer (only displayed when [!] is used) unlisted-buffer
%	the buffer in the current window
#	the alternate buffer for ":e #" and CTRL-^

```
                  a     an active buffer: it is loaded and visible
                  h     a hidden buffer: It is loaded, but currently not
                           displayed in a window  hidden-buffer
                   -    a buffer with 'modifiable' off
                   =    a readonly buffer
                   R    a terminal buffer with a running job
                   F    a terminal buffer with a finished job
                   ?    a terminal buffer without a job: `:terminal NONE`
                    +   a modified buffer
                    x   a buffer with read errors

                [flags] can be a combination of the following characters,
                which restrict the buffers to be listed:
                     +   modified buffers
                     -   buffers with 'modifiable' off
                     =   readonly buffers
                     a   active buffers
                     u   unlisted buffers (overrides the "!")
                     h   hidden buffers
                     x   buffers with a read error
                     %   current buffer
                     #   alternate buffer
                     R   terminal buffers with a running job
                     F   terminal buffers with a finished job
                     ?   terminal buffers without a job: `:terminal NONE`
                Combining flags means they are "and"ed together, e.g.:
                     h+   hidden buffers which are modified
                     a+   active buffers which are modified

                When using  :filter  the pattern is matched against the
                displayed buffer name, e.g.:
                        filter /\.vim/ ls

                                                    :bad   :badd
:bad[d] [+lnum] {fname}
                Add file name {fname} to the buffer list, without loading it.
                If "lnum" is specified, the cursor will be positioned at that
                line when the buffer is first entered.  Note that other
                commands after the + will be ignored.

:[N]bd[elete][!]                        :bd   :bdel   :bdelete   E516
:bd[elete][!] [N]
                Unload buffer [N] (default: current buffer) and delete it from
                the buffer list.  If the buffer was changed, this fails,
                unless when [!] is specified, in which case changes are lost.
                The file remains unaffected.  Any windows for this buffer are
                closed.  If buffer [N] is the current buffer, another buffer
                will be displayed instead.  This is the most recent entry in
                the jump list that points into a loaded buffer.
                Actually, the buffer isn't completely deleted, it is removed
                from the buffer list  unlisted-buffer  and option values,
                variables and mappings/abbreviations for the buffer are
                cleared. Examples:
                    :.,$-bdelete    " delete buffers from the current one to
```

```
                                " last but one
                    :%bdelete       " delete all buffers

:bdelete[!] {bufname}                                               E93   E94
                Like ":bdelete[!] [N]", but buffer given by name, see
                 {bufname} .

:bdelete[!] N1 N2 ...
                Do ":bdelete[!]" for buffer N1, N2, etc.  The arguments can be
                buffer numbers or buffer names (but not buffer names that are
                a number).  Insert a backslash before a space in a buffer
                name.

:N,Mbdelete[!]  Do ":bdelete[!]" for all buffers in the range N to M
                 inclusive .

:[N]bw[ipeout][!]                          :bw   :bwipe   :bwipeout   E517
:bw[ipeout][!] {bufname}
:N,Mbw[ipeout][!]
:bw[ipeout][!] N1 N2 ...
                Like  :bdelete , but really delete the buffer.  Everything
                related to the buffer is lost.  All marks in this buffer
                become invalid, option settings are lost, etc.  Don't use this
                unless you know what you are doing. Examples:
                    :.+,$bwipeout   " wipe out all buffers after the current
                                    " one
                    :%bwipeout      " wipe out all buffers

:[N]bun[load][!]                                    :bun   :bunload   E515
:bun[load][!] [N]
                Unload buffer [N] (default: current buffer).  The memory
                allocated for this buffer will be freed.  The buffer remains
                in the buffer list.
                If the buffer was changed, this fails, unless when [!] is
                specified, in which case the changes are lost.
                Any windows for this buffer are closed.  If buffer [N] is the
                current buffer, another buffer will be displayed instead.
                This is the most recent entry in the jump list that points
                into a loaded buffer.

:bunload[!] {bufname}
                Like ":bunload[!] [N]", but buffer given by name.
                Also see  {bufname} .

:N,Mbunload[!]  Do ":bunload[!]" for all buffers in the range N to M
                 inclusive .

:bunload[!] N1 N2 ...
                Do ":bunload[!]" for buffer N1, N2, etc.  The arguments can be
                buffer numbers or buffer names (but not buffer names that are
                a number).  Insert a backslash before a space in a buffer
                name.
```

:[N]b[uffer][!] [+cmd] [N] :b :bu :buf :buffer E86
Edit buffer [N] from the buffer list. If [N] is not given, the current buffer remains being edited. See :buffer-! for [!]. This will also edit a buffer that is not in the buffer list, without setting the 'buflisted' flag.
Also see +cmd .

:[N]b[uffer][!] [+cmd] {bufname} {bufname}
Edit buffer for {bufname} from the buffer list. A partial name also works, so long as it is unique in the list of buffers.
Note that a buffer whose name is a number cannot be referenced by that name; use the buffer number instead.
Insert a backslash before a space in a buffer name.
See :buffer-! for [!].
This will also edit a buffer that is not in the buffer list, without setting the 'buflisted' flag.
Also see +cmd .

:[N]sb[uffer] [+cmd] [N] :sb :sbuffer
Split window and edit buffer [N] from the buffer list. If [N] is not given, the current buffer is edited. Respects the "useopen" setting of 'switchbuf' when splitting. This will also edit a buffer that is not in the buffer list, without setting the 'buflisted' flag.
Also see +cmd .

:[N]sb[uffer] [+cmd] {bufname}
Split window and edit buffer for {bufname} from the buffer list. This will also edit a buffer that is not in the buffer list, without setting the 'buflisted' flag.
Note: If what you want to do is split the buffer, make a copy under another name, you can do it this way:

```
:w foobar | sp #
```

Also see +cmd .

:[N]bn[ext][!] [+cmd] [N] :bn :bnext E87
Go to [N]th next buffer in buffer list. [N] defaults to one. Wraps around the end of the buffer list.
See :buffer-! for [!].
Also see +cmd .
If you are in a help buffer, this takes you to the next help buffer (if there is one). Similarly, if you are in a normal (non-help) buffer, this takes you to the next normal buffer. This is so that if you have invoked help, it doesn't get in the way when you're browsing code/text buffers. The next three commands also work like this.

:[N]sbn[ext] [+cmd] [N] :sbn :sbnext
Split window and go to [N]th next buffer in buffer list. Wraps around the end of the buffer list. Uses 'switchbuf'

Also see +cmd .

:[N]bN[ext][!] [+cmd] [N] :bN :bNext :bp :bprevious E88
:[N]bp[revious][!] [+cmd] [N]
Go to [N]th previous buffer in buffer list. [N] defaults to
one. Wraps around the start of the buffer list.
See :buffer-! for [!] and 'switchbuf'.
Also see +cmd .

:[N]sbN[ext] [+cmd] [N] :sbN :sbNext :sbp :sbprevious
:[N]sbp[revious] [+cmd] [N]
Split window and go to [N]th previous buffer in buffer list.
Wraps around the start of the buffer list.
Uses 'switchbuf'.
Also see +cmd .

:br[ewind][!] [+cmd] :br :brewind
Go to first buffer in buffer list. If the buffer list is
empty, go to the first unlisted buffer.
See :buffer-! for [!].

:bf[irst] [+cmd] :bf :bfirst
Same as :brewind .
Also see +cmd .

:sbr[ewind] [+cmd] :sbr :sbrewind
Split window and go to first buffer in buffer list. If the
buffer list is empty, go to the first unlisted buffer.
Respects the 'switchbuf' option.
Also see +cmd .

:sbf[irst] [+cmd] :sbf :sbfirst
Same as ":sbrewind".

:bl[ast][!] [+cmd] :bl :blast
Go to last buffer in buffer list. If the buffer list is
empty, go to the last unlisted buffer.
See :buffer-! for [!].

:sbl[ast] [+cmd] :sbl :sblast
Split window and go to last buffer in buffer list. If the
buffer list is empty, go to the last unlisted buffer.
Respects 'switchbuf' option.

:[N]bm[odified][!] [+cmd] [N] :bm :bmodified E84
Go to [N]th next modified buffer. Note: this command also
finds unlisted buffers. If there is no modified buffer the
command fails.

:[N]sbm[odified] [+cmd] [N] :sbm :sbmodified
Split window and go to [N]th next modified buffer.
Respects 'switchbuf' option.
Note: this command also finds buffers not in the buffer list.

:[N]unh[ide] [N] :unh :unhide :sun :sunhide
:[N]sun[hide] [N]
Rearrange the screen to open one window for each loaded buffer in the buffer list. When a count is given, this is the maximum number of windows to open.

:[N]ba[ll] [N] :ba :ball :sba :sball
:[N]sba[ll] [N] Rearrange the screen to open one window for each buffer in the buffer list. When a count is given, this is the maximum number of windows to open. 'winheight' also limits the number of windows opened ('winwidth' if :vertical was prepended). Buf/Win Enter/Leave autocommands are not executed for the new windows here, that's only done when they are really entered. When the :tab modifier is used new windows are opened in a new tab, up to 'tabpagemax'.

Note: All the commands above that start editing another buffer, keep the 'readonly' flag as it was. This differs from the ":edit" command, which sets the 'readonly' flag each time the file is read.

==
12. Special kinds of buffers special-buffers

Instead of containing the text of a file, buffers can also be used for other purposes. A few options can be set to change the behavior of a buffer:

'bufhidden'	what happens when the buffer is no longer displayed in a window.
'buftype'	what kind of a buffer this is
'swapfile'	whether the buffer will have a swap file
'buflisted'	buffer shows up in the buffer list

A few useful kinds of a buffer:

quickfix Used to contain the error list or the location list. See :cwindow and :lwindow . This command sets the 'buftype' option to "quickfix". You are not supposed to change this! 'swapfile' is off.

help Contains a help file. Will only be created with the :help command. The flag that indicates a help buffer is internal and can't be changed. The 'buflisted' option will be reset for a help buffer.

terminal A terminal window buffer, see terminal . The contents cannot be read or changed until the job ends.

directory Displays directory contents. Can be used by a file explorer plugin. The buffer is created with these settings:

```
:setlocal buftype=nowrite
:setlocal bufhidden=delete
:setlocal noswapfile
```

The buffer name is the name of the directory and is adjusted when using the :cd command.

scratch		Contains text that can be discarded at any time. It is kept
		when closing the window, it must be deleted explicitly.
		Settings:
			:setlocal buftype=nofile
			:setlocal bufhidden=hide
			:setlocal noswapfile
		The buffer name can be used to identify the buffer, if you
		give it a meaningful name.

		unlisted-buffer
unlisted	The buffer is not in the buffer list. It is not used for
		normal editing, but to show a help file, remember a file name
		or marks. The ":bdelete" command will also set this option,
		thus it doesn't completely delete the buffer. Settings:
			:setlocal nobuflisted

tabpage.txt For Vim version 8.1. Last change: 2018 Mar 29

VIM REFERENCE MANUAL by Bram Moolenaar

Editing with windows in multiple tab pages. tab-page tabpage

The commands which have been added to use multiple tab pages are explained here. Additionally, there are explanations for commands that work differently when used in combination with more than one tab page.

{Vi does not have any of these commands}
{not able to use multiple tab pages when the +windows feature was disabled at compile time}

==
1. Introduction tab-page-intro

A tab page holds one or more windows. You can easily switch between tab pages, so that you have several collections of windows to work on different things.

Usually you will see a list of labels at the top of the Vim window, one for each tab page. With the mouse you can click on the label to jump to that tab page. There are other ways to move between tab pages, see below.

Most commands work only in the current tab page. That includes the CTRL-W commands, :windo, :all and :ball (when not using the :tab modifier). The commands that are aware of other tab pages than the current one are mentioned below.

Tabs are also a nice way to edit a buffer temporarily without changing the current window layout. Open a new tab page, do whatever you want to do and close the tab page.

==
2. Commands tab-page-commands

OPENING A NEW TAB PAGE:

When starting Vim "vim -p filename ..." opens each file argument in a separate tab page (up to 'tabpagemax'). See -p

A double click with the mouse in the non-GUI tab pages line opens a new, empty tab page. It is placed left of the position of the click. The first click may select another tab page first, causing an extra screen update.

This also works in a few GUI versions, esp. Win32 and Motif. But only when clicking right of the labels.

In the GUI tab pages line you can use the right mouse button to open menu.
 tabline-menu .

For the related autocommands see tabnew-autocmd .

:[count]tabe[dit]   :tabe   :tabedit   :tabnew
:[count]tabnew
                Open a new tab page with an empty window, after the current
                tab page. If [count] is given the new tab page appears after
                the tab page [count] otherwise the new tab page will appear
                after the current one.
                    :tabnew   " opens tabpage after the current one
                    :.tabnew   " as above
                    :+tabnew   " opens tabpage after the next tab page
                                " note: it is one further than :tabnew
                    :-tabnew   " opens tabpage before the current one
                    :0tabnew   " opens tabpage before the first one
                    :$tabnew   " opens tabpage after the last one

:[count]tabe[dit] [++opt] [+cmd] {file}
:[count]tabnew [++opt] [+cmd] {file}
                Open a new tab page and edit {file}, like with :edit .
                For [count] see :tabnew above.

:[count]tabf[ind] [++opt] [+cmd] {file}   :tabf   :tabfind
                Open a new tab page and edit {file} in 'path', like with
                 :find . For [count] see :tabnew above.
                {not available when the +file_in_path feature was disabled
                at compile time}

:[count]tab {cmd}   :tab
                Execute {cmd} and when it opens a new window open a new tab
                page instead. Doesn't work for :diffsplit , :diffpatch ,
                 :execute and :normal .
                If [count] is given the new tab page appears after the tab
                page [count] otherwise the new tab page will appear after the
                current one.
                Examples:
                    :tab split   " opens current buffer in new tab page
                    :tab help gt   " opens tab page with help for "gt"
                    :.tab help gt   " as above
                    :+tab help   " opens tab page with help after the next
                                    " tab page
                    :-tab help   " opens tab page with help before the
                                    " current one
                    :0tab help   " opens tab page with help before the
                                    " first one
                    :$tab help   " opens tab page with help after the last
                                    " one

CTRL-W gf   Open a new tab page and edit the file name under the cursor.

See CTRL-W_gf .

CTRL-W gF	Open a new tab page and edit the file name under the cursor
and jump to the line number following the file name.
See CTRL-W_gF .

CLOSING A TAB PAGE:

Closing the last window of a tab page closes the tab page too, unless there is only one tab page.

Using the mouse: If the tab page line is displayed you can click in the "X" at the top right to close the current tab page. A custom 'tabline' may show something else.

:tabc :tabclose

:tabc[lose][!] Close current tab page.
This command fails when:
- There is only one tab page on the screen. E784
- When 'hidden' is not set, [!] is not used, a buffer has changes, and there is no other window on this buffer.
Changes to the buffer are not written and won't get lost, so this is a "safe" command.

```
:tabclose       " close the current tab page
```

:{count}tabc[lose][!]
:tabc[lose][!] {count}
Close tab page {count}. Fails in the same way as `:tabclose` above.

```
:-tabclose      " close the previous tab page
:+tabclose      " close the next tab page
:1tabclose      " close the first tab page
:$tabclose      " close the last tab page
:tabclose -2    " close the two previous tab page
:tabclose +     " close the next tab page
:tabclose 3     " close the third tab page
:tabclose $     " close the last tab page
```

:tabo :tabonly

:tabo[nly][!] Close all other tab pages.
When the 'hidden' option is set, all buffers in closed windows become hidden.
When 'hidden' is not set, and the 'autowrite' option is set, modified buffers are written. Otherwise, windows that have buffers that are modified are not removed, unless the [!] is given, then they become hidden. But modified buffers are never abandoned, so changes cannot get lost.

```
:tabonly        " close all tab pages except the current
                " one
```

:{count}tabo[nly][!]
:tabo[nly][!] {count}
Close all tab pages except {count} one.

```
:.tabonly       " as above
```

```
                    :-tabonly       " close all tab pages except the previous
                                    " one
                    :+tabonly       " close all tab pages except the next one
                    :1tabonly       " close all tab pages except the first one
                    :$tabonly       " close all tab pages except the last one
                    :tabonly -      " close all tab pages except the previous
                                    " one
                    :tabonly +2     " close all tab pages except the two next
                                    " one
                    :tabonly 1      " close all tab pages except the first one
                    :tabonly $      " close all tab pages except the last one
```

SWITCHING TO ANOTHER TAB PAGE:

Using the mouse: If the tab page line is displayed you can click in a tab page label to switch to that tab page. Click where there is no label to go to the next tab page. 'tabline'

:tabn[ext] :tabn :tabnext gt
<C-PageDown> CTRL-<PageDown> <C-PageDown>
gt i_CTRL-<PageDown> i_<C-PageDown>
Go to the next tab page. Wraps around from the last to the first one.

:{count}tabn[ext]
:tabn[ext] {count}
Go to tab page {count}. The first tab page has number one.

```
    :-tabnext   " go to the previous tab page
    :+tabnext   " go to the next tab page
    :+2tabnext  " go to the two next tab page
    :1tabnext   " go to the first tab page
    :$tabnext   " go to the last tab page
    :tabnext $  " as above
    :tabnext -  " go to the previous tab page
    :tabnext -1 " as above
    :tabnext +  " go to the next tab page
    :tabnext +1 " as above
```

{count}<C-PageDown>
{count}gt Go to tab page {count}. The first tab page has number one.

:tabp[revious] :tabp :tabprevious gT :tabN
:tabN[ext] :tabNext CTRL-<PageUp>
<C-PageUp> <C-PageUp> i_CTRL-<PageUp> i_<C-PageUp>
gT Go to the previous tab page. Wraps around from the first one to the last one.

:tabp[revious] {count}
:tabN[ext] {count}
{count}<C-PageUp>
{count}gT Go {count} tab pages back. Wraps around from the first one to the last one. Note that the use of {count} is different

from :tabnext , where it is used as the tab page number.

:tabr[ewind] :tabfir :tabfirst :tabr :tabrewind
:tabfir[st] Go to the first tab page.

:tabl :tablast
:tabl[ast] Go to the last tab page.

Other commands:

:tabs :tabs
List the tab pages and the windows they contain.
Shows a ">" for the current window.
Shows a "+" for modified buffers.
For example:

```
Tab page 1
  + tabpage.txt
    ex_docmd.c
Tab page 2
>   main.c
```

REORDERING TAB PAGES:

:tabm[ove] [N] :tabm :tabmove
:[N]tabm[ove]
Move the current tab page to after tab page N. Use zero to make the current tab page the first one. Without N the tab page is made the last one.

```
:.tabmove   " do nothing
:-tabmove   " move the tab page to the left
:+tabmove   " move the tab page to the right
:0tabmove   " move the tab page to the beginning of the tab
            " list
:tabmove 0  " as above
:tabmove    " move the tab page to the last
:$tabmove   " as above
:tabmove $  " as above
```

:tabm[ove] +[N]
:tabm[ove] -[N]
Move the current tab page N places to the right (with +) or to the left (with -).

```
:tabmove -  " move the tab page to the left
:tabmove -1 " as above
:tabmove +  " move the tab page to the right
:tabmove +1 " as above
```

Note that although it is possible to move a tab behind the N-th one by using :Ntabmove. And move it by N places by using :+Ntabmove. For clarification what +N means in this context see [range] .

LOOPING OVER TAB PAGES:

:tabd :tabdo

:[range]tabd[o] {cmd}
Execute {cmd} in each tab page or if [range] is given only in tab pages which tab page number is in the [range]. It works like doing this:

```
:tabfirst
:{cmd}
:tabnext
:{cmd}
etc.
```

This only operates in the current window of each tab page. When an error is detected on one tab page, further tab pages will not be visited.
The last tab page (or where an error occurred) becomes the current tab page.
{cmd} can contain '|' to concatenate several commands.
{cmd} must not open or close tab pages or reorder them.
{not in Vi}
Also see :windo , :argdo , :bufdo , :cdo , :ldo , :cfdo and :lfdo

==========

3. Other items tab-page-other

tabline-menu

The GUI tab pages line has a popup menu. It is accessed with a right click. The entries are:

Close	Close the tab page under the mouse pointer. The current one if there is no label under the mouse pointer.
New Tab	Open a tab page, editing an empty buffer. It appears to the left of the mouse pointer.
Open Tab...	Like "New Tab" and additionally use a file selector to select a file to edit.

Diff mode works per tab page. You can see the diffs between several files within one tab page. Other tab pages can show differences between other files.

Variables local to a tab page start with "t:". tabpage-variable

Currently there is only one option local to a tab page: 'cmdheight'.

tabnew-autocmd

The TabLeave and TabEnter autocommand events can be used to do something when switching from one tab page to another. The exact order depends on what you are doing. When creating a new tab page this works as if you create a new window on the same buffer and then edit another buffer. Thus ":tabnew" triggers:

WinLeave	leave current window
TabLeave	leave current tab page
WinEnter	enter window in new tab page

```
        TabEnter                enter new tab page
        BufLeave                leave current buffer
        BufEnter                enter new empty buffer

When switching to another tab page the order is:
        BufLeave
        WinLeave
        TabLeave
        TabEnter
        WinEnter
        BufEnter

==============================================================================
4. Setting 'tabline'                                    setting-tabline

The 'tabline' option specifies what the line with tab pages labels looks like.
It is only used when there is no GUI tab line.

You can use the 'showtabline' option to specify when you want the line with
tab page labels to appear: never, when there is more than one tab page or
always.

The highlighting of the tab pages line is set with the groups TabLine
TabLineSel and TabLineFill.   hl-TabLine   hl-TabLineSel   hl-TabLineFill

A "+" will be shown for a tab page that has a modified window.  The number of
windows in a tabpage is also shown.  Thus "3+" means three windows and one of
them has a modified buffer.

The 'tabline' option allows you to define your preferred way to tab pages
labels.  This isn't easy, thus an example will be given here.

For basics see the 'statusline' option.  The same items can be used in the
'tabline' option.  Additionally, the  tabpagebuflist() ,  tabpagenr()  and
 tabpagewinnr()  functions are useful.

Since the number of tab labels will vary, you need to use an expression for
the whole option.  Something like:
        :set tabline=%!MyTabLine()

Then define the MyTabLine() function to list all the tab pages labels.  A
convenient method is to split it in two parts:  First go over all the tab
pages and define labels for them.  Then get the label for each tab page.

        function MyTabLine()
          let s = ''
          for i in range(tabpagenr('$'))
            " select the highlighting
            if i + 1 == tabpagenr()
              let s .= '%#TabLineSel#'
            else
              let s .= '%#TabLine#'
            endif
```

```
      " set the tab page number (for mouse clicks)
      let s .= '%' . (i + 1) . 'T'

      " the label is made by MyTabLabel()
      let s .= ' %{MyTabLabel(' . (i + 1) . ')} '
    endfor

    " after the last tab fill with TabLineFill and reset tab page nr
    let s .= '%#TabLineFill#%T'

    " right-align the label to close the current tab page
    if tabpagenr('$') > 1
      let s .= '%=%#TabLine#%999Xclose'
    endif

    return s
  endfunction
```

Now the MyTabLabel() function is called for each tab page to get its label.

```
  function MyTabLabel(n)
    let buflist = tabpagebuflist(a:n)
    let winnr = tabpagewinnr(a:n)
    return bufname(buflist[winnr - 1])
  endfunction
```

This is just a simplistic example that results in a tab pages line that resembles the default, but without adding a + for a modified buffer or truncating the names. You will want to reduce the width of labels in a clever way when there is not enough room. Check the 'columns' option for the space available.

==========

5. Setting 'guitablabel' setting-guitablabel

When the GUI tab pages line is displayed, 'guitablabel' can be used to specify the label to display for each tab page. Unlike 'tabline', which specifies the whole tab pages line at once, 'guitablabel' is used for each label separately.

'guitabtooltip' is very similar and is used for the tooltip of the same label. This only appears when the mouse pointer hovers over the label, thus it usually is longer. Only supported on some systems though.

See the 'statusline' option for the format of the value.

The "%N" item can be used for the current tab page number. The v:lnum variable is also set to this number when the option is evaluated.
The items that use a file name refer to the current window of the tab page.

Note that syntax highlighting is not used for the option. The %T and %X items are also ignored.

A simple example that puts the tab page number and the buffer name in the

label:

```
:set guitablabel=%N\ %f
```

An example that resembles the default 'guitablabel': Show the number of windows in the tab page and a '+' if there is a modified buffer:

```
function GuiTabLabel()
  let label = ''
  let bufnrlist = tabpagebuflist(v:lnum)

  " Add '+' if one of the buffers in the tab page is modified
  for bufnr in bufnrlist
    if getbufvar(bufnr, "&modified")
      let label = '+'
      break
    endif
  endfor

  " Append the number of windows in the tab page if more than one
  let wincount = tabpagewinnr(v:lnum, '$')
  if wincount > 1
    let label .= wincount
  endif
  if label != ''
    let label .= ' '
  endif

  " Append the buffer name
  return label . bufname(bufnrlist[tabpagewinnr(v:lnum) - 1])
endfunction

set guitablabel=%{GuiTabLabel()}
```

Note that the function must be defined before setting the option, otherwise you get an error message for the function not being known.

If you want to fall back to the default label, return an empty string.

If you want to show something specific for a tab page, you might want to use a tab page local variable. t:var

vim:tw=78:ts=8:noet:ft=help:norl:

VIM REFERENCE MANUAL by Bram Moolenaar

Syntax highlighting syntax syntax-highlighting coloring

Syntax highlighting enables Vim to show parts of the text in another font or color. Those parts can be specific keywords or text matching a pattern. Vim doesn't parse the whole file (to keep it fast), so the highlighting has its limitations. Lexical highlighting might be a better name, but since everybody calls it syntax highlighting we'll stick with that.

Vim supports syntax highlighting on all terminals. But since most ordinary terminals have very limited highlighting possibilities, it works best in the GUI version, gvim.

In the User Manual:
usr_06.txt introduces syntax highlighting.
usr_44.txt introduces writing a syntax file.

{Vi does not have any of these commands}

Syntax highlighting is not available when the +syntax feature has been disabled at compile time.

==========

1. Quick start :syn-qstart

:syn-enable :syntax-enable

This command switches on syntax highlighting:

```
:syntax enable
```

What this command actually does is to execute the command
	:source $VIMRUNTIME/syntax/syntax.vim

If the VIM environment variable is not set, Vim will try to find
the path in another way (see $VIMRUNTIME). Usually this works just
fine. If it doesn't, try setting the VIM environment variable to the
directory where the Vim stuff is located. For example, if your syntax files
are in the "/usr/vim/vim50/syntax" directory, set $VIMRUNTIME to
"/usr/vim/vim50". You must do this in the shell, before starting Vim.
This command also sources the menu.vim script when the GUI is running or
will start soon. See 'go-M' about avoiding that.

:syn-on :syntax-on
The `:syntax enable` command will keep your current color settings. This
allows using `:highlight` commands to set your preferred colors before or
after using this command. If you want Vim to overrule your settings with the
defaults, use:
	:syntax on

:hi-normal :highlight-normal
If you are running in the GUI, you can get white text on a black background
with:
	:highlight Normal guibg=Black guifg=White
For a color terminal see :hi-normal-cterm .
For setting up your own colors syntax highlighting see syncolor .

NOTE: The syntax files on MS-DOS and Windows have lines that end in <CR><NL>.
The files for Unix end in <NL>. This means you should use the right type of
file for your system. Although on MS-DOS and Windows the right format is
automatically selected if the 'fileformats' option is not empty.

NOTE: When using reverse video ("gvim -fg white -bg black"), the default value
of 'background' will not be set until the GUI window is opened, which is after
reading the gvimrc . This will cause the wrong default highlighting to be
used. To set the default value of 'background' before switching on
highlighting, include the ":gui" command in the gvimrc :

```
:gui         " open window and set default for 'background'
:syntax on   " start highlighting, use 'background' to set colors
```

NOTE: Using ":gui" in the gvimrc means that "gvim -f" won't start in the
foreground! Use ":gui -f" then.

g:syntax_on
You can toggle the syntax on/off with this command:
```
:if exists("g:syntax_on") | syntax off | else | syntax enable | endif
```

To put this into a mapping, you can use:
```
:map <F7> :if exists("g:syntax_on") <Bar>
     \   syntax off <Bar>
     \ else <Bar>
     \   syntax enable <Bar>
     \ endif <CR>
```
[using the <> notation, type this literally]

Details:
The ":syntax" commands are implemented by sourcing a file. To see exactly how this works, look in the file:

command	file
:syntax enable	$VIMRUNTIME/syntax/syntax.vim
:syntax on	$VIMRUNTIME/syntax/syntax.vim
:syntax manual	$VIMRUNTIME/syntax/manual.vim
:syntax off	$VIMRUNTIME/syntax/nosyntax.vim

Also see syntax-loading .

NOTE: If displaying long lines is slow and switching off syntax highlighting makes it fast, consider setting the 'synmaxcol' option to a lower value.

==
2. Syntax files   :syn-files

The syntax and highlighting commands for one language are normally stored in a syntax file. The name convention is: "{name}.vim". Where {name} is the name of the language, or an abbreviation (to fit the name in 8.3 characters, a requirement in case the file is used on a DOS filesystem).
Examples:

c.vim	perl.vim	java.vim	html.vim
cpp.vim	sh.vim	csh.vim	

The syntax file can contain any Ex commands, just like a vimrc file. But the idea is that only commands for a specific language are included. When a language is a superset of another language, it may include the other one, for example, the cpp.vim file could include the c.vim file:

```
:so $VIMRUNTIME/syntax/c.vim
```

The .vim files are normally loaded with an autocommand. For example:

```
:au Syntax c     runtime! syntax/c.vim
:au Syntax cpp   runtime! syntax/cpp.vim
```

These commands are normally in the file $VIMRUNTIME/syntax/synload.vim.

MAKING YOUR OWN SYNTAX FILES   mysyntaxfile

When you create your own syntax files, and you want to have Vim use these automatically with ":syntax enable", do this:

1. Create your user runtime directory. You would normally use the first item of the 'runtimepath' option. Example for Unix:
   ```
   mkdir ~/.vim
   ```

2. Create a directory in there called "syntax". For Unix:
   ```
   mkdir ~/.vim/syntax
   ```

3. Write the Vim syntax file. Or download one from the internet. Then write it in your syntax directory. For example, for the "mine" syntax:
   ```
   :w ~/.vim/syntax/mine.vim
   ```

Now you can start using your syntax file manually:

```
	:set syntax=mine
```
You don't have to exit Vim to use this.

If you also want Vim to detect the type of file, see new-filetype .

If you are setting up a system with many users and you don't want each user
to add the same syntax file, you can use another directory from 'runtimepath'.

ADDING TO AN EXISTING SYNTAX FILE mysyntaxfile-add

If you are mostly satisfied with an existing syntax file, but would like to
add a few items or change the highlighting, follow these steps:

1. Create your user directory from 'runtimepath', see above.

2. Create a directory in there called "after/syntax". For Unix:
```
	mkdir ~/.vim/after
	mkdir ~/.vim/after/syntax
```

3. Write a Vim script that contains the commands you want to use. For
   example, to change the colors for the C syntax:
```
	highlight cComment ctermfg=Green guifg=Green
```

4. Write that file in the "after/syntax" directory. Use the name of the
   syntax, with ".vim" added. For our C syntax:
```
	:w ~/.vim/after/syntax/c.vim
```

That's it. The next time you edit a C file the Comment color will be
different. You don't even have to restart Vim.

If you have multiple files, you can use the filetype as the directory name.
All the "*.vim" files in this directory will be used, for example:
```
	~/.vim/after/syntax/c/one.vim
	~/.vim/after/syntax/c/two.vim
```

REPLACING AN EXISTING SYNTAX FILE mysyntaxfile-replace

If you don't like a distributed syntax file, or you have downloaded a new
version, follow the same steps as for mysyntaxfile above. Just make sure
that you write the syntax file in a directory that is early in 'runtimepath'.
Vim will only load the first syntax file found, assuming that it sets
b:current_syntax.

NAMING CONVENTIONS group-name {group-name} E669 W18

A syntax group name is to be used for syntax items that match the same kind of
thing. These are then linked to a highlight group that specifies the color.
A syntax group name doesn't specify any color or attributes itself.

The name for a highlight or syntax group must consist of ASCII letters, digits
and the underscore. As a regexp: "[a-zA-Z0-9_]*". However, Vim does not give

an error when using other characters.

To be able to allow each user to pick his favorite set of colors, there must
be preferred names for highlight groups that are common for many languages.
These are the suggested group names (if syntax highlighting works properly
you can see the actual color, except for "Ignore"):

```
        *Comment        any comment

        *Constant       any constant
         String         a string constant: "this is a string"
         Character      a character constant: 'c', '\n'
         Number         a number constant: 234, 0xff
         Boolean        a boolean constant: TRUE, false
         Float          a floating point constant: 2.3e10

        *Identifier     any variable name
         Function       function name (also: methods for classes)

        *Statement      any statement
         Conditional    if, then, else, endif, switch, etc.
         Repeat         for, do, while, etc.
         Label          case, default, etc.
         Operator       "sizeof", "+", "*", etc.
         Keyword        any other keyword
         Exception      try, catch, throw

        *PreProc        generic Preprocessor
         Include        preprocessor #include
         Define         preprocessor #define
         Macro          same as Define
         PreCondit      preprocessor #if, #else, #endif, etc.

        *Type           int, long, char, etc.
         StorageClass   static, register, volatile, etc.
         Structure      struct, union, enum, etc.
         Typedef        A typedef

        *Special        any special symbol
         SpecialChar    special character in a constant
         Tag            you can use CTRL-] on this
         Delimiter      character that needs attention
         SpecialComment special things inside a comment
         Debug          debugging statements

        *Underlined     text that stands out, HTML links

        *Ignore         left blank, hidden   hl-Ignore

        *Error          any erroneous construct

        *Todo           anything that needs extra attention; mostly the
                        keywords TODO FIXME and XXX
```

The names marked with * are the preferred groups; the others are minor groups.
For the preferred groups, the "syntax.vim" file contains default highlighting.
The minor groups are linked to the preferred groups, so they get the same
highlighting. You can override these defaults by using ":highlight" commands
after sourcing the "syntax.vim" file.

Note that highlight group names are not case sensitive. "String" and "string"
can be used for the same group.

The following names are reserved and cannot be used as a group name:
        NONE   ALL   ALLBUT   contains   contained

                                                              hl-Ignore
When using the Ignore group, you may also consider using the conceal
mechanism. See conceal .

==
3. Syntax loading procedure   syntax-loading

This explains the details that happen when the command ":syntax enable" is
issued. When Vim initializes itself, it finds out where the runtime files are
located. This is used here as the variable $VIMRUNTIME .

":syntax enable" and ":syntax on" do the following:

    Source $VIMRUNTIME/syntax/syntax.vim
    |
    +- Clear out any old syntax by sourcing $VIMRUNTIME/syntax/nosyntax.vim
    |
    +- Source first syntax/synload.vim in 'runtimepath'
    | |
    | +- Setup the colors for syntax highlighting. If a color scheme is
    | | defined it is loaded again with ":colors {name}". Otherwise
    | | ":runtime! syntax/syncolor.vim" is used. ":syntax on" overrules
    | | existing colors, ":syntax enable" only sets groups that weren't
    | | set yet.
    | |
    | +- Set up syntax autocmds to load the appropriate syntax file when
    | | the 'syntax' option is set. synload-1
    | |
    | +- Source the user's optional file, from the mysyntaxfile variable.
    | This is for backwards compatibility with Vim 5.x only. synload-2
    |
    +- Do ":filetype on", which does ":runtime! filetype.vim". It loads any
    | filetype.vim files found. It should always Source
    | $VIMRUNTIME/filetype.vim, which does the following.
    | |
    | +- Install autocmds based on suffix to set the 'filetype' option
    | | This is where the connection between file name and file type is
    | | made for known file types. synload-3
    | |
    | +- Source the user's optional file, from the myfiletypefile
    | | variable. This is for backwards compatibility with Vim 5.x only.
    | | synload-4

```
    |   |
    |   +-  Install one autocommand which sources scripts.vim when no file
    |   |   type was detected yet.  synload-5
    |   |
    |   +-  Source $VIMRUNTIME/menu.vim, to setup the Syntax menu.  menu.vim
    |
    +-  Install a FileType autocommand to set the 'syntax' option when a file
    |   type has been detected.  synload-6
    |
    +-  Execute syntax autocommands to start syntax highlighting for each
        already loaded buffer.

Upon loading a file, Vim finds the relevant syntax file as follows:

    Loading the file triggers the BufReadPost autocommands.
    |
    +-  If there is a match with one of the autocommands from  synload-3
    |   (known file types) or  synload-4  (user's file types), the 'filetype'
    |   option is set to the file type.
    |
    +-  The autocommand at  synload-5  is triggered.  If the file type was not
    |   found yet, then scripts.vim is searched for in 'runtimepath'.  This
    |   should always load $VIMRUNTIME/scripts.vim, which does the following.
    |   |
    |   +-  Source the user's optional file, from the  myscriptsfile
    |   |   variable.  This is for backwards compatibility with Vim 5.x only.
    |   |
    |   +-  If the file type is still unknown, check the contents of the file,
    |       again with checks like "getline(1) =~ pattern" as to whether the
    |       file type can be recognized, and set 'filetype'.
    |
    +-  When the file type was determined and 'filetype' was set, this
    |   triggers the FileType autocommand  synload-6  above.  It sets
    |   'syntax' to the determined file type.
    |
    +-  When the 'syntax' option was set above, this triggers an autocommand
    |   from  synload-1  (and  synload-2 ).  This find the main syntax file in
    |   'runtimepath', with this command:
    |           runtime! syntax/<name>.vim
    |
    +-  Any other user installed FileType or Syntax autocommands are
        triggered.  This can be used to change the highlighting for a specific
        syntax.

==============================================================================
4. Syntax file remarks                                  :syn-file-remarks

                                                  b:current_syntax-variable
Vim stores the name of the syntax that has been loaded in the
"b:current_syntax" variable.  You can use this if you want to load other
settings, depending on which syntax is active.  Example:
   :au BufReadPost * if b:current_syntax == "csh"
   :au BufReadPost *   do-some-things
```

```
   :au BufReadPost * endif
```

2HTML   2html.vim   convert-to-HTML

This is not a syntax file itself, but a script that converts the current
window into HTML. Vim opens a new window in which it builds the HTML file.

After you save the resulting file, you can view it with any browser. The
colors should be exactly the same as you see them in Vim. With
 g:html_line_ids you can jump to specific lines by adding (for example) #L123
or #123 to the end of the URL in your browser's address bar. And with
 g:html_dynamic_folds enabled, you can show or hide the text that is folded
in Vim.

You are not supposed to set the 'filetype' or 'syntax' option to "2html"!
Source the script to convert the current file:

```
        :runtime! syntax/2html.vim
```

Many variables affect the output of 2html.vim; see below. Any of the on/off
options listed below can be enabled or disabled by setting them explicitly to
the desired value, or restored to their default by removing the variable using
 :unlet .

Remarks:
- Some truly ancient browsers may not show the background colors.
- From most browsers you can also print the file (in color)!
- The latest TOhtml may actually work with older versions of Vim, but some
  features such as conceal support will not function, and the colors may be
  incorrect for an old Vim without GUI support compiled in.

Here is an example how to run the script over all .c and .h files from a
Unix shell:
```
   for f in *.[ch]; do gvim -f +"syn on" +"run! syntax/2html.vim" +"wq" +"q" $f; done
```

                                        g:html_start_line   g:html_end_line
To restrict the conversion to a range of lines, use a range with the :TOhtml
command below, or set "g:html_start_line" and "g:html_end_line" to the first
and last line to be converted. Example, using the last set Visual area:

```
        :let g:html_start_line = line("'<")
        :let g:html_end_line = line("'>")
        :runtime! syntax/2html.vim
```

                                                              :TOhtml
:[range]TOhtml   The ":TOhtml" command is defined in a standard plugin.
                        This command will source 2html.vim for you. When a
                        range is given, this command sets g:html_start_line
                        and g:html_end_line to the start and end of the
                        range, respectively. Default range is the entire
                        buffer.

                        If the current window is part of a diff , unless

g:html_diff_one_file is set, :TOhtml will convert all windows which are part of the diff in the current tab and place them side-by-side in a <table> element in the generated HTML. With g:html_line_ids you can jump to lines in specific windows with (for example) #W1L42 for line 42 in the first diffed window, or #W3L87 for line 87 in the third.

Examples:

```
:10,40TOhtml " convert lines 10-40 to html
:'<,'>TOhtml " convert current/last visual selection
:TOhtml      " convert entire buffer
```

g:html_diff_one_file

Default: 0.
When 0, and using :TOhtml all windows involved in a diff in the current tab page are converted to HTML and placed side-by-side in a <table> element. When 1, only the current buffer is converted.
Example:

```
let g:html_diff_one_file = 1
```

g:html_whole_filler

Default: 0.
When 0, if g:html_diff_one_file is 1, a sequence of more than 3 filler lines is displayed as three lines with the middle line mentioning the total number of inserted lines.
When 1, always display all inserted lines as if g:html_diff_one_file were not set.

```
:let g:html_whole_filler = 1
```

TOhtml-performance g:html_no_progress

Default: 0.
When 0, display a progress bar in the statusline for each major step in the 2html.vim conversion process.
When 1, do not display the progress bar. This offers a minor speed improvement but you won't have any idea how much longer the conversion might take; for big files it can take a long time!
Example:

```
let g:html_no_progress = 1
```

You can obtain better performance improvements by also instructing Vim to not run interactively, so that too much time is not taken to redraw as the script moves through the buffer, switches windows, and the like:

```
vim -E -s -c "let g:html_no_progress=1" -c "syntax on" -c "set ft=c" -c "runtime syntax/2
```

Note that the -s flag prevents loading your .vimrc and any plugins, so you need to explicitly source/enable anything that will affect the HTML conversion. See -E and -s-ex for details. It is probably best to create a script to replace all the -c commands and use it with the -u flag instead of

specifying each command separately.

g:html_number_lines

Default: current 'number' setting.
When 0, buffer text is displayed in the generated HTML without line numbering.
When 1, a column of line numbers is added to the generated HTML with the same highlighting as the line number column in Vim (hl-LineNr).
Force line numbers even if 'number' is not set:
```
:let g:html_number_lines = 1
```
Force to omit the line numbers:
```
:let g:html_number_lines = 0
```
Go back to the default to use 'number' by deleting the variable:
```
:unlet g:html_number_lines
```

g:html_line_ids

Default: 1 if g:html_number_lines is set, 0 otherwise.
When 1, adds an HTML id attribute to each line number, or to an empty inserted for that purpose if no line numbers are shown. This ID attribute takes the form of L123 for single-buffer HTML pages, or W2L123 for diff-view pages, and is used to jump to a specific line (in a specific window of a diff view). Javascript is inserted to open any closed dynamic folds (g:html_dynamic_folds) containing the specified line before jumping. The javascript also allows omitting the window ID in the url, and the leading L. For example:

```
page.html#L123  jumps to line 123 in a single-buffer file
page.html#123   does the same

diff.html#W1L42 jumps to line 42 in the first window in a diff
diff.html#42    does the same
```

g:html_use_css

Default: 1.
When 1, generate valid HTML 4.01 markup with CSS1 styling, supported in all modern browsers and most old browsers.
When 0, generate <font> tags and similar outdated markup. This is not recommended but it may work better in really old browsers, email clients, forum posts, and similar situations where basic CSS support is unavailable.
Example:
```
:let g:html_use_css = 0
```

g:html_ignore_conceal

Default: 0.
When 0, concealed text is removed from the HTML and replaced with a character from :syn-cchar or 'listchars' as appropriate, depending on the current value of 'conceallevel'.
When 1, include all text from the buffer in the generated HTML, even if it is conceal ed.

Either of the following commands will ensure that all text in the buffer is included in the generated HTML (unless it is folded):
```
:let g:html_ignore_conceal = 1
:setl conceallevel=0
```

g:html_ignore_folding

Default: 0.
When 0, text in a closed fold is replaced by the text shown for the fold in Vim (fold-foldtext). See g:html_dynamic_folds if you also want to allow the user to expand the fold as in Vim to see the text inside.
When 1, include all text from the buffer in the generated HTML; whether the text is in a fold has no impact at all. g:html_dynamic_folds has no effect.

Either of these commands will ensure that all text in the buffer is included in the generated HTML (unless it is concealed):

```
zR
:let g:html_ignore_folding = 1
```

g:html_dynamic_folds

Default: 0.
When 0, text in a closed fold is not included at all in the generated HTML.
When 1, generate javascript to open a fold and show the text within, just like in Vim.

Setting this variable to 1 causes 2html.vim to always use CSS for styling, regardless of what g:html_use_css is set to.

This variable is ignored when g:html_ignore_folding is set.

```
:let g:html_dynamic_folds = 1
```

g:html_no_foldcolumn

Default: 0.
When 0, if g:html_dynamic_folds is 1, generate a column of text similar to Vim's foldcolumn (fold-foldcolumn) the user can click on to toggle folds open or closed. The minimum width of the generated text column is the current 'foldcolumn' setting.
When 1, do not generate this column; instead, hovering the mouse cursor over folded text will open the fold as if g:html_hover_unfold were set.

```
:let g:html_no_foldcolumn = 1
```

TOhtml-uncopyable-text g:html_prevent_copy

Default: empty string.
This option prevents certain regions of the generated HTML from being copied, when you select all text in document rendered in a browser and copy it. Useful for allowing users to copy-paste only the source text even if a fold column or line numbers are shown in the generated content. Specify regions to be affected in this way as follows:

```
        f:      fold column
        n:      line numbers (also within fold text)
        t:      fold text
        d:      diff filler
```

Example, to make the fold column and line numbers uncopyable:

```
        :let g:html_prevent_copy = "fn"
```

This feature is currently implemented by inserting read-only <input> elements into the markup to contain the uncopyable areas. This does not work well in

all cases. When pasting to some applications which understand HTML, the <input> elements also get pasted. But plain-text paste destinations should always work.

g:html_no_invalid

Default: 0.
When 0, if g:html_prevent_copy is non-empty, an invalid attribute is intentionally inserted into the <input> element for the uncopyable areas. This increases the number of applications you can paste to without also pasting the <input> elements. Specifically, Microsoft Word will not paste the <input> elements if they contain this invalid attribute.
When 1, no invalid markup is ever intentionally inserted, and the generated page should validate. However, be careful pasting into Microsoft Word when g:html_prevent_copy is non-empty; it can be hard to get rid of the <input> elements which get pasted.

g:html_hover_unfold

Default: 0.
When 0, the only way to open a fold generated by 2html.vim with g:html_dynamic_folds set, is to click on the generated fold column.
When 1, use CSS 2.0 to allow the user to open a fold by moving the mouse cursor over the displayed fold text. This is useful to allow users with disabled javascript to view the folded text.

Note that old browsers (notably Internet Explorer 6) will not support this feature. Browser-specific markup for IE6 is included to fall back to the normal CSS1 styling so that the folds show up correctly for this browser, but they will not be openable without a foldcolumn.

```
:let g:html_hover_unfold = 1
```

g:html_id_expr

Default: ""
Dynamic folding and jumping to line IDs rely on unique IDs within the document to work. If generated HTML is copied into a larger document, these IDs are no longer guaranteed to be unique. Set g:html_id_expr to an expression Vim can evaluate to get a unique string to append to each ID used in a given document, so that the full IDs will be unique even when combined with other content in a larger HTML document. Example, to append _ and the buffer number to each ID:

```
:let g:html_id_expr = '"_".bufnr("%")'
```

To append a string "_mystring" to the end of each ID:

```
:let g:html_id_expr = '"_mystring"'
```

Note, when converting a diff view to HTML, the expression will only be evaluated for the first window in the diff, and the result used for all the windows.

TOhtml-wrap-text g:html_pre_wrap

Default: current 'wrap' setting.
When 0, if g:html_no_pre is 0 or unset, the text in the generated HTML does not wrap at the edge of the browser window.

When 1, if g:html_use_css is 1, the CSS 2.0 "white-space:pre-wrap" value is used, causing the text to wrap at whitespace at the edge of the browser window.
Explicitly enable text wrapping:
```
:let g:html_pre_wrap = 1
```
Explicitly disable wrapping:
```
:let g:html_pre_wrap = 0
```
Go back to default, determine wrapping from 'wrap' setting:
```
:unlet g:html_pre_wrap
```

g:html_no_pre

Default: 0.
When 0, buffer text in the generated HTML is surrounded by <pre>...</pre> tags. Series of whitespace is shown as in Vim without special markup, and tab characters can be included literally (see g:html_expand_tabs).
When 1 (not recommended), the <pre> tags are omitted, and a plain is used instead. Whitespace is replaced by a series of   character references, and <br> is used to end each line. This is another way to allow text in the generated HTML is wrap (see g:html_pre_wrap) which also works in old browsers, but may cause noticeable differences between Vim's display and the rendered page generated by 2html.vim.

```
:let g:html_no_pre = 1
```

g:html_expand_tabs

Default: 1 if 'tabstop' is 8, 'expandtab' is 0, and no fold column or line
                numbers occur in the generated HTML;
         0 otherwise.
When 0, <Tab> characters in the buffer text are replaced with an appropriate number of space characters, or   references if g:html_no_pre is 1.
When 1, if g:html_no_pre is 0 or unset, <Tab> characters in the buffer text are included as-is in the generated HTML. This is useful for when you want to allow copy and paste from a browser without losing the actual whitespace in the source document. Note that this can easily break text alignment and indentation in the HTML, unless set by default.

Force 2html.vim to keep <Tab> characters:
```
:let g:html_expand_tabs = 0
```

Force tabs to be expanded:
```
:let g:html_expand_tabs = 1
```

TOhtml-encoding-detect TOhtml-encoding

It is highly recommended to set your desired encoding with
 g:html_use_encoding for any content which will be placed on a web server.

If you do not specify an encoding, 2html.vim uses the preferred IANA name for the current value of 'fileencoding' if set, or 'encoding' if not. 'encoding' is always used for certain 'buftype' values. 'fileencoding' will be set to match the chosen document encoding.

Automatic detection works for the encodings mentioned specifically by name in
 encoding-names , but TOhtml will only automatically use those encodings with wide browser support. However, you can override this to support specific

encodings that may not be automatically detected by default (see options below). See http://www.iana.org/assignments/character-sets for the IANA names.

Note, by default all Unicode encodings are converted to UTF-8 with no BOM in the generated HTML, as recommended by W3C:

        http://www.w3.org/International/questions/qa-choosing-encodings
        http://www.w3.org/International/questions/qa-byte-order-mark

                                                                g:html_use_encoding
Default: none, uses IANA name for current 'fileencoding' as above.
To overrule all automatic charset detection, set g:html_use_encoding to the name of the charset to be used. It is recommended to set this variable to something widely supported, like UTF-8, for anything you will be hosting on a webserver:
   :let g:html_use_encoding = "UTF-8"
You can also use this option to omit the line that specifies the charset entirely, by setting g:html_use_encoding to an empty string (NOT recommended):
   :let g:html_use_encoding = ""
To go back to the automatic mechanism, delete the g:html_use_encoding variable:
   :unlet g:html_use_encoding

                                                          g:html_encoding_override
Default: none, autoload/tohtml.vim contains default conversions for encodings mentioned by name at encoding-names .
This option allows 2html.vim to detect the correct 'fileencoding' when you specify an encoding with g:html_use_encoding which is not in the default list of conversions.

This is a dictionary of charset-encoding pairs that will replace existing pairs automatically detected by TOhtml, or supplement with new pairs.

Detect the HTML charset "windows-1252" as the encoding "8bit-cp1252":
   :let g:html_encoding_override = {'windows-1252': '8bit-cp1252'}

                                                            g:html_charset_override
Default: none, autoload/tohtml.vim contains default conversions for encodings mentioned by name at encoding-names and which have wide browser support.
This option allows 2html.vim to detect the HTML charset for any 'fileencoding' or 'encoding' which is not detected automatically. You can also use it to override specific existing encoding-charset pairs. For example, TOhtml will by default use UTF-8 for all Unicode/UCS encodings. To use UTF-16 and UTF-32 instead, use:
   :let g:html_charset_override = {'ucs-4': 'UTF-32', 'utf-16': 'UTF-16'}

Note that documents encoded in either UTF-32 or UTF-16 have known compatibility problems with some major browsers.

                                                                    g:html_font
Default: "monospace"
You can specify the font or fonts used in the converted document using g:html_font. If this option is set to a string, then the value will be

surrounded with single quotes. If this option is set to a list then each list item is surrounded by single quotes and the list is joined with commas. Either way, "monospace" is added as the fallback generic family name and the entire result used as the font family (using CSS) or font face (if not using CSS). Examples:

```
" font-family: 'Consolas', monospace;
:let g:html_font = "Consolas"

" font-family: 'DejaVu Sans Mono', 'Consolas', monospace;
:let g:html_font = ["DejaVu Sans Mono", "Consolas"]
```

convert-to-XML convert-to-XHTML g:html_use_xhtml

Default: 0.
When 0, generate standard HTML 4.01 (strict when possible).
When 1, generate XHTML 1.0 instead (XML compliant HTML).

```
:let g:html_use_xhtml = 1
```

ABEL abel.vim ft-abel-syntax

ABEL highlighting provides some user-defined options. To enable them, assign any value to the respective variable. Example:

```
:let abel_obsolete_ok=1
```

To disable them use ":unlet". Example:

```
:unlet abel_obsolete_ok
```

Variable	Highlight
abel_obsolete_ok	obsolete keywords are statements, not errors
abel_cpp_comments_illegal	do not interpret '//' as inline comment leader

ADA

See ft-ada-syntax

ANT ant.vim ft-ant-syntax

The ant syntax file provides syntax highlighting for javascript and python by default. Syntax highlighting for other script languages can be installed by the function AntSyntaxScript(), which takes the tag name as first argument and the script syntax file name as second argument. Example:

```
:call AntSyntaxScript('perl', 'perl.vim')
```

will install syntax perl highlighting for the following ant code

```
<script language = 'perl'><![CDATA[
    # everything inside is highlighted as perl
]]></script>
```

See mysyntaxfile-add for installing script languages permanently.

APACHE apache.vim ft-apache-syntax

The apache syntax file provides syntax highlighting for Apache HTTP server version 2.2.3.

ASSEMBLY asm.vim asmh8300.vim nasm.vim masm.vim asm68k ft-asm-syntax ft-asmh8300-syntax ft-nasm-syntax ft-masm-syntax ft-asm68k-syntax fasm.vim

Files matching "*.i" could be Progress or Assembly. If the automatic detection doesn't work for you, or you don't edit Progress at all, use this in your startup vimrc:

```
:let filetype_i = "asm"
```

Replace "asm" with the type of assembly you use.

There are many types of assembly languages that all use the same file name extensions. Therefore you will have to select the type yourself, or add a line in the assembly file that Vim will recognize. Currently these syntax files are included:

asm	GNU assembly (the default)
asm68k	Motorola 680x0 assembly
asmh8300	Hitachi H-8300 version of GNU assembly
ia64	Intel Itanium 64
fasm	Flat assembly (http://flatassembler.net)
masm	Microsoft assembly (probably works for any 80x86)
nasm	Netwide assembly
tasm	Turbo Assembly (with opcodes 80x86 up to Pentium, and MMX)
pic	PIC assembly (currently for PIC16F84)

The most flexible is to add a line in your assembly file containing:

```
asmsyntax=nasm
```

Replace "nasm" with the name of the real assembly syntax. This line must be one of the first five lines in the file. No non-white text must be immediately before or after this text. Note that specifying asmsyntax=foo is equivalent to setting ft=foo in a modeline , and that in case of a conflict between the two settings the one from the modeline will take precedence (in particular, if you have ft=asm in the modeline, you will get the GNU syntax highlighting regardless of what is specified as asmsyntax).

The syntax type can always be overruled for a specific buffer by setting the b:asmsyntax variable:

```
:let b:asmsyntax = "nasm"
```

If b:asmsyntax is not set, either automatically or by hand, then the value of the global variable asmsyntax is used. This can be seen as a default assembly language:

```
:let asmsyntax = "nasm"
```

As a last resort, if nothing is defined, the "asm" syntax is used.

Netwide assembler (nasm.vim) optional highlighting

To enable a feature:
        :let   {variable}=1|set syntax=nasm
To disable a feature:
        :unlet {variable} |set syntax=nasm

Variable	Highlight
nasm_loose_syntax	unofficial parser allowed syntax not as Error (parser dependent; not recommended)
nasm_ctx_outside_macro	contexts outside macro not as Error
nasm_no_warn	potentially risky syntax not as ToDo

ASPPERL and ASPVBS   ft-aspperl-syntax   ft-aspvbs-syntax

*.asp and *.asa files could be either Perl or Visual Basic script. Since it's
hard to detect this you can set two global variables to tell Vim what you are
using. For Perl script use:
        :let g:filetype_asa = "aspperl"
        :let g:filetype_asp = "aspperl"
For Visual Basic use:
        :let g:filetype_asa = "aspvbs"
        :let g:filetype_asp = "aspvbs"

BAAN   baan.vim   baan-syntax

The baan.vim gives syntax support for BaanC of release BaanIV upto SSA ERP LN
for both 3 GL and 4 GL programming. Large number of standard defines/constants
are supported.

Some special violation of coding standards will be signalled when one specify
in ones .vimrc :
        let baan_code_stds=1

 baan-folding

Syntax folding can be enabled at various levels through the variables
mentioned below (Set those in your .vimrc). The more complex folding on
source blocks and SQL can be CPU intensive.

To allow any folding and enable folding at function level use:
        let baan_fold=1
Folding can be enabled at source block level as if, while, for ,... The
indentation preceding the begin/end keywords has to match (spaces are not
considered equal to a tab).
        let baan_fold_block=1
Folding can be enabled for embedded SQL blocks as SELECT, SELECTDO,
SELECTEMPTY, ... The indentation preceding the begin/end keywords has to
match (spaces are not considered equal to a tab).
        let baan_fold_sql=1
Note: Block folding can result in many small folds. It is suggested to :set

the options 'foldminlines' and 'foldnestmax' in .vimrc or use :setlocal in .../after/syntax/baan.vim (see after-directory). Eg:

```
set foldminlines=5
set foldnestmax=6
```

BASIC basic.vim vb.vim ft-basic-syntax ft-vb-syntax

Both Visual Basic and "normal" basic use the extension ".bas". To detect which one should be used, Vim checks for the string "VB_Name" in the first five lines of the file. If it is not found, filetype will be "basic", otherwise "vb". Files with the ".frm" extension will always be seen as Visual Basic.

C c.vim ft-c-syntax

A few things in C highlighting are optional. To enable them assign any value to the respective variable. Example:

```
:let c_comment_strings = 1
```

To disable them use ":unlet". Example:

```
:unlet c_comment_strings
```

Variable	Highlight
c_gnu	GNU gcc specific items
c_comment_strings	strings and numbers inside a comment
c_space_errors	trailing white space and spaces before a <Tab>
c_no_trail_space_error	... but no trailing spaces
c_no_tab_space_error	... but no spaces before a <Tab>
c_no_bracket_error	don't highlight {}; inside [] as errors
c_no_curly_error	don't highlight {}; inside [] and () as errors; except { and } in first column Default is to highlight them, otherwise you can't spot a missing ")".
c_curly_error	highlight a missing }; this forces syncing from the start of the file, can be slow
c_no_ansi	don't do standard ANSI types and constants
c_ansi_typedefs	... but do standard ANSI types
c_ansi_constants	... but do standard ANSI constants
c_no_utf	don't highlight \u and \U in strings
c_syntax_for_h	for *.h files use C syntax instead of C++ and use objc syntax instead of objcpp
c_no_if0	don't highlight "#if 0" blocks as comments
c_no_cformat	don't highlight %-formats in strings
c_no_c99	don't highlight C99 standard items
c_no_c11	don't highlight C11 standard items
c_no_bsd	don't highlight BSD specific types

When 'foldmethod' is set to "syntax" then /* */ comments and { } blocks will become a fold. If you don't want comments to become a fold use:

```
:let c_no_comment_fold = 1
```

"#if 0" blocks are also folded, unless:

```
:let c_no_if0_fold = 1
```

If you notice highlighting errors while scrolling backwards, which are fixed
when redrawing with CTRL-L, try setting the "c_minlines" internal variable
to a larger number:
        :let c_minlines = 100
This will make the syntax synchronization start 100 lines before the first
displayed line. The default value is 50 (15 when c_no_if0 is set). The
disadvantage of using a larger number is that redrawing can become slow.

When using the "#if 0" / "#endif" comment highlighting, notice that this only
works when the "#if 0" is within "c_minlines" from the top of the window. If
you have a long "#if 0" construct it will not be highlighted correctly.

To match extra items in comments, use the cCommentGroup cluster.
Example:
```
   :au Syntax c call MyCadd()
   :function MyCadd()
   :  syn keyword cMyItem contained Ni
   :  syn cluster cCommentGroup add=cMyItem
   :  hi link cMyItem Title
   :endfun
```

ANSI constants will be highlighted with the "cConstant" group. This includes
"NULL", "SIG_IGN" and others. But not "TRUE", for example, because this is
not in the ANSI standard. If you find this confusing, remove the cConstant
highlighting:
        :hi link cConstant NONE

If you see '{' and '}' highlighted as an error where they are OK, reset the
highlighting for cErrInParen and cErrInBracket.

If you want to use folding in your C files, you can add these lines in a file
in the "after" directory in 'runtimepath'. For Unix this would be
~/.vim/after/syntax/c.vim.
```
    syn sync fromstart
    set foldmethod=syntax
```

CH   ch.vim   ft-ch-syntax

C/C++ interpreter. Ch has similar syntax highlighting to C and builds upon
the C syntax file. See c.vim for all the settings that are available for C.

By setting a variable you can tell Vim to use Ch syntax for *.h files, instead
of C or C++:
        :let ch_syntax_for_h = 1

CHILL   chill.vim   ft-chill-syntax

Chill syntax highlighting is similar to C. See c.vim for all the settings
that are available. Additionally there is:

```
chill_space_errors      like c_space_errors
chill_comment_string    like c_comment_strings
chill_minlines          like c_minlines
```

CHANGELOG changelog.vim ft-changelog-syntax

ChangeLog supports highlighting spaces at the start of a line.
If you do not like this, add following line to your .vimrc:

```
let g:changelog_spacing_errors = 0
```

This works the next time you edit a changelog file. You can also use "b:changelog_spacing_errors" to set this per buffer (before loading the syntax file).

You can change the highlighting used, e.g., to flag the spaces as an error:

```
:hi link ChangelogError Error
```

Or to avoid the highlighting:

```
:hi link ChangelogError NONE
```

This works immediately.

CLOJURE ft-clojure-syntax

The default syntax groups can be augmented through the g:clojure_syntax_keywords and b:clojure_syntax_keywords variables. The value should be a Dictionary of syntax group names to a List of custom identifiers:

```
let g:clojure_syntax_keywords = {
    \ 'clojureMacro': ["defproject", "defcustom"],
    \ 'clojureFunc': ["string/join", "string/replace"]
    \ }
```

Refer to the Clojure syntax script for valid syntax group names.

If the buffer-variable b:clojure_syntax_without_core_keywords is set, only language constants and special forms are matched.

Setting g:clojure_fold enables folding Clojure code via the syntax engine. Any list, vector, or map that extends over more than one line can be folded using the standard Vim fold-commands .

Please note that this option does not work with scripts that redefine the bracket syntax regions, such as rainbow-parentheses plugins.

This option is off by default.

```
" Default
let g:clojure_fold = 0
```

COBOL cobol.vim ft-cobol-syntax

COBOL highlighting has different needs for legacy code than it does for fresh development. This is due to differences in what is being done (maintenance versus development) and other factors. To enable legacy code highlighting, add this line to your .vimrc:

```
        :let cobol_legacy_code = 1
To disable it again, use this:
        :unlet cobol_legacy_code
```

COLD FUSION coldfusion.vim ft-coldfusion-syntax

The ColdFusion has its own version of HTML comments. To turn on ColdFusion comment highlighting, add the following line to your startup file:

```
        :let html_wrong_comments = 1
```

The ColdFusion syntax file is based on the HTML syntax file.

CPP cpp.vim ft-cpp-syntax

Most of things are same as ft-c-syntax .

Variable	Highlight
cpp_no_cpp11	don't highlight C++11 standard items
cpp_no_cpp14	don't highlight C++14 standard items

CSH csh.vim ft-csh-syntax

This covers the shell named "csh". Note that on some systems tcsh is actually used.

Detecting whether a file is csh or tcsh is notoriously hard. Some systems symlink /bin/csh to /bin/tcsh, making it almost impossible to distinguish between csh and tcsh. In case VIM guesses wrong you can set the "filetype_csh" variable. For using csh: g:filetype_csh

```
        :let g:filetype_csh = "csh"
```

For using tcsh:

```
        :let g:filetype_csh = "tcsh"
```

Any script with a tcsh extension or a standard tcsh filename (.tcshrc, tcsh.tcshrc, tcsh.login) will have filetype tcsh. All other tcsh/csh scripts will be classified as tcsh, UNLESS the "filetype_csh" variable exists. If the "filetype_csh" variable exists, the filetype will be set to the value of the variable.

CYNLIB cynlib.vim ft-cynlib-syntax

Cynlib files are C++ files that use the Cynlib class library to enable hardware modelling and simulation using C++. Typically Cynlib files have a .cc or a .cpp extension, which makes it very difficult to distinguish them from a normal C++ file. Thus, to enable Cynlib highlighting for .cc files, add this line to your .vimrc file:

```
:let cynlib_cyntax_for_cc=1
```

Similarly for cpp files (this extension is only usually used in Windows)

```
:let cynlib_cyntax_for_cpp=1
```

To disable these again, use this:

```
:unlet cynlib_cyntax_for_cc
:unlet cynlib_cyntax_for_cpp
```

CWEB cweb.vim ft-cweb-syntax

Files matching "*.w" could be Progress or cweb. If the automatic detection doesn't work for you, or you don't edit Progress at all, use this in your startup vimrc:

```
:let filetype_w = "cweb"
```

DESKTOP desktop.vim ft-desktop-syntax

Primary goal of this syntax file is to highlight .desktop and .directory files according to freedesktop.org standard:
http://standards.freedesktop.org/desktop-entry-spec/latest/
But actually almost none implements this standard fully. Thus it will highlight all Unix ini files. But you can force strict highlighting according to standard by placing this in your vimrc file:

```
:let enforce_freedesktop_standard = 1
```

DIFF diff.vim

The diff highlighting normally finds translated headers. This can be slow if there are very long lines in the file. To disable translations:

```
:let diff_translations = 0
```

Also see diff-slow .

DIRCOLORS dircolors.vim ft-dircolors-syntax

The dircolors utility highlighting definition has one option. It exists to provide compatibility with the Slackware GNU/Linux distributions version of the command. It adds a few keywords that are generally ignored by most versions. On Slackware systems, however, the utility accepts the keywords and uses them for processing. To enable the Slackware keywords add the following line to your startup file:

```
let dircolors_is_slackware = 1
```

DOCBOOK docbk.vim ft-docbk-syntax docbook

DOCBOOK XML   docbkxml.vim   ft-docbkxml-syntax
DOCBOOK SGML   docbksgml.vim   ft-docbksgml-syntax

There are two types of DocBook files: SGML and XML. To specify what type you
are using the "b:docbk_type" variable should be set. Vim does this for you
automatically if it can recognize the type. When Vim can't guess it the type
defaults to XML.
You can set the type manually:
        :let docbk_type = "sgml"
or:
        :let docbk_type = "xml"
You need to do this before loading the syntax file, which is complicated.
Simpler is setting the filetype to "docbkxml" or "docbksgml":
        :set filetype=docbksgml
or:
        :set filetype=docbkxml

You can specify the DocBook version:
        :let docbk_ver = 3
When not set 4 is used.

DOSBATCH   dosbatch.vim   ft-dosbatch-syntax

There is one option with highlighting DOS batch files. This covers new
extensions to the Command Interpreter introduced with Windows 2000 and
is controlled by the variable dosbatch_cmdextversion. For Windows NT
this should have the value 1, and for Windows 2000 it should be 2.
Select the version you want with the following line:

   :let dosbatch_cmdextversion = 1

If this variable is not defined it defaults to a value of 2 to support
Windows 2000.

A second option covers whether *.btm files should be detected as type
"dosbatch" (MS-DOS batch files) or type "btm" (4DOS batch files). The latter
is used by default. You may select the former with the following line:

   :let g:dosbatch_syntax_for_btm = 1

If this variable is undefined or zero, btm syntax is selected.

DOXYGEN   doxygen.vim   doxygen-syntax

Doxygen generates code documentation using a special documentation format
(similar to Javadoc). This syntax script adds doxygen highlighting to c, cpp,
idl and php files, and should also work with java.

There are a few of ways to turn on doxygen formatting. It can be done
explicitly or in a modeline by appending '.doxygen' to the syntax of the file.
Example:
        :set syntax=c.doxygen

or

```
// vim:syntax=c.doxygen
```

It can also be done automatically for C, C++, C#, IDL and PHP files by setting the global or buffer-local variable load_doxygen_syntax. This is done by adding the following to your .vimrc.

```
:let g:load_doxygen_syntax=1
```

There are a couple of variables that have an effect on syntax highlighting, and are to do with non-standard highlighting options.

Variable	Default	Effect
g:doxygen_enhanced_color g:doxygen_enhanced_colour	0	Use non-standard highlighting for doxygen comments.
doxygen_my_rendering	0	Disable rendering of HTML bold, italic and html_my_rendering underline.
doxygen_javadoc_autobrief	1	Set to 0 to disable javadoc autobrief colour highlighting.
doxygen_end_punctuation	'[.]'	Set to regexp match for the ending punctuation of brief

There are also some hilight groups worth mentioning as they can be useful in configuration.

Highlight	Effect
doxygenErrorComment	The colour of an end-comment when missing punctuation in a code, verbatim or dot section
doxygenLinkError	The colour of an end-comment when missing the \endlink from a \link section.

DTD dtd.vim ft-dtd-syntax

The DTD syntax highlighting is case sensitive by default. To disable case-sensitive highlighting, add the following line to your startup file:

```
:let dtd_ignore_case=1
```

The DTD syntax file will highlight unknown tags as errors. If this is annoying, it can be turned off by setting:

```
:let dtd_no_tag_errors=1
```

before sourcing the dtd.vim syntax file.
Parameter entity names are highlighted in the definition using the 'Type' highlighting group and 'Comment' for punctuation and '%'.
Parameter entity instances are highlighted using the 'Constant' highlighting group and the 'Type' highlighting group for the delimiters % and ;. This can be turned off by setting:

```
:let dtd_no_param_entities=1
```

The DTD syntax file is also included by xml.vim to highlight included dtd's.

EIFFEL eiffel.vim ft-eiffel-syntax

While Eiffel is not case-sensitive, its style guidelines are, and the
syntax highlighting file encourages their use. This also allows to
highlight class names differently. If you want to disable case-sensitive
highlighting, add the following line to your startup file:

```
:let eiffel_ignore_case=1
```

Case still matters for class names and TODO marks in comments.

Conversely, for even stricter checks, add one of the following lines:

```
:let eiffel_strict=1
:let eiffel_pedantic=1
```

Setting eiffel_strict will only catch improper capitalization for the
five predefined words "Current", "Void", "Result", "Precursor", and
"NONE", to warn against their accidental use as feature or class names.

Setting eiffel_pedantic will enforce adherence to the Eiffel style
guidelines fairly rigorously (like arbitrary mixes of upper- and
lowercase letters as well as outdated ways to capitalize keywords).

If you want to use the lower-case version of "Current", "Void",
"Result", and "Precursor", you can use

```
:let eiffel_lower_case_predef=1
```

instead of completely turning case-sensitive highlighting off.

Support for ISE's proposed new creation syntax that is already
experimentally handled by some compilers can be enabled by:

```
:let eiffel_ise=1
```

Finally, some vendors support hexadecimal constants. To handle them, add

```
:let eiffel_hex_constants=1
```

to your startup file.

EUPHORIA euphoria3.vim euphoria4.vim ft-euphoria-syntax

Two syntax highlighting files exists for Euphoria. One for Euphoria
version 3.1.1, which is the default syntax highlighting file, and one for
Euphoria version 4.0.5 or later.

Euphoria version 3.1.1 (http://www.rapideuphoria.com/) is still necessary
for developing applications for the DOS platform, which Euphoria version 4
(http://www.openeuphoria.org/) does not support.

The following file extensions are auto-detected as Euphoria file type:

	*.e, *.eu, *.ew, *.ex, *.exu, *.exw
	*.E, *.EU, *.EW, *.EX, *.EXU, *.EXW

To select syntax highlighting file for Euphoria, as well as for
auto-detecting the *.e and *.E file extensions as Euphoria file type,
add the following line to your startup file:

	:let filetype_euphoria="euphoria3"

	or

	:let filetype_euphoria="euphoria4"

ERLANG	erlang.vim	ft-erlang-syntax

Erlang is a functional programming language developed by Ericsson. Files with
the following extensions are recognized as Erlang files: erl, hrl, yaws.

The BIFs (built-in functions) are highlighted by default. To disable this,
put the following line in your vimrc:

	:let g:erlang_highlight_bifs = 0

To enable highlighting some special atoms, put this in your vimrc:

	:let g:erlang_highlight_special_atoms = 1

FLEXWIKI	flexwiki.vim	ft-flexwiki-syntax

FlexWiki is an ASP.NET-based wiki package available at http://www.flexwiki.com
NOTE: this site currently doesn't work, on Wikipedia is mentioned that
development stopped in 2009.

Syntax highlighting is available for the most common elements of FlexWiki
syntax. The associated ftplugin script sets some buffer-local options to make
editing FlexWiki pages more convenient. FlexWiki considers a newline as the
start of a new paragraph, so the ftplugin sets 'tw'=0 (unlimited line length),
'wrap' (wrap long lines instead of using horizontal scrolling), 'linebreak'
(to wrap at a character in 'breakat' instead of at the last char on screen),
and so on. It also includes some keymaps that are disabled by default.

If you want to enable the keymaps that make "j" and "k" and the cursor keys
move up and down by display lines, add this to your .vimrc:
	:let flexwiki_maps = 1

FORM form.vim ft-form-syntax

The coloring scheme for syntax elements in the FORM file uses the default modes Conditional, Number, Statement, Comment, PreProc, Type, and String, following the language specifications in 'Symbolic Manipulation with FORM' by J.A.M. Vermaseren, CAN, Netherlands, 1991.

If you want include your own changes to the default colors, you have to redefine the following syntax groups:

- formConditional
- formNumber
- formStatement
- formHeaderStatement
- formComment
- formPreProc
- formDirective
- formType
- formString

Note that the form.vim syntax file implements FORM preprocessor commands and directives per default in the same syntax group.

A predefined enhanced color mode for FORM is available to distinguish between header statements and statements in the body of a FORM program. To activate this mode define the following variable in your vimrc file

```
:let form_enhanced_color=1
```

The enhanced mode also takes advantage of additional color features for a dark gvim display. Here, statements are colored LightYellow instead of Yellow, and conditionals are LightBlue for better distinction.

FORTRAN fortran.vim ft-fortran-syntax

Default highlighting and dialect

Highlighting appropriate for Fortran 2008 is used by default. This choice should be appropriate for most users most of the time because Fortran 2008 is almost a superset of previous versions (Fortran 2003, 95, 90, and 77).

Fortran source code form

Fortran code can be in either fixed or free source form. Note that the syntax highlighting will not be correct if the form is incorrectly set.

When you create a new fortran file, the syntax script assumes fixed source form. If you always use free source form, then

```
:let fortran_free_source=1
```

in your .vimrc prior to the :syntax on command. If you always use fixed source form, then

```
:let fortran_fixed_source=1
```

in your .vimrc prior to the :syntax on command.

If the form of the source code depends, in a non-standard way, upon the file

extension, then it is most convenient to set fortran_free_source in a ftplugin file. For more information on ftplugin files, see ftplugin . Note that this will work only if the "filetype plugin indent on" command precedes the "syntax on" command in your .vimrc file.

When you edit an existing fortran file, the syntax script will assume free source form if the fortran_free_source variable has been set, and assumes fixed source form if the fortran_fixed_source variable has been set. If neither of these variables have been set, the syntax script attempts to determine which source form has been used by examining the file extension using conventions common to the ifort, gfortran, Cray, NAG, and PathScale compilers (.f, .for, .f77 for fixed-source, .f90, .f95, .f03, .f08 for free-source). If none of this works, then the script examines the first five columns of the first 500 lines of your file. If no signs of free source form are detected, then the file is assumed to be in fixed source form. The algorithm should work in the vast majority of cases. In some cases, such as a file that begins with 500 or more full-line comments, the script may incorrectly decide that the fortran code is in fixed form. If that happens, just add a non-comment statement beginning anywhere in the first five columns of the first twenty-five lines, save (:w) and then reload (:e!) the file.

Tabs in fortran files
Tabs are not recognized by the Fortran standards. Tabs are not a good idea in fixed format fortran source code which requires fixed column boundaries. Therefore, tabs are marked as errors. Nevertheless, some programmers like using tabs. If your fortran files contain tabs, then you should set the variable fortran_have_tabs in your .vimrc with a command such as
    :let fortran_have_tabs=1
placed prior to the :syntax on command. Unfortunately, the use of tabs will mean that the syntax file will not be able to detect incorrect margins.

Syntax folding of fortran files
If you wish to use foldmethod=syntax, then you must first set the variable fortran_fold with a command such as
    :let fortran_fold=1
to instruct the syntax script to define fold regions for program units, that is main programs starting with a program statement, subroutines, function subprograms, block data subprograms, interface blocks, and modules. If you also set the variable fortran_fold_conditionals with a command such as
    :let fortran_fold_conditionals=1
then fold regions will also be defined for do loops, if blocks, and select case constructs. If you also set the variable fortran_fold_multilinecomments with a command such as
    :let fortran_fold_multilinecomments=1
then fold regions will also be defined for three or more consecutive comment lines. Note that defining fold regions can be slow for large files.

If fortran_fold, and possibly fortran_fold_conditionals and/or fortran_fold_multilinecomments, have been set, then vim will fold your file if you set foldmethod=syntax. Comments or blank lines placed between two program units are not folded because they are seen as not belonging to any program unit.

More precise fortran syntax

If you set the variable fortran_more_precise with a command such as
    :let fortran_more_precise=1
then the syntax coloring will be more precise but slower. In particular, statement labels used in do, goto and arithmetic if statements will be recognized, as will construct names at the end of a do, if, select or forall construct.

Non-default fortran dialects
The syntax script supports two Fortran dialects: f08 and F. You will probably find the default highlighting (f08) satisfactory. A few legacy constructs deleted or declared obsolescent in the 2008 standard are highlighted as todo items.

If you use F, the advantage of setting the dialect appropriately is that other legacy features excluded from F will be highlighted as todo items and that free source form will be assumed.

The dialect can be selected in various ways. If all your fortran files use the same dialect, set the global variable fortran_dialect in your .vimrc prior to your syntax on statement. The case-sensitive, permissible values of fortran_dialect are "f08" or "F". Invalid values of fortran_dialect are ignored.

If the dialect depends upon the file extension, then it is most convenient to set a buffer-local variable in a ftplugin file. For more information on ftplugin files, see ftplugin . For example, if all your fortran files with an .f90 extension are written in the F subset, your ftplugin file should contain the code
```
    let s:extfname = expand("%:e")
    if s:extfname ==? "f90"
        let b:fortran_dialect="F"
    else
        unlet! b:fortran_dialect
    endif
```
Note that this will work only if the "filetype plugin indent on" command precedes the "syntax on" command in your .vimrc file.

Finer control is necessary if the file extension does not uniquely identify the dialect. You can override the default dialect, on a file-by-file basis, by including a comment with the directive "fortran_dialect=xx" (where xx=F or f08) in one of the first three lines in your file. For example, your older .f files may be legacy code but your newer ones may be F codes, and you would identify the latter by including in the first three lines of those files a Fortran comment of the form
```
  ! fortran_dialect=F
```

For previous versions of the syntax, you may have set fortran_dialect to the now-obsolete values "f77", "f90", "f95", or "elf". Such settings will be silently handled as "f08". Users of "elf" may wish to experiment with "F" instead.

The syntax/fortran.vim script contains embedded comments that tell you how to comment and/or uncomment some lines to (a) activate recognition of some non-standard, vendor-supplied intrinsics and (b) to prevent features deleted

or declared obsolescent in the 2008 standard from being highlighted as todo items.

Limitations
Parenthesis checking does not catch too few closing parentheses. Hollerith strings are not recognized. Some keywords may be highlighted incorrectly because Fortran90 has no reserved words.

For further information related to fortran, see ft-fortran-indent and ft-fortran-plugin .

FVWM CONFIGURATION FILES fvwm.vim ft-fvwm-syntax

In order for Vim to recognize Fvwm configuration files that do not match the patterns fvwmrc or fvwm2rc , you must put additional patterns appropriate to your system in your myfiletypes.vim file. For these patterns, you must set the variable "b:fvwm_version" to the major version number of Fvwm, and the 'filetype' option to fvwm.

For example, to make Vim identify all files in /etc/X11/fvwm2/ as Fvwm2 configuration files, add the following:

```
:au! BufNewFile,BufRead /etc/X11/fvwm2/*  let b:fvwm_version = 2 |
                                        \ set filetype=fvwm
```

If you'd like Vim to highlight all valid color names, tell it where to find the color database (rgb.txt) on your system. Do this by setting "rgb_file" to its location. Assuming your color database is located in /usr/X11/lib/X11/, you should add the line

```
:let rgb_file = "/usr/X11/lib/X11/rgb.txt"
```

to your .vimrc file.

GSP gsp.vim ft-gsp-syntax

The default coloring style for GSP pages is defined by html.vim , and the coloring for java code (within java tags or inline between backticks) is defined by java.vim . The following HTML groups defined in html.vim are redefined to incorporate and highlight inline java code:

```
htmlString
htmlValue
htmlEndTag
htmlTag
htmlTagN
```

Highlighting should look fine most of the places where you'd see inline java code, but in some special cases it may not. To add another HTML group where you will have inline java code where it does not highlight correctly, just copy the line you want from html.vim and add gspJava to the contains clause.

The backticks for inline java are highlighted according to the htmlError
group to make them easier to see.

GROFF groff.vim ft-groff-syntax

The groff syntax file is a wrapper for nroff.vim , see the notes
under that heading for examples of use and configuration. The purpose
of this wrapper is to set up groff syntax extensions by setting the
filetype from a modeline or in a personal filetype definitions file
(see filetype.txt).

HASKELL haskell.vim lhaskell.vim ft-haskell-syntax

The Haskell syntax files support plain Haskell code as well as literate
Haskell code, the latter in both Bird style and TeX style. The Haskell
syntax highlighting will also highlight C preprocessor directives.

If you want to highlight delimiter characters (useful if you have a
light-coloured background), add to your .vimrc:

```
:let hs_highlight_delimiters = 1
```

To treat True and False as keywords as opposed to ordinary identifiers,
add:

```
:let hs_highlight_boolean = 1
```

To also treat the names of primitive types as keywords:

```
:let hs_highlight_types = 1
```

And to treat the names of even more relatively common types as keywords:

```
:let hs_highlight_more_types = 1
```

If you want to highlight the names of debugging functions, put in
your .vimrc:

```
:let hs_highlight_debug = 1
```

The Haskell syntax highlighting also highlights C preprocessor
directives, and flags lines that start with # but are not valid
directives as erroneous. This interferes with Haskell's syntax for
operators, as they may start with #. If you want to highlight those
as operators as opposed to errors, put in your .vimrc:

```
:let hs_allow_hash_operator = 1
```

The syntax highlighting for literate Haskell code will try to
automatically guess whether your literate Haskell code contains
TeX markup or not, and correspondingly highlight TeX constructs
or nothing at all. You can override this globally by putting
in your .vimrc

```
:let lhs_markup = none
```

for no highlighting at all, or

```
:let lhs_markup = tex
```

to force the highlighting to always try to highlight TeX markup.
For more flexibility, you may also use buffer local versions of
this variable, so e.g.

```
:let b:lhs_markup = tex
```

will force TeX highlighting for a particular buffer. It has to be

set before turning syntax highlighting on for the buffer or
loading a file.

HTML html.vim ft-html-syntax

The coloring scheme for tags in the HTML file works as follows.

The <> of opening tags are colored differently than the </> of a closing tag.
This is on purpose! For opening tags the 'Function' color is used, while for
closing tags the 'Type' color is used (See syntax.vim to check how those are
defined for you)

Known tag names are colored the same way as statements in C. Unknown tag
names are colored with the same color as the <> or </> respectively which
makes it easy to spot errors

Note that the same is true for argument (or attribute) names. Known attribute
names are colored differently than unknown ones.

Some HTML tags are used to change the rendering of text. The following tags
are recognized by the html.vim syntax coloring file and change the way normal
text is shown: <B> <I> <U> <EM> <STRONG> (<EM> is used as an alias for <I>,
while <STRONG> as an alias for <B>), <H1> - <H6>, <HEAD>, <TITLE> and <A>, but
only if used as a link (that is, it must include a href as in
<A href="somefile.html">).

If you want to change how such text is rendered, you must redefine the
following syntax groups:

- htmlBold
- htmlBoldUnderline
- htmlBoldUnderlineItalic
- htmlUnderline
- htmlUnderlineItalic
- htmlItalic
- htmlTitle for titles
- htmlH1 - htmlH6 for headings

To make this redefinition work you must redefine them all with the exception
of the last two (htmlTitle and htmlH[1-6], which are optional) and define the
following variable in your vimrc (this is due to the order in which the files
are read during initialization)

```
:let html_my_rendering=1
```

If you'd like to see an example download mysyntax.vim at
http://www.fleiner.com/vim/download.html

You can also disable this rendering by adding the following line to your
vimrc file:

```
:let html_no_rendering=1
```

HTML comments are rather special (see an HTML reference document for the
details), and the syntax coloring scheme will highlight all errors.

However, if you prefer to use the wrong style (starts with <!-- and
ends with -->) you can define
        :let html_wrong_comments=1

JavaScript and Visual Basic embedded inside HTML documents are highlighted as
'Special' with statements, comments, strings and so on colored as in standard
programming languages. Note that only JavaScript and Visual Basic are currently
supported, no other scripting language has been added yet.

Embedded and inlined cascading style sheets (CSS) are highlighted too.

There are several html preprocessor languages out there. html.vim has been
written such that it should be trivial to include it. To do so add the
following two lines to the syntax coloring file for that language
(the example comes from the asp.vim file):

    runtime! syntax/html.vim
    syn cluster htmlPreproc add=asp

Now you just need to make sure that you add all regions that contain
the preprocessor language to the cluster htmlPreproc.

HTML/OS (by Aestiva)   htmlos.vim   ft-htmlos-syntax

The coloring scheme for HTML/OS works as follows:

Functions and variable names are the same color by default, because VIM
doesn't specify different colors for Functions and Identifiers. To change
this (which is recommended if you want function names to be recognizable in a
different color) you need to add the following line to either your ~/.vimrc:
  :hi Function term=underline cterm=bold ctermfg=LightGray

Of course, the ctermfg can be a different color if you choose.

Another issues that HTML/OS runs into is that there is no special filetype to
signify that it is a file with HTML/OS coding. You can change this by opening
a file and turning on HTML/OS syntax by doing the following:
  :set syntax=htmlos

Lastly, it should be noted that the opening and closing characters to begin a
block of HTML/OS code can either be << or [[and >> or]], respectively.

IA64   ia64.vim   intel-itanium   ft-ia64-syntax

Highlighting for the Intel Itanium 64 assembly language. See asm.vim for
how to recognize this filetype.

To have *.inc files be recognized as IA64, add this to your .vimrc file:
        :let g:filetype_inc = "ia64"

INFORM   inform.vim   ft-inform-syntax

Inform highlighting includes symbols provided by the Inform Library, as most programs make extensive use of it. If do not wish Library symbols to be highlighted add this to your vim startup:

```
:let inform_highlight_simple=1
```

By default it is assumed that Inform programs are Z-machine targeted, and highlights Z-machine assembly language symbols appropriately. If you intend your program to be targeted to a Glulx/Glk environment you need to add this to your startup sequence:

```
:let inform_highlight_glulx=1
```

This will highlight Glulx opcodes instead, and also adds glk() to the set of highlighted system functions.

The Inform compiler will flag certain obsolete keywords as errors when it encounters them. These keywords are normally highlighted as errors by Vim. To prevent such error highlighting, you must add this to your startup sequence:

```
:let inform_suppress_obsolete=1
```

By default, the language features highlighted conform to Compiler version 6.30 and Library version 6.11. If you are using an older Inform development environment, you may with to add this to your startup sequence:

```
:let inform_highlight_old=1
```

IDL idl.vim idl-syntax

IDL (Interface Definition Language) files are used to define RPC calls. In Microsoft land, this is also used for defining COM interfaces and calls.

IDL's structure is simple enough to permit a full grammar based approach to rather than using a few heuristics. The result is large and somewhat repetitive but seems to work.

There are some Microsoft extensions to idl files that are here. Some of them are disabled by defining idl_no_ms_extensions.

The more complex of the extensions are disabled by defining idl_no_extensions.

Variable	Effect
idl_no_ms_extensions	Disable some of the Microsoft specific extensions
idl_no_extensions	Disable complex extensions
idlsyntax_showerror	Show IDL errors (can be rather intrusive, but quite helpful)
idlsyntax_showerror_soft	Use softer colours by default for errors

JAVA java.vim ft-java-syntax

The java.vim syntax highlighting file offers several options:

In Java 1.0.2 it was never possible to have braces inside parens, so this was
flagged as an error. Since Java 1.1 this is possible (with anonymous
classes), and therefore is no longer marked as an error. If you prefer the old
way, put the following line into your vim startup file:
        :let java_mark_braces_in_parens_as_errors=1

All identifiers in java.lang.* are always visible in all classes. To
highlight them use:
        :let java_highlight_java_lang_ids=1

You can also highlight identifiers of most standard Java packages if you
download the javaid.vim script at http://www.fleiner.com/vim/download.html.
If you prefer to only highlight identifiers of a certain package, say java.io
use the following:
        :let java_highlight_java_io=1
Check the javaid.vim file for a list of all the packages that are supported.

Function names are not highlighted, as the way to find functions depends on
how you write Java code. The syntax file knows two possible ways to highlight
functions:

If you write function declarations that are always indented by either
a tab, 8 spaces or 2 spaces you may want to set
        :let java_highlight_functions="indent"
However, if you follow the Java guidelines about how functions and classes are
supposed to be named (with respect to upper and lowercase), use
        :let java_highlight_functions="style"
If both options do not work for you, but you would still want function
declarations to be highlighted create your own definitions by changing the
definitions in java.vim or by creating your own java.vim which includes the
original one and then adds the code to highlight functions.

In Java 1.1 the functions System.out.println() and System.err.println() should
only be used for debugging. Therefore it is possible to highlight debugging
statements differently. To do this you must add the following definition in
your startup file:
        :let java_highlight_debug=1
The result will be that those statements are highlighted as 'Special'
characters. If you prefer to have them highlighted differently you must define
new highlightings for the following groups.:
    Debug, DebugSpecial, DebugString, DebugBoolean, DebugType
which are used for the statement itself, special characters used in debug
strings, strings, boolean constants and types (this, super) respectively. I
have opted to chose another background for those statements.

Javadoc is a program that takes special comments out of Java program files and
creates HTML pages. The standard configuration will highlight this HTML code
similarly to HTML files (see html.vim). You can even add Javascript
and CSS inside this code (see below). There are four differences however:
  1. The title (all characters up to the first '.' which is followed by
     some white space or up to the first '@') is colored differently (to change
     the color change the group CommentTitle).
  2. The text is colored as 'Comment'.

  3. HTML comments are colored as 'Special'
  4. The special Javadoc tags (@see, @param, ...) are highlighted as specials
     and the argument (for @see, @param, @exception) as Function.
To turn this feature off add the following line to your startup file:
```
:let java_ignore_javadoc=1
```

If you use the special Javadoc comment highlighting described above you
can also turn on special highlighting for Javascript, visual basic
scripts and embedded CSS (stylesheets). This makes only sense if you
actually have Javadoc comments that include either Javascript or embedded
CSS. The options to use are
```
:let java_javascript=1
:let java_css=1
:let java_vb=1
```

In order to highlight nested parens with different colors define colors
for javaParen, javaParen1 and javaParen2, for example with
```
:hi link javaParen Comment
```
or
```
:hi javaParen ctermfg=blue guifg=#0000ff
```

If you notice highlighting errors while scrolling backwards, which are fixed
when redrawing with CTRL-L, try setting the "java_minlines" internal variable
to a larger number:
```
:let java_minlines = 50
```
This will make the syntax synchronization start 50 lines before the first
displayed line. The default value is 10. The disadvantage of using a larger
number is that redrawing can become slow.

LACE lace.vim ft-lace-syntax

Lace (Language for Assembly of Classes in Eiffel) is case insensitive, but the
style guide lines are not. If you prefer case insensitive highlighting, just
define the vim variable 'lace_case_insensitive' in your startup file:
```
:let lace_case_insensitive=1
```

LEX lex.vim ft-lex-syntax

Lex uses brute-force synchronizing as the "^%%$" section delimiter
gives no clue as to what section follows. Consequently, the value for
```
:syn sync minlines=300
```
may be changed by the user if s/he is experiencing synchronization
difficulties (such as may happen with large lex files).

LIFELINES lifelines.vim ft-lifelines-syntax

To highlight deprecated functions as errors, add in your .vimrc:

```
:let g:lifelines_deprecated = 1
```

LISP lisp.vim ft-lisp-syntax

The lisp syntax highlighting provides two options:

```
        g:lisp_instring : if it exists, then "(...)" strings are highlighted
                          as if the contents of the string were lisp.
                          Useful for AutoLisp.
        g:lisp_rainbow  : if it exists and is nonzero, then differing levels
                          of parenthesization will receive different
                          highlighting.
```

The g:lisp_rainbow option provides 10 levels of individual colorization for the parentheses and backquoted parentheses. Because of the quantity of colorization levels, unlike non-rainbow highlighting, the rainbow mode specifies its highlighting using ctermfg and guifg, thereby bypassing the usual colorscheme control using standard highlighting groups. The actual highlighting used depends on the dark/bright setting (see 'bg').

LITE lite.vim ft-lite-syntax

There are two options for the lite syntax highlighting.

If you like SQL syntax highlighting inside Strings, use this:

```
        :let lite_sql_query = 1
```

For syncing, minlines defaults to 100. If you prefer another value, you can set "lite_minlines" to the value you desire. Example:

```
        :let lite_minlines = 200
```

LPC lpc.vim ft-lpc-syntax

LPC stands for a simple, memory-efficient language: Lars Pensjö C. The file name of LPC is usually *.c. Recognizing these files as LPC would bother users writing only C programs. If you want to use LPC syntax in Vim, you should set a variable in your .vimrc file:

```
        :let lpc_syntax_for_c = 1
```

If it doesn't work properly for some particular C or LPC files, use a modeline. For a LPC file:

```
        // vim:set ft=lpc:
```

For a C file that is recognized as LPC:

```
        // vim:set ft=c:
```

If you don't want to set the variable, use the modeline in EVERY LPC file.

There are several implementations for LPC, we intend to support most widely

used ones. Here the default LPC syntax is for MudOS series, for MudOS v22
and before, you should turn off the sensible modifiers, and this will also
assert the new efuns after v22 to be invalid, don't set this variable when
you are using the latest version of MudOS:

```
:let lpc_pre_v22 = 1
```

For LpMud 3.2 series of LPC:

```
:let lpc_compat_32 = 1
```

For LPC4 series of LPC:

```
:let lpc_use_lpc4_syntax = 1
```

For uLPC series of LPC:
uLPC has been developed to Pike, so you should use Pike syntax
instead, and the name of your source file should be *.pike

LUA lua.vim ft-lua-syntax

The Lua syntax file can be used for versions 4.0, 5.0, 5.1 and 5.2 (5.2 is
the default). You can select one of these versions using the global variables
lua_version and lua_subversion. For example, to activate Lua
5.1 syntax highlighting, set the variables like this:

```
:let lua_version = 5
:let lua_subversion = 1
```

MAIL mail.vim ft-mail.vim

Vim highlights all the standard elements of an email (headers, signatures,
quoted text and URLs / email addresses). In keeping with standard conventions,
signatures begin in a line containing only "--" followed optionally by
whitespaces and end with a newline.

Vim treats lines beginning with ']', '}', '|', '>' or a word followed by '>'
as quoted text. However Vim highlights headers and signatures in quoted text
only if the text is quoted with '>' (optionally followed by one space).

By default mail.vim synchronises syntax to 100 lines before the first
displayed line. If you have a slow machine, and generally deal with emails
with short headers, you can change this to a smaller value:

```
:let mail_minlines = 30
```

MAKE make.vim ft-make-syntax

In makefiles, commands are usually highlighted to make it easy for you to spot
errors. However, this may be too much coloring for you. You can turn this
feature off by using:

```
:let make_no_commands = 1
```

MAPLE maple.vim ft-maple-syntax

Maple V, by Waterloo Maple Inc, supports symbolic algebra. The language supports many packages of functions which are selectively loaded by the user. The standard set of packages' functions as supplied in Maple V release 4 may be highlighted at the user's discretion. Users may place in their .vimrc file:

```
:let mvpkg_all= 1
```

to get all package functions highlighted, or users may select any subset by choosing a variable/package from the table below and setting that variable to 1, also in their .vimrc file (prior to sourcing $VIMRUNTIME/syntax/syntax.vim).

Table of Maple V Package Function Selectors

mv_DEtools	mv_genfunc	mv_networks	mv_process
mv_Galois	mv_geometry	mv_numapprox	mv_simplex
mv_GaussInt	mv_grobner	mv_numtheory	mv_stats
mv_LREtools	mv_group	mv_orthopoly	mv_student
mv_combinat	mv_inttrans	mv_padic	mv_sumtools
mv_combstruct	mv_liesymm	mv_plots	mv_tensor
mv_difforms	mv_linalg	mv_plottools	mv_totorder
mv_finance	mv_logic	mv_powseries	

MATHEMATICA mma.vim ft-mma-syntax ft-mathematica-syntax

Empty *.m files will automatically be presumed to be Matlab files unless you have the following in your .vimrc:

```
let filetype_m = "mma"
```

MOO moo.vim ft-moo-syntax

If you use C-style comments inside expressions and find it mangles your highlighting, you may want to use extended (slow!) matches for C-style comments:

```
:let moo_extended_cstyle_comments = 1
```

To disable highlighting of pronoun substitution patterns inside strings:

```
:let moo_no_pronoun_sub = 1
```

To disable highlighting of the regular expression operator '%|', and matching '%(' and '%)' inside strings:

```
:let moo_no_regexp = 1
```

Unmatched double quotes can be recognized and highlighted as errors:

```
:let moo_unmatched_quotes = 1
```

To highlight builtin properties (.name, .location, .programmer etc.):

```
:let moo_builtin_properties = 1
```

Unknown builtin functions can be recognized and highlighted as errors. If you use this option, add your own extensions to the mooKnownBuiltinFunction group. To enable this option:

```
:let moo_unknown_builtin_functions = 1
```

An example of adding sprintf() to the list of known builtin functions:

```
:syn keyword mooKnownBuiltinFunction sprintf contained
```

MSQL msql.vim ft-msql-syntax

There are two options for the msql syntax highlighting.

If you like SQL syntax highlighting inside Strings, use this:

```
:let msql_sql_query = 1
```

For syncing, minlines defaults to 100. If you prefer another value, you can set "msql_minlines" to the value you desire. Example:

```
:let msql_minlines = 200
```

N1QL n1ql.vim ft-n1ql-syntax

N1QL is a SQL-like declarative language for manipulating JSON documents in Couchbase Server databases.

Vim syntax highlights N1QL statements, keywords, operators, types, comments, and special values. Vim ignores syntactical elements specific to SQL or its many dialects, like COLUMN or CHAR, that don't exist in N1QL.

NCF ncf.vim ft-ncf-syntax

There is one option for NCF syntax highlighting.

If you want to have unrecognized (by ncf.vim) statements highlighted as errors, use this:

```
:let ncf_highlight_unknowns = 1
```

If you don't want to highlight these errors, leave it unset.

NROFF nroff.vim ft-nroff-syntax

The nroff syntax file works with AT&T n/troff out of the box. You need to activate the GNU groff extra features included in the syntax file before you can use them.

For example, Linux and BSD distributions use groff as their default text processing package. In order to activate the extra syntax highlighting features for groff, add the following option to your start-up files:

```
:let b:nroff_is_groff = 1
```

Groff is different from the old AT&T n/troff that you may still find in Solaris. Groff macro and request names can be longer than 2 characters and there are extensions to the language primitives. For example, in AT&T troff you access the year as a 2-digit number with the request \(yr. In groff you can use the same request, recognized for compatibility, or you can use groff's native syntax, \[yr]. Furthermore, you can use a 4-digit year directly: \[year]. Macro requests can be longer than 2 characters, for example, GNU mm accepts the requests ".VERBON" and ".VERBOFF" for creating verbatim environments.

In order to obtain the best formatted output g/troff can give you, you should follow a few simple rules about spacing and punctuation.

1. Do not leave empty spaces at the end of lines.

2. Leave one space and one space only after an end-of-sentence period, exclamation mark, etc.

3. For reasons stated below, it is best to follow all period marks with a carriage return.

The reason behind these unusual tips is that g/n/troff have a line breaking algorithm that can be easily upset if you don't follow the rules given above.

Unlike TeX, troff fills text line-by-line, not paragraph-by-paragraph and, furthermore, it does not have a concept of glue or stretch, all horizontal and vertical space input will be output as is.

Therefore, you should be careful about not using more space between sentences than you intend to have in your final document. For this reason, the common practice is to insert a carriage return immediately after all punctuation marks. If you want to have "even" text in your final processed output, you need to maintain regular spacing in the input text. To mark both trailing spaces and two or more spaces after a punctuation as an error, use:

```
:let nroff_space_errors = 1
```

Another technique to detect extra spacing and other errors that will interfere with the correct typesetting of your file, is to define an eye-catching highlighting definition for the syntax groups "nroffDefinition" and "nroffDefSpecial" in your configuration files. For example:

```
  hi def nroffDefinition term=italic cterm=italic gui=reverse
  hi def nroffDefSpecial term=italic,bold cterm=italic,bold
                        \ gui=reverse,bold
```

If you want to navigate preprocessor entries in your source file as easily as with section markers, you can activate the following option in your .vimrc file:

```
        let b:preprocs_as_sections = 1
```

As well, the syntax file adds an extra paragraph marker for the extended paragraph macro (.XP) in the ms package.

Finally, there is a groff.vim syntax file that can be used for enabling groff syntax highlighting either on a file basis or globally by default.

OCAML ocaml.vim ft-ocaml-syntax

The OCaml syntax file handles files having the following prefixes: .ml, .mli, .mll and .mly. By setting the following variable

```
        :let ocaml_revised = 1
```

you can switch from standard OCaml-syntax to revised syntax as supported by the camlp4 preprocessor. Setting the variable

```
        :let ocaml_noend_error = 1
```

prevents highlighting of "end" as error, which is useful when sources contain very long structures that Vim does not synchronize anymore.

PAPP papp.vim ft-papp-syntax

The PApp syntax file handles .papp files and, to a lesser extend, .pxml and .pxsl files which are all a mixture of perl/xml/html/other using xml as the top-level file format. By default everything inside phtml or pxml sections is treated as a string with embedded preprocessor commands. If you set the variable:

```
        :let papp_include_html=1
```

in your startup file it will try to syntax-hilight html code inside phtml sections, but this is relatively slow and much too colourful to be able to edit sensibly. ;)

The newest version of the papp.vim syntax file can usually be found at http://papp.plan9.de.

PASCAL pascal.vim ft-pascal-syntax

Files matching "*.p" could be Progress or Pascal. If the automatic detection doesn't work for you, or you don't edit Progress at all, use this in your startup vimrc:

```
:let filetype_p = "pascal"
```

The Pascal syntax file has been extended to take into account some extensions provided by Turbo Pascal, Free Pascal Compiler and GNU Pascal Compiler. Delphi keywords are also supported. By default, Turbo Pascal 7.0 features are enabled. If you prefer to stick with the standard Pascal keywords, add the following line to your startup file:

```
:let pascal_traditional=1
```

To switch on Delphi specific constructions (such as one-line comments, keywords, etc):

```
:let pascal_delphi=1
```

The option pascal_symbol_operator controls whether symbol operators such as +, *, .., etc. are displayed using the Operator color or not. To colorize symbol operators, add the following line to your startup file:

```
:let pascal_symbol_operator=1
```

Some functions are highlighted by default. To switch it off:

```
:let pascal_no_functions=1
```

Furthermore, there are specific variables for some compilers. Besides pascal_delphi, there are pascal_gpc and pascal_fpc. Default extensions try to match Turbo Pascal.

```
:let pascal_gpc=1
```

or

```
:let pascal_fpc=1
```

To ensure that strings are defined on a single line, you can define the pascal_one_line_string variable.

```
:let pascal_one_line_string=1
```

If you dislike <Tab> chars, you can set the pascal_no_tabs variable. Tabs will be highlighted as Error.

```
:let pascal_no_tabs=1
```

PERL perl.vim ft-perl-syntax

There are a number of possible options to the perl syntax highlighting.

Inline POD highlighting is now turned on by default. If you don't wish
to have the added complexity of highlighting POD embedded within Perl
files, you may set the 'perl_include_pod' option to 0:

```
:let perl_include_pod = 0
```

To reduce the complexity of parsing (and increase performance) you can switch
off two elements in the parsing of variable names and contents.

To handle package references in variable and function names not differently
from the rest of the name (like 'PkgName::' in '$PkgName::VarName'):

```
:let perl_no_scope_in_variables = 1
```

(In Vim 6.x it was the other way around: "perl_want_scope_in_variables"
enabled it.)

If you do not want complex things like '@{${"foo"}}' to be parsed:

```
:let perl_no_extended_vars = 1
```

(In Vim 6.x it was the other way around: "perl_extended_vars" enabled it.)

The coloring strings can be changed. By default strings and qq friends will be
highlighted like the first line. If you set the variable
perl_string_as_statement, it will be highlighted as in the second line.

```
   "hello world!"; qq|hello world|;
   ^^^^^^^^^^^^^^NN^^^^^^^^^^^^^^^N      (unlet perl_string_as_statement)
   S^^^^^^^^^^^^SNNSSS^^^^^^^^^^^SN      (let perl_string_as_statement)
```

(^ = perlString, S = perlStatement, N = None at all)

The syncing has 3 options. The first two switch off some triggering of
synchronization and should only be needed in case it fails to work properly.
If while scrolling all of a sudden the whole screen changes color completely
then you should try and switch off one of those. Let me know if you can figure
out the line that causes the mistake.

One triggers on "^\s*sub\s*" and the other on "^[$@%]" more or less.

```
:let perl_no_sync_on_sub
:let perl_no_sync_on_global_var
```

Below you can set the maximum distance VIM should look for starting points for
its attempts in syntax highlighting.

```
:let perl_sync_dist = 100
```

If you want to use folding with perl, set perl_fold:

```
:let perl_fold = 1
```

If you want to fold blocks in if statements, etc. as well set the following:

```
:let perl_fold_blocks = 1
```

Subroutines are folded by default if 'perl_fold' is set. If you do not want this, you can set 'perl_nofold_subs':

```
:let perl_nofold_subs = 1
```

Anonymous subroutines are not folded by default; you may enable their folding via 'perl_fold_anonymous_subs':

```
:let perl_fold_anonymous_subs = 1
```

Packages are also folded by default if 'perl_fold' is set. To disable this behavior, set 'perl_nofold_packages':

```
:let perl_nofold_packages = 1
```

PHP3 and PHP4 php.vim php3.vim ft-php-syntax ft-php3-syntax

[note: previously this was called "php3", but since it now also supports php4 it has been renamed to "php"]

There are the following options for the php syntax highlighting.

If you like SQL syntax highlighting inside Strings:

```
let php_sql_query = 1
```

For highlighting the Baselib methods:

```
let php_baselib = 1
```

Enable HTML syntax highlighting inside strings:

```
let php_htmlInStrings = 1
```

Using the old colorstyle:

```
let php_oldStyle = 1
```

Enable highlighting ASP-style short tags:

```
let php_asp_tags = 1
```

Disable short tags:

```
let php_noShortTags = 1
```

For highlighting parent error] or):

```
let php_parent_error_close = 1
```

For skipping a php end tag, if there exists an open (or [without a closing one:

```
  let php_parent_error_open = 1
```

Enable folding for classes and functions:

```
  let php_folding = 1
```

Selecting syncing method:

```
  let php_sync_method = x
```

x = -1 to sync by search (default),
x > 0 to sync at least x lines backwards,
x = 0 to sync from start.

PLAINTEX plaintex.vim ft-plaintex-syntax

TeX is a typesetting language, and plaintex is the file type for the "plain" variant of TeX. If you never want your *.tex files recognized as plain TeX, see ft-tex-plugin .

This syntax file has the option

```
        let g:plaintex_delimiters = 1
```

if you want to highlight brackets "[]" and braces "{}".

PPWIZARD ppwiz.vim ft-ppwiz-syntax

PPWizard is a preprocessor for HTML and OS/2 INF files

This syntax file has the options:

- ppwiz_highlight_defs : determines highlighting mode for PPWizard's definitions. Possible values are

  ppwiz_highlight_defs = 1 : PPWizard #define statements retain the colors of their contents (e.g. PPWizard macros and variables)

  ppwiz_highlight_defs = 2 : preprocessor #define and #evaluate statements are shown in a single color with the exception of line continuation symbols

  The default setting for ppwiz_highlight_defs is 1.

- ppwiz_with_html : If the value is 1 (the default), highlight literal HTML code; if 0, treat HTML code like ordinary text.

PHTML phtml.vim ft-phtml-syntax

There are two options for the phtml syntax highlighting.

If you like SQL syntax highlighting inside Strings, use this:

```
:let phtml_sql_query = 1
```

For syncing, minlines defaults to 100. If you prefer another value, you can set "phtml_minlines" to the value you desire. Example:

```
:let phtml_minlines = 200
```

POSTSCRIPT postscr.vim ft-postscr-syntax

There are several options when it comes to highlighting PostScript.

First which version of the PostScript language to highlight. There are currently three defined language versions, or levels. Level 1 is the original and base version, and includes all extensions prior to the release of level 2. Level 2 is the most common version around, and includes its own set of extensions prior to the release of level 3. Level 3 is currently the highest level supported. You select which level of the PostScript language you want highlighted by defining the postscr_level variable as follows:

```
:let postscr_level=2
```

If this variable is not defined it defaults to 2 (level 2) since this is the most prevalent version currently.

Note, not all PS interpreters will support all language features for a particular language level. In particular the %!PS-Adobe-3.0 at the start of PS files does NOT mean the PostScript present is level 3 PostScript!

If you are working with Display PostScript, you can include highlighting of Display PS language features by defining the postscr_display variable as follows:

```
:let postscr_display=1
```

If you are working with Ghostscript, you can include highlighting of Ghostscript specific language features by defining the variable postscr_ghostscript as follows:

```
:let postscr_ghostscript=1
```

PostScript is a large language, with many predefined elements. While it useful to have all these elements highlighted, on slower machines this can cause Vim to slow down. In an attempt to be machine friendly font names and character encodings are not highlighted by default. Unless you are working explicitly with either of these this should be ok. If you want them to be highlighted you should set one or both of the following variables:

```
        :let postscr_fonts=1
        :let postscr_encodings=1
```

There is a stylistic option to the highlighting of and, or, and not. In PostScript the function of these operators depends on the types of their operands - if the operands are booleans then they are the logical operators, if they are integers then they are binary operators. As binary and logical operators can be highlighted differently they have to be highlighted one way or the other. By default they are treated as logical operators. They can be highlighted as binary operators by defining the variable postscr_andornot_binary as follows:

```
        :let postscr_andornot_binary=1
```

PRINTCAP + TERMCAP ptcap.vim ft-printcap-syntax ft-ptcap-syntax ft-termcap-syntax

This syntax file applies to the printcap and termcap databases.

In order for Vim to recognize printcap/termcap files that do not match the patterns *printcap*, or *termcap*, you must put additional patterns appropriate to your system in your myfiletypefile file. For these patterns, you must set the variable "b:ptcap_type" to either "print" or "term", and then the 'filetype' option to ptcap.

For example, to make Vim identify all files in /etc/termcaps/ as termcap files, add the following:

```
   :au BufNewFile,BufRead /etc/termcaps/* let b:ptcap_type = "term" |
                                        \ set filetype=ptcap
```

If you notice highlighting errors while scrolling backwards, which are fixed when redrawing with CTRL-L, try setting the "ptcap_minlines" internal variable to a larger number:

```
   :let ptcap_minlines = 50
```

(The default is 20 lines.)

PROGRESS progress.vim ft-progress-syntax

Files matching "*.w" could be Progress or cweb. If the automatic detection doesn't work for you, or you don't edit cweb at all, use this in your startup vimrc:

```
   :let filetype_w = "progress"
```

The same happens for "*.i", which could be assembly, and "*.p", which could be Pascal. Use this if you don't use assembly and Pascal:

```
   :let filetype_i = "progress"
   :let filetype_p = "progress"
```

PYTHON python.vim ft-python-syntax

There are six options to control Python syntax highlighting.

For highlighted numbers:
        :let python_no_number_highlight = 1

For highlighted builtin functions:
        :let python_no_builtin_highlight = 1

For highlighted standard exceptions:
        :let python_no_exception_highlight = 1

For highlighted doctests and code inside:
        :let python_no_doctest_highlight = 1
or
        :let python_no_doctest_code_highlight = 1
(first option implies second one).

For highlighted trailing whitespace and mix of spaces and tabs:
        :let python_space_error_highlight = 1

If you want all possible Python highlighting (the same as setting the
preceding last option and unsetting all other ones):
        :let python_highlight_all = 1

Note: only existence of these options matter, not their value. You can replace
      1 above with anything.

QUAKE quake.vim ft-quake-syntax

The Quake syntax definition should work for most any FPS (First Person
Shooter) based on one of the Quake engines. However, the command names vary
a bit between the three games (Quake, Quake 2, and Quake 3 Arena) so the
syntax definition checks for the existence of three global variables to allow
users to specify what commands are legal in their files. The three variables
can be set for the following effects:

set to highlight commands only available in Quake:
        :let quake_is_quake1 = 1

set to highlight commands only available in Quake 2:
        :let quake_is_quake2 = 1

set to highlight commands only available in Quake 3 Arena:
        :let quake_is_quake3 = 1

Any combination of these three variables is legal, but might highlight more
commands than are actually available to you by the game.

READLINE readline.vim ft-readline-syntax

The readline library is primarily used by the BASH shell, which adds quite a

few commands and options to the ones already available. To highlight these items as well you can add the following to your vimrc or just type it in the command line before loading a file with the readline syntax:

```
let readline_has_bash = 1
```

This will add highlighting for the commands that BASH (version 2.05a and later, and part earlier) adds.

RESTRUCTURED TEXT rst.vim ft-rst-syntax

You may set what syntax definitions should be used for code blocks via

```
let rst_syntax_code_list = ['vim', 'lisp', ...]
```

REXX rexx.vim ft-rexx-syntax

If you notice highlighting errors while scrolling backwards, which are fixed when redrawing with CTRL-L, try setting the "rexx_minlines" internal variable to a larger number:

```
:let rexx_minlines = 50
```

This will make the syntax synchronization start 50 lines before the first displayed line. The default value is 10. The disadvantage of using a larger number is that redrawing can become slow.

Vim tries to guess what type a ".r" file is. If it can't be detected (from comment lines), the default is "r". To make the default rexx add this line to your .vimrc: g:filetype_r

```
:let g:filetype_r = "r"
```

RUBY ruby.vim ft-ruby-syntax

Ruby: Operator highlighting	ruby_operators
Ruby: Whitespace errors	ruby_space_errors
Ruby: Folding	ruby_fold ruby_foldable_groups
Ruby: Reducing expensive operations	ruby_no_expensive ruby_minlines
Ruby: Spellchecking strings	ruby_spellcheck_strings

Ruby: Operator highlighting ruby_operators

Operators can be highlighted by defining "ruby_operators":

```
:let ruby_operators = 1
```

Ruby: Whitespace errors ruby_space_errors

Whitespace errors can be highlighted by defining "ruby_space_errors":

```
:let ruby_space_errors = 1
```

This will highlight trailing whitespace and tabs preceded by a space character as errors. This can be refined by defining "ruby_no_trail_space_error" and "ruby_no_tab_space_error" which will ignore trailing whitespace and tabs after spaces respectively.

                                        ruby_fold   ruby_foldable_groups
Ruby: Folding

Folding can be enabled by defining "ruby_fold":

```
:let ruby_fold = 1
```

This will set the value of 'foldmethod' to "syntax" locally to the current buffer or window, which will enable syntax-based folding when editing Ruby filetypes.

Default folding is rather detailed, i.e., small syntax units like "if", "do", "%w[]" may create corresponding fold levels.

You can set "ruby_foldable_groups" to restrict which groups are foldable:

```
:let ruby_foldable_groups = 'if case %'
```

The value is a space-separated list of keywords:

keyword	meaning
ALL	Most block syntax (default)
NONE	Nothing
if	"if" or "unless" block
def	"def" block
class	"class" block
module	"module" block
do	"do" block
begin	"begin" block
case	"case" block
for	"for", "while", "until" loops
{	Curly bracket block or hash literal
[	Array literal
%	Literal with "%" notation, e.g.: %w(STRING), %!STRING!
/	Regexp
string	String and shell command output (surrounded by ', ", `)
:	Symbol
#	Multiline comment
<<	Here documents
__END__	Source code after "__END__" directive

                                                ruby_no_expensive
Ruby: Reducing expensive operations

By default, the "end" keyword is colorized according to the opening statement of the block it closes. While useful, this feature can be expensive; if you experience slow redrawing (or you are on a terminal with poor color support) you may want to turn it off by defining the "ruby_no_expensive" variable:

```
:let ruby_no_expensive = 1
```

In this case the same color will be used for all control keywords.

ruby_minlines

If you do want this feature enabled, but notice highlighting errors while scrolling backwards, which are fixed when redrawing with CTRL-L, try setting the "ruby_minlines" variable to a value larger than 50:

```
:let ruby_minlines = 100
```

Ideally, this value should be a number of lines large enough to embrace your largest class or module.

ruby_spellcheck_strings

Ruby: Spellchecking strings

Ruby syntax will perform spellchecking of strings if you define "ruby_spellcheck_strings":

```
:let ruby_spellcheck_strings = 1
```

SCHEME

scheme.vim ft-scheme-syntax

By default only R7RS keywords are highlighted and properly indented.

scheme.vim also supports extensions of the CHICKEN Scheme->C compiler. Define b:is_chicken or g:is_chicken, if you need them.

SDL

sdl.vim ft-sdl-syntax

The SDL highlighting probably misses a few keywords, but SDL has so many of them it's almost impossibly to cope.

The new standard, SDL-2000, specifies that all identifiers are case-sensitive (which was not so before), and that all keywords can be used either completely lowercase or completely uppercase. To have the highlighting reflect this, you can set the following variable:

```
:let sdl_2000=1
```

This also sets many new keywords. If you want to disable the old keywords, which is probably a good idea, use:

```
:let SDL_no_96=1
```

The indentation is probably also incomplete, but right now I am very satisfied with it for my own projects.

SED

sed.vim ft-sed-syntax

To make tabs stand out from regular blanks (accomplished by using Todo
highlighting on the tabs), define "highlight_sedtabs" by putting

        :let highlight_sedtabs = 1

in the vimrc file. (This special highlighting only applies for tabs
inside search patterns, replacement texts, addresses or text included
by an Append/Change/Insert command.) If you enable this option, it is
also a good idea to set the tab width to one character; by doing that,
you can easily count the number of tabs in a string.

Bugs:

  The transform command (y) is treated exactly like the substitute
  command. This means that, as far as this syntax file is concerned,
  transform accepts the same flags as substitute, which is wrong.
  (Transform accepts no flags.) I tolerate this bug because the
  involved commands need very complex treatment (95 patterns, one for
  each plausible pattern delimiter).

SGML   sgml.vim   ft-sgml-syntax

The coloring scheme for tags in the SGML file works as follows.

The <> of opening tags are colored differently than the </> of a closing tag.
This is on purpose! For opening tags the 'Function' color is used, while for
closing tags the 'Type' color is used (See syntax.vim to check how those are
defined for you)

Known tag names are colored the same way as statements in C. Unknown tag
names are not colored which makes it easy to spot errors.

Note that the same is true for argument (or attribute) names. Known attribute
names are colored differently than unknown ones.

Some SGML tags are used to change the rendering of text. The following tags
are recognized by the sgml.vim syntax coloring file and change the way normal
text is shown: <varname> <emphasis> <command> <function> <literal>
<replaceable> <ulink> and <link>.

If you want to change how such text is rendered, you must redefine the
following syntax groups:

    - sgmlBold
    - sgmlBoldItalic
    - sgmlUnderline
    - sgmlItalic
    - sgmlLink for links

To make this redefinition work you must redefine them all and define the
following variable in your vimrc (this is due to the order in which the files
are read during initialization)

```
   let sgml_my_rendering=1

You can also disable this rendering by adding the following line to your
vimrc file:
   let sgml_no_rendering=1

(Adapted from the html.vim help text by Claudio Fleiner <claudio@fleiner.com>)

                ft-posix-synax   ft-dash-syntax
SH              sh.vim    ft-sh-syntax    ft-bash-syntax    ft-ksh-syntax

This covers syntax highlighting for the older Unix (Bourne) sh, and newer
shells such as bash, dash, posix, and the Korn shells.

Vim attempts to determine which shell type is in use by specifying that
various filenames are of specific types, e.g.:

    ksh : .kshrc* *.ksh
    bash: .bashrc* bashrc bash.bashrc .bash_profile* *.bash

See $VIMRUNTIME/filetype.vim for the full list of patterns.  If none of these
cases pertain, then the first line of the file is examined (ex. looking for
/bin/sh  /bin/ksh  /bin/bash).  If the first line specifies a shelltype, then
that shelltype is used.  However some files (ex. .profile) are known to be
shell files but the type is not apparent.  Furthermore, on many systems sh is
symbolically linked to "bash" (Linux, Windows+cygwin) or "ksh" (Posix).

One may specify a global default by instantiating one of the following
variables in your <.vimrc>:

   ksh:
        let g:is_kornshell = 1
   posix:  (using this is the nearly the same as setting g:is_kornshell to 1)
        let g:is_posix     = 1
   bash:
        let g:is_bash      = 1
   sh: (default) Bourne shell
        let g:is_sh        = 1

   (dash users should use posix)

If there's no "#! ..." line, and the user hasn't availed himself/herself of a
default sh.vim syntax setting as just shown, then syntax/sh.vim will assume
the Bourne shell syntax.  No need to quote RFCs or market penetration
statistics in error reports, please -- just select the default version of the
sh your system uses and install the associated "let..." in your <.vimrc>.

The syntax/sh.vim file provides several levels of syntax-based folding:

        let g:sh_fold_enabled= 0     (default, no syntax folding)
        let g:sh_fold_enabled= 1     (enable function folding)
        let g:sh_fold_enabled= 2     (enable heredoc folding)
        let g:sh_fold_enabled= 4     (enable if/do/for folding)
```

then various syntax items (ie. HereDocuments and function bodies) become
syntax-foldable (see :syn-fold). You also may add these together
to get multiple types of folding:

```
        let g:sh_fold_enabled= 3     (enables function and heredoc folding)
```

If you notice highlighting errors while scrolling backwards which are fixed
when one redraws with CTRL-L, try setting the "sh_minlines" internal variable
to a larger number. Example:

```
        let sh_minlines = 500
```

This will make syntax synchronization start 500 lines before the first
displayed line. The default value is 200. The disadvantage of using a larger
number is that redrawing can become slow.

If you don't have much to synchronize on, displaying can be very slow. To
reduce this, the "sh_maxlines" internal variable can be set. Example:

```
        let sh_maxlines = 100
```

The default is to use the twice sh_minlines. Set it to a smaller number to
speed up displaying. The disadvantage is that highlight errors may appear.

syntax/sh.vim tries to flag certain problems as errors; usually things like
extra ']'s, 'done's, 'fi's, etc. If you find the error handling problematic
for your purposes, you may suppress such error highlighting by putting
the following line in your .vimrc:

```
        let g:sh_no_error= 1
```

Sh: EMBEDDING LANGUAGES sh-embed sh-awk

You may wish to embed languages into sh. I'll give an example courtesy of
Lorance Stinson on how to do this with awk as an example. Put the following
file into $HOME/.vim/after/syntax/sh/awkembed.vim:

```
    " AWK Embedding:
    " ==============
    " Shamelessly ripped from aspperl.vim by Aaron Hope.
    if exists("b:current_syntax")
      unlet b:current_syntax
    endif
    syn include @AWKScript syntax/awk.vim
    syn region AWKScriptCode matchgroup=AWKCommand start=+[=\\]\@<!'+ skip=+\\'+ end=+'+ co
    syn region AWKScriptEmbedded matchgroup=AWKCommand start=+\<awk\>+ skip=+\\$+ end=+[=\'
    syn cluster shCommandSubList add=AWKScriptEmbedded
    hi def link AWKCommand Type
```

This code will then let the awk code in the single quotes:

```
        awk '...awk code here...'
```

be highlighted using the awk highlighting syntax. Clearly this may be
extended to other languages.

SPEEDUP   spup.vim   ft-spup-syntax
(AspenTech plant simulator)

The Speedup syntax file has some options:

- strict_subsections : If this variable is defined, only keywords for
  sections and subsections will be highlighted as statements but not
  other keywords (like WITHIN in the OPERATION section).

- highlight_types : Definition of this variable causes stream types
  like temperature or pressure to be highlighted as Type, not as a
  plain Identifier. Included are the types that are usually found in
  the DECLARE section; if you defined own types, you have to include
  them in the syntax file.

- oneline_comments : this value ranges from 1 to 3 and determines the
  highlighting of # style comments.

  oneline_comments = 1 : allow normal Speedup code after an even
  number of #s.

  oneline_comments = 2 : show code starting with the second # as
  error. This is the default setting.

  oneline_comments = 3 : show the whole line as error if it contains
  more than one #.

Since especially OPERATION sections tend to become very large due to
PRESETting variables, syncing may be critical. If your computer is
fast enough, you can increase minlines and/or maxlines near the end of
the syntax file.

SQL   sql.vim   ft-sql-syntax
                                              sqlinformix.vim   ft-sqlinformix-syntax
                                              sqlanywhere.vim   ft-sqlanywhere-syntax

While there is an ANSI standard for SQL, most database engines add their own
custom extensions. Vim currently supports the Oracle and Informix dialects of
SQL. Vim assumes "*.sql" files are Oracle SQL by default.

Vim currently has SQL support for a variety of different vendors via syntax
scripts. You can change Vim's default from Oracle to any of the current SQL
supported types. You can also easily alter the SQL dialect being used on a
buffer by buffer basis.

For more detailed instructions see ft_sql.txt .

TCSH   tcsh.vim   ft-tcsh-syntax

This covers the shell named "tcsh". It is a superset of csh. See csh.vim
for how the filetype is detected.

Tcsh does not allow \" in strings unless the "backslash_quote" shell variable
is set. If you want VIM to assume that no backslash quote constructs exist add
this line to your .vimrc:

```
:let tcsh_backslash_quote = 0
```

If you notice highlighting errors while scrolling backwards, which are fixed
when redrawing with CTRL-L, try setting the "tcsh_minlines" internal variable
to a larger number:

```
:let tcsh_minlines = 1000
```

This will make the syntax synchronization start 1000 lines before the first
displayed line. If you set "tcsh_minlines" to "fromstart", then
synchronization is done from the start of the file. The default value for
tcsh_minlines is 100. The disadvantage of using a larger number is that
redrawing can become slow.

TEX tex.vim ft-tex-syntax latex-syntax

Tex Contents

tex-folding g:tex_fold_enabled

Tex: Want Syntax Folding?

As of version 28 of <syntax/tex.vim>, syntax-based folding of parts, chapters,
sections, subsections, etc are supported. Put

```
let g:tex_fold_enabled=1
```

in your <.vimrc>, and :set fdm=syntax. I suggest doing the latter via a
modeline at the end of your LaTeX file:

```
% vim: fdm=syntax
```

If your system becomes too slow, then you might wish to look into

```
https://vimhelp.appspot.com/vim_faq.txt.html#faq-29.7
```

g:tex_nospell

Tex: No Spell Checking Wanted

If you don't want spell checking anywhere in your LaTeX document, put
```
let g:tex_nospell=1
```
into your .vimrc. If you merely wish to suppress spell checking inside comments only, see g:tex_comment_nospell .

tex-nospell g:tex_comment_nospell

Tex: Don't Want Spell Checking In Comments?

Some folks like to include things like source code in comments and so would prefer that spell checking be disabled in comments in LaTeX files. To do this, put the following in your <.vimrc>:
```
let g:tex_comment_nospell= 1
```
If you want to suppress spell checking everywhere inside your LaTeX document, see g:tex_nospell .

tex-verb g:tex_verbspell

Tex: Want Spell Checking in Verbatim Zones?

Often verbatim regions are used for things like source code; seldom does one want source code spell-checked. However, for those of you who do want your verbatim zones spell-checked, put the following in your <.vimrc>:
```
let g:tex_verbspell= 1
```

tex-runon tex-stopzone

Tex: Run-on Comments or MathZones

The <syntax/tex.vim> highlighting supports TeX, LaTeX, and some AmsTeX. The highlighting supports three primary zones/regions: normal, texZone, and texMathZone. Although considerable effort has been made to have these zones terminate properly, zones delineated by $..$ and $$..$$ cannot be synchronized as there's no difference between start and end patterns. Consequently, a special "TeX comment" has been provided
```
%stopzone
```
which will forcibly terminate the highlighting of either a texZone or a texMathZone.

tex-slow tex-sync

Tex: Slow Syntax Highlighting?

If you have a slow computer, you may wish to reduce the values for
```
:syn sync maxlines=200
:syn sync minlines=50
```
(especially the latter). If your computer is fast, you may wish to increase them. This primarily affects synchronizing (i.e. just what group, if any, is the text at the top of the screen supposed to be in?).

Another cause of slow highlighting is due to syntax-driven folding; see tex-folding for a way around this.

g:tex_fast

Finally, if syntax highlighting is still too slow, you may set

```
        :let g:tex_fast= ""
```

in your .vimrc. Used this way, the g:tex_fast variable causes the syntax highlighting script to avoid defining any regions and associated synchronization. The result will be much faster syntax highlighting; the price: you will no longer have as much highlighting or any syntax-based folding, and you will be missing syntax-based error checking.

You may decide that some syntax is acceptable; you may use the following table selectively to enable just some syntax highlighting:

```
    b : allow bold and italic syntax
    c : allow texComment syntax
    m : allow texMatcher syntax (ie. {...} and [...])
    M : allow texMath syntax
    p : allow parts, chapter, section, etc syntax
    r : allow texRefZone syntax (nocite, bibliography, label, pageref, eqref)
    s : allow superscript/subscript regions
    S : allow texStyle syntax
    v : allow verbatim syntax
    V : allow texNewEnv and texNewCmd syntax
```

As an example, let g:tex_fast= "M" will allow math-associated highlighting but suppress all the other region-based syntax highlighting.
(also see: g:tex_conceal and tex-supersub)

                                                tex-morecommands tex-package
Tex: Want To Highlight More Commands?

LaTeX is a programmable language, and so there are thousands of packages full of specialized LaTeX commands, syntax, and fonts. If you're using such a package you'll often wish that the distributed syntax/tex.vim would support it. However, clearly this is impractical. So please consider using the techniques in mysyntaxfile-add to extend or modify the highlighting provided by syntax/tex.vim. Please consider uploading any extensions that you write, which typically would go in $HOME/after/syntax/tex/[pkgname].vim, to http://vim.sf.net/.

                                                tex-error g:tex_no_error
Tex: Excessive Error Highlighting?

The <tex.vim> supports lexical error checking of various sorts. Thus, although the error checking is ofttimes very useful, it can indicate errors where none actually are. If this proves to be a problem for you, you may put in your <.vimrc> the following statement:

```
        let g:tex_no_error=1
```

and all error checking by <syntax/tex.vim> will be suppressed.

                                                                tex-math
Tex: Need a new Math Group?

If you want to include a new math group in your LaTeX, the following code shows you an example as to how you might do so:

```
        call TexNewMathZone(sfx,mathzone,starform)
```
You'll want to provide the new math group with a unique suffix
(currently, A-L and V-Z are taken by <syntax/tex.vim> itself).
As an example, consider how eqnarray is set up by <syntax/tex.vim>:
```
        call TexNewMathZone("D","eqnarray",1)
```
You'll need to change "mathzone" to the name of your new math group,
and then to the call to it in .vim/after/syntax/tex.vim.
The "starform" variable, if true, implies that your new math group
has a starred form (ie. eqnarray*).

tex-style b:tex_stylish

Tex: Starting a New Style?

One may use "\makeatletter" in *.tex files, thereby making the use of "@" in
commands available. However, since the *.tex file doesn't have one of the
following suffices: sty cls clo dtx ltx, the syntax highlighting will flag
such use of @ as an error. To solve this:

```
        :let b:tex_stylish = 1
        :set ft=tex
```

Putting "let g:tex_stylish=1" into your <.vimrc> will make <syntax/tex.vim>
always accept such use of @.

tex-cchar tex-cole tex-conceal

Tex: Taking Advantage of Conceal Mode

If you have 'conceallevel' set to 2 and if your encoding is utf-8, then a
number of character sequences can be translated into appropriate utf-8 glyphs,
including various accented characters, Greek characters in MathZones, and
superscripts and subscripts in MathZones. Not all characters can be made into
superscripts or subscripts; the constraint is due to what utf-8 supports.
In fact, only a few characters are supported as subscripts.

One way to use this is to have vertically split windows (see CTRL-W_v); one
with 'conceallevel' at 0 and the other at 2; and both using 'scrollbind' .

g:tex_conceal

Tex: Selective Conceal Mode

You may selectively use conceal mode by setting g:tex_conceal in your
<.vimrc>. By default, g:tex_conceal is set to "admgs" to enable concealment
for the following sets of characters:

```
        a = accents/ligatures
        b = bold and italic
        d = delimiters
        m = math symbols
        g = Greek
        s = superscripts/subscripts
```

By leaving one or more of these out, the associated conceal-character
substitution will not be made.

g:tex_isk g:tex_stylish

Tex: Controlling iskeyword

Normally, LaTeX keywords support 0-9, a-z, A-z, and 192-255 only. Latex keywords don't support the underscore - except when in *.sty files. The syntax highlighting script handles this with the following logic:

```
* If g:tex_stylish exists and is 1
        then the file will be treated as a "sty" file, so the "_"
        will be allowed as part of keywords
        (regardless of g:tex_isk)
* Else if the file's suffix is sty, cls, clo, dtx, or ltx,
        then the file will be treated as a "sty" file, so the "_"
        will be allowed as part of keywords
        (regardless of g:tex_isk)

* If g:tex_isk exists, then it will be used for the local 'iskeyword'
* Else the local 'iskeyword' will be set to 48-57,a-z,A-Z,192-255
```

tex-supersub g:tex_superscripts g:tex_subscripts

Tex: Fine Subscript and Superscript Control

See tex-conceal for how to enable concealed character replacement.

See g:tex_conceal for selectively concealing accents, bold/italic, math, Greek, and superscripts/subscripts.

One may exert fine control over which superscripts and subscripts one wants syntax-based concealment for (see :syn-cchar). Since not all fonts support all characters, one may override the concealed-replacement lists; by default these lists are given by:

```
    let g:tex_superscripts= "[0-9a-zA-W.,:;+-<>/()=]"
    let g:tex_subscripts= "[0-9aehijklmnoprstuvx,+-/().]"
```

For example, I use Luxi Mono Bold; it doesn't support subscript characters for "hklmnpst", so I put

```
        let g:tex_subscripts= "[0-9aeijoruvx,+-/().]"
```

in ~/.vim/ftplugin/tex/tex.vim in order to avoid having inscrutable utf-8 glyphs appear.

TF tf.vim ft-tf-syntax

There is one option for the tf syntax highlighting.

For syncing, minlines defaults to 100. If you prefer another value, you can set "tf_minlines" to the value you desire. Example:

```
:let tf_minlines = your choice
```

VIM vim.vim ft-vim-syntax

g:vimsyn_minlines g:vimsyn_maxlines

There is a trade-off between more accurate syntax highlighting versus screen

updating speed. To improve accuracy, you may wish to increase the g:vimsyn_minlines variable. The g:vimsyn_maxlines variable may be used to improve screen updating rates (see :syn-sync for more on this).

```
g:vimsyn_minlines : used to set synchronization minlines
g:vimsyn_maxlines : used to set synchronization maxlines

(g:vim_minlines and g:vim_maxlines are deprecated variants of
these two options)
```

g:vimsyn_embed

The g:vimsyn_embed option allows users to select what, if any, types of embedded script highlighting they wish to have.

```
g:vimsyn_embed == 0   : don't support any embedded scripts
g:vimsyn_embed =~ 'l' : support embedded lua
g:vimsyn_embed =~ 'm' : support embedded mzscheme
g:vimsyn_embed =~ 'p' : support embedded perl
g:vimsyn_embed =~ 'P' : support embedded python
g:vimsyn_embed =~ 'r' : support embedded ruby
g:vimsyn_embed =~ 't' : support embedded tcl
```

By default, g:vimsyn_embed is a string supporting interpreters that your vim itself supports. Concatenate multiple characters to support multiple types of embedded interpreters; ie. g:vimsyn_embed= "mp" supports embedded mzscheme and embedded perl.

g:vimsyn_folding

Some folding is now supported with syntax/vim.vim:

```
g:vimsyn_folding == 0 or doesn't exist: no syntax-based folding
g:vimsyn_folding =~ 'a' : augroups
g:vimsyn_folding =~ 'f' : fold functions
g:vimsyn_folding =~ 'l' : fold lua      script
g:vimsyn_folding =~ 'm' : fold mzscheme script
g:vimsyn_folding =~ 'p' : fold perl     script
g:vimsyn_folding =~ 'P' : fold python   script
g:vimsyn_folding =~ 'r' : fold ruby     script
g:vimsyn_folding =~ 't' : fold tcl      script
```

g:vimsyn_noerror

Not all error highlighting that syntax/vim.vim does may be correct; Vim script is a difficult language to highlight correctly. A way to suppress error highlighting is to put the following line in your vimrc :

```
let g:vimsyn_noerror = 1
```

XF86CONFIG xf86conf.vim ft-xf86conf-syntax

The syntax of XF86Config file differs in XFree86 v3.x and v4.x. Both variants are supported. Automatic detection is used, but is far from perfect. You may need to specify the version manually. Set the variable

xf86conf_xfree86_version to 3 or 4 according to your XFree86 version in
your .vimrc. Example:
        :let xf86conf_xfree86_version=3
When using a mix of versions, set the b:xf86conf_xfree86_version variable.

Note that spaces and underscores in option names are not supported. Use
"SyncOnGreen" instead of "__s yn con gr_e_e_n" if you want the option name
highlighted.

XML xml.vim ft-xml-syntax

Xml namespaces are highlighted by default. This can be inhibited by
setting a global variable:

        :let g:xml_namespace_transparent=1

xml-folding
The xml syntax file provides syntax folding (see :syn-fold) between
start and end tags. This can be turned on by

        :let g:xml_syntax_folding = 1
        :set foldmethod=syntax

Note: syntax folding might slow down syntax highlighting significantly,
especially for large files.

X Pixmaps (XPM) xpm.vim ft-xpm-syntax

xpm.vim creates its syntax items dynamically based upon the contents of the
XPM file. Thus if you make changes e.g. in the color specification strings,
you have to source it again e.g. with ":set syn=xpm".

To copy a pixel with one of the colors, yank a "pixel" with "yl" and insert it
somewhere else with "P".

Do you want to draw with the mouse? Try the following:
```
:function! GetPixel()
:   let c = getline(".")[col(".") - 1]
:   echo c
:   exe "noremap <LeftMouse> <LeftMouse>r".c
:   exe "noremap <LeftDrag>  <LeftMouse>r".c
:endfunction
:noremap <RightMouse> <LeftMouse>:call GetPixel()<CR>
:set guicursor=n:hor20          " to see the color beneath the cursor
```
This turns the right button into a pipette and the left button into a pen.
It will work with XPM files that have one character per pixel only and you
must not click outside of the pixel strings, but feel free to improve it.

It will look much better with a font in a quadratic cell size, e.g. for X:
        :set guifont=-*-clean-medium-r-*-*-8-*-*-*-*-80-*

YAML yaml.vim ft-yaml-syntax

g:yaml_schema b:yaml_schema

A YAML schema is a combination of a set of tags and a mechanism for resolving non-specific tags. For user this means that YAML parser may, depending on plain scalar contents, treat plain scalar (which can actually be only string and nothing else) as a value of the other type: null, boolean, floating-point, integer. `g:yaml_schema` option determines according to which schema values will be highlighted specially. Supported schemas are

Schema	Description
failsafe	No additional highlighting.
json	Supports JSON-style numbers, booleans and null.
core	Supports more number, boolean and null styles.
pyyaml	In addition to core schema supports highlighting timestamps, but there are some differences in what is recognized as numbers and many additional boolean values not present in core schema.

Default schema is `core`.

Note that schemas are not actually limited to plain scalars, but this is the only difference between schemas defined in YAML specification and the only difference defined in the syntax file.

ZSH zsh.vim ft-zsh-syntax

The syntax script for zsh allows for syntax-based folding:

```
:let g:zsh_fold_enable = 1
```

==

5. Defining a syntax :syn-define E410

Vim understands three types of syntax items:

1. Keyword
   It can only contain keyword characters, according to the 'iskeyword' option. It cannot contain other syntax items. It will only match with a complete word (there are no keyword characters before or after the match). The keyword "if" would match in "if(a=b)", but not in "ifdef x", because "(" is not a keyword character and "d" is.

2. Match
   This is a match with a single regexp pattern.

3. Region
   This starts at a match of the "start" regexp pattern and ends with a match with the "end" regexp pattern. Any other text can appear in between. A "skip" regexp pattern can be used to avoid matching the "end" pattern.

Several syntax ITEMs can be put into one syntax GROUP. For a syntax group you can give highlighting attributes. For example, you could have an item

to define a "/* .. */" comment and another one that defines a "// .." comment, and put them both in the "Comment" group. You can then specify that a "Comment" will be in bold font and have a blue color. You are free to make one highlight group for one syntax item, or put all items into one group. This depends on how you want to specify your highlighting attributes. Putting each item in its own group results in having to specify the highlighting for a lot of groups.

Note that a syntax group and a highlight group are similar. For a highlight group you will have given highlight attributes. These attributes will be used for the syntax group with the same name.

In case more than one item matches at the same position, the one that was defined LAST wins. Thus you can override previously defined syntax items by using an item that matches the same text. But a keyword always goes before a match or region. And a keyword with matching case always goes before a keyword with ignoring case.

PRIORITY :syn-priority

When several syntax items may match, these rules are used:

1. When multiple Match or Region items start in the same position, the item defined last has priority.
2. A Keyword has priority over Match and Region items.
3. An item that starts in an earlier position has priority over items that start in later positions.

DEFINING CASE :syn-case E390

:sy[ntax] case [match | ignore]
        This defines if the following ":syntax" commands will work with matching case, when using "match", or with ignoring case, when using "ignore". Note that any items before this are not affected, and all items until the next ":syntax case" command are affected.

:sy[ntax] case
        Show either "syntax case match" or "syntax case ignore" (translated).

SPELL CHECKING :syn-spell

:sy[ntax] spell [toplevel | notoplevel | default]
        This defines where spell checking is to be done for text that is not in a syntax item:

        toplevel: Text is spell checked.
        notoplevel: Text is not spell checked.
        default: When there is a @Spell cluster no spell checking.

        For text in syntax items use the @Spell and @NoSpell clusters
         spell-syntax . When there is no @Spell and no @NoSpell cluster then spell checking is done for "default" and "toplevel".

To activate spell checking the 'spell' option must be set.

:sy[ntax] spell
Show either "syntax spell toplevel", "syntax spell notoplevel" or "syntax spell default" (translated).

SYNTAX ISKEYWORD SETTING :syn-iskeyword

:sy[ntax] iskeyword [clear | {option}]
This defines the keyword characters. It's like the 'iskeyword' option for but only applies to syntax highlighting.

clear: Syntax specific iskeyword setting is disabled and the buffer-local 'iskeyword' setting is used.
{option} Set the syntax 'iskeyword' option to a new value.

Example:

```
:syntax iskeyword @,48-57,192-255,$,_
```

This would set the syntax specific iskeyword option to include all alphabetic characters, plus the numeric characters, all accented characters and also includes the "_" and the "$".

If no argument is given, the current value will be output.

Setting this option influences what /\k matches in syntax patterns and also determines where :syn-keyword will be checked for a new match.

It is recommended when writing syntax files, to use this command to set the correct value for the specific syntax language and not change the 'iskeyword' option.

DEFINING KEYWORDS :syn-keyword

:sy[ntax] keyword {group-name} [{options}] {keyword} .. [{options}]

This defines a number of keywords.

{group-name} Is a syntax group name such as "Comment".
[{options}] See :syn-arguments below.
{keyword} .. Is a list of keywords which are part of this group.

Example:

```
:syntax keyword   Type   int long char
```

The {options} can be given anywhere in the line. They will apply to all keywords given, also for options that come after a keyword. These examples do exactly the same:

```
:syntax keyword   Type   contained int long char
:syntax keyword   Type   int long contained char
:syntax keyword   Type   int long char contained
```

E789 E890

When you have a keyword with an optional tail, like Ex commands in Vim, you can put the optional characters inside [], to define all the variations at once:

```
:syntax keyword   vimCommand   ab[breviate] n[ext]
```

Don't forget that a keyword can only be recognized if all the characters are included in the 'iskeyword' option. If one character isn't, the keyword will never be recognized.
Multi-byte characters can also be used. These do not have to be in 'iskeyword'.
See :syn-iskeyword for defining syntax specific iskeyword settings.

A keyword always has higher priority than a match or region, the keyword is used if more than one item matches. Keywords do not nest and a keyword can't contain anything else.

Note that when you have a keyword that is the same as an option (even one that isn't allowed here), you can not use it. Use a match instead.

The maximum length of a keyword is 80 characters.

The same keyword can be defined multiple times, when its containment differs. For example, you can define the keyword once not contained and use one highlight group, and once contained, and use a different highlight group. Example:

```
:syn keyword vimCommand tag
:syn keyword vimSetting contained tag
```

When finding "tag" outside of any syntax item, the "vimCommand" highlight group is used. When finding "tag" in a syntax item that contains "vimSetting", the "vimSetting" group is used.

DEFINING MATCHES :syn-match

```
:sy[ntax] match {group-name} [{options}]
                [excludenl]
                [keepend]
                {pattern}
                [{options}]
```

This defines one match.

{group-name}	A syntax group name such as "Comment".
[{options}]	See :syn-arguments below.
[excludenl]	Don't make a pattern with the end-of-line "$" extend a containing match or region. Must be given before the pattern. :syn-excludenl
keepend	Don't allow contained matches to go past a match with the end pattern. See :syn-keepend .
{pattern}	The search pattern that defines the match. See :syn-pattern below.

Note that the pattern may match more than one line, which makes the match depend on where Vim starts searching for the pattern. You need to make sure syncing takes care of this.

Example (match a character constant):

```
:syntax match Character /'.'/hs=s+1,he=e-1
```

DEFINING REGIONS :syn-region :syn-start :syn-skip :syn-end E398 E399

```
:sy[ntax] region {group-name} [{options}]
                [matchgroup={group-name}]
                [keepend]
                [extend]
                [excludenl]
                start={start_pattern} ..
                [skip={skip_pattern}]
                end={end_pattern} ..
                [{options}]
```

This defines one region. It may span several lines.

{group-name}	A syntax group name such as "Comment".
[{options}]	See :syn-arguments below.
[matchgroup={group-name}]	The syntax group to use for the following start or end pattern matches only. Not used for the text in between the matched start and end patterns. Use NONE to reset to not using a different group for the start or end match. See :syn-matchgroup .
keepend	Don't allow contained matches to go past a match with the end pattern. See :syn-keepend .
extend	Override a "keepend" for an item this region is contained in. See :syn-extend .
excludenl	Don't make a pattern with the end-of-line "$" extend a containing match or item. Only useful for end patterns. Must be given before the patterns it applies to. :syn-excludenl
start={start_pattern}	The search pattern that defines the start of the region. See :syn-pattern below.
skip={skip_pattern}	The search pattern that defines text inside the region where not to look for the end pattern. See :syn-pattern below.
end={end_pattern}	The search pattern that defines the end of the region. See :syn-pattern below.

Example:

```
:syntax region String   start=+"+  skip=+\\"+  end=+"+
```

The start/skip/end patterns and the options can be given in any order. There can be zero or one skip pattern. There must be one or more start and end patterns. This means that you can omit the skip

pattern, but you must give at least one start and one end pattern. It is allowed to have white space before and after the equal sign (although it mostly looks better without white space).

When more than one start pattern is given, a match with one of these is sufficient. This means there is an OR relation between the start patterns. The last one that matches is used. The same is true for the end patterns.

The search for the end pattern starts right after the start pattern. Offsets are not used for this. This implies that the match for the end pattern will never overlap with the start pattern.

The skip and end pattern can match across line breaks, but since the search for the pattern can start in any line it often does not do what you want. The skip pattern doesn't avoid a match of an end pattern in the next line. Use single-line patterns to avoid trouble.

Note: The decision to start a region is only based on a matching start pattern. There is no check for a matching end pattern. This does NOT work:

```
:syn region First  start="("  end=":"
:syn region Second start="("  end=";"
```

The Second always matches before the First (last defined pattern has higher priority). The Second region then continues until the next ';', no matter if there is a ':' before it. Using a match does work:

```
:syn match First  "(\_.\{-}:"
:syn match Second "(\_.\{-};"
```

This pattern matches any character or line break with "_." and repeats that with "\{-}" (repeat as few as possible).

:syn-keepend

By default, a contained match can obscure a match for the end pattern. This is useful for nesting. For example, a region that starts with "{" and ends with "}", can contain another region. An encountered "}" will then end the contained region, but not the outer region:

```
{           starts outer "{}" region
    {       starts contained "{}" region
    }       ends contained "{}" region
}           ends outer "{} region
```

If you don't want this, the "keepend" argument will make the matching of an end pattern of the outer region also end any contained item. This makes it impossible to nest the same region, but allows for contained items to highlight parts of the end pattern, without causing that to skip the match with the end pattern. Example:

```
:syn match  vimComment +"[^"]\+$+
:syn region vimCommand start="set" end="$" contains=vimComment keepend
```

The "keepend" makes the vimCommand always end at the end of the line, even though the contained vimComment includes a match with the <EOL>.

When "keepend" is not used, a match with an end pattern is retried after each contained match. When "keepend" is included, the first encountered match with an end pattern is used, truncating any contained matches.

:syn-extend

The "keepend" behavior can be changed by using the "extend" argument. When an item with "extend" is contained in an item that uses "keepend", the "keepend" is ignored and the containing region will be extended.
This can be used to have some contained items extend a region while others don't. Example:

```
:syn region htmlRef start=+<a>+ end=+</a>+ keepend contains=htmlItem,htmlScript
:syn match htmlItem +<[^>]*>+ contained
:syn region htmlScript start=+<script+ end=+</script[^>]*>+ contained extend
```

Here the htmlItem item does not make the htmlRef item continue further, it is only used to highlight the <> items. The htmlScript item does extend the htmlRef item.

Another example:

```
:syn region xmlFold start="<a>" end="</a>" fold transparent keepend extend
```

This defines a region with "keepend", so that its end cannot be changed by contained items, like when the "" is matched to highlight it differently. But when the xmlFold region is nested (it includes itself), the "extend" applies, so that the "" of a nested region only ends that region, and not the one it is contained in.

:syn-excludenl

When a pattern for a match or end pattern of a region includes a '$' to match the end-of-line, it will make a region item that it is contained in continue on the next line. For example, a match with "\\$" (backslash at the end of the line) can make a region continue that would normally stop at the end of the line. This is the default behavior. If this is not wanted, there are two ways to avoid it:

1. Use "keepend" for the containing item. This will keep all contained matches from extending the match or region. It can be used when all contained items must not extend the containing item.
2. Use "excludenl" in the contained item. This will keep that match from extending the containing match or region. It can be used if only some contained items must not extend the containing item. "excludenl" must be given before the pattern it applies to.

:syn-matchgroup

"matchgroup" can be used to highlight the start and/or end pattern differently than the body of the region. Example:

```
:syntax region String matchgroup=Quote start=+"+  skip=+\\"+  end=+"+
```

This will highlight the quotes with the "Quote" group, and the text in between with the "String" group.
The "matchgroup" is used for all start and end patterns that follow, until the next "matchgroup". Use "matchgroup=NONE" to go back to not using a matchgroup.

In a start or end pattern that is highlighted with "matchgroup" the contained items of the region are not used. This can be used to avoid that a contained item matches in the start or end pattern match. When using "transparent", this does not apply to a start or end pattern match that is highlighted with "matchgroup".

Here is an example, which highlights three levels of parentheses in
different colors:

```
:sy region par1 matchgroup=par1 start=/(/ end=/)/ contains=par2
:sy region par2 matchgroup=par2 start=/(/ end=/)/ contains=par3 contained
:sy region par3 matchgroup=par3 start=/(/ end=/)/ contains=par1 contained
:hi par1 ctermfg=red guifg=red
:hi par2 ctermfg=blue guifg=blue
:hi par3 ctermfg=darkgreen guifg=darkgreen
```

E849

The maximum number of syntax groups is 19999.

==

6. :syntax arguments :syn-arguments

The :syntax commands that define syntax items take a number of arguments.
The common ones are explained here. The arguments may be given in any order
and may be mixed with patterns.

Not all commands accept all arguments. This table shows which arguments
can not be used for all commands:

E395

	contains	oneline	fold	display	extend	concealends
:syntax keyword	-	-	-	-	-	-
:syntax match	yes	-	yes	yes	yes	-
:syntax region	yes	yes	yes	yes	yes	yes

These arguments can be used for all three commands:

- conceal
- cchar
- contained
- containedin
- nextgroup
- transparent
- skipwhite
- skipnl
- skipempty

conceal conceal :syn-conceal

When the "conceal" argument is given, the item is marked as concealable.
Whether or not it is actually concealed depends on the value of the
'conceallevel' option. The 'concealcursor' option is used to decide whether
concealable items in the current line are displayed unconcealed to be able to
edit the line.
Another way to conceal text is with matchadd() .

concealends :syn-concealends

When the "concealends" argument is given, the start and end matches of
the region, but not the contents of the region, are marked as concealable.
Whether or not they are actually concealed depends on the setting on the
'conceallevel' option. The ends of a region can only be concealed separately

in this way when they have their own highlighting via "matchgroup"

cchar :syn-cchar
E844

The "cchar" argument defines the character shown in place of the item when it is concealed (setting "cchar" only makes sense when the conceal argument is given.) If "cchar" is not set then the default conceal character defined in the 'listchars' option is used. The character cannot be a control character such as Tab. Example:

```
:syntax match Entity "&amp;" conceal cchar=&
```

See hl-Conceal for highlighting.

contained :syn-contained

When the "contained" argument is given, this item will not be recognized at the top level, but only when it is mentioned in the "contains" field of another match. Example:

```
:syntax keyword Todo    TODO    contained
:syntax match   Comment "//.*"  contains=Todo
```

display :syn-display

If the "display" argument is given, this item will be skipped when the detected highlighting will not be displayed. This will speed up highlighting, by skipping this item when only finding the syntax state for the text that is to be displayed.

Generally, you can use "display" for match and region items that meet these conditions:
- The item does not continue past the end of a line. Example for C: A region for a "/*" comment can't contain "display", because it continues on the next line.
- The item does not contain items that continue past the end of the line or make it continue on the next line.
- The item does not change the size of any item it is contained in. Example for C: A match with "\\$" in a preprocessor match can't have "display", because it may make that preprocessor match shorter.
- The item does not allow other items to match that didn't match otherwise, and that item may extend the match too far. Example for C: A match for a "//" comment can't use "display", because a "/*" inside that comment would match then and start a comment which extends past the end of the line.

Examples, for the C language, where "display" can be used:
- match with a number
- match with a label

transparent :syn-transparent

If the "transparent" argument is given, this item will not be highlighted itself, but will take the highlighting of the item it is contained in. This is useful for syntax items that don't need any highlighting but are used only to skip over a part of the text.

The "contains=" argument is also inherited from the item it is contained in, unless a "contains" argument is given for the transparent item itself. To avoid that unwanted items are contained, use "contains=NONE". Example, which highlights words in strings, but makes an exception for "vim":

```
:syn match myString /'[^']*'/ contains=myWord,myVim
:syn match myWord   /\<[a-z]*\>/ contained
:syn match myVim    /\<vim\>/ transparent contained contains=NONE
:hi link myString String
:hi link myWord   Comment
```

Since the "myVim" match comes after "myWord" it is the preferred match (last match in the same position overrules an earlier one). The "transparent" argument makes the "myVim" match use the same highlighting as "myString". But it does not contain anything. If the "contains=NONE" argument would be left out, then "myVim" would use the contains argument from myString and allow "myWord" to be contained, which will be highlighted as a Constant. This happens because a contained match doesn't match inside itself in the same position, thus the "myVim" match doesn't overrule the "myWord" match here.

When you look at the colored text, it is like looking at layers of contained items. The contained item is on top of the item it is contained in, thus you see the contained item. When a contained item is transparent, you can look through, thus you see the item it is contained in. In a picture:

```
               look from here

           |   |   |   |   |   |
           V   V   V   V   V   V

              xxxx       yyy          more contained items
           .....................       contained item (transparent)
       ============================    first item
```

The 'x', 'y' and '=' represent a highlighted syntax item. The '.' represent a transparent group.

What you see is:

```
       =======xxxx=======yyy========
```

Thus you look through the transparent "....".

oneline :syn-oneline

The "oneline" argument indicates that the region does not cross a line boundary. It must match completely in the current line. However, when the region has a contained item that does cross a line boundary, it continues on the next line anyway. A contained item can be used to recognize a line continuation pattern. But the "end" pattern must still match in the first line, otherwise the region doesn't even start.

When the start pattern includes a "\n" to match an end-of-line, the end pattern must be found in the same line as where the start pattern ends. The

end pattern may also include an end-of-line. Thus the "oneline" argument means that the end of the start pattern and the start of the end pattern must be within one line. This can't be changed by a skip pattern that matches a line break.

fold   :syn-fold

The "fold" argument makes the fold level increase by one for this item. Example:

```
:syn region myFold start="{" end="}" transparent fold
:syn sync fromstart
:set foldmethod=syntax
```

This will make each {} block form one fold.

The fold will start on the line where the item starts, and end where the item ends. If the start and end are within the same line, there is no fold. The 'foldnestmax' option limits the nesting of syntax folds.
{not available when Vim was compiled without |+folding| feature}

:syn-contains E405 E406 E407 E408 E409

contains={group-name},..

The "contains" argument is followed by a list of syntax group names. These groups will be allowed to begin inside the item (they may extend past the containing group's end). This allows for recursive nesting of matches and regions. If there is no "contains" argument, no groups will be contained in this item. The group names do not need to be defined before they can be used here.

contains=ALL
: If the only item in the contains list is "ALL", then all groups will be accepted inside the item.

contains=ALLBUT,{group-name},..
: If the first item in the contains list is "ALLBUT", then all groups will be accepted inside the item, except the ones that are listed. Example:

```
:syntax region Block start="{" end="}" ... contains=ALLBUT,Function
```

contains=TOP
: If the first item in the contains list is "TOP", then all groups will be accepted that don't have the "contained" argument.

contains=TOP,{group-name},..
: Like "TOP", but excluding the groups that are listed.

contains=CONTAINED
: If the first item in the contains list is "CONTAINED", then all groups will be accepted that have the "contained" argument.

contains=CONTAINED,{group-name},..
: Like "CONTAINED", but excluding the groups that are

listed.

The {group-name} in the "contains" list can be a pattern. All group names that match the pattern will be included (or excluded, if "ALLBUT" is used). The pattern cannot contain white space or a ','. Example:

```
... contains=Comment.*,Keyw[0-3]
```

The matching will be done at moment the syntax command is executed. Groups that are defined later will not be matched. Also, if the current syntax command defines a new group, it is not matched. Be careful: When putting syntax commands in a file you can't rely on groups NOT being defined, because the file may have been sourced before, and ":syn clear" doesn't remove the group names.

The contained groups will also match in the start and end patterns of a region. If this is not wanted, the "matchgroup" argument can be used :syn-matchgroup . The "ms=" and "me=" offsets can be used to change the region where contained items do match. Note that this may also limit the area that is highlighted

containedin={group-name}... :syn-containedin

The "containedin" argument is followed by a list of syntax group names. The item will be allowed to begin inside these groups. This works as if the containing item has a "contains=" argument that includes this item.

The {group-name}... can be used just like for "contains", as explained above.

This is useful when adding a syntax item afterwards. An item can be told to be included inside an already existing item, without changing the definition of that item. For example, to highlight a word in a C comment after loading the C syntax:

```
:syn keyword myword HELP containedin=cComment contained
```

Note that "contained" is also used, to avoid that the item matches at the top level.

Matches for "containedin" are added to the other places where the item can appear. A "contains" argument may also be added as usual. Don't forget that keywords never contain another item, thus adding them to "containedin" won't work.

nextgroup={group-name},.. :syn-nextgroup

The "nextgroup" argument is followed by a list of syntax group names, separated by commas (just like with "contains", so you can also use patterns).

If the "nextgroup" argument is given, the mentioned syntax groups will be tried for a match, after the match or region ends. If none of the groups have a match, highlighting continues normally. If there is a match, this group will be used, even when it is not mentioned in the "contains" field of the current group. This is like giving the mentioned group priority over all other groups. Example:

```
   :syntax match  ccFoobar  "Foo.\{-}Bar"  contains=ccFoo
   :syntax match  ccFoo     "Foo"           contained nextgroup=ccFiller
   :syntax region ccFiller  start="."  matchgroup=ccBar  end="Bar"  contained
```

This will highlight "Foo" and "Bar" differently, and only when there is a "Bar" after "Foo". In the text line below, "f" shows where ccFoo is used for highlighting, and "bbb" where ccBar is used.

```
   Foo asdfasd Bar asdf Foo asdf Bar asdf
   fff         bbb      fff      bbb
```

Note the use of ".\{-}" to skip as little as possible until the next Bar. when ".*" would be used, the "asdf" in between "Bar" and "Foo" would be highlighted according to the "ccFoobar" group, because the ccFooBar match would include the first "Foo" and the last "Bar" in the line (see pattern).

skipwhite :syn-skipwhite
skipnl :syn-skipnl
skipempty :syn-skipempty

These arguments are only used in combination with "nextgroup". They can be used to allow the next group to match after skipping some text:

skipwhite	skip over space and tab characters
skipnl	skip over the end of a line
skipempty	skip over empty lines (implies a "skipnl")

When "skipwhite" is present, the white space is only skipped if there is no next group that matches the white space.

When "skipnl" is present, the match with nextgroup may be found in the next line. This only happens when the current item ends at the end of the current line! When "skipnl" is not present, the nextgroup will only be found after the current item in the same line.

When skipping text while looking for a next group, the matches for other groups are ignored. Only when no next group matches, other items are tried for a match again. This means that matching a next group and skipping white space and <EOL>s has a higher priority than other items.

Example:

```
  :syn match ifstart "\<if.*"     nextgroup=ifline skipwhite skipempty
  :syn match ifline  "[^ \t].*" nextgroup=ifline skipwhite skipempty contained
  :syn match ifline  "endif"    contained
```

Note that the "[^ \t].*" match matches all non-white text. Thus it would also match "endif". Therefore the "endif" match is put last, so that it takes precedence.
Note that this example doesn't work for nested "if"s. You need to add "contains" arguments to make that work (omitted for simplicity of the example).

IMPLICIT CONCEAL :syn-conceal-implicit

:sy[ntax] conceal [on|off]

This defines if the following ":syntax" commands will define keywords, matches or regions with the "conceal" flag set. After ":syn conceal on", all subsequent ":syn keyword", ":syn match" or ":syn region" defined will have the "conceal" flag set implicitly. ":syn conceal off" returns to the normal state where the "conceal" flag must be given explicitly.

:sy[ntax] conceal
This defines if the following ":syntax" commands will define keywords, matches or regions with the "conceal" flag set. After ":syn conceal on", all subsequent ":syn keyword", ":syn match" or ":syn region" defined will have the "conceal" flag set implicitly. ":syn conceal off" returns to the normal state where the "conceal" flag must be given explicitly.

:sy[ntax] conceal
Show either "syntax conceal on" or "syntax conceal off" (translated).

==
7. Syntax patterns :syn-pattern E401 E402

In the syntax commands, a pattern must be surrounded by two identical characters. This is like it works for the ":s" command. The most common to use is the double quote. But if the pattern contains a double quote, you can use another character that is not used in the pattern. Examples:

```
:syntax region Comment  start="/\*"  end="\*/"
:syntax region String   start=+"+    end=+"+   skip=+\\"+
```

See pattern for the explanation of what a pattern is. Syntax patterns are always interpreted like the 'magic' option is set, no matter what the actual value of 'magic' is. And the patterns are interpreted like the 'l' flag is not included in 'cpoptions'. This was done to make syntax files portable and independent of 'compatible' and 'magic' settings.

Try to avoid patterns that can match an empty string, such as "[a-z]*". This slows down the highlighting a lot, because it matches everywhere.

:syn-pattern-offset
The pattern can be followed by a character offset. This can be used to change the highlighted part, and to change the text area included in the match or region (which only matters when trying to match other items). Both are relative to the matched pattern. The character offset for a skip pattern can be used to tell where to continue looking for an end pattern.

The offset takes the form of "{what}={offset}"
The {what} can be one of seven strings:

```
ms      Match Start     offset for the start of the matched text
me      Match End       offset for the end of the matched text
hs      Highlight Start offset for where the highlighting starts
he      Highlight End   offset for where the highlighting ends
rs      Region Start    offset for where the body of a region starts
re      Region End      offset for where the body of a region ends
lc      Leading Context offset past "leading context" of pattern
```

The {offset} can be:

```
s       start of the matched pattern
s+{nr}  start of the matched pattern plus {nr} chars to the right
s-{nr}  start of the matched pattern plus {nr} chars to the left
e       end of the matched pattern
e+{nr}  end of the matched pattern plus {nr} chars to the right
```

e-{nr} end of the matched pattern plus {nr} chars to the left
{nr}   (for "lc" only): start matching {nr} chars right of the start

Examples: "ms=s+1", "hs=e-2", "lc=3".

Although all offsets are accepted after any pattern, they are not always
meaningful. This table shows which offsets are actually used:

```
                    ms   me   hs   he   rs   re   lc
match item          yes  yes  yes  yes  -    -    yes
region item start   yes  -    yes  -    yes  -    yes
region item skip    -    yes  -    -    -    -    yes
region item end     -    yes  -    yes  -    yes  yes
```

Offsets can be concatenated, with a ',' in between. Example:
```
  :syn match String  /"[^"]*"/hs=s+1,he=e-1

    some "string" text
         ^^^^^^               highlighted
```

Notes:
- There must be no white space between the pattern and the character
  offset(s).
- The highlighted area will never be outside of the matched text.
- A negative offset for an end pattern may not always work, because the end
  pattern may be detected when the highlighting should already have stopped.
- Before Vim 7.2 the offsets were counted in bytes instead of characters.
  This didn't work well for multi-byte characters, so it was changed with the
  Vim 7.2 release.
- The start of a match cannot be in a line other than where the pattern
  matched. This doesn't work: "a\nb"ms=e. You can make the highlighting
  start in another line, this does work: "a\nb"hs=e.

Example (match a comment but don't highlight the /* and */):
```
  :syntax region Comment start="/\*"hs=e+1 end="\*/"he=s-1

        /* this is a comment */
          ^^^^^^^^^^^^^^^^^^     highlighted
```

A more complicated Example:
```
  :syn region Exa matchgroup=Foo start="foo"hs=s+2,rs=e+2 matchgroup=Bar end="bar"me=e-1,he

         abcfoostringbarabc
            mmmmmmmmmmm     match
              sssrrreee     highlight start/region/end ("Foo", "Exa" and "Bar")
```

Leading context   :syn-lc   :syn-leading   :syn-context

Note: This is an obsolete feature, only included for backwards compatibility
with previous Vim versions. It's now recommended to use the /\@<= construct
in the pattern.

The "lc" offset specifies leading context -- a part of the pattern that must
be present, but is not considered part of the match. An offset of "lc=n" will

cause Vim to step back n columns before attempting the pattern match, allowing characters which have already been matched in previous patterns to also be used as leading context for this match. This can be used, for instance, to specify that an "escaping" character must not precede the match:

```
:syn match ZNoBackslash "[^\\]z"ms=s+1
:syn match WNoBackslash "[^\\]w"lc=1
:syn match Underline "_\+"

        ___zzzz ___wwww
        ^^^     ^^^     matches Underline
            ^ ^         matches ZNoBackslash
                  ^^^^  matches WNoBackslash
```

The "ms" offset is automatically set to the same value as the "lc" offset, unless you set "ms" explicitly.

Multi-line patterns :syn-multi-line

The patterns can include "\n" to match an end-of-line. Mostly this works as expected, but there are a few exceptions.

When using a start pattern with an offset, the start of the match is not allowed to start in a following line. The highlighting can start in a following line though. Using the "\zs" item also requires that the start of the match doesn't move to another line.

The skip pattern can include the "\n", but the search for an end pattern will continue in the first character of the next line, also when that character is matched by the skip pattern. This is because redrawing may start in any line halfway a region and there is no check if the skip pattern started in a previous line. For example, if the skip pattern is "a\nb" and an end pattern is "b", the end pattern does match in the second line of this:

```
x x a
b x x
```

Generally this means that the skip pattern should not match any characters after the "\n".

External matches :syn-ext-match

These extra regular expression items are available in region patterns:

/\z(/\z(\) E50 E52 E879

\z(\) Marks the sub-expression as "external", meaning that it can be accessed from another pattern match. Currently only usable in defining a syntax region start pattern.

/\z1 /\z2 /\z3 /\z4 /\z5
/\z6 /\z7 /\z8 /\z9 E66 E67

\z1 ... \z9 Matches the same string that was matched by the corresponding sub-expression in a previous start pattern match.

Sometimes the start and end patterns of a region need to share a common sub-expression. A common example is the "here" document in Perl and many Unix shells. This effect can be achieved with the "\z" special regular expression items, which marks a sub-expression as "external", in the sense that it can be referenced from outside the pattern in which it is defined. The here-document example, for instance, can be done like this:

```
:syn region hereDoc start="<<\z(\I\i*\)" end="^\z1$"
```

As can be seen here, the \z actually does double duty. In the start pattern, it marks the "\(\I\i*\)" sub-expression as external; in the end pattern, it changes the \z1 back-reference into an external reference referring to the first external sub-expression in the start pattern. External references can also be used in skip patterns:

```
:syn region foo start="start \(\I\i*\)" skip="not end \z1" end="end \z1"
```

Note that normal and external sub-expressions are completely orthogonal and indexed separately; for instance, if the pattern "\z(..\)\(..\)" is applied to the string "aabb", then \1 will refer to "bb" and \z1 will refer to "aa". Note also that external sub-expressions cannot be accessed as back-references within the same pattern like normal sub-expressions. If you want to use one sub-expression as both a normal and an external sub-expression, you can nest the two, as in "\(\z(...\)\)".

Note that only matches within a single line can be used. Multi-line matches cannot be referred to.

==
8. Syntax clusters :syn-cluster E400

```
:sy[ntax] cluster {cluster-name} [contains={group-name}..]
                                 [add={group-name}..]
                                 [remove={group-name}..]
```

This command allows you to cluster a list of syntax groups together under a single name.

```
        contains={group-name}..
                The cluster is set to the specified list of groups.
        add={group-name}..
                The specified groups are added to the cluster.
        remove={group-name}..
                The specified groups are removed from the cluster.
```

A cluster so defined may be referred to in a contains=.., containedin=.., nextgroup=.., add=.. or remove=.. list with a "@" prefix. You can also use this notation to implicitly declare a cluster before specifying its contents.

Example:

```
   :syntax match Thing "# [^#]\+ #" contains=@ThingMembers
   :syntax cluster ThingMembers contains=ThingMember1,ThingMember2
```

As the previous example suggests, modifications to a cluster are effectively retroactive; the membership of the cluster is checked at the last minute, so to speak:

```
   :syntax keyword A aaa
   :syntax keyword B bbb
   :syntax cluster AandB contains=A
   :syntax match Stuff "( aaa bbb )" contains=@AandB
   :syntax cluster AandB add=B    " now both keywords are matched in Stuff
```

This also has implications for nested clusters:

```
   :syntax keyword A aaa
   :syntax keyword B bbb
   :syntax cluster SmallGroup contains=B
   :syntax cluster BigGroup contains=A,@SmallGroup
   :syntax match Stuff "( aaa bbb )" contains=@BigGroup
   :syntax cluster BigGroup remove=B    " no effect, since B isn't in BigGroup
   :syntax cluster SmallGroup remove=B  " now bbb isn't matched within Stuff
```

E848

The maximum number of clusters is 9767.

==========

9. Including syntax files :syn-include E397

It is often useful for one language's syntax file to include a syntax file for a related language. Depending on the exact relationship, this can be done in two different ways:

- If top-level syntax items in the included syntax file are to be allowed at the top level in the including syntax, you can simply use the :runtime command:

```
  " In cpp.vim:
  :runtime! syntax/c.vim
  :unlet b:current_syntax
```

- If top-level syntax items in the included syntax file are to be contained within a region in the including syntax, you can use the ":syntax include" command:

:sy[ntax] include [@{grouplist-name}] {file-name}

All syntax items declared in the included file will have the "contained" flag added. In addition, if a group list is specified, all top-level syntax items in the included file will be added to that list.

```
   " In perl.vim:
   :syntax include @Pod <sfile>:p:h/pod.vim
   :syntax region perlPOD start="^=head" end="^=cut" contains=@Pod
```

When {file-name} is an absolute path (starts with "/", "c:", "$VAR" or "<sfile>") that file is sourced. When it is a relative path (e.g., "syntax/pod.vim") the file is searched for in 'runtimepath'. All matching files are loaded. Using a relative path is recommended, because it allows a user to replace the included file with his own version, without replacing the file that does the ":syn

include".

E847

The maximum number of includes is 999.

==
10. Synchronizing :syn-sync E403 E404

Vim wants to be able to start redrawing in any position in the document. To make this possible it needs to know the syntax state at the position where redrawing starts.

:sy[ntax] sync [ccomment [group-name] | minlines={N} | ...]

There are four ways to synchronize:
1. Always parse from the start of the file.
   :syn-sync-first
2. Based on C-style comments. Vim understands how C-comments work and can figure out if the current line starts inside or outside a comment.
   :syn-sync-second
3. Jumping back a certain number of lines and start parsing there.
   :syn-sync-third
4. Searching backwards in the text for a pattern to sync on.
   :syn-sync-fourth

:syn-sync-maxlines :syn-sync-minlines
For the last three methods, the line range where the parsing can start is limited by "minlines" and "maxlines".

If the "minlines={N}" argument is given, the parsing always starts at least that many lines backwards. This can be used if the parsing may take a few lines before it's correct, or when it's not possible to use syncing.

If the "maxlines={N}" argument is given, the number of lines that are searched for a comment or syncing pattern is restricted to N lines backwards (after adding "minlines"). This is useful if you have few things to sync on and a slow machine. Example:
```
:syntax sync maxlines=500 ccomment
```

:syn-sync-linebreaks
When using a pattern that matches multiple lines, a change in one line may cause a pattern to no longer match in a previous line. This means has to start above where the change was made. How many lines can be specified with the "linebreaks" argument. For example, when a pattern may include one line break use this:
```
:syntax sync linebreaks=1
```
The result is that redrawing always starts at least one line before where a change was made. The default value for "linebreaks" is zero. Usually the value for "minlines" is bigger than "linebreaks".

First syncing method: :syn-sync-first

```
:syntax sync fromstart
```

The file will be parsed from the start. This makes syntax highlighting
accurate, but can be slow for long files. Vim caches previously parsed text,
so that it's only slow when parsing the text for the first time. However,
when making changes some part of the text needs to be parsed again (worst
case: to the end of the file).

Using "fromstart" is equivalent to using "minlines" with a very large number.

Second syncing method: :syn-sync-second :syn-sync-ccomment

For the second method, only the "ccomment" argument needs to be given.
Example:
```
:syntax sync ccomment
```

When Vim finds that the line where displaying starts is inside a C-style
comment, the last region syntax item with the group-name "Comment" will be
used. This requires that there is a region with the group-name "Comment"!
An alternate group name can be specified, for example:
```
:syntax sync ccomment javaComment
```
This means that the last item specified with "syn region javaComment" will be
used for the detected C comment region. This only works properly if that
region does have a start pattern "\/*" and an end pattern "*\/".

The "maxlines" argument can be used to restrict the search to a number of
lines. The "minlines" argument can be used to at least start a number of
lines back (e.g., for when there is some construct that only takes a few
lines, but it hard to sync on).

Note: Syncing on a C comment doesn't work properly when strings are used
that cross a line and contain a "*/". Since letting strings cross a line
is a bad programming habit (many compilers give a warning message), and the
chance of a "*/" appearing inside a comment is very small, this restriction
is hardly ever noticed.

Third syncing method: :syn-sync-third

For the third method, only the "minlines={N}" argument needs to be given.
Vim will subtract {N} from the line number and start parsing there. This
means {N} extra lines need to be parsed, which makes this method a bit slower.
Example:
```
:syntax sync minlines=50
```

"lines" is equivalent to "minlines" (used by older versions).

Fourth syncing method: :syn-sync-fourth

The idea is to synchronize on the end of a few specific regions, called a
sync pattern. Only regions can cross lines, so when we find the end of some
region, we might be able to know in which syntax item we are. The search
starts in the line just above the one where redrawing starts. From there

the search continues backwards in the file.

This works just like the non-syncing syntax items. You can use contained matches, nextgroup, etc. But there are a few differences:
- Keywords cannot be used.
- The syntax items with the "sync" keyword form a completely separated group of syntax items. You can't mix syncing groups and non-syncing groups.
- The matching works backwards in the buffer (line by line), instead of forwards.
- A line continuation pattern can be given. It is used to decide which group of lines need to be searched like they were one line. This means that the search for a match with the specified items starts in the first of the consecutive that contain the continuation pattern.
- When using "nextgroup" or "contains", this only works within one line (or group of continued lines).
- When using a region, it must start and end in the same line (or group of continued lines). Otherwise the end is assumed to be at the end of the line (or group of continued lines).
- When a match with a sync pattern is found, the rest of the line (or group of continued lines) is searched for another match. The last match is used. This is used when a line can contain both the start end the end of a region (e.g., in a C-comment like /* this */, the last "*/" is used).

There are two ways how a match with a sync pattern can be used:
1. Parsing for highlighting starts where redrawing starts (and where the search for the sync pattern started). The syntax group that is expected to be valid there must be specified. This works well when the regions that cross lines cannot contain other regions.
2. Parsing for highlighting continues just after the match. The syntax group that is expected to be present just after the match must be specified. This can be used when the previous method doesn't work well. It's much slower, because more text needs to be parsed.

Both types of sync patterns can be used at the same time.

Besides the sync patterns, other matches and regions can be specified, to avoid finding unwanted matches.

[The reason that the sync patterns are given separately, is that mostly the search for the sync point can be much simpler than figuring out the highlighting. The reduced number of patterns means it will go (much) faster.]

syn-sync-grouphere E393 E394

:syntax sync match {sync-group-name} grouphere {group-name} "pattern" ..

Define a match that is used for syncing. {group-name} is the name of a syntax group that follows just after the match. Parsing of the text for highlighting starts just after the match. A region must exist for this {group-name}. The first one defined will be used. "NONE" can be used for when there is no syntax group after the match.

syn-sync-groupthere

:syntax sync match {sync-group-name} groupthere {group-name} "pattern" ..

Like "grouphere", but {group-name} is the name of a syntax group that is to be used at the start of the line where searching for the sync point started. The text between the match and the start of the sync pattern searching is assumed not to change the syntax highlighting. For example, in C you could search backwards for "/*" and "*/". If "/*" is found first, you know that you are inside a comment, so the "groupthere" is "cComment". If "*/" is found first, you know that you are not in a comment, so the "groupthere" is "NONE". (in practice it's a bit more complicated, because the "/*" and "*/" could appear inside a string. That's left as an exercise to the reader...).

:syntax sync match ..
:syntax sync region ..

Without a "groupthere" argument. Define a region or match that is skipped while searching for a sync point.

syn-sync-linecont

:syntax sync linecont {pattern}

When {pattern} matches in a line, it is considered to continue in the next line. This means that the search for a sync point will consider the lines to be concatenated.

If the "maxlines={N}" argument is given too, the number of lines that are searched for a match is restricted to N. This is useful if you have very few things to sync on and a slow machine. Example:

```
:syntax sync maxlines=100
```

You can clear all sync settings with:

```
:syntax sync clear
```

You can clear specific sync patterns with:

```
:syntax sync clear {sync-group-name} ..
```

==

11. Listing syntax items :syntax :sy :syn :syn-list

This command lists all the syntax items:

:sy[ntax] [list]

To show the syntax items for one syntax group:

:sy[ntax] list {group-name}

To list the syntax groups in one cluster: E392

:sy[ntax] list @{cluster-name}

See above for other arguments for the ":syntax" command.

Note that the ":syntax" command can be abbreviated to ":sy", although ":syn" is mostly used, because it looks better.

==
12. Highlight command   :highlight   :hi   E28   E411   E415

There are three types of highlight groups:
- The ones used for specific languages. For these the name starts with the
  name of the language. Many of these don't have any attributes, but are
  linked to a group of the second type.
- The ones used for all syntax languages.
- The ones used for the 'highlight' option.
                                                              hitest.vim
You can see all the groups currently active with this command:
    :so $VIMRUNTIME/syntax/hitest.vim
This will open a new window containing all highlight group names, displayed
in their own color.

                                                  :colo   :colorscheme   E185
:colo[rscheme]   Output the name of the currently active color scheme.
                        This is basically the same as
                                :echo g:colors_name
                       In case g:colors_name has not been defined :colo will
                        output "default". When compiled without the +eval
                        feature it will output "unknown".

:colo[rscheme] {name}   Load color scheme {name}. This searches 'runtimepath'
                        for the file "colors/{name}.vim". The first one that
                        is found is loaded.
                        Also searches all plugins in 'packpath', first below
                        "start" and then under "opt".

                        Doesn't work recursively, thus you can't use
                        ":colorscheme" in a color scheme script.

                        To customize a colorscheme use another name, e.g.
                        "~/.vim/colors/mine.vim", and use `:runtime` to load
                        the original colorscheme:
                                runtime colors/evening.vim
                                hi Statement ctermfg=Blue guifg=Blue

                       Before the color scheme will be loaded the
                         ColorSchemePre autocommand event is triggered.
                        After the color scheme has been loaded the
                         ColorScheme autocommand event is triggered.
                        For info about writing a colorscheme file:
                                :edit $VIMRUNTIME/colors/README.txt

:hi[ghlight]   List all the current highlight groups that have
                        attributes set.

:hi[ghlight] {group-name}
                        List one highlight group.

:hi[ghlight] clear   Reset all highlighting to the defaults. Removes all
                        highlighting for groups added by the user!

Uses the current value of 'background' to decide which
default colors to use.

:hi[ghlight] clear {group-name}
:hi[ghlight] {group-name} NONE
Disable the highlighting for one highlight group. It
is _not_ set back to the default colors.

:hi[ghlight] [default] {group-name} {key}={arg} ..
Add a highlight group, or change the highlighting for
an existing group.
See highlight-args for the {key}={arg} arguments.
See :highlight-default for the optional [default]
argument.

Normally a highlight group is added once when starting up. This sets the
default values for the highlighting. After that, you can use additional
highlight commands to change the arguments that you want to set to non-default
values. The value "NONE" can be used to switch the value off or go back to
the default value.

A simple way to change colors is with the :colorscheme command. This loads
a file with ":highlight" commands such as this:

```
:hi Comment  gui=bold
```

Note that all settings that are not included remain the same, only the
specified field is used, and settings are merged with previous ones. So, the
result is like this single command has been used:

```
:hi Comment  term=bold ctermfg=Cyan guifg=#80a0ff gui=bold
```

:highlight-verbose
When listing a highlight group and 'verbose' is non-zero, the listing will
also tell where it was last set. Example:

```
:verbose hi Comment
Comment        xxx term=bold ctermfg=4 guifg=Blue
    Last set from /home/mool/vim/vim7/runtime/syntax/syncolor.vim
```

When ":hi clear" is used then the script where this command is used will be
mentioned for the default values. See :verbose-cmd for more information.

highlight-args E416 E417 E423
There are three types of terminals for highlighting:
term a normal terminal (vt100, xterm)
cterm a color terminal (MS-DOS console, color-xterm, these have the "Co"
termcap entry)
gui the GUI

For each type the highlighting can be given. This makes it possible to use
the same syntax file on all terminals, and use the optimal highlighting.

1. highlight arguments for normal terminals

bold underline undercurl

                                        inverse   italic   standout
                                        nocombine   strikethrough
term={attr-list}   attr-list   highlight-term   E418
        attr-list is a comma separated list (without spaces) of the
        following items (in any order):
                bold
                underline
                undercurl   not always available
                strikethrough   not always available
                reverse
                inverse   same as reverse
                italic
                standout
                nocombine   override attributes instead of combining them
                NONE   no attributes used (used to reset it)

        Note that "bold" can be used here and by using a bold font. They
        have the same effect.
        "undercurl" is a curly underline. When "undercurl" is not possible
        then "underline" is used. In general "undercurl" and "strikethrough"
        is only available in the GUI. The color is set with highlight-guisp .

start={term-list}   highlight-start   E422
stop={term-list}   term-list   highlight-stop
        These lists of terminal codes can be used to get
        non-standard attributes on a terminal.

        The escape sequence specified with the "start" argument
        is written before the characters in the highlighted
        area. It can be anything that you want to send to the
        terminal to highlight this area. The escape sequence
        specified with the "stop" argument is written after the
        highlighted area. This should undo the "start" argument.
        Otherwise the screen will look messed up.

        The {term-list} can have two forms:

        1. A string with escape sequences.
           This is any string of characters, except that it can't start with
           "t_" and blanks are not allowed. The <> notation is recognized
           here, so you can use things like "<Esc>" and "<Space>". Example:
                start=<Esc>[27h;<Esc>[<Space>r;

        2. A list of terminal codes.
           Each terminal code has the form "t_xx", where "xx" is the name of
           the termcap entry. The codes have to be separated with commas.
           White space is not allowed. Example:
                start=t_C1,t_BL
           The terminal codes must exist for this to work.

2. highlight arguments for color terminals

cterm={attr-list}   highlight-cterm

See above for the description of {attr-list} attr-list .
The "cterm" argument is likely to be different from "term", when
colors are used. For example, in a normal terminal comments could
be underlined, in a color terminal they can be made Blue.
Note: Many terminals (e.g., DOS console) can't mix these attributes
with coloring. Use only one of "cterm=" OR "ctermfg=" OR "ctermbg=".

ctermfg={color-nr} highlight-ctermfg E421
ctermbg={color-nr} highlight-ctermbg
The {color-nr} argument is a color number. Its range is zero to
(not including) the number given by the termcap entry "Co".
The actual color with this number depends on the type of terminal
and its settings. Sometimes the color also depends on the settings of
"cterm". For example, on some systems "cterm=bold ctermfg=3" gives
another color, on others you just get color 3.

For an xterm this depends on your resources, and is a bit
unpredictable. See your xterm documentation for the defaults. The
colors for a color-xterm can be changed from the .Xdefaults file.
Unfortunately this means that it's not possible to get the same colors
for each user. See xterm-color for info about color xterms.

The MSDOS standard colors are fixed (in a console window), so these
have been used for the names. But the meaning of color names in X11
are fixed, so these color settings have been used, to make the
highlighting settings portable (complicated, isn't it?). The
following names are recognized, with the color number used:

cterm-colors

NR-16	NR-8	COLOR NAME
0	0	Black
1	4	DarkBlue
2	2	DarkGreen
3	6	DarkCyan
4	1	DarkRed
5	5	DarkMagenta
6	3	Brown, DarkYellow
7	7	LightGray, LightGrey, Gray, Grey
8	0*	DarkGray, DarkGrey
9	4*	Blue, LightBlue
10	2*	Green, LightGreen
11	6*	Cyan, LightCyan
12	1*	Red, LightRed
13	5*	Magenta, LightMagenta
14	3*	Yellow, LightYellow
15	7*	White

The number under "NR-16" is used for 16-color terminals ('t_Co'
greater than or equal to 16). The number under "NR-8" is used for
8-color terminals ('t_Co' less than 16). The '*' indicates that the
bold attribute is set for ctermfg. In many 8-color terminals (e.g.,
"linux"), this causes the bright colors to appear. This doesn't work
for background colors! Without the '*' the bold attribute is removed.
If you want to set the bold attribute in a different way, put a

"cterm=" argument AFTER the "ctermfg=" or "ctermbg=" argument. Or use a number instead of a color name.

The case of the color names is ignored.
Note that for 16 color ansi style terminals (including xterms), the numbers in the NR-8 column is used. Here '*' means 'add 8' so that Blue is 12, DarkGray is 8 etc.

Note that for some color terminals these names may result in the wrong colors!

You can also use "NONE" to remove the color.

:hi-normal-cterm
When setting the "ctermfg" or "ctermbg" colors for the Normal group, these will become the colors used for the non-highlighted text.
Example:
```
:highlight Normal ctermfg=grey ctermbg=darkblue
```
When setting the "ctermbg" color for the Normal group, the 'background' option will be adjusted automatically, under the condition that the color is recognized and 'background' was not set explicitly. This causes the highlight groups that depend on 'background' to change! This means you should set the colors for Normal first, before setting other colors.
When a colorscheme is being used, changing 'background' causes it to be reloaded, which may reset all colors (including Normal). First delete the "g:colors_name" variable when you don't want this.

When you have set "ctermfg" or "ctermbg" for the Normal group, Vim needs to reset the color when exiting. This is done with the "op" termcap entry t_op . If this doesn't work correctly, try setting the 't_op' option in your .vimrc.

E419 E420
When Vim knows the normal foreground and background colors, "fg" and "bg" can be used as color names. This only works after setting the colors for the Normal group and for the MS-DOS console. Example, for reverse video:
```
:highlight Visual ctermfg=bg ctermbg=fg
```
Note that the colors are used that are valid at the moment this command are given. If the Normal group colors are changed later, the "fg" and "bg" colors will not be adjusted.

3. highlight arguments for the GUI

gui={attr-list} highlight-gui
These give the attributes to use in the GUI mode.
See attr-list for a description.
Note that "bold" can be used here and by using a bold font. They have the same effect.
Note that the attributes are ignored for the "Normal" group.

font={font-name} highlight-font
font-name is the name of a font, as it is used on the system Vim

runs on. For X11 this is a complicated name, for example:
font=-misc-fixed-bold-r-normal--14-130-75-75-c-70-iso8859-1

The font-name "NONE" can be used to revert to the default font.
When setting the font for the "Normal" group, this becomes the default
font (until the 'guifont' option is changed; the last one set is
used).
The following only works with Motif and Athena, not with other GUIs:
When setting the font for the "Menu" group, the menus will be changed.
When setting the font for the "Tooltip" group, the tooltips will be
changed.
All fonts used, except for Menu and Tooltip, should be of the same
character size as the default font! Otherwise redrawing problems will
occur.
To use a font name with an embedded space or other special character,
put it in single quotes. The single quote cannot be used then.
Example:
    :hi comment font='Monospace 10'

guifg={color-name}   highlight-guifg
guibg={color-name}   highlight-guibg
guisp={color-name}   highlight-guisp
These give the foreground (guifg), background (guibg) and special
(guisp) color to use in the GUI. "guisp" is used for undercurl and
strikethrough.
There are a few special names:
        NONE   no color (transparent)
        bg   use normal background color
        background   use normal background color
        fg   use normal foreground color
        foreground   use normal foreground color
To use a color name with an embedded space or other special character,
put it in single quotes. The single quote cannot be used then.
Example:
    :hi comment guifg='salmon pink'

                                                            gui-colors
Suggested color names (these are available on most systems):
    Red   LightRed   DarkRed
    Green   LightGreen   DarkGreen   SeaGreen
    Blue   LightBlue   DarkBlue   SlateBlue
    Cyan   LightCyan   DarkCyan
    Magenta   LightMagenta   DarkMagenta
    Yellow   LightYellow   Brown   DarkYellow
    Gray   LightGray   DarkGray
    Black   White
    Orange   Purple   Violet

In the Win32 GUI version, additional system colors are available. See
 win32-colors .

You can also specify a color by its Red, Green and Blue values.
The format is "#rrggbb", where
        "rr"   is the Red value

"gg"   is the Green value
"bb"   is the Blue value
All values are hexadecimal, range from "00" to "ff". Examples:
:highlight Comment guifg=#11f0c3 guibg=#ff00ff

highlight-groups highlight-default
These are the default highlighting groups. These groups are used by the 'highlight' option default. Note that the highlighting depends on the value of 'background'. You can see the current settings with the ":highlight" command.

hl-ColorColumn
ColorColumn used for the columns set with 'colorcolumn'

hl-Conceal
Conceal placeholder characters substituted for concealed text (see 'conceallevel')

hl-Cursor
Cursor the character under the cursor

hl-CursorIM
CursorIM like Cursor, but used when in IME mode CursorIM

hl-CursorColumn
CursorColumn the screen column that the cursor is in when 'cursorcolumn' is set

hl-CursorLine
CursorLine the screen line that the cursor is in when 'cursorline' is set

hl-Directory
Directory directory names (and other special names in listings)

hl-DiffAdd
DiffAdd diff mode: Added line diff.txt

hl-DiffChange
DiffChange diff mode: Changed line diff.txt

hl-DiffDelete
DiffDelete diff mode: Deleted line diff.txt

hl-DiffText
DiffText diff mode: Changed text within a changed line diff.txt

hl-EndOfBuffer
EndOfBuffer filler lines (~) after the last line in the buffer. By default, this is highlighted like hl-NonText .

hl-ErrorMsg
ErrorMsg error messages on the command line

hl-VertSplit
VertSplit the column separating vertically split windows

hl-Folded
Folded line used for closed folds

hl-FoldColumn
FoldColumn 'foldcolumn'

hl-SignColumn
SignColumn column where signs are displayed

hl-IncSearch
IncSearch 'incsearch' highlighting; also used for the text replaced with ":s///c"

hl-LineNr
LineNr Line number for ":number" and ":#" commands, and when 'number' or 'relativenumber' option is set.

hl-CursorLineNr

CursorLineNr Like LineNr when 'cursorline' or 'relativenumber' is set for the cursor line.

hl-MatchParen

MatchParen The character under the cursor or just before it, if it is a paired bracket, and its match. pi_paren.txt

hl-ModeMsg

ModeMsg 'showmode' message (e.g., "-- INSERT --")

hl-MoreMsg

MoreMsg more-prompt

hl-NonText

NonText '@' at the end of the window, characters from 'showbreak' and other characters that do not really exist in the text (e.g., ">" displayed when a double-wide character doesn't fit at the end of the line).

hl-Normal

Normal normal text

hl-Pmenu

Pmenu Popup menu: normal item.

hl-PmenuSel

PmenuSel Popup menu: selected item.

hl-PmenuSbar

PmenuSbar Popup menu: scrollbar.

hl-PmenuThumb

PmenuThumb Popup menu: Thumb of the scrollbar.

hl-Question

Question hit-enter prompt and yes/no questions

hl-QuickFixLine

QuickFixLine Current quickfix item in the quickfix window.

hl-Search

Search Last search pattern highlighting (see 'hlsearch').
Also used for similar items that need to stand out.

hl-SpecialKey

SpecialKey Meta and special keys listed with ":map", also for text used to show unprintable characters in the text, 'listchars'.
Generally: text that is displayed differently from what it really is.

hl-SpellBad

SpellBad Word that is not recognized by the spellchecker. spell
This will be combined with the highlighting used otherwise.

hl-SpellCap

SpellCap Word that should start with a capital. spell
This will be combined with the highlighting used otherwise.

hl-SpellLocal

SpellLocal Word that is recognized by the spellchecker as one that is used in another region. spell
This will be combined with the highlighting used otherwise.

hl-SpellRare

SpellRare Word that is recognized by the spellchecker as one that is hardly ever used. spell
This will be combined with the highlighting used otherwise.

hl-StatusLine

StatusLine status line of current window

hl-StatusLineNC
StatusLineNC status lines of not-current windows
              Note: if this is equal to "StatusLine" Vim will use "^^^" in
              the status line of the current window.
hl-StatusLineTerm
StatusLineTerm status line of current window, if it is a terminal window.
hl-StatusLineTermNC
StatusLineTermNC status lines of not-current windows that is a terminal
              window.
hl-TabLine
TabLine   tab pages line, not active tab page label
hl-TabLineFill
TabLineFill   tab pages line, where there are no labels
hl-TabLineSel
TabLineSel   tab pages line, active tab page label
hl-Terminal
Terminal   terminal window (see terminal-size-color)
hl-Title
Title   titles for output from ":set all", ":autocmd" etc.
hl-Visual
Visual   Visual mode selection
hl-VisualNOS
VisualNOS   Visual mode selection when vim is "Not Owning the Selection".
              Only X11 Gui's gui-x11 and xterm-clipboard supports this.
hl-WarningMsg
WarningMsg   warning messages
hl-WildMenu
WildMenu   current match in 'wildmenu' completion

hl-User1 hl-User1..9 hl-User9
The 'statusline' syntax allows the use of 9 different highlights in the
statusline and ruler (via 'rulerformat'). The names are User1 to User9.

For the GUI you can use the following groups to set the colors for the menu,
scrollbars and tooltips. They don't have defaults. This doesn't work for the
Win32 GUI. Only three highlight arguments have any effect here: font, guibg,
and guifg.

hl-Menu
Menu   Current font, background and foreground colors of the menus.
              Also used for the toolbar.
              Applicable highlight arguments: font, guibg, guifg.

              NOTE: For Motif and Athena the font argument actually
              specifies a fontset at all times, no matter if 'guifontset' is
              empty, and as such it is tied to the current :language when
              set.

hl-Scrollbar
Scrollbar   Current background and foreground of the main window's
              scrollbars.
              Applicable highlight arguments: guibg, guifg.

hl-Tooltip

```
Tooltip         Current font, background and foreground of the tooltips.
                Applicable highlight arguments: font, guibg, guifg.

                NOTE: For Motif and Athena the font argument actually
                specifies a fontset at all times, no matter if 'guifontset' is
                empty, and as such it is tied to the current  :language  when
                set.

==============================================================================
13. Linking groups              :hi-link   :highlight-link   E412   E413

When you want to use the same highlighting for several syntax groups, you
can do this more easily by linking the groups into one common highlight
group, and give the color attributes only for that group.

To set a link:

    :hi[ghlight][!] [default] link {from-group} {to-group}

To remove a link:

    :hi[ghlight][!] [default] link {from-group} NONE

Notes:                                                          E414
- If the {from-group} and/or {to-group} doesn't exist, it is created.  You
  don't get an error message for a non-existing group.
- As soon as you use a ":highlight" command for a linked group, the link is
  removed.
- If there are already highlight settings for the {from-group}, the link is
  not made, unless the '!' is given.  For a ":highlight link" command in a
  sourced file, you don't get an error message.  This can be used to skip
  links for groups that already have settings.

                                            :hi-default   :highlight-default
The [default] argument is used for setting the default highlighting for a
group.  If highlighting has already been specified for the group the command
will be ignored.  Also when there is an existing link.

Using [default] is especially useful to overrule the highlighting of a
specific syntax file.  For example, the C syntax file contains:
        :highlight default link cComment Comment
If you like Question highlighting for C comments, put this in your vimrc file:
        :highlight link cComment Question
Without the "default" in the C syntax file, the highlighting would be
overruled when the syntax file is loaded.

==============================================================================
14. Cleaning up                                         :syn-clear   E391

If you want to clear the syntax stuff for the current buffer, you can use this
command:
  :syntax clear

This command should be used when you want to switch off syntax highlighting,
```

or when you want to switch to using another syntax. It's normally not needed
in a syntax file itself, because syntax is cleared by the autocommands that
load the syntax file.
The command also deletes the "b:current_syntax" variable, since no syntax is
loaded after this command.

If you want to disable syntax highlighting for all buffers, you need to remove
the autocommands that load the syntax files:
  :syntax off

What this command actually does, is executing the command
  :source $VIMRUNTIME/syntax/nosyntax.vim
See the "nosyntax.vim" file for details. Note that for this to work
$VIMRUNTIME must be valid. See $VIMRUNTIME .

To clean up specific syntax groups for the current buffer:
  :syntax clear {group-name} ..
This removes all patterns and keywords for {group-name}.

To clean up specific syntax group lists for the current buffer:
  :syntax clear @{grouplist-name} ..
This sets {grouplist-name}'s contents to an empty list.

                                                    :syntax-reset   :syn-reset
If you have changed the colors and messed them up, use this command to get the
defaults back:

  :syntax reset

It is a bit of a wrong name, since it does not reset any syntax items, it only
affects the highlighting.

This doesn't change the colors for the 'highlight' option.

Note that the syntax colors that you set in your vimrc file will also be reset
back to their Vim default.
Note that if you are using a color scheme, the colors defined by the color
scheme for syntax highlighting will be lost.

What this actually does is:

        let g:syntax_cmd = "reset"
        runtime! syntax/syncolor.vim

Note that this uses the 'runtimepath' option.

                                                              syncolor
If you want to use different colors for syntax highlighting, you can add a Vim
script file to set these colors. Put this file in a directory in
'runtimepath' which comes after $VIMRUNTIME, so that your settings overrule
the default colors. This way these colors will be used after the ":syntax
reset" command.

For Unix you can use the file ~/.vim/after/syntax/syncolor.vim. Example:

```
        if &background == "light"
          highlight comment ctermfg=darkgreen guifg=darkgreen
        else
          highlight comment ctermfg=green guifg=green
        endif
```

E679

Do make sure this syncolor.vim script does not use a "syntax on", set the 'background' option or uses a "colorscheme" command, because it results in an endless loop.

Note that when a color scheme is used, there might be some confusion whether your defined colors are to be used or the colors from the scheme. This depends on the color scheme file. See :colorscheme .

syntax_cmd

The "syntax_cmd" variable is set to one of these values when the syntax/syncolor.vim files are loaded:

"on"	":syntax on" command. Highlight colors are overruled but links are kept
"enable"	":syntax enable" command. Only define colors for groups that don't have highlighting yet. Use ":syntax default".
"reset"	":syntax reset" command or loading a color scheme. Define all the colors.
"skip"	Don't define colors. Used to skip the default settings when a syncolor.vim file earlier in 'runtimepath' has already set them.

==

15. Highlighting tags tag-highlight

If you want to highlight all the tags in your file, you can use the following mappings.

```
        <F11>   -- Generate tags.vim file, and highlight tags.
        <F12>   -- Just highlight tags based on existing tags.vim file.

  :map <F11>  :sp tags<CR>:%s/^\([^     :]*:\)\=\([^    ]*\).*/syntax keyword Tag \2/<CR>:w
  :map <F12>  :so tags.vim<CR>
```

WARNING: The longer the tags file, the slower this will be, and the more memory Vim will consume.

Only highlighting typedefs, unions and structs can be done too. For this you must use Exuberant ctags (found at http://ctags.sf.net).

Put these lines in your Makefile:

```
# Make a highlight file for types.  Requires Exuberant ctags and awk
types: types.vim
types.vim: *.[ch]
        ctags --c-kinds=gstu -o- *.[ch] |\
                awk 'BEGIN{printf("syntax keyword Type\t")}\
```

```
                    {printf("%s ", $$1)}END{print ""}' > $@
```

And put these lines in your .vimrc:

```
   " load the types.vim highlighting file, if it exists
   autocmd BufRead,BufNewFile *.[ch] let fname = expand('<afile>:p:h') . '/types.vim'
   autocmd BufRead,BufNewFile *.[ch] if filereadable(fname)
   autocmd BufRead,BufNewFile *.[ch]   exe 'so ' . fname
   autocmd BufRead,BufNewFile *.[ch] endif
```

==
16. Window-local syntax   :ownsyntax

Normally all windows on a buffer share the same syntax settings. It is
possible, however, to set a particular window on a file to have its own
private syntax setting. A possible example would be to edit LaTeX source
with conventional highlighting in one window, while seeing the same source
highlighted differently (so as to hide control sequences and indicate bold,
italic etc regions) in another. The 'scrollbind' option is useful here.

To set the current window to have the syntax "foo", separately from all other
windows on the buffer:

```
   :ownsyntax foo
```

                                                        w:current_syntax
This will set the "w:current_syntax" variable to "foo". The value of
"b:current_syntax" does not change. This is implemented by saving and
restoring "b:current_syntax", since the syntax files do set
"b:current_syntax". The value set by the syntax file is assigned to
"w:current_syntax".
Note: This resets the 'spell', 'spellcapcheck' and 'spellfile' options.

Once a window has its own syntax, syntax commands executed from other windows
on the same buffer (including :syntax clear) have no effect. Conversely,
syntax commands executed from that window do not affect other windows on the
same buffer.

A window with its own syntax reverts to normal behavior when another buffer
is loaded into that window or the file is reloaded.
When splitting the window, the new window will use the original syntax.

==
17. Color xterms   xterm-color   color-xterm

Most color xterms have only eight colors. If you don't get colors with the
default setup, it should work with these lines in your .vimrc:

```
   :if &term =~ "xterm"
   :  if has("terminfo")
   :    set t_Co=8
   :    set t_Sf=<Esc>[3%p1%dm
   :    set t_Sb=<Esc>[4%p1%dm
   :  else
   :    set t_Co=8
   :    set t_Sf=<Esc>[3%dm
   :    set t_Sb=<Esc>[4%dm
```

```
   :  endif
   :endif
       [<Esc> is a real escape, type CTRL-V <Esc>]
```

You might want to change the first "if" to match the name of your terminal,
e.g. "dtterm" instead of "xterm".

Note: Do these settings BEFORE doing ":syntax on". Otherwise the colors may
be wrong.

xiterm rxvt

The above settings have been mentioned to work for xiterm and rxvt too.
But for using 16 colors in an rxvt these should work with terminfo:

```
        :set t_AB=<Esc>[%?%p1%{8}%<%t25;%p1%{40}%+%e5;%p1%{32}%+%;%dm
        :set t_AF=<Esc>[%?%p1%{8}%<%t22;%p1%{30}%+%e1;%p1%{22}%+%;%dm
```

colortest.vim

To test your color setup, a file has been included in the Vim distribution.
To use it, execute this command:

```
   :runtime syntax/colortest.vim
```

Some versions of xterm (and other terminals, like the Linux console) can
output lighter foreground colors, even though the number of colors is defined
at 8. Therefore Vim sets the "cterm=bold" attribute for light foreground
colors, when 't_Co' is 8.

xfree-xterm

To get 16 colors or more, get the newest xterm version (which should be
included with XFree86 3.3 and later). You can also find the latest version
at:

```
        http://invisible-island.net/xterm/xterm.html
```

Here is a good way to configure it. This uses 88 colors and enables the
termcap-query feature, which allows Vim to ask the xterm how many colors it
supports.

```
        ./configure --disable-bold-color --enable-88-color --enable-tcap-query
```

If you only get 8 colors, check the xterm compilation settings.
(Also see UTF8-xterm for using this xterm with UTF-8 character encoding).

This xterm should work with these lines in your .vimrc (for 16 colors):

```
   :if has("terminfo")
   :  set t_Co=16
   :  set t_AB=<Esc>[%?%p1%{8}%<%t%p1%{40}%+%e%p1%{92}%+%;%dm
   :  set t_AF=<Esc>[%?%p1%{8}%<%t%p1%{30}%+%e%p1%{82}%+%;%dm
   :else
   :  set t_Co=16
   :  set t_Sf=<Esc>[3%dm
   :  set t_Sb=<Esc>[4%dm
   :endif
       [<Esc> is a real escape, type CTRL-V <Esc>]
```

Without +terminfo , Vim will recognize these settings, and automatically
translate cterm colors of 8 and above to "<Esc>[9%dm" and "<Esc>[10%dm".
Colors above 16 are also translated automatically.

For 256 colors this has been reported to work:

```
   :set t_AB=<Esc>[48;5;%dm
   :set t_AF=<Esc>[38;5;%dm
```

Or just set the TERM environment variable to "xterm-color" or "xterm-16color"
and try if that works.

You probably want to use these X resources (in your ~/.Xdefaults file):

```
        XTerm*color0:                   #000000
        XTerm*color1:                   #c00000
        XTerm*color2:                   #008000
        XTerm*color3:                   #808000
        XTerm*color4:                   #0000c0
        XTerm*color5:                   #c000c0
        XTerm*color6:                   #008080
        XTerm*color7:                   #c0c0c0
        XTerm*color8:                   #808080
        XTerm*color9:                   #ff6060
        XTerm*color10:                  #00ff00
        XTerm*color11:                  #ffff00
        XTerm*color12:                  #8080ff
        XTerm*color13:                  #ff40ff
        XTerm*color14:                  #00ffff
        XTerm*color15:                  #ffffff
        Xterm*cursorColor:              Black
```

[Note: The cursorColor is required to work around a bug, which changes the
cursor color to the color of the last drawn text. This has been fixed by a
newer version of xterm, but not everybody is using it yet.]

To get these right away, reload the .Xdefaults file to the X Option database
Manager (you only need to do this when you just changed the .Xdefaults file):

```
  xrdb -merge ~/.Xdefaults
```

xterm-blink xterm-blinking-cursor

To make the cursor blink in an xterm, see tools/blink.c. Or use Thomas
Dickey's xterm above patchlevel 107 (see above for where to get it), with
these resources:

```
        XTerm*cursorBlink:      on
        XTerm*cursorOnTime:     400
        XTerm*cursorOffTime:    250
        XTerm*cursorColor:      White
```

hpterm-color

These settings work (more or less) for an hpterm, which only supports 8
foreground colors:

```
   :if has("terminfo")
   :  set t_Co=8
   :  set t_Sf=<Esc>[&v%p1%dS
   :  set t_Sb=<Esc>[&v7S
   :else
   :  set t_Co=8
   :  set t_Sf=<Esc>[&v%dS
   :  set t_Sb=<Esc>[&v7S
```

```
  :endif
      [<Esc> is a real escape, type CTRL-V <Esc>]
```

Eterm enlightened-terminal

These settings have been reported to work for the Enlightened terminal emulator, or Eterm. They might work for all xterm-like terminals that use the bold attribute to get bright colors. Add an ":if" like above when needed.

```
:set t_Co=16
:set t_AF=^[[%?%p1%{8}%<%t3%p1%d%e%p1%{22}%+%d;1%;m
:set t_AB=^[[%?%p1%{8}%<%t4%p1%d%e%p1%{32}%+%d;1%;m
```

TTpro-telnet

These settings should work for TTpro telnet. Tera Term Pro is a freeware / open-source program for MS-Windows.

```
set t_Co=16
set t_AB=^[[%?%p1%{8}%<%t%p1%{40}%+%e%p1%{32}%+5;%;%dm
set t_AF=^[[%?%p1%{8}%<%t%p1%{30}%+%e%p1%{22}%+1;%;%dm
```

Also make sure TTpro's Setup / Window / Full Color is enabled, and make sure that Setup / Font / Enable Bold is NOT enabled.
(info provided by John Love-Jensen <eljay@Adobe.COM>)

==

18. When syntax is slow :syntime

This is aimed at authors of a syntax file.

If your syntax causes redrawing to be slow, here are a few hints on making it faster. To see slowness switch on some features that usually interfere, such as 'relativenumber' and folding .

Note: this is only available when compiled with the +profile feature.
You many need to build Vim with "huge" features.

To find out what patterns are consuming most time, get an overview with this sequence:

```
:syntime on
[ redraw the text at least once with CTRL-L ]
:syntime report
```

This will display a list of syntax patterns that were used, sorted by the time it took to match them against the text.

:syntime on	Start measuring syntax times. This will add some overhead to compute the time spent on syntax pattern matching.
:syntime off	Stop measuring syntax times.
:syntime clear	Set all the counters to zero, restart measuring.
:syntime report	Show the syntax items used since ":syntime on" in the current window. Use a wider display to see more of the output.

The list is sorted by total time. The columns are:

TOTAL	Total time in seconds spent on matching this pattern.
COUNT	Number of times the pattern was used.
MATCH	Number of times the pattern actually matched
SLOWEST	The longest time for one try.
AVERAGE	The average time for one try.
NAME	Name of the syntax item. Note that this is not unique.
PATTERN	The pattern being used.

Pattern matching gets slow when it has to try many alternatives. Try to include as much literal text as possible to reduce the number of ways a pattern does NOT match.

When using the "\@<=" and "\@<!" items, add a maximum size to avoid trying at all positions in the current and previous line. For example, if the item is literal text specify the size of that text (in bytes):

"<\@<=span"	Matches "span" in "<span". This tries matching with "<" in many places.
"<\@1<=span"	Matches the same, but only tries one byte before "span".

vim:tw=78:sw=4:ts=8:noet:ft=help:norl:

spell.txt For Vim version 8.1. Last change: 2018 Mar 29

VIM REFERENCE MANUAL by Bram Moolenaar

Spell checking spell

1. Quick start spell-quickstart
2. Remarks on spell checking spell-remarks
3. Generating a spell file spell-mkspell
4. Spell file format spell-file-format

{Vi does not have any of these commands}

Spell checking is not available when the +syntax feature has been disabled at compile time.

Note: There also is a vimspell plugin. If you have it you can do ":help vimspell" to find about it. But you will probably want to get rid of the plugin and use the 'spell' option instead, it works better.

==========

1. Quick start spell-quickstart E756

This command switches on spell checking:

```
:setlocal spell spelllang=en_us
```

This switches on the 'spell' option and specifies to check for US English.

The words that are not recognized are highlighted with one of these:

SpellBad	word not recognized	hl-SpellBad
SpellCap	word not capitalised	hl-SpellCap
SpellRare	rare word	hl-SpellRare
SpellLocal	wrong spelling for selected region	hl-SpellLocal

Vim only checks words for spelling, there is no grammar check.

If the 'mousemodel' option is set to "popup" and the cursor is on a badly spelled word or it is "popup_setpos" and the mouse pointer is on a badly spelled word, then the popup menu will contain a submenu to replace the bad word. Note: this slows down the appearance of the popup menu. Note for GTK: don't release the right mouse button until the menu appears, otherwise it won't work.

To search for the next misspelled word:

]s

]s Move to next misspelled word after the cursor.
A count before the command can be used to repeat.
'wrapscan' applies.

[s

[s		Like "]s" but search backwards, find the misspelled
		word before the cursor. Doesn't recognize words
		split over two lines, thus may stop at words that are
		not highlighted as bad. Does not stop at word with
		missing capital at the start of a line.

]S
]S		Like "]s" but only stop at bad words, not at rare
		words or words for another region.

[S
[S		Like "]S" but search backwards.

To add words to your own word list:

zg
zg		Add word under the cursor as a good word to the first
		name in 'spellfile'. A count may precede the command
		to indicate the entry in 'spellfile' to be used. A
		count of two uses the second entry.

		In Visual mode the selected characters are added as a
		word (including white space!).
		When the cursor is on text that is marked as badly
		spelled then the marked text is used.
		Otherwise the word under the cursor, separated by
		non-word characters, is used.

		If the word is explicitly marked as bad word in
		another spell file the result is unpredictable.

zG
zG		Like "zg" but add the word to the internal word list
		 internal-wordlist .

zw
zw		Like "zg" but mark the word as a wrong (bad) word.
		If the word already appears in 'spellfile' it is
		turned into a comment line. See spellfile-cleanup
		for getting rid of those.

zW
zW		Like "zw" but add the word to the internal word list
		 internal-wordlist .

zuw
zug		Undo zw and zg , remove the word from the entry in
		'spellfile'. Count used as with zg .

zuW
zuG		Undo zW and zG , remove the word from the internal
		word list. Count used as with zg .

:spe :spellgood

:[count]spe[llgood] {word}
Add {word} as a good word to 'spellfile', like with zg . Without count the first name is used, with a count of two the second entry, etc.

:spe[llgood]! {word} Add {word} as a good word to the internal word list, like with zG .

:spellw :spellwrong

:[count]spellw[rong] {word}
Add {word} as a wrong (bad) word to 'spellfile', as with zw . Without count the first name is used, with a count of two the second entry, etc.

:spellw[rong]! {word} Add {word} as a wrong (bad) word to the internal word list, like with zW .

:[count]spellu[ndo] {word} :spellu :spellundo
Like zuw . [count] used as with :spellgood .

:spellu[ndo]! {word} Like zuW . [count] used as with :spellgood .

After adding a word to 'spellfile' with the above commands its associated ".spl" file will automatically be updated and reloaded. If you change 'spellfile' manually you need to use the :mkspell command. This sequence of commands mostly works well:

```
:edit <file in 'spellfile'>
(make changes to the spell file)
:mkspell! %
```

More details about the 'spellfile' format below spell-wordlist-format .

internal-wordlist

The internal word list is used for all buffers where 'spell' is set. It is not stored, it is lost when you exit Vim. It is also cleared when 'encoding' is set.

Finding suggestions for bad words:

z=

z= For the word under/after the cursor suggest correctly spelled words. This also works to find alternatives for a word that is not highlighted as a bad word, e.g., when the word after it is bad.
In Visual mode the highlighted text is taken as the word to be replaced.
The results are sorted on similarity to the word being replaced.
This may take a long time. Hit CTRL-C when you get bored.

If the command is used without a count the

alternatives are listed and you can enter the number of your choice or press <Enter> if you don't want to replace. You can also use the mouse to click on your choice (only works if the mouse can be used in Normal mode and when there are no line wraps). Click on the first line (the header) to cancel.

The suggestions listed normally replace a highlighted bad word. Sometimes they include other text, in that case the replaced text is also listed after a "<".

If a count is used that suggestion is used, without prompting. For example, "1z=" always takes the first suggestion.

If 'verbose' is non-zero a score will be displayed with the suggestions to indicate the likeliness to the badly spelled word (the higher the score the more different).
When a word was replaced the redo command "." will repeat the word replacement. This works like "ciw", the good word and <Esc>. This does NOT work for Thai and other languages without spaces between words.

:spellr :spellrepall E752 E753

:spellr[epall] Repeat the replacement done by z= for all matches with the replaced word in the current window.

In Insert mode, when the cursor is after a badly spelled word, you can use CTRL-X s to find suggestions. This works like Insert mode completion. Use CTRL-N to use the next suggestion, CTRL-P to go back. i_CTRL-X_s

The 'spellsuggest' option influences how the list of suggestions is generated and sorted. See 'spellsuggest' .

The 'spellcapcheck' option is used to check the first word of a sentence starts with a capital. This doesn't work for the first word in the file. When there is a line break right after a sentence the highlighting of the next line may be postponed. Use CTRL-L when needed. Also see set-spc-auto for how it can be set automatically when 'spelllang' is set.

Vim counts the number of times a good word is encountered. This is used to sort the suggestions: words that have been seen before get a small bonus, words that have been seen often get a bigger bonus. The COMMON item in the affix file can be used to define common words, so that this mechanism also works in a new or short file spell-COMMON .

==
2. Remarks on spell checking spell-remarks

PERFORMANCE

Vim does on-the-fly spell checking. To make this work fast the word list is loaded in memory. Thus this uses a lot of memory (1 Mbyte or more). There

might also be a noticeable delay when the word list is loaded, which happens when 'spell' is set and when 'spelllang' is set while 'spell' was already set. To minimize the delay each word list is only loaded once, it is not deleted when 'spelllang' is made empty or 'spell' is reset. When 'encoding' is set all the word lists are reloaded, thus you may notice a delay then too.

REGIONS

A word may be spelled differently in various regions. For example, English comes in (at least) these variants:

en	all regions
en_au	Australia
en_ca	Canada
en_gb	Great Britain
en_nz	New Zealand
en_us	USA

Words that are not used in one region but are used in another region are highlighted with SpellLocal hl-SpellLocal .

Always use lowercase letters for the language and region names.

When adding a word with zg or another command it's always added for all regions. You can change that by manually editing the 'spellfile'. See spell-wordlist-format . Note that the regions as specified in the files in 'spellfile' are only used when all entries in 'spelllang' specify the same region (not counting files specified by their .spl name).

spell-german

Specific exception: For German these special regions are used:

de	all German words accepted
de_de	old and new spelling
de_19	old spelling
de_20	new spelling
de_at	Austria
de_ch	Switzerland

spell-russian

Specific exception: For Russian these special regions are used:

ru	all Russian words accepted
ru_ru	"IE" letter spelling
ru_yo	"YO" letter spelling

spell-yiddish

Yiddish requires using "utf-8" encoding, because of the special characters used. If you are using latin1 Vim will use transliterated (romanized) Yiddish instead. If you want to use transliterated Yiddish with utf-8 use "yi-tr". In a table:

'encoding'	'spelllang'	
utf-8	yi	Yiddish
latin1	yi	transliterated Yiddish
utf-8	yi-tr	transliterated Yiddish

spell-cjk

Chinese, Japanese and other East Asian characters are normally marked as errors, because spell checking of these characters is not supported. If 'spelllang' includes "cjk", these characters are not marked as errors. This is useful when editing text with spell checking while some Asian words are present.

SPELL FILES

spell-load

Vim searches for spell files in the "spell" subdirectory of the directories in 'runtimepath'. The name is: LL.EEE.spl, where:

```
        LL      the language name
        EEE     the value of 'encoding'
```

The value for "LL" comes from 'spelllang', but excludes the region name. Examples:

```
        'spelllang'     LL
        en_us           en
        en-rare         en-rare
        medical_ca      medical
```

Only the first file is loaded, the one that is first in 'runtimepath'. If this succeeds then additionally files with the name LL.EEE.add.spl are loaded. All the ones that are found are used.

If no spell file is found the SpellFileMissing autocommand event is triggered. This may trigger the spellfile.vim plugin to offer you downloading the spell file.

Additionally, the files related to the names in 'spellfile' are loaded. These are the files that zg and zw add good and wrong words to.

Exceptions:
- Vim uses "latin1" when 'encoding' is "iso-8859-15". The euro sign doesn't matter for spelling.
- When no spell file for 'encoding' is found "ascii" is tried. This only works for languages where nearly all words are ASCII, such as English. It helps when 'encoding' is not "latin1", such as iso-8859-2, and English text is being edited. For the ".add" files the same name as the found main spell file is used.

For example, with these values:

```
        'runtimepath' is "~/.vim,/usr/share/vim70,~/.vim/after"
        'encoding'    is "iso-8859-2"
        'spelllang'   is "pl"
```

Vim will look for:

1. ~/.vim/spell/pl.iso-8859-2.spl
2. /usr/share/vim70/spell/pl.iso-8859-2.spl
3. ~/.vim/spell/pl.iso-8859-2.add.spl
4. /usr/share/vim70/spell/pl.iso-8859-2.add.spl
5. ~/.vim/after/spell/pl.iso-8859-2.add.spl

This assumes 1. is not found and 2. is found.

If 'encoding' is "latin1" Vim will look for:
1. ~/.vim/spell/pl.latin1.spl
2. /usr/share/vim70/spell/pl.latin1.spl
3. ~/.vim/after/spell/pl.latin1.spl
4. ~/.vim/spell/pl.ascii.spl
5. /usr/share/vim70/spell/pl.ascii.spl
6. ~/.vim/after/spell/pl.ascii.spl

This assumes none of them are found (Polish doesn't make sense when leaving out the non-ASCII characters).

Spelling for EBCDIC is currently not supported.

A spell file might not be available in the current 'encoding'. See spell-mkspell about how to create a spell file. Converting a spell file with "iconv" will NOT work!

Note: on VMS ".{enc}.spl" is changed to "_{enc}.spl" to avoid trouble with filenames.

spell-sug-file E781

If there is a file with exactly the same name as the ".spl" file but ending in ".sug", that file will be used for giving better suggestions. It isn't loaded before suggestions are made to reduce memory use.

E758 E759 E778 E779 E780 E782

When loading a spell file Vim checks that it is properly formatted. If you get an error the file may be truncated, modified or intended for another Vim version.

SPELLFILE CLEANUP spellfile-cleanup

The zw command turns existing entries in 'spellfile' into comment lines. This avoids having to write a new file every time, but results in the file only getting longer, never shorter. To clean up the comment lines in all ".add" spell files do this:

```
:runtime spell/cleanadd.vim
```

This deletes all comment lines, except the ones that start with "##". Use "##" lines to add comments that you want to keep.

You can invoke this script as often as you like. A variable is provided to skip updating files that have been changed recently. Set it to the number of seconds that has passed since a file was changed before it will be cleaned. For example, to clean only files that were not changed in the last hour:

```
let g:spell_clean_limit = 60 * 60
```

The default is one second.

WORDS

Vim uses a fixed method to recognize a word. This is independent of 'iskeyword', so that it also works in help files and for languages that include characters like '-' in 'iskeyword'. The word characters do depend on 'encoding'.

The table with word characters is stored in the main .spl file. Therefore it matters what the current locale is when generating it! A .add.spl file does not contain a word table though.

For a word that starts with a digit the digit is ignored, unless the word as a whole is recognized. Thus if "3D" is a word and "D" is not then "3D" is recognized as a word, but if "3D" is not a word then only the "D" is marked as bad. Hex numbers in the form 0x12ab and 0X12AB are recognized.

WORD COMBINATIONS

It is possible to spell-check words that include a space. This is used to recognize words that are invalid when used by themselves, e.g. for "et al.". It can also be used to recognize "the the" and highlight it.

The number of spaces is irrelevant. In most cases a line break may also appear. However, this makes it difficult to find out where to start checking for spelling mistakes. When you make a change to one line and only that line is redrawn Vim won't look in the previous line, thus when "et" is at the end of the previous line "al." will be flagged as an error. And when you type "the<CR>the" the highlighting doesn't appear until the first line is redrawn. Use CTRL-L to redraw right away. "[s" will also stop at a word combination with a line break.

When encountering a line break Vim skips characters such as '*', '>' and '"', so that comments in C, shell and Vim code can be spell checked.

SYNTAX HIGHLIGHTING spell-syntax

Files that use syntax highlighting can specify where spell checking should be done:

1.	everywhere	default
2.	in specific items	use "contains=@Spell"
3.	everywhere but specific items	use "contains=@NoSpell"

For the second method adding the @NoSpell cluster will disable spell checking again. This can be used, for example, to add @Spell to the comments of a program, and add @NoSpell for items that shouldn't be checked.
Also see :syn-spell for text that is not in a syntax item.

VIM SCRIPTS

If you want to write a Vim script that does something with spelling, you may find these functions useful:

```
    spellbadword()      find badly spelled word at the cursor
    spellsuggest()      get list of spelling suggestions
    soundfold()         get the sound-a-like version of a word
```

SETTING 'spellcapcheck' AUTOMATICALLY *set-spc-auto*

After the 'spelllang' option has been set successfully, Vim will source the files "spell/LANG.vim" in 'runtimepath'. "LANG" is the value of 'spelllang' up to the first comma, dot or underscore. This can be used to set options specifically for the language, especially 'spellcapcheck'.

The distribution includes a few of these files. Use this command to see what they do:

```
:next $VIMRUNTIME/spell/*.vim
```

Note that the default scripts don't set 'spellcapcheck' if it was changed from the default value. This assumes the user prefers another value then.

DOUBLE SCORING *spell-double-scoring*

The 'spellsuggest' option can be used to select "double" scoring. This mechanism is based on the principle that there are two kinds of spelling mistakes:

1. You know how to spell the word, but mistype something. This results in a small editing distance (character swapped/omitted/inserted) and possibly a word that sounds completely different.

2. You don't know how to spell the word and type something that sounds right. The edit distance can be big but the word is similar after sound-folding.

Since scores for these two mistakes will be very different we use a list for each and mix them.

The sound-folding is slow and people that know the language won't make the second kind of mistakes. Therefore 'spellsuggest' can be set to select the preferred method for scoring the suggestions.

==========

3. Generating a spell file *spell-mkspell*

Vim uses a binary file format for spelling. This greatly speeds up loading the word list and keeps it small.

.aff *.dic* *Myspell*

You can create a Vim spell file from the .aff and .dic files that Myspell uses. Myspell is used by OpenOffice.org and Mozilla. The OpenOffice .oxt files are zip files which contain the .aff and .dic files. You should be able to find them here:

http://extensions.services.openoffice.org/dictionary

The older, OpenOffice 2 files may be used if this doesn't work:

http://wiki.services.openoffice.org/wiki/Dictionaries

You can also use a plain word list. The results are the same, the choice
depends on what word lists you can find.

If you install Aap (from www.a-a-p.org) you can use the recipes in the
runtime/spell/??/ directories. Aap will take care of downloading the files,
apply patches needed for Vim and build the .spl file.

Make sure your current locale is set properly, otherwise Vim doesn't know what
characters are upper/lower case letters. If the locale isn't available (e.g.,
when using an MS-Windows codepage on Unix) add tables to the .aff file
 spell-affix-chars . If the .aff file doesn't define a table then the word
table of the currently active spelling is used. If spelling is not active
then Vim will try to guess.

                                                        :mksp   :mkspell
:mksp[ell][!] [-ascii] {outname} {inname} ...
                        Generate a Vim spell file from word lists. Example:
                :mkspell /tmp/nl nl_NL.words
                                                                E751
                        When {outname} ends in ".spl" it is used as the output
                        file name. Otherwise it should be a language name,
                        such as "en", without the region name. The file
                        written will be "{outname}.{encoding}.spl", where
                        {encoding} is the value of the 'encoding' option.

                        When the output file already exists [!] must be used
                        to overwrite it.

                        When the [-ascii] argument is present, words with
                        non-ascii characters are skipped. The resulting file
                        ends in "ascii.spl".

                        The input can be the Myspell format files {inname}.aff
                        and {inname}.dic. If {inname}.aff does not exist then
                        {inname} is used as the file name of a plain word
                        list.

                        Multiple {inname} arguments can be given to combine
                        regions into one Vim spell file. Example:
              :mkspell ~/.vim/spell/en /tmp/en_US /tmp/en_CA /tmp/en_AU
                       This combines the English word lists for US, CA and AU
                        into one en.spl file.
                        Up to eight regions can be combined. E754   E755
                        The REP and SAL items of the first .aff file where
                        they appear are used. spell-REP   spell-SAL
                                                                E845
                        This command uses a lot of memory, required to find
                        the optimal word tree (Polish, Italian and Hungarian
                        require several hundred Mbyte). The final result will
                        be much smaller, because compression is used. To
                        avoid running out of memory compression will be done
                        now and then. This can be tuned with the 'mkspellmem'
                        option.

After the spell file was written and it was being used
in a buffer it will be reloaded automatically.

:mksp[ell] [-ascii] {name}.{enc}.add
Like ":mkspell" above, using {name}.{enc}.add as the
input file and producing an output file in the same
directory that has ".spl" appended.

:mksp[ell] [-ascii] {name}
Like ":mkspell" above, using {name} as the input file
and producing an output file in the same directory
that has ".{enc}.spl" appended.

Vim will report the number of duplicate words. This might be a mistake in the list of words. But sometimes it is used to have different prefixes and suffixes for the same basic word to avoid them combining (e.g. Czech uses this). If you want Vim to report all duplicate words set the 'verbose' option.

Since you might want to change a Myspell word list for use with Vim the following procedure is recommended:

1. Obtain the xx_YY.aff and xx_YY.dic files from Myspell.
2. Make a copy of these files to xx_YY.orig.aff and xx_YY.orig.dic.
3. Change the xx_YY.aff and xx_YY.dic files to remove bad words, add missing words, define word characters with FOL/LOW/UPP, etc. The distributed "*.diff" files can be used.
4. Start Vim with the right locale and use :mkspell to generate the Vim spell file.
5. Try out the spell file with ":set spell spelllang=xx" if you wrote it in a spell directory in 'runtimepath', or ":set spelllang=xx.enc.spl" if you wrote it somewhere else.

When the Myspell files are updated you can merge the differences:
1. Obtain the new Myspell files as xx_YY.new.aff and xx_UU.new.dic.
2. Use Vimdiff to see what changed:
vimdiff xx_YY.orig.dic xx_YY.new.dic
3. Take over the changes you like in xx_YY.dic.
You may also need to change xx_YY.aff.
4. Rename xx_YY.new.dic to xx_YY.orig.dic and xx_YY.new.aff to xx_YY.new.aff.

SPELL FILE VERSIONS E770 E771 E772

Spell checking is a relatively new feature in Vim, thus it's possible that the .spl file format will be changed to support more languages. Vim will check the validity of the spell file and report anything wrong.

E771: Old spell file, needs to be updated
This spell file is older than your Vim. You need to update the .spl file.

E772: Spell file is for newer version of Vim
This means the spell file was made for a later version of Vim. You need to update Vim.

E770: Unsupported section in spell file
This means the spell file was made for a later version of Vim and contains a section that is required for the spell file to work. In this case it's probably a good idea to upgrade your Vim.

SPELL FILE DUMP

If for some reason you want to check what words are supported by the currently used spelling files, use this command:

:spelldump :spelld

:spelld[ump] Open a new window and fill it with all currently valid words. Compound words are not included.
Note: For some languages the result may be enormous, causing Vim to run out of memory.

:spelld[ump]! Like ":spelldump" and include the word count. This is the number of times the word was found while updating the screen. Words that are in COMMON items get a starting count of 10.

The format of the word list is used spell-wordlist-format . You should be able to read it with ":mkspell" to generate one .spl file that includes all the words.

When all entries to 'spelllang' use the same regions or no regions at all then the region information is included in the dumped words. Otherwise only words for the current region are included and no "/regions" line is generated.

Comment lines with the name of the .spl file are used as a header above the words that were generated from that .spl file.

SPELL FILE MISSING spell-SpellFileMissing spellfile.vim

If the spell file for the language you are using is not available, you will get an error message. But if the "spellfile.vim" plugin is active it will offer you to download the spell file. Just follow the instructions, it will ask you where to write the file (there must be a writable directory in 'runtimepath' for this).

The plugin has a default place where to look for spell files, on the Vim ftp server. If you want to use another location or another protocol, set the g:spellfile_URL variable to the directory that holds the spell files. The netrw plugin is used for getting the file, look there for the specific syntax of the URL. Example:

```
let g:spellfile_URL = 'http://ftp.vim.org/vim/runtime/spell'
```

You may need to escape special characters.

The plugin will only ask about downloading a language once. If you want to try again anyway restart Vim, or set g:spellfile_URL to another value (e.g., prepend a space).

To avoid using the "spellfile.vim" plugin do this in your vimrc file:

```
let loaded_spellfile_plugin = 1
```

Instead of using the plugin you can define a SpellFileMissing autocommand to handle the missing file yourself. You can use it like this:

```
:au SpellFileMissing * call Download_spell_file(expand('<amatch>'))
```

Thus the <amatch> item contains the name of the language. Another important value is 'encoding', since every encoding has its own spell file. With two exceptions:
- For ISO-8859-15 (latin9) the name "latin1" is used (the encodings only differ in characters not used in dictionary words).
- The name "ascii" may also be used for some languages where the words use only ASCII letters for most of the words.

The default "spellfile.vim" plugin uses this autocommand, if you define your autocommand afterwards you may want to use ":au! SpellFileMissing" to overrule it. If you define your autocommand before the plugin is loaded it will notice this and not do anything.

E797

Note that the SpellFileMissing autocommand must not change or destroy the buffer the user was editing.

==========

4. Spell file format spell-file-format

This is the format of the files that are used by the person who creates and maintains a word list.

Note that we avoid the word "dictionary" here. That is because the goal of spell checking differs from writing a dictionary (as in the book). For spelling we need a list of words that are OK, thus should not be highlighted. Person and company names will not appear in a dictionary, but do appear in a word list. And some old words are rarely used while they are common misspellings. These do appear in a dictionary but not in a word list.

There are two formats: A straight list of words and a list using affix compression. The files with affix compression are used by Myspell (Mozilla and OpenOffice.org). This requires two files, one with .aff and one with .dic extension.

FORMAT OF STRAIGHT WORD LIST spell-wordlist-format

The words must appear one per line. That is all that is required.

Additionally the following items are recognized:

- Empty and blank lines are ignored.

```
# comment
```

- Lines starting with a # are ignored (comment lines).

        /encoding=utf-8
- A line starting with "/encoding=", before any word, specifies the encoding
  of the file. After the second '=' comes an encoding name. This tells Vim
  to setup conversion from the specified encoding to 'encoding'. Thus you can
  use one word list for several target encodings.

        /regions=usca
- A line starting with "/regions=" specifies the region names that are
  supported. Each region name must be two ASCII letters. The first one is
  region 1. Thus "/regions=usca" has region 1 "us" and region 2 "ca".
  In an addition word list the region names should be equal to the main word
  list!

- Other lines starting with '/' are reserved for future use. The ones that
  are not recognized are ignored. You do get a warning message, so that you
  know something won't work.

- A "/" may follow the word with the following items:
    =   Case must match exactly.
    ?   Rare word.
    !   Bad (wrong) word.
    1 to 9   A region in which the word is valid. If no regions are
                specified the word is valid in all regions.

Example:

```
        # This is an example word list          comment
        /encoding=latin1                        encoding of the file
        /regions=uscagb                         regions "us", "ca" and "gb"
        example                                 word for all regions
        blah/12                                 word for regions "us" and "ca"
        vim/!                                   bad word
        Campbell/?3                             rare word in region 3 "gb"
        's mornings/=                           keep-case word
```

Note that when "/=" is used the same word with all upper-case letters is not
accepted. This is different from a word with mixed case that is automatically
marked as keep-case, those words may appear in all upper-case letters.

FORMAT WITH .AFF AND .DIC FILES aff-dic-format

There are two files: the basic word list and an affix file. The affix file
specifies settings for the language and can contain affixes. The affixes are
used to modify the basic words to get the full word list. This significantly
reduces the number of words, especially for a language like Polish. This is
called affix compression.

The basic word list and the affix file are combined with the ":mkspell"
command and results in a binary spell file. All the preprocessing has been
done, thus this file loads fast. The binary spell file format is described in
the source code (src/spell.c). But only developers need to know about it.

The preprocessing also allows us to take the Myspell language files and modify them before the Vim word list is made. The tools for this can be found in the "src/spell" directory.

The format for the affix and word list files is based on what Myspell uses (the spell checker of Mozilla and OpenOffice.org). A description can be found here:
	http://lingucomponent.openoffice.org/affix.readme
Note that affixes are case sensitive, this isn't obvious from the description.

Vim supports quite a few extras. They are described below spell-affix-vim . Attempts have been made to keep this compatible with other spell checkers, so that the same files can often be used. One other project that offers more than Myspell is Hunspell (http://hunspell.sf.net).

WORD LIST FORMAT spell-dic-format

A short example, with line numbers:

```
1	1234
2	aan
3	Als
4	Etten-Leur
5	et al.
6	's-Gravenhage
7	's-Gravenhaags
8	# word that differs between regions
9	kado/1
10	cadeau/2
11	TCP,IP
12	/the S affix may add a 's'
13	bedel/S
```

The first line contains the number of words. Vim ignores it, but you do get an error message if it's not there. E760

What follows is one word per line. White space at the end of the line is ignored, all other white space matters. The encoding is specified in the affix file spell-SET .

Comment lines start with '#' or '/'. See the example lines 8 and 12. Note that putting a comment after a word is NOT allowed:

```
someword	# comment that causes an error!
```

After the word there is an optional slash and flags. Most of these flags are letters that indicate the affixes that can be used with this word. These are specified with SFX and PFX lines in the .aff file, see spell-SFX and spell-PFX . Vim allows using other flag types with the FLAG item in the affix file spell-FLAG .

When the word only has lower-case letters it will also match with the word

starting with an upper-case letter.

When the word includes an upper-case letter, this means the upper-case letter is required at this position. The same word with a lower-case letter at this position will not match. When some of the other letters are upper-case it will not match either.

The word with all upper-case characters will always be OK,

word list	matches	does not match
als	als Als ALS	ALs AlS aLs aLS
Als	Als ALS	als ALs AlS aLs aLS
ALS	ALS	als Als ALs AlS aLs aLS
AlS	AlS ALS	als Als ALs aLs aLS

The KEEPCASE affix ID can be used to specifically match a word with identical case only, see below spell-KEEPCASE .

Note: in line 5 to 7 non-word characters are used. You can include any character in a word. When checking the text a word still only matches when it appears with a non-word character before and after it. For Myspell a word starting with a non-word character probably won't work.

In line 12 the word "TCP/IP" is defined. Since the slash has a special meaning the comma is used instead. This is defined with the SLASH item in the affix file, see spell-SLASH . Note that without this SLASH item the word will be "TCP,IP".

AFFIX FILE FORMAT

spell-aff-format spell-affix-vim

spell-affix-comment

Comment lines in the .aff file start with a '#':

```
# comment line
```

Items with a fixed number of arguments can be followed by a comment. But only if none of the arguments can contain white space. The comment must start with a "#" character. Example:

```
KEEPCASE =  # fix case for words with this flag
```

ENCODING

spell-SET

The affix file can be in any encoding that is supported by "iconv". However, in some cases the current locale should also be set properly at the time :mkspell is invoked. Adding FOL/LOW/UPP lines removes this requirement spell-FOL .

The encoding should be specified before anything where the encoding matters. The encoding applies both to the affix file and the dictionary file. It is done with a SET line:

```
        SET utf-8
```

The encoding can be different from the value of the 'encoding' option at the time ":mkspell" is used. Vim will then convert everything to 'encoding' and generate a spell file for 'encoding'. If some of the used characters to not fit in 'encoding' you will get an error message.

spell-affix-mbyte

When using a multi-byte encoding it's possible to use more different affix flags. But Myspell doesn't support that, thus you may not want to use it anyway. For compatibility use an 8-bit encoding.

INFORMATION

These entries in the affix file can be used to add information to the spell file. There are no restrictions on the format, but they should be in the right encoding.

spell-NAME spell-VERSION spell-HOME
spell-AUTHOR spell-EMAIL spell-COPYRIGHT

```
        NAME            Name of the language
        VERSION         1.0.1  with fixes
        HOME            http://www.myhome.eu
        AUTHOR          John Doe
        EMAIL           john AT Doe DOT net
        COPYRIGHT       LGPL
```

These fields are put in the .spl file as-is. The :spellinfo command can be used to view the info.

:spellinfo :spelli

```
:spelli[nfo]            Display the information for the spell file(s) used for
                        the current buffer.
```

CHARACTER TABLES

spell-affix-chars

When using an 8-bit encoding the affix file should define what characters are word characters. This is because the system where ":mkspell" is used may not support a locale with this encoding and isalpha() won't work. For example when using "cp1250" on Unix.

E761 E762 spell-FOL
spell-LOW spell-UPP

Three lines in the affix file are needed. Simplistic example:

```
        FOL  áëñ
        LOW  áëñ
        UPP  ÁËÑ
```

All three lines must have exactly the same number of characters.

The "FOL" line specifies the case-folded characters. These are used to compare words while ignoring case. For most encodings this is identical to the lower case line.

The "LOW" line specifies the characters in lower-case. Mostly it's equal to the "FOL" line.

The "UPP" line specifies the characters with upper-case. That is, a character is upper-case where it's different from the character at the same position in "FOL".

An exception is made for the German sharp s ß. The upper-case version is "SS". In the FOL/LOW/UPP lines it should be included, so that it's recognized as a word character, but use the ß character in all three.

ASCII characters should be omitted, Vim always handles these in the same way. When the encoding is UTF-8 no word characters need to be specified.

E763

Vim allows you to use spell checking for several languages in the same file. You can list them in the 'spelllang' option. As a consequence all spell files for the same encoding must use the same word characters, otherwise they can't be combined without errors.

If you get an E763 warning that the word tables differ you need to update your ".spl" spell files. If you downloaded the files, get the latest version of all spell files you use. If you are only using one, e.g., German, then also download the recent English spell files. Otherwise generate the .spl file again with :mkspell . If you still get errors check the FOL, LOW and UPP lines in the used .aff files.

The XX.ascii.spl spell file generated with the "-ascii" argument will not contain the table with characters, so that it can be combine with spell files for any encoding. The .add.spl files also do not contain the table.

MID-WORD CHARACTERS

spell-midword

Some characters are only to be considered word characters if they are used in between two ordinary word characters. An example is the single quote: It is often used to put text in quotes, thus it can't be recognized as a word character, but when it appears in between word characters it must be part of the word. This is needed to detect a spelling error such as they'are. That should be they're, but since "they" and "are" are words themselves that would go unnoticed.

These characters are defined with MIDWORD in the .aff file. Example:

```
MIDWORD '-
```

FLAG TYPES

spell-FLAG

Flags are used to specify the affixes that can be used with a word and for other properties of the word. Normally single-character flags are used. This limits the number of possible flags, especially for 8-bit encodings. The FLAG item can be used if more affixes are to be used. Possible values:

```
        FLAG long       use two-character flags
        FLAG num        use numbers, from 1 up to 65000
        FLAG caplong    use one-character flags without A-Z and two-character
                        flags that start with A-Z
```

With "FLAG num" the numbers in a list of affixes need to be separated with a comma: "234,2143,1435". This method is inefficient, but useful if the file is generated with a program.

When using "caplong" the two-character flags all start with a capital: "Aa", "B1", "BB", etc. This is useful to use one-character flags for the most common items and two-character flags for uncommon items.

Note: When using utf-8 only characters up to 65000 may be used for flags.

Note: even when using "num" or "long" the number of flags available to compounding and prefixes is limited to about 250.

AFFIXES

spell-PFX spell-SFX

The usual PFX (prefix) and SFX (suffix) lines are supported (see the Myspell documentation or the Aspell manual: http://aspell.net/man-html/Affix-Compression.html).

Summary:

```
        SFX L Y 2
        SFX L 0 re [^x]
        SFX L 0 ro x
```

The first line is a header and has four fields:

```
        SFX {flag} {combine} {count}
```

{flag} The name used for the suffix. Mostly it's a single letter, but other characters can be used, see spell-FLAG .

{combine} Can be 'Y' or 'N'. When 'Y' then the word plus suffix can also have a prefix. When 'N' then a prefix is not allowed.

{count} The number of lines following. If this is wrong you will get an error message.

For PFX the fields are exactly the same.

The basic format for the following lines is:

```
        SFX {flag} {strip} {add} {condition} {extra}
```

{flag} Must be the same as the {flag} used in the first line.

{strip} Characters removed from the basic word. There is no check if the characters are actually there, only the length is used (in bytes). This better match the {condition}, otherwise strange things may happen. If the {strip} length is equal to or

longer than the basic word the suffix won't be used.
When {strip} is 0 (zero) then nothing is stripped.

{add}	Characters added to the basic word, after removing {strip}.
Optionally there is a '/' followed by flags. The flags apply
to the word plus affix. See spell-affix-flags

{condition}	A simplistic pattern. Only when this matches with a basic
word will the suffix be used for that word. This is normally
for using one suffix letter with different {add} and {strip}
fields for words with different endings.
When {condition} is a . (dot) there is no condition.
The pattern may contain:
- Literal characters.
- A set of characters in []. [abc] matches a, b and c.
A dash is allowed for a range [a-c], but this is
Vim-specific.
- A set of characters that starts with a ^, meaning the
complement of the specified characters. [^abc] matches any
character but a, b and c.

{extra}	Optional extra text:
# comment	Comment is ignored
-	Hunspell uses this, ignored

For PFX the fields are the same, but the {strip}, {add} and {condition} apply to the start of the word.

Note: Myspell ignores any extra text after the relevant info. Vim requires this text to start with a "#" so that mistakes don't go unnoticed. Example:

```
SFX F 0 in   [^i]n      # Spion > Spionin
SFX F 0 nen  in         # Bauerin > Bauerinnen
```

However, to avoid lots of errors in affix files written for Myspell, you can add the IGNOREEXTRA flag.

Apparently Myspell allows an affix name to appear more than once. Since this might also be a mistake, Vim checks for an extra "S". The affix files for Myspell that use this feature apparently have this flag. Example:

```
SFX a Y 1 S
SFX a 0 an .

SFX a Y 2 S
SFX a 0 en .
SFX a 0 on .
```

## AFFIX FLAGS	spell-affix-flags

This is a feature that comes from Hunspell: The affix may specify flags. This works similar to flags specified on a basic word. The flags apply to the basic word plus the affix (but there are restrictions). Example:

```
SFX S Y 1
SFX S 0 s .

SFX A Y 1
SFX A 0 able/S .
```

When the dictionary file contains "drink/AS" then these words are possible:

```
drink
drinks          uses S suffix
drinkable       uses A suffix
drinkables      uses A suffix and then S suffix
```

Generally the flags of the suffix are added to the flags of the basic word, both are used for the word plus suffix. But the flags of the basic word are only used once for affixes, except that both one prefix and one suffix can be used when both support combining.

Specifically, the affix flags can be used for:
- Suffixes on suffixes, as in the example above. This works once, thus you can have two suffixes on a word (plus one prefix).
- Making the word with the affix rare, by using the spell-RARE flag.
- Exclude the word with the affix from compounding, by using the spell-COMPOUNDFORBIDFLAG flag.
- Allow the word with the affix to be part of a compound word on the side of the affix with the spell-COMPOUNDPERMITFLAG .
- Use the NEEDCOMPOUND flag: word plus affix can only be used as part of a compound word. spell-NEEDCOMPOUND
- Compound flags: word plus affix can be part of a compound word at the end, middle, start, etc. The flags are combined with the flags of the basic word. spell-compound
- NEEDAFFIX: another affix is needed to make a valid word.
- CIRCUMFIX, as explained just below.

IGNOREEXTRA spell-IGNOREEXTRA

Normally Vim gives an error for an extra field that does not start with '#'. This avoids errors going unnoticed. However, some files created for Myspell or Hunspell may contain many entries with an extra field. Use the IGNOREEXTRA flag to avoid lots of errors.

CIRCUMFIX spell-CIRCUMFIX

The CIRCUMFIX flag means a prefix and suffix must be added at the same time. If a prefix has the CIRCUMFIX flag than only suffixes with the CIRCUMFIX flag can be added, and the other way around.
An alternative is to only specify the suffix, and give the that suffix two flags: The required prefix and the NEEDAFFIX flag. spell-NEEDAFFIX

PFXPOSTPONE spell-PFXPOSTPONE

When an affix file has very many prefixes that apply to many words it's not possible to build the whole word list in memory. This applies to Hebrew (a list with all words is over a Gbyte). In that case applying prefixes must be postponed. This makes spell checking slower. It is indicated by this keyword in the .aff file:

```
PFXPOSTPONE
```

Only prefixes without a chop string and without flags can be postponed. Prefixes with a chop string or with flags will still be included in the word list. An exception if the chop string is one character and equal to the last character of the added string, but in lower case. Thus when the chop string is used to allow the following word to start with an upper case letter.

WORDS WITH A SLASH spell-SLASH

The slash is used in the .dic file to separate the basic word from the affix letters and other flags. Unfortunately, this means you cannot use a slash in a word. Thus "TCP/IP" is not a word but "TCP" with the flags "IP". To include a slash in the word put a backslash before it: "TCP\/IP". In the rare case you want to use a backslash inside a word you need to use two backslashes. Any other use of the backslash is reserved for future expansion.

KEEP-CASE WORDS spell-KEEPCASE

In the affix file a KEEPCASE line can be used to define the affix name used for keep-case words. Example:

```
KEEPCASE =
```

This flag is not supported by Myspell. It has the meaning that case matters. This can be used if the word does not have the first letter in upper case at the start of a sentence. Example:

```
word list       matches                 does not match
's morgens/=    's morgens              'S morgens 's Morgens 'S MORGENS
's Morgens      's Morgens 'S MORGENS   'S morgens 's morgens
```

The flag can also be used to avoid that the word matches when it is in all upper-case letters.

RARE WORDS spell-RARE

In the affix file a RARE line can be used to define the affix name used for rare words. Example:

```
RARE ?
```

Rare words are highlighted differently from bad words. This is to be used for words that are correct for the language, but are hardly ever used and could be

a typing mistake anyway. When the same word is found as good it won't be highlighted as rare.

This flag can also be used on an affix, so that a basic word is not rare but the basic word plus affix is rare spell-affix-flags . However, if the word also appears as a good word in another way (e.g., in another region) it won't be marked as rare.

BAD WORDS spell-BAD

In the affix file a BAD line can be used to define the affix name used for bad words. Example:

```
BAD !
```

This can be used to exclude words that would otherwise be good. For example "the the" in the .dic file:

```
the the/!
```

Once a word has been marked as bad it won't be undone by encountering the same word as good.

The flag also applies to the word with affixes, thus this can be used to mark a whole bunch of related words as bad.

spell-FORBIDDENWORD

FORBIDDENWORD can be used just like BAD. For compatibility with Hunspell.

spell-NEEDAFFIX

The NEEDAFFIX flag is used to require that a word is used with an affix. The word itself is not a good word (unless there is an empty affix). Example:

```
NEEDAFFIX +
```

COMPOUND WORDS spell-compound

A compound word is a longer word made by concatenating words that appear in the .dic file. To specify which words may be concatenated a character is used. This character is put in the list of affixes after the word. We will call this character a flag here. Obviously these flags must be different from any affix IDs used.

spell-COMPOUNDFLAG

The Myspell compatible method uses one flag, specified with COMPOUNDFLAG. All words with this flag combine in any order. This means there is no control over which word comes first. Example:

```
COMPOUNDFLAG c
```

spell-COMPOUNDRULE

A more advanced method to specify how compound words can be formed uses multiple items with multiple flags. This is not compatible with Myspell 3.0.

```
Let's start with an example:
        COMPOUNDRULE c+
        COMPOUNDRULE se

The first line defines that words with the "c" flag can be concatenated in any
order.  The second line defines compound words that are made of one word with
the "s" flag and one word with the "e" flag.  With this dictionary:
        bork/c
        onion/s
        soup/e

You can make these words:
        bork
        borkbork
        borkborkbork
        (etc.)
        onion
        soup
        onionsoup

The COMPOUNDRULE item may appear multiple times.  The argument is made out of
one or more groups, where each group can be:
        one flag                        e.g., c
        alternate flags inside []       e.g., [abc]
Optionally this may be followed by:
        *       the group appears zero or more times, e.g., sm*e
        +       the group appears one or more times, e.g., c+
        ?       the group appears zero times or once, e.g., x?

This is similar to the regexp pattern syntax (but not the same!).  A few
examples with the sequence of word flags they require:
    COMPOUNDRULE x+         x xx xxx etc.
    COMPOUNDRULE yz         yz
    COMPOUNDRULE x+z        xz xxz xxxz etc.
    COMPOUNDRULE yx+        yx yxx yxxx etc.
    COMPOUNDRULE xy?z       xz xyz

    COMPOUNDRULE [abc]z    az bz cz
    COMPOUNDRULE [abc]+z   az aaz abaz bz baz bcbz cz caz cbaz etc.
    COMPOUNDRULE a[xyz]+   ax axx axyz ay ayx ayzz az azy azxy etc.
    COMPOUNDRULE sm*e       se sme smme smmme etc.
    COMPOUNDRULE s[xyz]*e  se sxe sxye sxyxe sye syze sze szye szyxe  etc.

A specific example: Allow a compound to be made of two words and a dash:
        In the .aff file:
            COMPOUNDRULE sde
            NEEDAFFIX x
            COMPOUNDWORDMAX 3
            COMPOUNDMIN 1
        In the .dic file:
            start/s
            end/e
            -/xd
```

This allows for the word "start-end", but not "startend".

An additional implied rule is that, without further flags, a word with a prefix cannot be compounded after another word, and a word with a suffix cannot be compounded with a following word. Thus the affix cannot appear on the inside of a compound word. This can be changed with the
 spell-COMPOUNDPERMITFLAG .

spell-NEEDCOMPOUND

The NEEDCOMPOUND flag is used to require that a word is used as part of a compound word. The word itself is not a good word. Example:

```
NEEDCOMPOUND &
```

spell-ONLYINCOMPOUND

The ONLYINCOMPOUND does exactly the same as NEEDCOMPOUND. Supported for compatibility with Hunspell.

spell-COMPOUNDMIN

The minimal character length of a word used for compounding is specified with COMPOUNDMIN. Example:

```
COMPOUNDMIN 5
```

When omitted there is no minimal length. Obviously you could just leave out the compound flag from short words instead, this feature is present for compatibility with Myspell.

spell-COMPOUNDWORDMAX

The maximum number of words that can be concatenated into a compound word is specified with COMPOUNDWORDMAX. Example:

```
COMPOUNDWORDMAX 3
```

When omitted there is no maximum. It applies to all compound words.

To set a limit for words with specific flags make sure the items in COMPOUNDRULE where they appear don't allow too many words.

spell-COMPOUNDSYLMAX

The maximum number of syllables that a compound word may contain is specified with COMPOUNDSYLMAX. Example:

```
COMPOUNDSYLMAX 6
```

This has no effect if there is no SYLLABLE item. Without COMPOUNDSYLMAX there is no limit on the number of syllables.

If both COMPOUNDWORDMAX and COMPOUNDSYLMAX are defined, a compound word is accepted if it fits one of the criteria, thus is either made from up to COMPOUNDWORDMAX words or contains up to COMPOUNDSYLMAX syllables.

spell-COMPOUNDFORBIDFLAG

The COMPOUNDFORBIDFLAG specifies a flag that can be used on an affix. It means that the word plus affix cannot be used in a compound word. Example:

```
affix file:
        COMPOUNDFLAG c
```

```
		COMPOUNDFORBIDFLAG x
		SFX a Y 2
		SFX a 0 s   .
		SFX a 0 ize/x .
	dictionary:
		word/c
		util/ac
```

This allows for "wordutil" and "wordutils" but not "wordutilize".
Note: this doesn't work for postponed prefixes yet.

spell-COMPOUNDPERMITFLAG

The COMPOUNDPERMITFLAG specifies a flag that can be used on an affix. It means that the word plus affix can also be used in a compound word in a way where the affix ends up halfway the word. Without this flag that is not allowed.
Note: this doesn't work for postponed prefixes yet.

spell-COMPOUNDROOT

The COMPOUNDROOT flag is used for words in the dictionary that are already a compound. This means it counts for two words when checking the compounding rules. Can also be used for an affix to count the affix as a compounding word.

spell-CHECKCOMPOUNDPATTERN

CHECKCOMPOUNDPATTERN is used to define patterns that, when matching at the position where two words are compounded together forbids the compound.
For example:

```
	CHECKCOMPOUNDPATTERN o e
```

This forbids compounding if the first word ends in "o" and the second word starts with "e".

The arguments must be plain text, no patterns are actually supported, despite the item name. Case is always ignored.

The Hunspell feature to use three arguments and flags is not supported.

spell-NOCOMPOUNDSUGS

This item indicates that using compounding to make suggestions is not a good idea. Use this when compounding is used with very short or one-character words. E.g. to make numbers out of digits. Without this flag creating suggestions would spend most time trying all kind of weird compound words.

```
	NOCOMPOUNDSUGS
```

spell-SYLLABLE

The SYLLABLE item defines characters or character sequences that are used to count the number of syllables in a word. Example:

```
	SYLLABLE aáeéiíoóöõuúüûy/aa/au/ea/ee/ei/ie/oa/oe/oo/ou/uu/ui
```

Before the first slash is the set of characters that are counted for one syllable, also when repeated and mixed, until the next character that is not in this set. After the slash come sequences of characters that are counted

for one syllable. These are preferred over using characters from the set.
With the example "ideeen" has three syllables, counted by "i", "ee" and "e".

Only case-folded letters need to be included.

Another way to restrict compounding was mentioned above: Adding the
spell-COMPOUNDFORBIDFLAG flag to an affix causes all words that are made
with that affix to not be used for compounding.

UNLIMITED COMPOUNDING spell-NOBREAK

For some languages, such as Thai, there is no space in between words. This
looks like all words are compounded. To specify this use the NOBREAK item in
the affix file, without arguments:

```
NOBREAK
```

Vim will try to figure out where one word ends and a next starts. When there
are spelling mistakes this may not be quite right.

spell-COMMON

Common words can be specified with the COMMON item. This will give better
suggestions when editing a short file. Example:

```
COMMON  the of to and a in is it you that he was for on are
```

The words must be separated by white space, up to 25 per line.
When multiple regions are specified in a ":mkspell" command the common words
for all regions are combined and used for all regions.

spell-NOSPLITSUGS

This item indicates that splitting a word to make suggestions is not a good
idea. Split-word suggestions will appear only when there are few similar
words.

```
NOSPLITSUGS
```

spell-NOSUGGEST

The flag specified with NOSUGGEST can be used for words that will not be
suggested. Can be used for obscene words.

```
NOSUGGEST %
```

REPLACEMENTS spell-REP

In the affix file REP items can be used to define common mistakes. This is
used to make spelling suggestions. The items define the "from" text and the
"to" replacement. Example:

```
REP 4
REP f ph
REP ph f
```

```
REP k ch
REP ch k
```

The first line specifies the number of REP lines following. Vim ignores the number, but it must be there (for compatibility with Myspell).

Don't include simple one-character replacements or swaps. Vim will try these anyway. You can include whole words if you want to, but you might want to use the "file:" item in 'spellsuggest' instead.

You can include a space by using an underscore:

```
REP the_the the
```

SIMILAR CHARACTERS spell-MAP E783

In the affix file MAP items can be used to define letters that are very much alike. This is mostly used for a letter with different accents. This is used to prefer suggestions with these letters substituted. Example:

```
MAP 2
MAP eéëêè
MAP uüùúû
```

The first line specifies the number of MAP lines following. Vim ignores the number, but the line must be there.

Each letter must appear in only one of the MAP items. It's a bit more efficient if the first letter is ASCII or at least one without accents.

.SUG FILE spell-NOSUGFILE

When soundfolding is specified in the affix file then ":mkspell" will normally produce a .sug file next to the .spl file. This file is used to find suggestions by their sound-a-like form quickly. At the cost of a lot of memory (the amount depends on the number of words, :mkspell will display an estimate when it's done).

To avoid producing a .sug file use this item in the affix file:

```
NOSUGFILE
```

Users can simply omit the .sug file if they don't want to use it.

SOUND-A-LIKE spell-SAL

In the affix file SAL items can be used to define the sounds-a-like mechanism to be used. The main items define the "from" text and the "to" replacement. Simplistic example:

```
SAL CIA                 X
```

```
        SAL CH                  X
        SAL C                   K
        SAL K                   K
```

There are a few rules and this can become quite complicated. An explanation how it works can be found in the Aspell manual: http://aspell.net/man-html/Phonetic-Code.html.

There are a few special items:

```
        SAL followup            true
        SAL collapse_result     true
        SAL remove_accents      true
```

"1" has the same meaning as "true". Any other value means "false".

SIMPLE SOUNDFOLDING

spell-SOFOFROM spell-SOFOTO

The SAL mechanism is complex and slow. A simpler mechanism is mapping all characters to another character, mapping similar sounding characters to the same character. At the same time this does case folding. You can not have both SAL items and simple soundfolding.

There are two items required: one to specify the characters that are mapped and one that specifies the characters they are mapped to. They must have exactly the same number of characters. Example:

```
    SOFOFROM abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ
    SOFOTO   ebctefghejklnnepkrstevvkesebctefghejklnnepkrstevvkes
```

In the example all vowels are mapped to the same character 'e'. Another method would be to leave out all vowels. Some characters that sound nearly the same and are often mixed up, such as 'm' and 'n', are mapped to the same character. Don't do this too much, all words will start looking alike.

Characters that do not appear in SOFOFROM will be left out, except that all white space is replaced by one space. Sequences of the same character in SOFOFROM are replaced by one.

You can use the soundfold() function to try out the results. Or set the 'verbose' option to see the score in the output of the z= command.

UNSUPPORTED ITEMS

spell-affix-not-supported

These items appear in the affix file of other spell checkers. In Vim they are ignored, not supported or defined in another way.

ACCENT (Hunspell) spell-ACCENT
Use MAP instead. spell-MAP

BREAK (Hunspell) spell-BREAK
Define break points. Unclear how it works exactly.

Not supported.

CHECKCOMPOUNDCASE (Hunspell) spell-CHECKCOMPOUNDCASE
Disallow uppercase letters at compound word boundaries.
Not supported.

CHECKCOMPOUNDDUP (Hunspell) spell-CHECKCOMPOUNDDUP
Disallow using the same word twice in a compound. Not supported.

CHECKCOMPOUNDREP (Hunspell) spell-CHECKCOMPOUNDREP
Something about using REP items and compound words. Not supported.

CHECKCOMPOUNDTRIPLE (Hunspell) spell-CHECKCOMPOUNDTRIPLE
Forbid three identical characters when compounding. Not supported.

COMPLEXPREFIXES (Hunspell) spell-COMPLEXPREFIXES
Enables using two prefixes. Not supported.

COMPOUND (Hunspell) spell-COMPOUND
This is one line with the count of COMPOUND items, followed by that many COMPOUND lines with a pattern.
Remove the first line with the count and rename the other items to COMPOUNDRULE spell-COMPOUNDRULE

COMPOUNDFIRST (Hunspell) spell-COMPOUNDFIRST
Use COMPOUNDRULE instead. spell-COMPOUNDRULE

COMPOUNDBEGIN (Hunspell) spell-COMPOUNDBEGIN
Use COMPOUNDRULE instead. spell-COMPOUNDRULE

COMPOUNDEND (Hunspell) spell-COMPOUNDEND
Use COMPOUNDRULE instead. spell-COMPOUNDRULE

COMPOUNDMIDDLE (Hunspell) spell-COMPOUNDMIDDLE
Use COMPOUNDRULE instead. spell-COMPOUNDRULE

COMPOUNDRULES (Hunspell) spell-COMPOUNDRULES
Number of COMPOUNDRULE lines following. Ignored, but the argument must be a number.

COMPOUNDSYLLABLE (Hunspell) spell-COMPOUNDSYLLABLE
Use SYLLABLE and COMPOUNDSYLMAX instead. spell-SYLLABLE spell-COMPOUNDSYLMAX

KEY (Hunspell) spell-KEY
Define characters that are close together on the keyboard.
Used to give better suggestions. Not supported.

LANG (Hunspell) spell-LANG
This specifies language-specific behavior. This actually moves part of the language knowledge into the program,

therefore Vim does not support it. Each language property must be specified separately.

LEMMA_PRESENT (Hunspell) spell-LEMMA_PRESENT
Only needed for morphological analysis.

MAXNGRAMSUGS (Hunspell) spell-MAXNGRAMSUGS
Set number of n-gram suggestions. Not supported.

PSEUDOROOT (Hunspell) spell-PSEUDOROOT
Use NEEDAFFIX instead. spell-NEEDAFFIX

SUGSWITHDOTS (Hunspell) spell-SUGSWITHDOTS
Adds dots to suggestions. Vim doesn't need this.

SYLLABLENUM (Hunspell) spell-SYLLABLENUM
Not supported.

TRY (Myspell, Hunspell, others) spell-TRY
Vim does not use the TRY item, it is ignored. For making suggestions the actual characters in the words are used, that is much more efficient.

WORDCHARS (Hunspell) spell-WORDCHARS
Used to recognize words. Vim doesn't need it, because there is no need to separate words before checking them (using a trie instead of a hashtable).

vim:tw=78:sw=4:ts=8:noet:ft=help:norl:

diff.txt For Vim version 8.1. Last change: 2017 Oct 03

VIM REFERENCE MANUAL by Bram Moolenaar

diff vimdiff gvimdiff diff-mode

This file describes the +diff feature: Showing differences between two to eight versions of the same file.

The basics are explained in section 08.7 of the user manual.

{not in Vi}

==========

1. Starting diff mode start-vimdiff

The easiest way to start editing in diff mode is with the "vimdiff" command. This starts Vim as usual, and additionally sets up for viewing the differences between the arguments.

```
vimdiff file1 file2 [file3 [file4]]
```

This is equivalent to:

```
vim -d file1 file2 [file3 [file4]]
```

You may also use "gvimdiff" or "vim -d -g". The GUI is started then.
You may also use "viewdiff" or "gviewdiff". Vim starts in readonly mode then.
"r" may be prepended for restricted mode (see -Z).

The second and following arguments may also be a directory name. Vim will then append the file name of the first argument to the directory name to find the file.

This only works when a standard "diff" command is available. See 'diffexpr'.

Diffs are local to the current tab page tab-page . You can't see diffs with a window in another tab page. This does make it possible to have several diffs at the same time, each in their own tab page.

What happens is that Vim opens a window for each of the files. This is like using the -O argument. This uses vertical splits. If you prefer horizontal splits add the -o argument:

```
vimdiff -o file1 file2 [file3 [file4]]
```

If you always prefer horizontal splits include "horizontal" in 'diffopt'.

In each of the edited files these options are set:

```
        'diff'          on
        'scrollbind'    on
        'cursorbind'    on
        'scrollopt'     includes "hor"
        'wrap'          off
        'foldmethod'    "diff"
        'foldcolumn'    value from 'diffopt', default is 2
```

These options are set local to the window. When editing another file they are reset to the global value.
The options can still be overruled from a modeline when re-editing the file. However, 'foldmethod' and 'wrap' won't be set from a modeline when 'diff' is set.

The differences shown are actually the differences in the buffer. Thus if you make changes after loading a file, these will be included in the displayed diffs. You might have to do ":diffupdate" now and then, not all changes are immediately taken into account.

In your .vimrc file you could do something special when Vim was started in diff mode. You could use a construct like this:

```
        if &diff
           setup for diff mode
        else
           setup for non-diff mode
        endif
```

While already in Vim you can start diff mode in three ways.

E98
:diffs[plit] {filename} :diffs :diffsplit
Open a new window on the file {filename}. The options are set as for "vimdiff" for the current and the newly opened window. Also see 'diffexpr'.

:difft :diffthis
:difft[his] Make the current window part of the diff windows. This sets the options like for "vimdiff".

:diffp[atch] {patchfile} E816 :diffp :diffpatch
Use the current buffer, patch it with the diff found in {patchfile} and open a buffer on the result. The options are set as for "vimdiff".
{patchfile} can be in any format that the "patch" program understands or 'patchexpr' can handle.
Note that {patchfile} should only contain a diff for one file, the current file. If {patchfile} contains diffs for other files as well, the results are unpredictable. Vim changes directory to /tmp to avoid files in the current directory accidentally being patched. But it may still result in

various ".rej" files to be created. And when absolute path
names are present these files may get patched anyway.

To make these commands use a vertical split, prepend :vertical . Examples:

```
:vert diffsplit main.c~
:vert diffpatch /tmp/diff
```

If you always prefer a vertical split include "vertical" in 'diffopt'.

E96
There can be up to eight buffers with 'diff' set.

Since the option values are remembered with the buffer, you can edit another
file for a moment and come back to the same file and be in diff mode again.

:diffo :diffoff
:diffo[ff] Switch off diff mode for the current window. Resets related
options also when 'diff' was not set.

:diffo[ff]! Switch off diff mode for the current window and in all windows
in the current tab page where 'diff' is set. Resetting
related options only happens in a window that has 'diff' set,
if the current window does not have 'diff' set then no options
in it are changed.
Hidden buffers are also removed from the list of diff'ed
buffers.

The `:diffoff` command resets the relevant options to the values they had when
using `:diffsplit`, `:diffpatch` , `:diffthis`. or starting Vim in diff mode.
When using `:diffoff` twice the last saved values are restored.
Otherwise they are set to their default value:

```
'diff'          off
'scrollbind'    off
'cursorbind'    off
'scrollopt'     without "hor"
'wrap'          on
'foldmethod'    "manual"
'foldcolumn'    0
```

==
2. Viewing diffs view-diffs

The effect is that the diff windows show the same text, with the differences
highlighted. When scrolling the text, the 'scrollbind' option will make the
text in other windows to be scrolled as well. With vertical splits the text
should be aligned properly.

The alignment of text will go wrong when:
- 'wrap' is on, some lines will be wrapped and occupy two or more screen
  lines
- folds are open in one window but not another
- 'scrollbind' is off

- changes have been made to the text
- "filler" is not present in 'diffopt', deleted/inserted lines makes the
  alignment go wrong

All the buffers edited in a window where the 'diff' option is set will join in the diff. This is also possible for hidden buffers. They must have been edited in a window first for this to be possible. To get rid of the hidden buffers use `:diffoff!`.

:DiffOrig diff-original-file

Since 'diff' is a window-local option, it's possible to view the same buffer in diff mode in one window and "normal" in another window. It is also possible to view the changes you have made to a buffer since the file was loaded. Since Vim doesn't allow having two buffers for the same file, you need another buffer. This command is useful:

```
command DiffOrig vert new | set bt=nofile | r ++edit # | 0d_
      \ | diffthis | wincmd p | diffthis
```

(this is in vimrc_example.vim). Use ":DiffOrig" to see the differences between the current buffer and the file it was loaded from.

A buffer that is unloaded cannot be used for the diff. But it does work for hidden buffers. You can use ":hide" to close a window without unloading the buffer. If you don't want a buffer to remain used for the diff do ":set nodiff" before hiding it.

:dif :diffupdate

:dif[fupdate][!] Update the diff highlighting and folds.

Vim attempts to keep the differences updated when you make changes to the text. This mostly takes care of inserted and deleted lines. Changes within a line and more complicated changes do not cause the differences to be updated. To force the differences to be updated use:

```
:diffupdate
```

If the ! is included Vim will check if the file was changed externally and needs to be reloaded. It will prompt for each changed file, like `:checktime` was used.

Vim will show filler lines for lines that are missing in one window but are present in another. These lines were inserted in another file or deleted in this file. Removing "filler" from the 'diffopt' option will make Vim not display these filler lines.

Folds are used to hide the text that wasn't changed. See folding for all the commands that can be used with folds.

The context of lines above a difference that are not included in the fold can be set with the 'diffopt' option. For example, to set the context to three lines:

```
:set diffopt=filler,context:3
```

The diffs are highlighted with these groups:

hl-DiffAdd	DiffAdd	Added (inserted) lines. These lines exist in this buffer but not in another.
hl-DiffChange	DiffChange	Changed lines.
hl-DiffText	DiffText	Changed text inside a Changed line. Vim finds the first character that is different, and the last character that is different (searching from the end of the line). The text in between is highlighted. This means that parts in the middle that are still the same are highlighted anyway. The 'diffopt' flags "iwhite" and "icase" are used here.
hl-DiffDelete	DiffDelete	Deleted lines. Also called filler lines, because they don't really exist in this buffer.

==========
3. Jumping to diffs jumpto-diffs

Two commands can be used to jump to diffs:

[c
[c Jump backwards to the previous start of a change.
When a count is used, do it that many times.
]c
]c Jump forwards to the next start of a change.
When a count is used, do it that many times.

It is an error if there is no change for the cursor to move to.

==========
4. Diff copying copy-diffs E99 E100 E101 E102 E103
merge

There are two commands to copy text from one buffer to another. The result is that the buffers will be equal within the specified range.

:diffg :diffget
:[range]diffg[et] [bufspec]
Modify the current buffer to undo difference with another buffer. If [bufspec] is given, that buffer is used. If [bufspec] refers to the current buffer then nothing happens. Otherwise this only works if there is one other buffer in diff mode.
See below for [range].

:diffpu :diffput E793
:[range]diffpu[t] [bufspec]
Modify another buffer to undo difference with the current buffer. Just like ":diffget" but the other buffer is modified instead of the current one.
When [bufspec] is omitted and there is more than one other buffer in diff mode where 'modifiable' is set this fails.
See below for [range].

                                                        do
[count]do   Same as ":diffget" without range. The "o" stands for "obtain"
                ("dg" can't be used, it could be the start of "dgg"!). Note:
                this doesn't work in Visual mode.
                If you give a [count], it is used as the [bufspec] argument
                for ":diffget".

                                                        dp
[count]dp   Same as ":diffput" without range. Note: this doesn't work in
                Visual mode.
                If you give a [count], it is used as the [bufspec] argument
                for ":diffput".

When no [range] is given, the diff at the cursor position or just above it is affected. When [range] is used, Vim tries to only put or get the specified lines. When there are deleted lines, this may not always be possible.

There can be deleted lines below the last line of the buffer. When the cursor is on the last line in the buffer and there is no diff above this line, the ":diffget" and "do" commands will obtain lines from the other buffer.

To be able to get those lines from another buffer in a [range] it's allowed to use the last line number plus one. This command gets all diffs from the other buffer:

        :1,$+1diffget

Note that deleted lines are displayed, but not counted as text lines. You can't move the cursor into them. To fill the deleted lines with the lines from another buffer use ":diffget" on the line below them.
                                                                        E787
When the buffer that is about to be modified is read-only and the autocommand that is triggered by FileChangedRO changes buffers the command will fail. The autocommand must not change buffers.

The [bufspec] argument above can be a buffer number, a pattern for a buffer name or a part of a buffer name. Examples:

        :diffget   Use the other buffer which is in diff mode
        :diffget 3   Use buffer 3
        :diffget v2   Use the buffer which matches "v2" and is in
                                diff mode (e.g., "file.c.v2")

==
5. Diff options   diff-options

Also see 'diffopt' and the "diff" item of 'fillchars' .

                                                diff-slow   diff_translations
For very long lines, the diff syntax highlighting might be slow, especially since it tries to match all different kind of localisations. To disable localisations and speed up the syntax highlighting, set the global variable

g:diff_translations to zero:

```
    let g:diff_translations = 0
```

After setting this variable, reload the syntax script:

```
    set syntax=diff
```

FINDING THE DIFFERENCES diff-diffexpr

The 'diffexpr' option can be set to use something else than the standard "diff" program to compare two files and find the differences.

When 'diffexpr' is empty, Vim uses this command to find the differences between file1 and file2:

```
        diff file1 file2 > outfile
```

The ">" is replaced with the value of 'shellredir'.

The output of "diff" must be a normal "ed" style diff. Do NOT use a context diff. This example explains the format that Vim expects:

```
        1a2
        > bbb
        4d4
        < 111
        7c7
        < GGG
        ---
        > ggg
```

The "1a2" item appends the line "bbb".
The "4d4" item deletes the line "111".
The "7c7" item replaces the line "GGG" with "ggg".

When 'diffexpr' is not empty, Vim evaluates it to obtain a diff file in the format mentioned. These variables are set to the file names used:

```
        v:fname_in              original file
        v:fname_new             new version of the same file
        v:fname_out             resulting diff file
```

Additionally, 'diffexpr' should take care of "icase" and "iwhite" in the 'diffopt' option. 'diffexpr' cannot change the value of 'lines' and 'columns'.

Example (this does almost the same as 'diffexpr' being empty):

```
        set diffexpr=MyDiff()
        function MyDiff()
           let opt = ""
```

```
          if &diffopt =~ "icase"
            let opt = opt . "-i "
          endif
          if &diffopt =~ "iwhite"
            let opt = opt . "-b "
          endif
          silent execute "!diff -a --binary " . opt . v:fname_in . " " . v:fname_new .
              \  " > " . v:fname_out
        endfunction
```

The "-a" argument is used to force comparing the files as text, comparing as binaries isn't useful. The "--binary" argument makes the files read in binary mode, so that a CTRL-Z doesn't end the text on DOS.

E810 E97

Vim will do a test if the diff output looks alright. If it doesn't, you will get an error message. Possible causes:
- The "diff" program cannot be executed.
- The "diff" program doesn't produce normal "ed" style diffs (see above).
- The 'shell' and associated options are not set correctly. Try if filtering works with a command like ":!sort".
- You are using 'diffexpr' and it doesn't work.

If it's not clear what the problem is set the 'verbose' option to one or more to see more messages.

The self-installing Vim for MS-Windows includes a diff program. If you don't have it you might want to download a diff.exe. For example from http://gnuwin32.sourceforge.net/packages/diffutils.htm.

USING PATCHES diff-patchexpr

The 'patchexpr' option can be set to use something else than the standard "patch" program.

When 'patchexpr' is empty, Vim will call the "patch" program like this:

```
patch -o outfile origfile < patchfile
```

This should work fine with most versions of the "patch" program. Note that a CR in the middle of a line may cause problems, it is seen as a line break.

If the default doesn't work for you, set the 'patchexpr' to an expression that will have the same effect. These variables are set to the file names used:

```
v:fname_in              original file
v:fname_diff            patch file
v:fname_out             resulting patched file
```

Example (this does the same as 'patchexpr' being empty):

```
set patchexpr=MyPatch()
function MyPatch()
  :call system("patch -o " . v:fname_out . " " . v:fname_in .
```

```
          \  " < " . v:fname_diff)
      endfunction
```

Make sure that using the "patch" program doesn't have unwanted side effects.
For example, watch out for additionally generated files, which should be
deleted. It should just patch the file and nothing else.
   Vim will change directory to "/tmp" or another temp directory before
evaluating 'patchexpr'. This hopefully avoids that files in the current
directory are accidentally patched. Vim will also delete files starting with
v:fname_in and ending in ".rej" and ".orig".

 vim:tw=78:ts=8:noet:ft=help:norl:

autocmd.txt For Vim version 8.1. Last change: 2018 May 03

VIM REFERENCE MANUAL by Bram Moolenaar

Automatic commands autocommand autocommands

For a basic explanation, see section 40.3 in the user manual.

{Vi does not have any of these commands}

==========
1. Introduction autocmd-intro

You can specify commands to be executed automatically when reading or writing a file, when entering or leaving a buffer or window, and when exiting Vim. For example, you can create an autocommand to set the 'cindent' option for files matching *.c. You can also use autocommands to implement advanced features, such as editing compressed files (see gzip-example). The usual place to put autocommands is in your .vimrc or .exrc file.

E203 E204 E143 E855 E937 E952

WARNING: Using autocommands is very powerful, and may lead to unexpected side effects. Be careful not to destroy your text.
- It's a good idea to do some testing on an expendable copy of a file first. For example: If you use autocommands to decompress a file when starting to edit it, make sure that the autocommands for compressing when writing work correctly.
- Be prepared for an error halfway through (e.g., disk full). Vim will mostly be able to undo the changes to the buffer, but you may have to clean up the changes to other files by hand (e.g., compress a file that has been decompressed).
- If the BufRead* events allow you to edit a compressed file, the FileRead* events should do the same (this makes recovery possible in some rare cases). It's a good idea to use the same autocommands for the File* and Buf* events when possible.

==========
2. Defining autocommands autocmd-define

:au :autocmd

:au[tocmd] [group] {event} {pat} [nested] {cmd}
                        Add {cmd} to the list of commands that Vim will
                        execute automatically on {event} for a file matching
                        {pat} autocmd-patterns .
                        Note: A quote character is seen as argument to the
                        :autocmd and won't start a comment.
                        Vim always adds the {cmd} after existing autocommands,
                        so that the autocommands execute in the order in which
                        they were given. See autocmd-nested for [nested].

The special pattern <buffer> or <buffer=N> defines a buffer-local autocommand.
See autocmd-buflocal .

Note: The ":autocmd" command can only be followed by another command when the
'|' appears before {cmd}. This works:
        :augroup mine | au! BufRead | augroup END
But this sees "augroup" as part of the defined command:
        :augroup mine | au! BufRead * | augroup END
        :augroup mine | au BufRead * set tw=70 | augroup END
Instead you can put the group name into the command:
        :au! mine BufRead *
        :au mine BufRead * set tw=70
Or use `:execute`:
        :augroup mine | exe "au! BufRead *" | augroup END
        :augroup mine | exe "au BufRead * set tw=70" | augroup END

Note that special characters (e.g., "%", "<cword>") in the ":autocmd"
arguments are not expanded when the autocommand is defined. These will be
expanded when the Event is recognized, and the {cmd} is executed. The only
exception is that "<sfile>" is expanded when the autocmd is defined. Example:

        :au BufNewFile,BufRead *.html so <sfile>:h/html.vim

Here Vim expands <sfile> to the name of the file containing this line.

`:autocmd` adds to the list of autocommands regardless of whether they are
already present. When your .vimrc file is sourced twice, the autocommands
will appear twice. To avoid this, define your autocommands in a group, so
that you can easily clear them:

        augroup vimrc
          " Remove all vimrc autocommands
          autocmd!
          au BufNewFile,BufRead *.html so <sfile>:h/html.vim
        augroup END

If you don't want to remove all autocommands, you can instead use a variable
to ensure that Vim includes the autocommands only once:

        :if !exists("autocommands_loaded")
        : let autocommands_loaded = 1
        : au ...
        :endif

When the [group] argument is not given, Vim uses the current group (as defined with ":augroup"); otherwise, Vim uses the group defined with [group]. Note that [group] must have been defined before. You cannot define a new group with ":au group ..."; use ":augroup" for that.

While testing autocommands, you might find the 'verbose' option to be useful:
```
:set verbose=9
```
This setting makes Vim echo the autocommands as it executes them.

When defining an autocommand in a script, it will be able to call functions local to the script and use mappings local to the script. When the event is triggered and the command executed, it will run in the context of the script it was defined in. This matters if <SID> is used in a command.

When executing the commands, the message from one command overwrites a previous message. This is different from when executing the commands manually. Mostly the screen will not scroll up, thus there is no hit-enter prompt. When one command outputs two messages this can happen anyway.

==
3. Removing autocommands autocmd-remove

:au[tocmd]! [group] {event} {pat} [nested] {cmd}
Remove all autocommands associated with {event} and {pat}, and add the command {cmd}. See autocmd-nested for [nested].

:au[tocmd]! [group] {event} {pat}
Remove all autocommands associated with {event} and {pat}.

:au[tocmd]! [group] * {pat}
Remove all autocommands associated with {pat} for all events.

:au[tocmd]! [group] {event}
Remove ALL autocommands for {event}.
Warning: You should not do this without a group for BufRead and other common events, it can break plugins, syntax highlighting, etc.

:au[tocmd]! [group]
Remove ALL autocommands.
Note: a quote will be seen as argument to the :autocmd and won't start a comment.
Warning: You should normally not do this without a group, it breaks plugins, syntax highlighting, etc.

When the [group] argument is not given, Vim uses the current group (as defined with ":augroup"); otherwise, Vim uses the group defined with [group].

==
4. Listing autocommands autocmd-list

:au[tocmd] [group] {event} {pat}

Show the autocommands associated with {event} and {pat}.

:au[tocmd] [group] * {pat}
Show the autocommands associated with {pat} for all events.

:au[tocmd] [group] {event}
Show all autocommands for {event}.

:au[tocmd] [group] Show all autocommands.

If you provide the [group] argument, Vim lists only the autocommands for [group]; otherwise, Vim lists the autocommands for ALL groups. Note that this argument behavior differs from that for defining and removing autocommands.

In order to list buffer-local autocommands, use a pattern in the form <buffer> or <buffer=N>. See autocmd-buflocal .

:autocmd-verbose

When 'verbose' is non-zero, listing an autocommand will also display where it was last defined. Example:

```
:verbose autocmd BufEnter
FileExplorer  BufEnter
    *         call s:LocalBrowse(expand("<amatch>"))
        Last set from /usr/share/vim/vim-7.0/plugin/NetrwPlugin.vim
```

See :verbose-cmd for more information.

==
5. Events autocmd-events E215 E216

You can specify a comma-separated list of event names. No white space can be used in this list. The command applies to all the events in the list.

For READING FILES there are four kinds of events possible:

BufNewFile		starting to edit a non-existent file
BufReadPre	BufReadPost	starting to edit an existing file
FilterReadPre	FilterReadPost	read the temp file with filter output
FileReadPre	FileReadPost	any other file read

Vim uses only one of these four kinds when reading a file. The "Pre" and "Post" events are both triggered, before and after reading the file.

Note that the autocommands for the *ReadPre events and all the Filter events are not allowed to change the current buffer (you will get an error message if this happens). This is to prevent the file to be read into the wrong buffer.

Note that the 'modified' flag is reset AFTER executing the BufReadPost and BufNewFile autocommands. But when the 'modified' option was set by the autocommands, this doesn't happen.

You can use the 'eventignore' option to ignore a number of events or all events.

autocommand-events {event}

Vim recognizes the following events. Vim ignores the case of event names (e.g., you can use "BUFread" or "bufread" instead of "BufRead").

First an overview by function with a short explanation. Then the list alphabetically with full explanations autocmd-events-abc .

Name	triggered by
Reading	
BufNewFile	starting to edit a file that doesn't exist
BufReadPre	starting to edit a new buffer, before reading the file
BufRead	starting to edit a new buffer, after reading the file
BufReadPost	starting to edit a new buffer, after reading the file
BufReadCmd	before starting to edit a new buffer Cmd-event
FileReadPre	before reading a file with a ":read" command
FileReadPost	after reading a file with a ":read" command
FileReadCmd	before reading a file with a ":read" command Cmd-event
FilterReadPre	before reading a file from a filter command
FilterReadPost	after reading a file from a filter command
StdinReadPre	before reading from stdin into the buffer
StdinReadPost	After reading from the stdin into the buffer
Writing	
BufWrite	starting to write the whole buffer to a file
BufWritePre	starting to write the whole buffer to a file
BufWritePost	after writing the whole buffer to a file
BufWriteCmd	before writing the whole buffer to a file Cmd-event
FileWritePre	starting to write part of a buffer to a file
FileWritePost	after writing part of a buffer to a file
FileWriteCmd	before writing part of a buffer to a file Cmd-event
FileAppendPre	starting to append to a file
FileAppendPost	after appending to a file
FileAppendCmd	before appending to a file Cmd-event
FilterWritePre	starting to write a file for a filter command or diff
FilterWritePost	after writing a file for a filter command or diff
Buffers	
BufAdd	just after adding a buffer to the buffer list
BufCreate	just after adding a buffer to the buffer list
BufDelete	before deleting a buffer from the buffer list
BufWipeout	before completely deleting a buffer
TerminalOpen	after a terminal buffer was created
BufFilePre	before changing the name of the current buffer
BufFilePost	after changing the name of the current buffer
BufEnter	after entering a buffer

```
BufLeave                before leaving to another buffer
BufWinEnter             after a buffer is displayed in a window
BufWinLeave             before a buffer is removed from a window

BufUnload               before unloading a buffer
BufHidden               just after a buffer has become hidden
BufNew                  just after creating a new buffer

SwapExists              detected an existing swap file

        Options
FileType                when the 'filetype' option has been set
Syntax                  when the 'syntax' option has been set
EncodingChanged         after the 'encoding' option has been changed
TermChanged             after the value of 'term' has changed
OptionSet               after setting any option

        Startup and exit
VimEnter                after doing all the startup stuff
GUIEnter                after starting the GUI successfully
GUIFailed               after starting the GUI failed
TermResponse            after the terminal response to  t_RV  is received

QuitPre                 when using `:quit`, before deciding whether to exit
ExitPre                 when using a command that may make Vim exit
VimLeavePre             before exiting Vim, before writing the viminfo file
VimLeave                before exiting Vim, after writing the viminfo file

        Various
FileChangedShell        Vim notices that a file changed since editing started
FileChangedShellPost    After handling a file changed since editing started
FileChangedRO           before making the first change to a read-only file

DirChanged              after the working directory has changed

ShellCmdPost            after executing a shell command
ShellFilterPost         after filtering with a shell command

CmdUndefined            a user command is used but it isn't defined
FuncUndefined           a user function is used but it isn't defined
SpellFileMissing        a spell file is used but it can't be found
SourcePre               before sourcing a Vim script
SourceCmd               before sourcing a Vim script  Cmd-event

VimResized              after the Vim window size changed
FocusGained             Vim got input focus
FocusLost               Vim lost input focus
CursorHold              the user doesn't press a key for a while
CursorHoldI             the user doesn't press a key for a while in Insert mode
CursorMoved             the cursor was moved in Normal mode
CursorMovedI            the cursor was moved in Insert mode

WinNew                  after creating a new window
TabNew                  after creating a new tab page
```

TabClosed	after closing a tab page
WinEnter	after entering another window
WinLeave	before leaving a window
TabEnter	after entering another tab page
TabLeave	before leaving a tab page
CmdwinEnter	after entering the command-line window
CmdwinLeave	before leaving the command-line window
CmdlineChanged	after a change was made to the command-line text
CmdlineEnter	after the cursor moves to the command line
CmdlineLeave	before the cursor leaves the command line
InsertEnter	starting Insert mode
InsertChange	when typing <Insert> while in Insert or Replace mode
InsertLeave	when leaving Insert mode
InsertCharPre	when a character was typed in Insert mode, before inserting it
TextChanged	after a change was made to the text in Normal mode
TextChangedI	after a change was made to the text in Insert mode when popup menu is not visible
TextChangedP	after a change was made to the text in Insert mode when popup menu visible
TextYankPost	after text has been yanked or deleted
ColorSchemePre	before loading a color scheme
ColorScheme	after loading a color scheme
RemoteReply	a reply from a server Vim was received
QuickFixCmdPre	before a quickfix command is run
QuickFixCmdPost	after a quickfix command is run
SessionLoadPost	after loading a session file
MenuPopup	just before showing the popup menu
CompleteDone	after Insert mode completion is done
User	to be used in combination with ":doautocmd"

The alphabetical list of autocommand events: autocmd-events-abc

BufCreate BufAdd

BufAdd or BufCreate Just after creating a new buffer which is added to the buffer list, or adding a buffer to the buffer list.
Also used just after a buffer in the buffer list has been renamed.
The BufCreate event is for historic reasons.
NOTE: When this autocommand is executed, the current buffer "%" may be different from the buffer being created "<afile>".
BufDelete

BufDelete
Before deleting a buffer from the buffer list. The BufUnload may be called first (if the buffer was loaded).
Also used just before a buffer in the buffer list is renamed.
NOTE: When this autocommand is executed, the current buffer "%" may be different from the buffer being deleted "<afile>" and "<abuf>". Don't change to another buffer, it will cause problems.

BufEnter
After entering a buffer. Useful for setting options for a file type. Also executed when starting to edit a buffer, after the BufReadPost autocommands.

BufFilePost
After changing the name of the current buffer with the ":file" or ":saveas" command.

BufFilePre
Before changing the name of the current buffer with the ":file" or ":saveas" command.

BufHidden
Just after a buffer has become hidden. That is, when there are no longer windows that show the buffer, but the buffer is not unloaded or deleted. Not used for ":qa" or ":q" when exiting Vim.
NOTE: When this autocommand is executed, the current buffer "%" may be different from the buffer being unloaded "<afile>".

BufLeave
Before leaving to another buffer. Also when leaving or closing the current window and the new current window is not for the same buffer. Not used for ":qa" or ":q" when exiting Vim.

BufNew
Just after creating a new buffer. Also used just after a buffer has been renamed. When the buffer is added to the buffer list BufAdd will be triggered too.
NOTE: When this autocommand is executed, the current buffer "%" may be different from the buffer being created "<afile>".

BufNewFile
When starting to edit a file that doesn't exist. Can be used to read in a skeleton file.

BufRead or BufReadPost
When starting to edit a new buffer, after reading the file into the buffer, before executing the modelines. See BufWinEnter for when you need to do something after processing the modelines.
This does NOT work for ":r file". Not used

when the file doesn't exist. Also used after
successfully recovering a file.
Also triggered for the filetypedetect group
when executing ":filetype detect" and when
writing an unnamed buffer in a way that the
buffer gets a name.
BufReadCmd

BufReadCmd Before starting to edit a new buffer. Should
read the file into the buffer. Cmd-event
BufReadPre E200 E201

BufReadPre When starting to edit a new buffer, before
reading the file into the buffer. Not used
if the file doesn't exist.
BufUnload

BufUnload Before unloading a buffer. This is when the
text in the buffer is going to be freed. This
may be after a BufWritePost and before a
BufDelete. Also used for all buffers that are
loaded when Vim is going to exit.
NOTE: When this autocommand is executed, the
current buffer "%" may be different from the
buffer being unloaded "<afile>".
Don't change to another buffer or window, it
will cause problems!
When exiting and v:dying is 2 or more this
event is not triggered.
BufWinEnter

BufWinEnter After a buffer is displayed in a window. This
can be when the buffer is loaded (after
processing the modelines) or when a hidden
buffer is displayed in a window (and is no
longer hidden).
Does not happen for :split without
arguments, since you keep editing the same
buffer, or ":split" with a file that's already
open in a window, because it re-uses an
existing buffer. But it does happen for a
":split" with the name of the current buffer,
since it reloads that buffer.
Does not happen for a terminal window, because
it starts in Terminal-Job mode and Normal mode
commands won't work. Use TerminalOpen instead.
BufWinLeave

BufWinLeave Before a buffer is removed from a window.
Not when it's still visible in another window.
Also triggered when exiting. It's triggered
before BufUnload or BufHidden.
NOTE: When this autocommand is executed, the
current buffer "%" may be different from the
buffer being unloaded "<afile>".
When exiting and v:dying is 2 or more this
event is not triggered.
BufWipeout

BufWipeout Before completely deleting a buffer. The

BufUnload and BufDelete events may be called first (if the buffer was loaded and was in the buffer list). Also used just before a buffer is renamed (also when it's not in the buffer list).
NOTE: When this autocommand is executed, the current buffer "%" may be different from the buffer being deleted "<afile>".
Don't change to another buffer, it will cause problems.

BufWrite BufWritePre

BufWrite or BufWritePre — Before writing the whole buffer to a file.

BufWriteCmd

BufWriteCmd — Before writing the whole buffer to a file.
Should do the writing of the file and reset 'modified' if successful, unless '+' is in 'cpo' and writing to another file cpo-+ .
The buffer contents should not be changed.
When the command resets 'modified' the undo information is adjusted to mark older undo states as 'modified', like :write does.
Cmd-event

BufWritePost

BufWritePost — After writing the whole buffer to a file (should undo the commands for BufWritePre).

CmdUndefined

CmdUndefined — When a user command is used but it isn't defined. Useful for defining a command only when it's used. The pattern is matched against the command name. Both <amatch> and <afile> are set to the name of the command.
NOTE: Autocompletion won't work until the command is defined. An alternative is to always define the user command and have it invoke an autoloaded function. See autoload .

CmdlineChanged

CmdlineChanged — After a change was made to the text in the command line. Be careful not to mess up the command line, it may cause Vim to lock up.
<afile> is set to a single character, indicating the type of command-line.
cmdwin-char

CmdlineEnter

CmdlineEnter — After moving the cursor to the command line, where the user can type a command or search string.
<afile> is set to a single character, indicating the type of command-line.
cmdwin-char

CmdlineLeave

CmdlineLeave — Before leaving the command line.
Also when abandoning the command line, after typing CTRL-C or <Esc>.
When the commands result in an error the

command line is still executed.
<afile> is set to a single character,
indicating the type of command-line.
cmdwin-char

CmdwinEnter

CmdwinEnter After entering the command-line window.
Useful for setting options specifically for
this special type of window. This is
triggered _instead_ of BufEnter and WinEnter.
<afile> is set to a single character,
indicating the type of command-line.
cmdwin-char

CmdwinLeave

CmdwinLeave Before leaving the command-line window.
Useful to clean up any global setting done
with CmdwinEnter. This is triggered _instead_
of BufLeave and WinLeave.
<afile> is set to a single character,
indicating the type of command-line.
cmdwin-char

ColorScheme

ColorScheme After loading a color scheme. :colorscheme
The pattern is matched against the
colorscheme name. <afile> can be used for the
name of the actual file where this option was
set, and <amatch> for the new colorscheme
name.

ColorSchemePre

ColorSchemePre Before loading a color scheme. :colorscheme
Useful to setup removing things added by a
color scheme, before another one is loaded.

CompleteDone

CompleteDone After Insert mode completion is done. Either
when something was completed or abandoning
completion. ins-completion
The v:completed_item variable contains
information about the completed item.

CursorHold

CursorHold When the user doesn't press a key for the time
specified with 'updatetime'. Not re-triggered
until the user has pressed a key (i.e. doesn't
fire every 'updatetime' ms if you leave Vim to
make some coffee. :) See CursorHold-example
for previewing tags.
This event is only triggered in Normal mode.
It is not triggered when waiting for a command
argument to be typed, or a movement after an
operator.
While recording the CursorHold event is not
triggered. q
<CursorHold>

Internally the autocommand is triggered by the
<CursorHold> key. In an expression mapping
getchar() may see this character.

Note: Interactive commands cannot be used for
this event. There is no hit-enter prompt,
the screen is updated directly (when needed).
Note: In the future there will probably be
another option to set the time.
Hint: to force an update of the status lines
use:
:let &ro = &ro
{only on Amiga, Unix, Win32, MSDOS and all GUI
versions}

CursorHoldI

CursorHoldI Just like CursorHold, but in Insert mode.
Not triggered when waiting for another key,
e.g. after CTRL-V, and not when in CTRL-X mode
insert_expand .

CursorMoved

CursorMoved After the cursor was moved in Normal or Visual
mode. Also when the text of the cursor line
has been changed, e.g., with "x", "rx" or "p".
Not triggered when there is typeahead or when
an operator is pending.
For an example see match-parens .
Careful: This is triggered very often, don't
do anything that the user does not expect or
that is slow.

CursorMovedI

CursorMovedI After the cursor was moved in Insert mode.
Not triggered when the popup menu is visible.
Otherwise the same as CursorMoved.

EncodingChanged

EncodingChanged Fires off after the 'encoding' option has been
changed. Useful to set up fonts, for example.

FileAppendCmd

FileAppendCmd Before appending to a file. Should do the
appending to the file. Use the '[and ']
marks for the range of lines. Cmd-event

FileAppendPost

FileAppendPost After appending to a file.

FileAppendPre

FileAppendPre Before appending to a file. Use the '[and ']
marks for the range of lines.

FileChangedRO

FileChangedRO Before making the first change to a read-only
file. Can be used to check-out the file from
a source control system. Not triggered when
the change was caused by an autocommand.
This event is triggered when making the first
change in a buffer or the first change after
'readonly' was set, just before the change is

applied to the text.
WARNING: If the autocommand moves the cursor the effect of the change is undefined.
E788
It is not allowed to change to another buffer here. You can reload the buffer but not edit another one.
E881
If the number of lines changes saving for undo may fail and the change will be aborted.
DirChanged

DirChanged — The working directory has changed in response to the :cd or :lcd commands, or as a result of the 'autochdir' option.
The pattern can be:
"window" to trigger on `:lcd
"global" to trigger on `:cd`
"auto" to trigger on 'autochdir'.
"drop" to trigger on editing a file
<afile> is set to the new directory name.
ExitPre

ExitPre — When using `:quit`, `:wq` in a way it makes Vim exit, or using `:qall`, just after QuitPre. Can be used to close any non-essential window. Exiting may still be cancelled if there is a modified buffer that isn't automatically saved, use VimLeavePre for really exiting.
FileChangedShell

FileChangedShell — When Vim notices that the modification time of a file has changed since editing started. Also when the file attributes of the file change or when the size of the file changes. timestamp
Mostly triggered after executing a shell command, but also with a :checktime command or when gvim regains input focus.
This autocommand is triggered for each changed file. It is not used when 'autoread' is set and the buffer was not changed. If a FileChangedShell autocommand is present the warning message and prompt is not given.
The v:fcs_reason variable is set to indicate what happened and v:fcs_choice can be used to tell Vim what to do next.
NOTE: When this autocommand is executed, the current buffer "%" may be different from the buffer that was changed, which is in "<afile>".
NOTE: The commands must not change the current buffer, jump to another buffer or delete a buffer. E246 E811
NOTE: This event never nests, to avoid an endless loop. This means that while executing commands for the FileChangedShell event no

other FileChangedShell event will be triggered.

FileChangedShellPost — After handling a file that was changed outside of Vim. Can be used to update the statusline.

FileEncoding — Obsolete. It still works and is equivalent to EncodingChanged.

FileReadCmd — Before reading a file with a ":read" command. Should do the reading of the file. Cmd-event

FileReadPost — After reading a file with a ":read" command. Note that Vim sets the '[and '] marks to the first and last line of the read. This can be used to operate on the lines just read.

FileReadPre — Before reading a file with a ":read" command.

FileType — When the 'filetype' option has been set. The pattern is matched against the filetype. <afile> can be used for the name of the file where this option was set, and <amatch> for the new value of 'filetype'. Navigating to another window or buffer is not allowed. See filetypes.

FileWriteCmd — Before writing to a file, when not writing the whole buffer. Should do the writing to the file. Should not change the buffer. Use the '[and '] marks for the range of lines. Cmd-event

FileWritePost — After writing to a file, when not writing the whole buffer.

FileWritePre — Before writing to a file, when not writing the whole buffer. Use the '[and '] marks for the range of lines.

FilterReadPost — After reading a file from a filter command. Vim checks the pattern against the name of the current buffer as with FilterReadPre. Not triggered when 'shelltemp' is off.

FilterReadPre — Before reading a file from a filter command. Vim checks the pattern against the name of the current buffer, not the name of the temporary file that is the output of the filter command. Not triggered when 'shelltemp' is off.

FilterWritePost — After writing a file for a filter command or making a diff.

Vim checks the pattern against the name of
the current buffer as with FilterWritePre.
Not triggered when 'shelltemp' is off.

FilterWritePre

FilterWritePre Before writing a file for a filter command or making a diff.
Vim checks the pattern against the name of the current buffer, not the name of the temporary file that is the output of the filter command.
Not triggered when 'shelltemp' is off.

FocusGained

FocusGained When Vim got input focus. Only for the GUI version and a few console versions where this can be detected.

FocusLost

FocusLost When Vim lost input focus. Only for the GUI version and a few console versions where this can be detected. May also happen when a dialog pops up.

FuncUndefined

FuncUndefined When a user function is used but it isn't defined. Useful for defining a function only when it's used. The pattern is matched against the function name. Both <amatch> and <afile> are set to the name of the function.
NOTE: When writing Vim scripts a better alternative is to use an autoloaded function.
See autoload-functions .

GUIEnter

GUIEnter After starting the GUI successfully, and after opening the window. It is triggered before VimEnter when using gvim. Can be used to position the window from a .gvimrc file:

```
:autocmd GUIEnter * winpos 100 50
```

GUIFailed

GUIFailed After starting the GUI failed. Vim may continue to run in the terminal, if possible (only on Unix and alikes, when connecting the X server fails). You may want to quit Vim:

```
:autocmd GUIFailed * qall
```

InsertChange

InsertChange When typing <Insert> while in Insert or Replace mode. The v:insertmode variable indicates the new mode.
Be careful not to move the cursor or do anything else that the user does not expect.

InsertCharPre

InsertCharPre When a character is typed in Insert mode, before inserting the char.
The v:char variable indicates the char typed and can be changed during the event to insert a different character. When v:char is set to more than one character this text is

inserted literally.
It is not allowed to change the text |textlock|.
The event is not triggered when 'paste' is set. {only with the +eval feature}

InsertEnter

InsertEnter — Just before starting Insert mode. Also for Replace mode and Virtual Replace mode. The |v:insertmode| variable indicates the mode.
Be careful not to do anything else that the user does not expect.
The cursor is restored afterwards. If you do not want that set |v:char| to a non-empty string.

InsertLeave

InsertLeave — When leaving Insert mode. Also when using CTRL-O |i_CTRL-O|. But not for |i_CTRL-C|.

MenuPopup

MenuPopup — Just before showing the popup menu (under the right mouse button). Useful for adjusting the menu for what is under the cursor or mouse pointer.
The pattern is matched against a single character representing the mode:

n	Normal
v	Visual
o	Operator-pending
i	Insert
c	Command line

OptionSet

OptionSet — After setting an option. The pattern is matched against the long option name.
The |v:option_old| variable indicates the old option value, |v:option_new| variable indicates the newly set value, the |v:option_type| variable indicates whether it's global or local scoped and |<amatch>| indicates what option has been set.

Is not triggered on startup and for the 'key' option for obvious reasons.

Usage example: Check for the existence of the directory in the 'backupdir' and 'undodir' options, create the directory if it doesn't exist yet.

Note: It's a bad idea to reset an option during this autocommand, this may break a plugin. You can always use `:noa` to prevent triggering this autocommand.

QuickFixCmdPre

QuickFixCmdPre — Before a quickfix command is run (|:make|, |:lmake|, |:grep|, |:lgrep|, |:grepadd|,

:lgrepadd , :vimgrep , :lvimgrep ,
:vimgrepadd , :lvimgrepadd , :cscope ,
:cfile , :cgetfile , :caddfile , :lfile ,
:lgetfile , :laddfile , :helpgrep ,
:lhelpgrep , :cexpr , :cgetexpr ,
:caddexpr , :cbuffer , :cgetbuffer ,
:caddbuffer).
The pattern is matched against the command
being run. When :grep is used but 'grepprg'
is set to "internal" it still matches "grep".
This command cannot be used to set the
'makeprg' and 'grepprg' variables.
If this command causes an error, the quickfix
command is not executed.

QuickFixCmdPost

QuickFixCmdPost Like QuickFixCmdPre, but after a quickfix
command is run, before jumping to the first
location. For :cfile and :lfile commands
it is run after error file is read and before
moving to the first error.
See QuickFixCmdPost-example .

QuitPre

QuitPre When using `:quit`, `:wq` or `:qall`, before
deciding whether it closes the current window
or quits Vim. Can be used to close any
non-essential window if the current window is
the last ordinary window.
Also see ExitPre .

RemoteReply

RemoteReply When a reply from a Vim that functions as
server was received server2client() . The
pattern is matched against the {serverid}.
<amatch> is equal to the {serverid} from which
the reply was sent, and <afile> is the actual
reply string.
Note that even if an autocommand is defined,
the reply should be read with remote_read()
to consume it.

SessionLoadPost

SessionLoadPost After loading the session file created using
the :mksession command.

ShellCmdPost

ShellCmdPost After executing a shell command with :!cmd ,
:shell , :make and :grep . Can be used to
check for any changed files.

ShellFilterPost

ShellFilterPost After executing a shell command with
":{range}!cmd", ":w !cmd" or ":r !cmd".
Can be used to check for any changed files.

SourcePre

SourcePre Before sourcing a Vim script. :source
<afile> is the name of the file being sourced.

SourceCmd

SourceCmd When sourcing a Vim script. :source

<afile> is the name of the file being sourced.
The autocommand must source this file.
Cmd-event

SpellFileMissing

SpellFileMissing When trying to load a spell checking file and it can't be found. The pattern is matched against the language. <amatch> is the language, 'encoding' also matters. See spell-SpellFileMissing .

StdinReadPost

StdinReadPost After reading from the stdin into the buffer, before executing the modelines. Only used when the "-" argument was used when Vim was started -- .

StdinReadPre

StdinReadPre Before reading from stdin into the buffer. Only used when the "-" argument was used when Vim was started -- .

SwapExists

SwapExists Detected an existing swap file when starting to edit a file. Only when it is possible to select a way to handle the situation, when Vim would ask the user what to do.
The v:swapname variable holds the name of the swap file found, <afile> the file being edited. v:swapcommand may contain a command to be executed in the opened file.
The commands should set the v:swapchoice variable to a string with one character to tell Vim what should be done next:

```
'o'     open read-only
'e'     edit the file anyway
'r'     recover
'd'     delete the swap file
'q'     quit, don't edit the file
'a'     abort, like hitting CTRL-C
```

When set to an empty string the user will be asked, as if there was no SwapExists autocmd.
E812
It is not allowed to change to another buffer, change a buffer name or change directory here.
{only available with the +eval feature}

Syntax

Syntax When the 'syntax' option has been set. The pattern is matched against the syntax name. <afile> can be used for the name of the file where this option was set, and <amatch> for the new value of 'syntax'.
See :syn-on .

TabClosed

TabClosed After closing a tab page.

TabEnter

TabEnter Just after entering a tab page. tab-page

After triggering the WinEnter and before triggering the BufEnter event.

TabLeave

TabLeave Just before leaving a tab page. tab-page A WinLeave event will have been triggered first.

TabNew

TabNew When a tab page was created. tab-page A WinEnter event will have been triggered first, TabEnter follows.

TermChanged

TermChanged After the value of 'term' has changed. Useful for re-loading the syntax file to update the colors, fonts and other terminal-dependent settings. Executed for all loaded buffers.

TerminalOpen

TerminalOpen Just after a terminal buffer was created, with `:terminal` or term_start() . This event is triggered even if the buffer is created without a window, with the ++hidden option.

TermResponse

TermResponse After the response to t_RV is received from the terminal. The value of v:termresponse can be used to do things depending on the terminal version. Note that this event may be triggered halfway executing another event, especially if file I/O, a shell command or anything else that takes time is involved.

TextChanged

TextChanged After a change was made to the text in the current buffer in Normal mode. That is when b:changedtick has changed.
Not triggered when there is typeahead or when an operator is pending.
Careful: This is triggered very often, don't do anything that the user does not expect or that is slow.

TextChangedI

TextChangedI After a change was made to the text in the current buffer in Insert mode.
Not triggered when the popup menu is visible.
Otherwise the same as TextChanged.

TextChangedP

TextChangedP After a change was made to the text in the current buffer in Insert mode, only when the popup menu is visible. Otherwise the same as TextChanged.

TextYankPost

TextYankPost After text has been yanked or deleted in the current buffer. The following values of v:event can be used to determine the operation that triggered this autocmd:
operator The operation performed.
regcontents Text that was stored in the

register, as a list of lines, like with: getreg(r, 1, 1)

regname — Name of the register or empty string for the unnamed register.

regtype — Type of the register, see getregtype() .

Not triggered when quote_ is used nor when called recursively.
It is not allowed to change the buffer text, see textlock .
{only when compiled with the +eval feature}

User

User — Never executed automatically. To be used for autocommands that are only executed with ":doautocmd".
Note that when `:doautocmd User MyEvent` is used while there are no matching autocommands, you will get an error. If you don't want that, define a dummy autocommand yourself.

UserGettingBored

UserGettingBored — When the user presses the same key 42 times. Just kidding! :-)

VimEnter

VimEnter — After doing all the startup stuff, including loading .vimrc files, executing the "-c cmd" arguments, creating all windows and loading the buffers in them.
Just before this event is triggered the v:vim_did_enter variable is set, so that you can do:

```
if v:vim_did_enter
  call s:init()
else
  au VimEnter * call s:init()
endif
```

VimLeave

VimLeave — Before exiting Vim, just after writing the .viminfo file. Executed only once, like VimLeavePre.
To detect an abnormal exit use v:dying .
When v:dying is 2 or more this event is not triggered.

VimLeavePre

VimLeavePre — Before exiting Vim, just before writing the .viminfo file. This is executed only once, if there is a match with the name of what happens to be the current buffer when exiting.
Mostly useful with a "*" pattern.

```
:autocmd VimLeavePre * call CleanupStuff()
```

To detect an abnormal exit use v:dying .
When v:dying is 2 or more this event is not triggered.

VimResized

VimResized After the Vim window was resized, thus 'lines' and/or 'columns' changed. Not when starting up though.

WinEnter

WinEnter After entering another window. Not done for the first window, when Vim has just started. Useful for setting the window height.
If the window is for another buffer, Vim executes the BufEnter autocommands after the WinEnter autocommands.
Note: For split and tabpage commands the WinEnter event is triggered after the split or tab command but before the file is loaded.

WinLeave

WinLeave Before leaving a window. If the window to be entered next is for a different buffer, Vim executes the BufLeave autocommands before the WinLeave autocommands (but not for ":new"). Not used for ":qa" or ":q" when exiting Vim.

WinNew

WinNew When a new window was created. Not done for the first window, when Vim has just started. Before a WinEnter event.

==========

6. Patterns autocmd-patterns {pat}

The {pat} argument can be a comma separated list. This works as if the command was given with each pattern separately. Thus this command:

```
:autocmd BufRead *.txt,*.info set et
```

Is equivalent to:

```
:autocmd BufRead *.txt set et
:autocmd BufRead *.info set et
```

The file pattern {pat} is tested for a match against the file name in one of two ways:

1. When there is no '/' in the pattern, Vim checks for a match against only the tail part of the file name (without its leading directory path).
2. When there is a '/' in the pattern, Vim checks for a match against both the short file name (as you typed it) and the full file name (after expanding it to a full path and resolving symbolic links).

The special pattern <buffer> or <buffer=N> is used for buffer-local autocommands autocmd-buflocal . This pattern is not matched against the name of a buffer.

Examples:

```
:autocmd BufRead *.txt          set et
```

Set the 'et' option for all text files.

```
:autocmd BufRead /vim/src/*.c   set cindent
```

Set the 'cindent' option for C files in the /vim/src directory.

```
        :autocmd BufRead /tmp/*.c       set ts=5
```

If you have a link from "/tmp/test.c" to "/home/nobody/vim/src/test.c", and you start editing "/tmp/test.c", this autocommand will match.

Note: To match part of a path, but not from the root directory, use a '*' as the first character. Example:

```
        :autocmd BufRead */doc/*.txt    set tw=78
```

This autocommand will for example be executed for "/tmp/doc/xx.txt" and "/usr/home/piet/doc/yy.txt". The number of directories does not matter here.

The file name that the pattern is matched against is after expanding wildcards. Thus if you issue this command:

```
        :e $ROOTDIR/main.$EXT
```

The argument is first expanded to:

```
        /usr/root/main.py
```

Before it's matched with the pattern of the autocommand. Careful with this when using events like FileReadCmd, the value of <amatch> may not be what you expect.

Environment variables can be used in a pattern:

```
        :autocmd BufRead $VIMRUNTIME/doc/*.txt  set expandtab
```

And ~ can be used for the home directory (if $HOME is defined):

```
        :autocmd BufWritePost ~/.vimrc   so ~/.vimrc
        :autocmd BufRead ~archive/*      set readonly
```

The environment variable is expanded when the autocommand is defined, not when the autocommand is executed. This is different from the command!

file-pattern

The pattern is interpreted like mostly used in file names:

*	matches any sequence of characters; Unusual: includes path separators
?	matches any single character
\?	matches a '?'
.	matches a '.'
~	matches a '~'
,	separates patterns
\,	matches a ','
{ }	like \(\) in a pattern
,	inside { }: like | in a pattern
\}	literal }
\{	literal {
\\\{n,m\}	like \{n,m} in a pattern
\	special meaning like in a pattern
[ch]	matches 'c' or 'h'
[^ch]	match any character but 'c' and 'h'

Note that for all systems the '/' character is used for path separator (even MS-DOS and OS/2). This was done because the backslash is difficult to use in a pattern and to make the autocommands portable across different systems.

It is possible to use pattern items, but they may not work as expected,
because of the translation done for the above.

autocmd-changes
Matching with the pattern is done when an event is triggered. Changing the
buffer name in one of the autocommands, or even deleting the buffer, does not
change which autocommands will be executed. Example:

```
au BufEnter *.foo  bdel
au BufEnter *.foo  set modified
```

This will delete the current buffer and then set 'modified' in what has become
the current buffer instead. Vim doesn't take into account that "*.foo"
doesn't match with that buffer name. It matches "*.foo" with the name of the
buffer at the moment the event was triggered.

However, buffer-local autocommands will not be executed for a buffer that has
been wiped out with :bwipe . After deleting the buffer with :bdel the
buffer actually still exists (it becomes unlisted), thus the autocommands are
still executed.

==
7. Buffer-local autocommands autocmd-buflocal autocmd-buffer-local
                                  <buffer=N> <buffer=abuf> E680

Buffer-local autocommands are attached to a specific buffer. They are useful
if the buffer does not have a name and when the name does not match a specific
pattern. But it also means they must be explicitly added to each buffer.

Instead of a pattern buffer-local autocommands use one of these forms:
```
<buffer>        current buffer
<buffer=99>     buffer number 99
<buffer=abuf>   using <abuf> (only when executing autocommands)
                 <abuf>
```

Examples:
```
:au CursorHold <buffer>  echo 'hold'
:au CursorHold <buffer=33>  echo 'hold'
:au BufNewFile * au CursorHold <buffer=abuf>  echo 'hold'
```

All the commands for autocommands also work with buffer-local autocommands,
simply use the special string instead of the pattern. Examples:
```
:au! * <buffer>                 " remove buffer-local autocommands for
                                " current buffer
:au! * <buffer=33>              " remove buffer-local autocommands for
                                " buffer #33
:bufdo :au! CursorHold <buffer>  " remove autocmd for given event for all
                                " buffers
:au * <buffer>                  " list buffer-local autocommands for
                                " current buffer
```

Note that when an autocommand is defined for the current buffer, it is stored
with the buffer number. Thus it uses the form "<buffer=12>", where 12 is the
number of the current buffer. You will see this when listing autocommands,

for example.

To test for presence of buffer-local autocommands use the exists() function as follows:
```
:if exists("#CursorHold#<buffer=12>") | ... | endif
:if exists("#CursorHold#<buffer>") | ... | endif    " for current buffer
```

When a buffer is wiped out its buffer-local autocommands are also gone, of course. Note that when deleting a buffer, e.g., with ":bdel", it is only unlisted, the autocommands are still present. In order to see the removal of buffer-local autocommands:
```
:set verbose=6
```

It is not possible to define buffer-local autocommands for a non-existent buffer.

==
8. Groups autocmd-groups

Autocommands can be put together in a group. This is useful for removing or executing a group of autocommands. For example, all the autocommands for syntax highlighting are put in the "highlight" group, to be able to execute ":doautoall highlight BufRead" when the GUI starts.

When no specific group is selected, Vim uses the default group. The default group does not have a name. You cannot execute the autocommands from the default group separately; you can execute them only by executing autocommands for all groups.

Normally, when executing autocommands automatically, Vim uses the autocommands for all groups. The group only matters when executing autocommands with ":doautocmd" or ":doautoall", or when defining or deleting autocommands.

The group name can contain any characters except white space. The group name "end" is reserved (also in uppercase).

The group name is case sensitive. Note that this is different from the event name!

:aug[roup] {name} :aug :augroup
Define the autocmd group name for the following ":autocmd" commands. The name "end" or "END" selects the default group.
To avoid confusion, the name should be different from existing {event} names, as this most likely will not do what you intended.

:aug[roup]! {name} :augroup-delete E367 W19 E936
Delete the autocmd group {name}. Don't use this if there is still an autocommand using this group! You will get a warning if doing it anyway. when the group is the current group you will get error E936.

To enter autocommands for a specific group, use this method:
1. Select the group with ":augroup {name}".
2. Delete any old autocommands with ":au!".
3. Define the autocommands.
4. Go back to the default group with "augroup END".

Example:
```
:augroup uncompress
:  au!
:  au BufEnter *.gz     %!gunzip
:augroup END
```

This prevents having the autocommands defined twice (e.g., after sourcing the .vimrc file again).

==
9. Executing autocommands   autocmd-execute

Vim can also execute Autocommands non-automatically. This is useful if you have changed autocommands, or when Vim has executed the wrong autocommands (e.g., the file pattern match was wrong).

Note that the 'eventignore' option applies here too. Events listed in this option will not cause any commands to be executed.

                                              :do   :doau   :doautocmd   E217
:do[autocmd] [<nomodeline>] [group] {event} [fname]
                        Apply the autocommands matching [fname] (default:
                        current file name) for {event} to the current buffer.
                        You can use this when the current file name does not
                        match the right pattern, after changing settings, or
                        to execute autocommands for a certain event.
                        It's possible to use this inside an autocommand too,
                        so you can base the autocommands for one extension on
                        another extension. Example:
                                :au BufEnter *.cpp so ~/.vimrc_cpp
                                :au BufEnter *.cpp doau BufEnter x.c
                       Be careful to avoid endless loops. See
                         autocmd-nested .

                        When the [group] argument is not given, Vim executes
                        the autocommands for all groups. When the [group]
                        argument is included, Vim executes only the matching
                        autocommands for that group. Note: if you use an
                        undefined group name, Vim gives you an error message.
                                                              <nomodeline>
                        After applying the autocommands the modelines are
                        processed, so that their settings overrule the
                        settings from autocommands, like what happens when
                        editing a file. This is skipped when the <nomodeline>
                        argument is present. You probably want to use
                        <nomodeline> for events that are not used when loading
                        a buffer, such as User .
                        Processing modelines is also skipped when no

matching autocommands were executed.

:doautoa :doautoall
:doautoa[ll] [<nomodeline>] [group] {event} [fname]
Like ":doautocmd", but apply the autocommands to each loaded buffer. Note that [fname] is used to select the autocommands, not the buffers to which they are applied.
Careful: Don't use this for autocommands that delete a buffer, change to another buffer or change the contents of a buffer; the result is unpredictable.
This command is intended for autocommands that set options, change highlighting, and things like that.

==
10. Using autocommands autocmd-use

For WRITING FILES there are four possible sets of events. Vim uses only one of these sets for a write command:

BufWriteCmd	BufWritePre	BufWritePost	writing the whole buffer
	FilterWritePre	FilterWritePost	writing to filter temp file
FileAppendCmd	FileAppendPre	FileAppendPost	appending to a file
FileWriteCmd	FileWritePre	FileWritePost	any other file write

When there is a matching "*Cmd" autocommand, it is assumed it will do the writing. No further writing is done and the other events are not triggered.
Cmd-event

Note that the *WritePost commands should undo any changes to the buffer that were caused by the *WritePre commands; otherwise, writing the file will have the side effect of changing the buffer.

Before executing the autocommands, the buffer from which the lines are to be written temporarily becomes the current buffer. Unless the autocommands change the current buffer or delete the previously current buffer, the previously current buffer is made the current buffer again.

The *WritePre and *AppendPre autocommands must not delete the buffer from which the lines are to be written.

The '[and '] marks have a special position:
- Before the *ReadPre event the '[mark is set to the line just above where the new lines will be inserted.
- Before the *ReadPost event the '[mark is set to the first line that was just read, the '] mark to the last line.
- Before executing the *WriteCmd, *WritePre and *AppendPre autocommands the '[mark is set to the first line that will be written, the '] mark to the last line.

Careful: '[and '] change when using commands that change the buffer.

In commands which expect a file name, you can use "<afile>" for the file name that is being read :<afile> (you can also use "%" for the current file name). "<abuf>" can be used for the buffer number of the currently effective

buffer. This also works for buffers that don't have a name. But it doesn't
work for files without a buffer (e.g., with ":r file").

                                                        gzip-example
Examples for reading and writing compressed files:
```
  :augroup gzip
  :  autocmd!
  :  autocmd BufReadPre,FileReadPre     *.gz set bin
  :  autocmd BufReadPost,FileReadPost   *.gz '[,']!gunzip
  :  autocmd BufReadPost,FileReadPost   *.gz set nobin
  :  autocmd BufReadPost,FileReadPost   *.gz execute ":doautocmd BufReadPost " . expand("%
  :  autocmd BufWritePost,FileWritePost *.gz !mv <afile> <afile>:r
  :  autocmd BufWritePost,FileWritePost *.gz !gzip <afile>:r

  :  autocmd FileAppendPre              *.gz !gunzip <afile>
  :  autocmd FileAppendPre              *.gz !mv <afile>:r <afile>
  :  autocmd FileAppendPost             *.gz !mv <afile> <afile>:r
  :  autocmd FileAppendPost             *.gz !gzip <afile>:r
  :augroup END
```

The "gzip" group is used to be able to delete any existing autocommands with
":autocmd!", for when the file is sourced twice.

("<afile>:r" is the file name without the extension, see :_%:)

The commands executed for the BufNewFile, BufRead/BufReadPost, BufWritePost,
FileAppendPost and VimLeave events do not set or reset the changed flag of the
buffer. When you decompress the buffer with the BufReadPost autocommands, you
can still exit with ":q". When you use ":undo" in BufWritePost to undo the
changes made by BufWritePre commands, you can still do ":q" (this also makes
"ZZ" work). If you do want the buffer to be marked as modified, set the
'modified' option.

To execute Normal mode commands from an autocommand, use the ":normal"
command. Use with care! If the Normal mode command is not finished, the user
needs to type characters (e.g., after ":normal m" you need to type a mark
name).

If you want the buffer to be unmodified after changing it, reset the
'modified' option. This makes it possible to exit the buffer with ":q"
instead of ":q!".

                                                  autocmd-nested   E218
By default, autocommands do not nest. If you use ":e" or ":w" in an
autocommand, Vim does not execute the BufRead and BufWrite autocommands for
those commands. If you do want this, use the "nested" flag for those commands
in which you want nesting. For example:
```
  :autocmd FileChangedShell *.c nested e!
```
The nesting is limited to 10 levels to get out of recursive loops.

It's possible to use the ":au" command in an autocommand. This can be a
self-modifying command! This can be useful for an autocommand that should
execute only once.

If you want to skip autocommands for one command, use the :noautocmd command modifier or the 'eventignore' option.

Note: When reading a file (with ":read file" or with a filter command) and the last line in the file does not have an <EOL>, Vim remembers this. At the next write (with ":write file" or with a filter command), if the same line is written again as the last line in a file AND 'binary' is set, Vim does not supply an <EOL>. This makes a filter command on the just read lines write the same file as was read, and makes a write command on just filtered lines write the same file as was read from the filter. For example, another way to write a compressed file:

```
:autocmd FileWritePre *.gz   set bin|'[,']!gzip
:autocmd FileWritePost *.gz  undo|set nobin
```

autocommand-pattern

You can specify multiple patterns, separated by commas. Here are some examples:

```
:autocmd BufRead   *          set tw=79 nocin ic infercase fo=2croq
:autocmd BufRead   .letter    set tw=72 fo=2tcrq
:autocmd BufEnter  .letter    set dict=/usr/lib/dict/words
:autocmd BufLeave  .letter    set dict=
:autocmd BufRead,BufNewFile   *.c,*.h set tw=0 cin noic
:autocmd BufEnter  *.c,*.h    abbr FOR for (i = 0; i < 3; ++i)<CR>{<CR>}<Esc>O
:autocmd BufLeave  *.c,*.h    unabbr FOR
```

For makefiles (makefile, Makefile, imakefile, makefile.unix, etc.):

```
:autocmd BufEnter  ?akefile*  set include=^s\=include
:autocmd BufLeave  ?akefile*  set include&
```

To always start editing C files at the first function:

```
:autocmd BufRead   *.c,*.h    1;/^{
```

Without the "1;" above, the search would start from wherever the file was entered, rather than from the start of the file.

skeleton template

To read a skeleton (template) file when opening a new file:

```
:autocmd BufNewFile  *.c      0r ~/vim/skeleton.c
:autocmd BufNewFile  *.h      0r ~/vim/skeleton.h
:autocmd BufNewFile  *.java   0r ~/vim/skeleton.java
```

To insert the current date and time in a *.html file when writing it:

```
:autocmd BufWritePre,FileWritePre *.html   ks|call LastMod()|'s
:fun LastMod()
:  if line("$") > 20
:    let l = 20
:  else
:    let l = line("$")
```

```
  :  endif
  :  exe "1," . l . "g/Last modified: /s/Last modified: .*/Last modified: " .
  :  \ strftime("%Y %b %d")
  :endfun
```

You need to have a line "Last modified: <date time>" in the first 20 lines
of the file for this to work. Vim replaces <date time> (and anything in the
same line after it) with the current date and time. Explanation:

```
        ks              mark current position with mark 's'
        call LastMod()  call the LastMod() function to do the work
        's              return the cursor to the old position
```

The LastMod() function checks if the file is shorter than 20 lines, and then
uses the ":g" command to find lines that contain "Last modified: ". For those
lines the ":s" command is executed to replace the existing date with the
current one. The ":execute" command is used to be able to use an expression
for the ":g" and ":s" commands. The date is obtained with the strftime()
function. You can change its argument to get another date string.

When entering :autocmd on the command-line, completion of events and command
names may be done (with <Tab>, CTRL-D, etc.) where appropriate.

Vim executes all matching autocommands in the order that you specify them.
It is recommended that your first autocommand be used for all files by using
"*" as the file pattern. This means that you can define defaults you like
here for any settings, and if there is another matching autocommand it will
override these. But if there is no other matching autocommand, then at least
your default settings are recovered (if entering this file from another for
which autocommands did match). Note that "*" will also match files starting
with ".", unlike Unix shells.

autocmd-searchpat

Autocommands do not change the current search patterns. Vim saves the current
search patterns before executing autocommands then restores them after the
autocommands finish. This means that autocommands do not affect the strings
highlighted with the 'hlsearch' option. Within autocommands, you can still
use search patterns normally, e.g., with the "n" command.
If you want an autocommand to set the search pattern, such that it is used
after the autocommand finishes, use the ":let @/ =" command.
The search-highlighting cannot be switched off with ":nohlsearch" in an
autocommand. Use the 'h' flag in the 'viminfo' option to disable search-
highlighting when starting Vim.

Cmd-event

When using one of the "*Cmd" events, the matching autocommands are expected to
do the file reading, writing or sourcing. This can be used when working with
a special kind of file, for example on a remote system.
CAREFUL: If you use these events in a wrong way, it may have the effect of
making it impossible to read or write the matching files! Make sure you test
your autocommands properly. Best is to use a pattern that will never match a
normal file name, for example "ftp://*".

When defining a BufReadCmd it will be difficult for Vim to recover a crashed
editing session. When recovering from the original file, Vim reads only those
parts of a file that are not found in the swap file. Since that is not

possible with a BufReadCmd, use the :preserve command to make sure the original file isn't needed for recovery. You might want to do this only when you expect the file to be modified.

For file read and write commands the v:cmdarg variable holds the "++enc=" and "++ff=" argument that are effective. These should be used for the command that reads/writes the file. The v:cmdbang variable is one when "!" was used, zero otherwise.

See the $VIMRUNTIME/plugin/netrwPlugin.vim for examples.

==
11. Disabling autocommands autocmd-disable

To disable autocommands for some time use the 'eventignore' option. Note that this may cause unexpected behavior, make sure you restore 'eventignore' afterwards, using a :try block with :finally .

:noautocmd :noa
To disable autocommands for just one command use the ":noautocmd" command modifier. This will set 'eventignore' to "all" for the duration of the following command. Example:

```
:noautocmd w fname.gz
```

This will write the file without triggering the autocommands defined by the gzip plugin.

2. Filetype plugin filetype-plugins
3. Docs for the default filetype plugins. ftplugin-docs

Also see autocmd.txt .

{Vi does not have any of these commands}

==
1. Filetypes filetypes file-types

Vim can detect the type of file that is edited. This is done by checking the
file name and sometimes by inspecting the contents of the file for specific
text.

:filetype :filet
To enable file type detection, use this command in your vimrc:
	:filetype on
Each time a new or existing file is edited, Vim will try to recognize the type
of the file and set the 'filetype' option. This will trigger the FileType
event, which can be used to set the syntax highlighting, set options, etc.

NOTE: Filetypes and 'compatible' don't work together well, since being Vi
compatible means options are global. Resetting 'compatible' is recommended,
if you didn't do that already.

Detail: The ":filetype on" command will load one of these files:
		Amiga	$VIMRUNTIME/filetype.vim
		Mac	$VIMRUNTIME:filetype.vim
		MS-DOS	$VIMRUNTIME\filetype.vim
		RiscOS	Vim:Filetype
		Unix	$VIMRUNTIME/filetype.vim
		VMS	$VIMRUNTIME/filetype.vim
	This file is a Vim script that defines autocommands for the
	BufNewFile and BufRead events. If the file type is not found by the
	name, the file $VIMRUNTIME/scripts.vim is used to detect it from the
	contents of the file.
	When the GUI is running or will start soon, the menu.vim script is
	also sourced. See 'go-M' about avoiding that.

To add your own file types, see new-filetype below. To search for help on a
filetype prepend "ft-" and optionally append "-syntax", "-indent" or
"-plugin". For example:
	:help ft-vim-indent
	:help ft-vim-syntax
	:help ft-man-plugin

If the file type is not detected automatically, or it finds the wrong type,
you can either set the 'filetype' option manually, or add a modeline to your
file. Example, for an IDL file use the command:
	:set filetype=idl

or add this modeline to the file:
	/* vim: set filetype=idl : */

:filetype-plugin-on
You can enable loading the plugin files for specific file types with:
	:filetype plugin on
If filetype detection was not switched on yet, it will be as well.
This actually loads the file "ftplugin.vim" in 'runtimepath'.
The result is that when a file is edited its plugin file is loaded (if there
is one for the detected filetype). filetype-plugin

:filetype-plugin-off
You can disable it again with:
	:filetype plugin off
The filetype detection is not switched off then. But if you do switch off
filetype detection, the plugins will not be loaded either.
This actually loads the file "ftplugof.vim" in 'runtimepath'.

:filetype-indent-on
You can enable loading the indent file for specific file types with:
	:filetype indent on
If filetype detection was not switched on yet, it will be as well.
This actually loads the file "indent.vim" in 'runtimepath'.
The result is that when a file is edited its indent file is loaded (if there
is one for the detected filetype). indent-expression

:filetype-indent-off
You can disable it again with:
	:filetype indent off
The filetype detection is not switched off then. But if you do switch off
filetype detection, the indent files will not be loaded either.
This actually loads the file "indoff.vim" in 'runtimepath'.
This disables auto-indenting for files you will open. It will keep working in
already opened files. Reset 'autoindent', 'cindent', 'smartindent' and/or
'indentexpr' to disable indenting in an opened file.

:filetype-off
To disable file type detection, use this command:
	:filetype off
This will keep the flags for "plugin" and "indent", but since no file types
are being detected, they won't work until the next ":filetype on".

Overview: :filetype-overview

command	detection	plugin	indent
:filetype on	on	unchanged	unchanged
:filetype off	off	unchanged	unchanged

```
:filetype plugin on             on              on              unchanged
:filetype plugin off            unchanged       off             unchanged
:filetype indent on             on              unchanged       on
:filetype indent off            unchanged       unchanged       off
:filetype plugin indent on      on              on              on
:filetype plugin indent off     unchanged       off             off
```

To see the current status, type:

```
        :filetype
```

The output looks something like this:

```
        filetype detection:ON  plugin:ON  indent:OFF
```

The file types are also used for syntax highlighting. If the ":syntax on" command is used, the file type detection is installed too. There is no need to do ":filetype on" after ":syntax on".

To disable one of the file types, add a line in your filetype file, see remove-filetype .

filetype-detect

To detect the file type again:

```
        :filetype detect
```

Use this if you started with an empty file and typed text that makes it possible to detect the file type. For example, when you entered this in a shell script: "#!/bin/csh".

When filetype detection was off, it will be enabled first, like the "on" argument was used.

filetype-overrule

When the same extension is used for two filetypes, Vim tries to guess what kind of file it is. This doesn't always work. A number of global variables can be used to overrule the filetype used for certain extensions:

file name	variable		
*.asa	g:filetype_asa	ft-aspvbs-syntax	ft-aspperl-syntax
*.asp	g:filetype_asp	ft-aspvbs-syntax	ft-aspperl-syntax
*.asm	g:asmsyntax	ft-asm-syntax	
*.prg	g:filetype_prg		
*.pl	g:filetype_pl		
*.inc	g:filetype_inc		
*.w	g:filetype_w	ft-cweb-syntax	
*.i	g:filetype_i	ft-progress-syntax	
*.p	g:filetype_p	ft-pascal-syntax	
*.sh	g:bash_is_sh	ft-sh-syntax	
*.tex	g:tex_flavor	ft-tex-plugin	

filetype-ignore

To avoid that certain files are being inspected, the g:ft_ignore_pat variable is used. The default value is set like this:

```
        :let g:ft_ignore_pat = '\.\(Z\|gz\|bz2\|zip\|tgz\)$'
```

This means that the contents of compressed files are not inspected.

new-filetype

If a file type that you want to use is not detected yet, there are four ways

to add it. In any way, it's better not to modify the $VIMRUNTIME/filetype.vim file. It will be overwritten when installing a new version of Vim.

A. If you want to overrule all default file type checks.
   This works by writing one file for each filetype. The disadvantage is that means there can be many files. The advantage is that you can simply drop this file in the right directory to make it work.
                                                        ftdetect

   1. Create your user runtime directory. You would normally use the first item of the 'runtimepath' option. Then create the directory "ftdetect" inside it. Example for Unix:
      :!mkdir ~/.vim
      :!mkdir ~/.vim/ftdetect

   2. Create a file that contains an autocommand to detect the file type. Example:
      au BufRead,BufNewFile *.mine   set filetype=mine
     Note that there is no "augroup" command, this has already been done when sourcing your file. You could also use the pattern "*" and then check the contents of the file to recognize it.
      Write this file as "mine.vim" in the "ftdetect" directory in your user runtime directory. For example, for Unix:
      :w ~/.vim/ftdetect/mine.vim

   3. To use the new filetype detection you must restart Vim.

   The files in the "ftdetect" directory are used after all the default checks, thus they can overrule a previously detected file type. But you can also use :setfiletype to keep a previously detected filetype.

B. If you want to detect your file after the default file type checks.

   This works like A above, but instead of setting 'filetype' unconditionally use ":setfiletype". This will only set 'filetype' if no file type was detected yet. Example:
      au BufRead,BufNewFile *.txt   setfiletype text

   You can also use the already detected file type in your command. For example, to use the file type "mypascal" when "pascal" has been detected:
      au BufRead,BufNewFile *   if &ft == 'pascal' | set ft=mypascal
                                                                | endif

C. If your file type can be detected by the file name.
   1. Create your user runtime directory. You would normally use the first item of the 'runtimepath' option. Example for Unix:
      :!mkdir ~/.vim

   2. Create a file that contains autocommands to detect the file type. Example:
      " my filetype file
      if exists("did_load_filetypes")
        finish
      endif
      augroup filetypedetect

```
        au! BufRead,BufNewFile *.mine         setfiletype mine
        au! BufRead,BufNewFile *.xyz          setfiletype drawing
      augroup END
```
Write this file as "filetype.vim" in your user runtime directory. For example, for Unix:
```
:w ~/.vim/filetype.vim
```

3. To use the new filetype detection you must restart Vim.

Your filetype.vim will be sourced before the default FileType autocommands have been installed. Your autocommands will match first, and the ":setfiletype" command will make sure that no other autocommands will set 'filetype' after this.

new-filetype-scripts

D. If your filetype can only be detected by inspecting the contents of the file.

1. Create your user runtime directory. You would normally use the first item of the 'runtimepath' option. Example for Unix:
```
:!mkdir ~/.vim
```

2. Create a vim script file for doing this. Example:
```
    if did_filetype()       " filetype already set..
      finish                " ..don't do these checks
    endif
    if getline(1) =~ '^#!.*\<mine\>'
      setfiletype mine
    elseif getline(1) =~? '\<drawing\>'
      setfiletype drawing
    endif
```
See $VIMRUNTIME/scripts.vim for more examples.
Write this file as "scripts.vim" in your user runtime directory. For example, for Unix:
```
:w ~/.vim/scripts.vim
```

3. The detection will work right away, no need to restart Vim.

Your scripts.vim is loaded before the default checks for file types, which means that your rules override the default rules in $VIMRUNTIME/scripts.vim.

remove-filetype

If a file type is detected that is wrong for you, install a filetype.vim or scripts.vim to catch it (see above). You can set 'filetype' to a non-existing name to avoid that it will be set later anyway:
```
:set filetype=ignored
```

If you are setting up a system with many users, and you don't want each user to add/remove the same filetypes, consider writing the filetype.vim and scripts.vim files in a runtime directory that is used for everybody. Check the 'runtimepath' for a directory to use. If there isn't one, set 'runtimepath' in the system-vimrc . Be careful to keep the default directories!

autocmd-osfiletypes

NOTE: this code is currently disabled, as the RISC OS implementation was removed. In the future this will use the 'filetype' option.

On operating systems which support storing a file type with the file, you can specify that an autocommand should only be executed if the file is of a certain type.

The actual type checking depends on which platform you are running Vim on; see your system's documentation for details.

To use osfiletype checking in an autocommand you should put a list of types to match in angle brackets in place of a pattern, like this:

```
:au BufRead *.html,<&faf;HTML>  runtime! syntax/html.vim
```

This will match:

- Any file whose name ends in ".html"
- Any file whose type is "&faf" or "HTML", where the meaning of these types depends on which version of Vim you are using.
  Unknown types are considered NOT to match.

You can also specify a type and a pattern at the same time (in which case they must both match):

```
:au BufRead <&fff>diff*
```

This will match files of type "&fff" whose names start with "diff".

plugin-details

The "plugin" directory can be in any of the directories in the 'runtimepath' option. All of these directories will be searched for plugins and they are all loaded. For example, if this command:

```
set runtimepath
```

produces this output:

```
runtimepath=/etc/vim,~/.vim,/usr/local/share/vim/vim60
```

then Vim will load all plugins in these directories and below:

```
/etc/vim/plugin/
~/.vim/plugin/
/usr/local/share/vim/vim60/plugin/
```

Note that the last one is the value of $VIMRUNTIME which has been expanded.

Note that when using a plugin manager or packages many directories will be added to 'runtimepath'. These plugins each require their own directory, don't put them directly in ~/.vim/plugin.

What if it looks like your plugin is not being loaded? You can find out what happens when Vim starts up by using the -V argument:

```
vim -V2
```

You will see a lot of messages, in between them is a remark about loading the plugins. It starts with:

```
Searching for "plugin/**/*.vim" in
```

There you can see where Vim looks for your plugin scripts.

==
2. Filetype plugin filetype-plugins

When loading filetype plugins has been enabled :filetype-plugin-on , options will be set and mappings defined. These are all local to the buffer, they will not be used for other files.

Defining mappings for a filetype may get in the way of the mappings you define yourself. There are a few ways to avoid this:
1. Set the "maplocalleader" variable to the key sequence you want the mappings to start with. Example:
```
:let maplocalleader = ","
```
All mappings will then start with a comma instead of the default, which is a backslash. Also see <LocalLeader> .

2. Define your own mapping. Example:
```
:map ,p <Plug>MailQuote
```
You need to check the description of the plugin file below for the functionality it offers and the string to map to.
You need to define your own mapping before the plugin is loaded (before editing a file of that type). The plugin will then skip installing the default mapping.

no_mail_maps
3. Disable defining mappings for a specific filetype by setting a variable, which contains the name of the filetype. For the "mail" filetype this would be:
```
:let no_mail_maps = 1
```

no_plugin_maps
4. Disable defining mappings for all filetypes by setting a variable:
```
:let no_plugin_maps = 1
```

ftplugin-overrule
If a global filetype plugin does not do exactly what you want, there are three ways to change this:

1. Add a few settings.
You must create a new filetype plugin in a directory early in 'runtimepath'. For Unix, for example you could use this file:
```
vim ~/.vim/ftplugin/fortran.vim
```
You can set those settings and mappings that you would like to add. Note

that the global plugin will be loaded after this, it may overrule the settings that you do here. If this is the case, you need to use one of the following two methods.

2. Make a copy of the plugin and change it.
   You must put the copy in a directory early in 'runtimepath'. For Unix, for example, you could do this:
```
cp $VIMRUNTIME/ftplugin/fortran.vim ~/.vim/ftplugin/fortran.vim
```
  Then you can edit the copied file to your liking. Since the b:did_ftplugin variable will be set, the global plugin will not be loaded.
   A disadvantage of this method is that when the distributed plugin gets improved, you will have to copy and modify it again.

3. Overrule the settings after loading the global plugin.
   You must create a new filetype plugin in a directory from the end of 'runtimepath'. For Unix, for example, you could use this file:
```
vim ~/.vim/after/ftplugin/fortran.vim
```
  In this file you can change just those settings that you want to change.

==
3. Docs for the default filetype plugins. ftplugin-docs

CHANGELOG ft-changelog-plugin

Allows for easy entrance of Changelog entries in Changelog files. There are some commands, mappings, and variables worth exploring:

Options:

'comments'	is made empty to not mess up formatting.
'textwidth'	is set to 78, which is standard.
'formatoptions'	the 't' flag is added to wrap when inserting text.

Commands:

NewChangelogEntry	Adds a new Changelog entry in an intelligent fashion (see below).

Local mappings:

<Leader>o	Starts a new Changelog entry in an equally intelligent fashion (see below).

Global mappings:

	NOTE: The global mappings are accessed by sourcing the ftplugin/changelog.vim file first, e.g. with `runtime ftplugin/changelog.vim` in your .vimrc .
<Leader>o	Switches to the ChangeLog buffer opened for the current directory, or opens it in a new buffer if it exists in the current directory. Then it does the same as the local <Leader>o described above.

Variables:

g:changelog_timeformat	Deprecated; use g:changelog_dateformat instead.
g:changelog_dateformat	The date (and time) format used in ChangeLog entries.

```
                        The format accepted is the same as for the
                         strftime()  function.
                        The default is "%Y-%m-%d" which is the standard format
                        for many ChangeLog layouts.
g:changelog_username    The name and email address of the user.
                        The default is deduced from environment variables and
                        system files.  It searches /etc/passwd for the comment
                        part of the current user, which informally contains
                        the real name of the user up to the first separating
                        comma.  then it checks the $NAME environment variable
                        and finally runs `whoami` and `hostname` to build an
                        email address.  The final form is
                                Full Name  <user@host>

g:changelog_new_date_format
                        The format to use when creating a new date-entry.
                        The following table describes special tokens in the
                        string:
                                %%      insert a single '%' character
                                %d      insert the date from above
                                %u      insert the user from above
                                %p      insert result of b:changelog_entry_prefix
                                %c      where to position cursor when done
                        The default is "%d  %u\n\n\t* %p%c\n\n", which produces
                        something like (| is where cursor will be, unless at
                        the start of the line where it denotes the beginning
                        of the line)
                                |2003-01-14  Full Name  <user@host>
                                |
                                |       * prefix|

g:changelog_new_entry_format
                        The format used when creating a new entry.
                        The following table describes special tokens in the
                        string:
                                %p      insert result of b:changelog_entry_prefix
                                %c      where to position cursor when done
                        The default is "\t*%c", which produces something
                        similar to
                                |       * prefix|

g:changelog_date_entry_search
                        The search pattern to use when searching for a
                        date-entry.
                        The same tokens that can be used for
                        g:changelog_new_date_format can be used here as well.
                        The default is '^\s*%d\_s*%u' which finds lines
                        matching the form
                                |2003-01-14  Full Name  <user@host>
                       and some similar formats.

g:changelog_date_end_entry_search
                        The search pattern to use when searching for the end
                        of a date-entry.
```

The same tokens that can be used for
g:changelog_new_date_format can be used here as well.
The default is '^\s*$' which finds lines that contain
only whitespace or are completely empty.

b:changelog_name   b:changelog_name
Name of the ChangeLog file to look for.
The default is 'ChangeLog'.

b:changelog_path
Path of the ChangeLog to use for the current buffer.
The default is empty, thus looking for a file named
b:changelog_name in the same directory as the
current buffer. If not found, the parent directory of
the current buffer is searched. This continues
recursively until a file is found or there are no more
parent directories to search.

b:changelog_entry_prefix
Name of a function to call to generate a prefix to a
new entry. This function takes no arguments and
should return a string containing the prefix.
Returning an empty prefix is fine.
The default generates the shortest path between the
ChangeLog's pathname and the current buffers pathname.
In the future, it will also be possible to use other
variable contexts for this variable, for example, g:.

The Changelog entries are inserted where they add the least amount of text.
After figuring out the current date and user, the file is searched for an
entry beginning with the current date and user and if found adds another item
under it. If not found, a new entry and item is prepended to the beginning of
the Changelog.

FORTRAN   ft-fortran-plugin

Options:
'expandtab' is switched on to avoid tabs as required by the Fortran
standards unless the user has set fortran_have_tabs in .vimrc.
'textwidth' is set to 72 for fixed source format as required by the
Fortran standards and to 80 for free source format.
'formatoptions' is set to break code and comment lines and to preserve long
lines. You can format comments with gq .
For further discussion of fortran_have_tabs and the method used for the
detection of source format see ft-fortran-syntax .

GIT COMMIT   ft-gitcommit-plugin

One command, :DiffGitCached, is provided to show a diff of the current commit
in the preview window. It is equivalent to calling "git diff --cached" plus
any arguments given to the command.

MAIL ft-mail-plugin

Options:
'modeline' is switched off to avoid the danger of trojan horses, and to avoid that a Subject line with "Vim:" in it will cause an error message.
'textwidth' is set to 72. This is often recommended for e-mail.
'formatoptions' is set to break text lines and to repeat the comment leader in new lines, so that a leading ">" for quotes is repeated. You can also format quoted text with gq .

Local mappings:
<LocalLeader>q or \\MailQuote
Quotes the text selected in Visual mode, or from the cursor position to the end of the file in Normal mode. This means "> " is inserted in each line.

MAN ft-man-plugin :Man man.vim

Displays a manual page in a nice way. Also see the user manual find-manpage .

To start using the ":Man" command before any manual page was loaded, source this script from your startup vimrc file:

```
runtime ftplugin/man.vim
```

Options:
'iskeyword' the '.' character is added to be able to use CTRL-] on the manual page name.

Commands:
Man {name} Display the manual page for {name} in a window.
Man {number} {name}
Display the manual page for {name} in a section {number}.

Global mapping:
<Leader>K Displays the manual page for the word under the cursor.
<Plug>ManPreGetPage idem, allows for using a mapping:

```
nmap <F1> <Plug>ManPreGetPage<CR>
```

Local mappings:
CTRL-] Jump to the manual page for the word under the cursor.
CTRL-T Jump back to the previous manual page.
q Same as ":quit"

To use a vertical split instead of horizontal:

```
let g:ft_man_open_mode = 'vert'
```

To use a new tab:

```
let g:ft_man_open_mode = 'tab'
```

To enable folding use this:

```
let g:ft_man_folding_enable = 1
```

If you do not like the default folding, use an autocommand to add your desired folding style instead. For example:

```
autocmd FileType man setlocal foldmethod=indent foldenable
```

You may also want to set 'keywordprg' to make the K command open a manual page in a Vim window:

```
set keywordprg=:Man
```

MANPAGER manpager.vim

The :Man command allows you to turn Vim into a manpager (that syntax highlights manpages and follows linked manpages on hitting CTRL-]).

For bash,zsh,ksh or dash, add to the config file (.bashrc,.zshrc, ...)

```
export MANPAGER="vim -M +MANPAGER -"
```

For (t)csh, add to the config file

```
setenv MANPAGER "vim -M +MANPAGER -"
```

For fish, add to the config file

```
set -x MANPAGER "vim -M +MANPAGER -"
```

PDF ft-pdf-plugin

Two maps, <C-]> and <C-T>, are provided to simulate a tag stack for navigating the PDF. The following are treated as tags:

- The byte offset after "startxref" to the xref table
- The byte offset after the /Prev key in the trailer to an earlier xref table
- A line of the form "0123456789 00000 n" in the xref table
- An object reference like "1 0 R" anywhere in the PDF

These maps can be disabled with

```
:let g:no_pdf_maps = 1
```

PYTHON ft-python-plugin PEP8

By default the following options are set, in accordance with PEP8:

```
setlocal expandtab shiftwidth=4 softtabstop=4 tabstop=8
```

To disable this behaviour, set the following variable in your vimrc:

```
let g:python_recommended_style = 0
```

RPM SPEC ft-spec-plugin

Since the text for this plugin is rather long it has been put in a separate

file: pi_spec.txt .

RUST ft-rust

Since the text for this plugin is rather long it has been put in a separate
file: ft_rust.txt .

SQL ft-sql

Since the text for this plugin is rather long it has been put in a separate
file: ft_sql.txt .

TEX ft-tex-plugin g:tex_flavor

If the first line of a *.tex file has the form
```
	%&<format>
```
then this determined the file type: plaintex (for plain TeX), context (for
ConTeXt), or tex (for LaTeX). Otherwise, the file is searched for keywords to
choose context or tex. If no keywords are found, it defaults to plaintex.
You can change the default by defining the variable g:tex_flavor to the format
(not the file type) you use most. Use one of these:
```
	let g:tex_flavor = "plain"
	let g:tex_flavor = "context"
	let g:tex_flavor = "latex"
```
Currently no other formats are recognized.

VIM ft-vim-plugin

The Vim filetype plugin defines mappings to move to the start and end of
functions with [[and]]. Move around comments with]" and ["

The mappings can be disabled with:
```
	let g:no_vim_maps = 1
```

ZIMBU ft-zimbu-plugin

The Zimbu filetype plugin defines mappings to move to the start and end of
functions with [[and]].

The mappings can be disabled with:
```
	let g:no_zimbu_maps = 1
```

vim:tw=78:ts=8:noet:ft=help:norl:

eval.txt For Vim version 8.1. Last change: 2018 May 17

VIM REFERENCE MANUAL by Bram Moolenaar

Expression evaluation expression expr E15 eval

Using expressions is introduced in chapter 41 of the user manual usr_41.txt .

Note: Expression evaluation can be disabled at compile time. If this has been done, the features in this document are not available. See +eval and no-eval-feature .

{Vi does not have any of these commands}

==========

1. Variables variables

1.1 Variable types E712

There are nine types of variables:

Number A 32 or 64 bit signed number. expr-number Number
64-bit Numbers are available only when compiled with the +num64 feature.
Examples: -123 0x10 0177 0b1011

Float A floating point number. floating-point-format Float
{only when compiled with the |+float| feature}
Examples: 123.456 1.15e-6 -1.1e3

String A NUL terminated string of 8-bit unsigned characters (bytes). E928
expr-string Examples: "ab\txx\"--" 'x-z''a,c'

List An ordered sequence of items List .
Example: [1, 2, ['a', 'b']]

Dictionary An associative, unordered array: Each entry has a key and a value. Dictionary
Example: {'blue': "#0000ff", 'red': "#ff0000"}

Funcref A reference to a function Funcref .
Example: function("strlen")
It can be bound to a dictionary and arguments, it then works like a Partial.
Example: function("Callback", [arg], myDict)

Special v:false , v:true , v:none and v:null . Special

Job Used for a job, see job_start() . Job Jobs

Channel Used for a channel, see ch_open() . Channel Channels

The Number and String types are converted automatically, depending on how they are used.

Conversion from a Number to a String is by making the ASCII representation of the Number. Examples:
```
Number 123      -->     String "123"
Number 0        -->     String "0"
Number -1       -->     String "-1"
```
octal
Conversion from a String to a Number is done by converting the first digits to a number. Hexadecimal "0xf9", Octal "017", and Binary "0b10" numbers are recognized. If the String doesn't start with digits, the result is zero.
Examples:
```
String "456"    -->     Number 456
String "6bar"   -->     Number 6
String "foo"    -->     Number 0
String "0xf1"   -->     Number 241
String "0100"   -->     Number 64
String "0b101"  -->     Number 5
String "-8"     -->     Number -8
String "+8"     -->     Number 0
```

To force conversion from String to Number, add zero to it:
```
:echo "0100" + 0
64
```

To avoid a leading zero to cause octal conversion, or for using a different base, use str2nr() .

TRUE FALSE
For boolean operators Numbers are used. Zero is FALSE, non-zero is TRUE.
You can also use v:false and v:true . When TRUE is returned from a function it is the Number one, FALSE is the number zero.

Note that in the command:
```
:if "foo"
:" NOT executed
```
"foo" is converted to 0, which means FALSE. If the string starts with a non-zero number it means TRUE:
```
:if "8foo"
:" executed
```
To test for a non-empty string, use empty():
```
:if !empty("foo")
```

non-zero-arg
Function arguments often behave slightly different from TRUE : If the argument is present and it evaluates to a non-zero Number, v:true or a non-empty String, then the value is considered to be TRUE.
Note that " " and "0" are also non-empty strings, thus considered to be TRUE.
A List, Dictionary or Float is not a Number or String, thus evaluate to FALSE.

E745 E728 E703 E729 E730 E731 E908 E910 E913
List, Dictionary, Funcref, Job and Channel types are not automatically converted.

E805 E806 E808
When mixing Number and Float the Number is converted to Float. Otherwise there is no automatic conversion of Float. You can use str2float() for String to Float, printf() for Float to String and float2nr() for Float to Number.

E891 E892 E893 E894 E907 E911 E914
When expecting a Float a Number can also be used, but nothing else.

no-type-checking
You will not get an error if you try to change the type of a variable.

1.2 Function references

Funcref E695 E718
A Funcref variable is obtained with the function() function, the funcref() function or created with the lambda expression expr-lambda . It can be used in an expression in the place of a function name, before the parenthesis around the arguments, to invoke the function it refers to. Example:

```
:let Fn = function("MyFunc")
:echo Fn()
```

E704 E705 E707
A Funcref variable must start with a capital, "s:", "w:", "t:" or "b:". You can use "g:" but the following name must still start with a capital. You cannot have both a Funcref variable and a function with the same name.

A special case is defining a function and directly assigning its Funcref to a Dictionary entry. Example:
```
:function dict.init() dict
:   let self.val = 0
:endfunction
```

The key of the Dictionary can start with a lower case letter. The actual

function name is not used here. Also see numbered-function .

A Funcref can also be used with the :call command:
```
:call Fn()
:call dict.init()
```

The name of the referenced function can be obtained with string() .
```
:let func = string(Fn)
```

You can use call() to invoke a Funcref and use a list variable for the arguments:
```
:let r = call(Fn, mylist)
```

Partial

A Funcref optionally binds a Dictionary and/or arguments. This is also called a Partial. This is created by passing the Dictionary and/or arguments to function() or funcref(). When calling the function the Dictionary and/or arguments will be passed to the function. Example:

```
let Cb = function('Callback', ['foo'], myDict)
call Cb()
```

This will invoke the function as if using:
```
call myDict.Callback('foo')
```

This is very useful when passing a function around, e.g. in the arguments of ch_open() .

Note that binding a function to a Dictionary also happens when the function is a member of the Dictionary:

```
let myDict.myFunction = MyFunction
call myDict.myFunction()
```

Here MyFunction() will get myDict passed as "self". This happens when the "myFunction" member is accessed. When making assigning "myFunction" to otherDict and calling it, it will be bound to otherDict:

```
let otherDict.myFunction = myDict.myFunction
call otherDict.myFunction()
```

Now "self" will be "otherDict". But when the dictionary was bound explicitly this won't happen:

```
let myDict.myFunction = function(MyFunction, myDict)
let otherDict.myFunction = myDict.myFunction
call otherDict.myFunction()
```

Here "self" will be "myDict", because it was bound explicitly.

1.3 Lists

list List Lists E686

A List is an ordered sequence of items. An item can be of any type. Items

can be accessed by their index number. Items can be added and removed at any position in the sequence.

List creation

E696 E697

A List is created with a comma separated list of items in square brackets.
Examples:

```
:let mylist = [1, two, 3, "four"]
:let emptylist = []
```

An item can be any expression. Using a List for an item creates a List of Lists:

```
:let nestlist = [[11, 12], [21, 22], [31, 32]]
```

An extra comma after the last item is ignored.

List index

list-index E684

An item in the List can be accessed by putting the index in square brackets after the List. Indexes are zero-based, thus the first item has index zero.

```
:let item = mylist[0]          " get the first item: 1
:let item = mylist[2]          " get the third item: 3
```

When the resulting item is a list this can be repeated:

```
:let item = nestlist[0][1]     " get the first list, second item: 12
```

A negative index is counted from the end. Index -1 refers to the last item in the List, -2 to the last but one item, etc.

```
:let last = mylist[-1]         " get the last item: "four"
```

To avoid an error for an invalid index use the get() function. When an item is not available it returns zero or the default value you specify:

```
:echo get(mylist, idx)
:echo get(mylist, idx, "NONE")
```

List concatenation

Two lists can be concatenated with the "+" operator:

```
:let longlist = mylist + [5, 6]
:let mylist += [7, 8]
```

To prepend or append an item turn the item into a list by putting [] around it. To change a list in-place see list-modification below.

Sublist

sublist

A part of the List can be obtained by specifying the first and last index, separated by a colon in square brackets:

```
:let shortlist = mylist[2:-1]   " get List [3, "four"]
```

Omitting the first index is similar to zero. Omitting the last index is similar to -1.

```
:let endlist = mylist[2:]       " from item 2 to the end: [3, "four"]
:let shortlist = mylist[2:2]    " List with one item: [3]
:let otherlist = mylist[:]      " make a copy of the List
```

If the first index is beyond the last item of the List or the second item is before the first item, the result is an empty list. There is no error message.

If the second index is equal to or greater than the length of the list the length minus one is used:

```
:let mylist = [0, 1, 2, 3]
:echo mylist[2:8]               " result: [2, 3]
```

NOTE: mylist[s:e] means using the variable "s:e" as index. Watch out for using a single letter variable before the ":". Insert a space when needed: mylist[s : e].

List identity

list-identity

When variable "aa" is a list and you assign it to another variable "bb", both variables refer to the same list. Thus changing the list "aa" will also change "bb":

```
:let aa = [1, 2, 3]
:let bb = aa
:call add(aa, 4)
:echo bb
[1, 2, 3, 4]
```

Making a copy of a list is done with the `copy()` function. Using [:] also works, as explained above. This creates a shallow copy of the list: Changing a list item in the list will also change the item in the copied list:

```
:let aa = [[1, 'a'], 2, 3]
:let bb = copy(aa)
:call add(aa, 4)
:let aa[0][1] = 'aaa'
:echo aa
[[1, aaa], 2, 3, 4]
:echo bb
[[1, aaa], 2, 3]
```

To make a completely independent list use `deepcopy()`. This also makes a copy of the values in the list, recursively. Up to a hundred levels deep.

The operator "is" can be used to check if two variables refer to the same List. "isnot" does the opposite. In contrast "==" compares if two lists have the same value.

```
:let alist = [1, 2, 3]
:let blist = [1, 2, 3]
:echo alist is blist
0
:echo alist == blist
```

```
1
```

Note about comparing lists: Two lists are considered equal if they have the same length and all items compare equal, as with using "==". There is one exception: When comparing a number with a string they are considered different. There is no automatic type conversion, as with using "==" on variables. Example:

```
echo 4 == "4"
1
echo [4] == ["4"]
0
```

Thus comparing Lists is more strict than comparing numbers and strings. You can compare simple values this way too by putting them in a list:

```
:let a = 5
:let b = "5"
:echo a == b
1
:echo [a] == [b]
0
```

List unpack

To unpack the items in a list to individual variables, put the variables in square brackets, like list items:

```
:let [var1, var2] = mylist
```

When the number of variables does not match the number of items in the list this produces an error. To handle any extra items from the list append ";" and a variable name:

```
:let [var1, var2; rest] = mylist
```

This works like:

```
:let var1 = mylist[0]
:let var2 = mylist[1]
:let rest = mylist[2:]
```

Except that there is no error if there are only two items. "rest" will be an empty list then.

List modification

list-modification

To change a specific item of a list use :let this way:

```
:let list[4] = "four"
:let listlist[0][3] = item
```

To change part of a list you can specify the first and last item to be modified. The value must at least have the number of items in the range:

```
:let list[3:5] = [3, 4, 5]
```

Adding and removing items from a list is done with functions. Here are a few

```
examples:
        :call insert(list, 'a')         " prepend item 'a'
        :call insert(list, 'a', 3)      " insert item 'a' before list[3]
        :call add(list, "new")          " append String item
        :call add(list, [1, 2])         " append a List as one new item
        :call extend(list, [1, 2])      " extend the list with two more items
        :let i = remove(list, 3)        " remove item 3
        :unlet list[3]                  " idem
        :let l = remove(list, 3, -1)    " remove items 3 to last item
        :unlet list[3 : ]               " idem
        :call filter(list, 'v:val !~ "x"')  " remove items with an 'x'

Changing the order of items in a list:
        :call sort(list)                " sort a list alphabetically
        :call reverse(list)             " reverse the order of items
        :call uniq(sort(list))          " sort and remove duplicates
```

For loop

The :for loop executes commands for each item in a list. A variable is set to each item in the list in sequence. Example:

```
        :for item in mylist
        :   call Doit(item)
        :endfor
```

This works like:

```
        :let index = 0
        :while index < len(mylist)
        :   let item = mylist[index]
        :   :call Doit(item)
        :   let index = index + 1
        :endwhile
```

If all you want to do is modify each item in the list then the map() function will be a simpler method than a for loop.

Just like the :let command, :for also accepts a list of variables. This requires the argument to be a list of lists.

```
        :for [lnum, col] in [[1, 3], [2, 8], [3, 0]]
        :   call Doit(lnum, col)
        :endfor
```

This works like a :let command is done for each list item. Again, the types must remain the same to avoid an error.

It is also possible to put remaining items in a List variable:

```
        :for [i, j; rest] in listlist
        :   call Doit(i, j)
        :   if !empty(rest)
        :      echo "remainder: " . string(rest)
        :   endif
        :endfor
```

List functions

E714

Functions that are useful with a List:

```
:let r = call(funcname, list)   " call a function with an argument list
:if empty(list)                 " check if list is empty
:let l = len(list)              " number of items in list
:let big = max(list)            " maximum value in list
:let small = min(list)          " minimum value in list
:let xs = count(list, 'x')      " count nr of times 'x' appears in list
:let i = index(list, 'x')       " index of first 'x' in list
:let lines = getline(1, 10)     " get ten text lines from buffer
:call append('$', lines)        " append text lines in buffer
:let list = split("a b c")      " create list from items in a string
:let string = join(list, ', ')  " create string from list items
:let s = string(list)           " String representation of list
:call map(list, '">> " . v:val')  " prepend ">> " to each item
```

Don't forget that a combination of features can make things simple. For example, to add up all the numbers in a list:

```
:exe 'let sum = ' . join(nrlist, '+')
```

1.4 Dictionaries

dict Dictionaries Dictionary

A Dictionary is an associative array: Each entry has a key and a value. The entry can be located with the key. The entries are stored without a specific ordering.

Dictionary creation

E720 E721 E722 E723

A Dictionary is created with a comma separated list of entries in curly braces. Each entry has a key and a value, separated by a colon. Each key can only appear once. Examples:

```
:let mydict = {1: 'one', 2: 'two', 3: 'three'}
:let emptydict = {}
```

E713 E716 E717

A key is always a String. You can use a Number, it will be converted to a String automatically. Thus the String '4' and the number 4 will find the same entry. Note that the String '04' and the Number 04 are different, since the Number will be converted to the String '4'. The empty string can be used as a key.

A value can be any expression. Using a Dictionary for a value creates a nested Dictionary:

```
:let nestdict = {1: {11: 'a', 12: 'b'}, 2: {21: 'c'}}
```

An extra comma after the last entry is ignored.

Accessing entries

The normal way to access an entry is by putting the key in square brackets:

```
:let val = mydict["one"]
:let mydict["four"] = 4
```

You can add new entries to an existing Dictionary this way, unlike Lists.

For keys that consist entirely of letters, digits and underscore the following form can be used expr-entry :
```
:let val = mydict.one
:let mydict.four = 4
```

Since an entry can be any type, also a List and a Dictionary, the indexing and key lookup can be repeated:
```
:echo dict.key[idx].key
```

Dictionary to List conversion

You may want to loop over the entries in a dictionary. For this you need to turn the Dictionary into a List and pass it to :for .

Most often you want to loop over the keys, using the keys() function:
```
:for key in keys(mydict)
:   echo key . ': ' . mydict[key]
:endfor
```

The List of keys is unsorted. You may want to sort them first:
```
:for key in sort(keys(mydict))
```

To loop over the values use the values() function:
```
:for v in values(mydict)
:   echo "value: " . v
:endfor
```

If you want both the key and the value use the items() function. It returns a List in which each item is a List with two items, the key and the value:
```
:for [key, value] in items(mydict)
:   echo key . ': ' . value
:endfor
```

Dictionary identity

dict-identity

Just like Lists you need to use copy() and deepcopy() to make a copy of a Dictionary. Otherwise, assignment results in referring to the same Dictionary:
```
:let onedict = {'a': 1, 'b': 2}
:let adict = onedict
:let adict['a'] = 11
:echo onedict['a']
11
```

Two Dictionaries compare equal if all the key-value pairs compare equal. For more info see list-identity .

Dictionary modification

dict-modification

To change an already existing entry of a Dictionary, or to add a new entry, use :let this way:

```
:let dict[4] = "four"
:let dict['one'] = item
```

Removing an entry from a Dictionary is done with remove() or :unlet . Three ways to remove the entry with key "aaa" from dict:

```
:let i = remove(dict, 'aaa')
:unlet dict.aaa
:unlet dict['aaa']
```

Merging a Dictionary with another is done with extend() :

```
:call extend(adict, bdict)
```

This extends adict with all entries from bdict. Duplicate keys cause entries in adict to be overwritten. An optional third argument can change this. Note that the order of entries in a Dictionary is irrelevant, thus don't expect ":echo adict" to show the items from bdict after the older entries in adict.

Weeding out entries from a Dictionary can be done with filter() :

```
:call filter(dict, 'v:val =~ "x"')
```

This removes all entries from "dict" with a value not matching 'x'.

Dictionary function

Dictionary-function self E725 E862

When a function is defined with the "dict" attribute it can be used in a special way with a dictionary. Example:

```
:function Mylen() dict
:   return len(self.data)
:endfunction
:let mydict = {'data': [0, 1, 2, 3], 'len': function("Mylen")}
:echo mydict.len()
```

This is like a method in object oriented programming. The entry in the Dictionary is a Funcref . The local variable "self" refers to the dictionary the function was invoked from.

It is also possible to add a function without the "dict" attribute as a Funcref to a Dictionary, but the "self" variable is not available then.

numbered-function anonymous-function

To avoid the extra name for the function it can be defined and directly assigned to a Dictionary in this way:

```
:let mydict = {'data': [0, 1, 2, 3]}
:function mydict.len()
:   return len(self.data)
:endfunction
:echo mydict.len()
```

The function will then get a number and the value of dict.len is a Funcref

that references this function. The function can only be used through a
 Funcref . It will automatically be deleted when there is no Funcref
remaining that refers to it.

It is not necessary to use the "dict" attribute for a numbered function.

If you get an error for a numbered function, you can find out what it is with
a trick. Assuming the function is 42, the command is:
```
:function {42}
```

Functions for Dictionaries

E715

Functions that can be used with a Dictionary:
```
:if has_key(dict, 'foo')        " TRUE if dict has entry with key "foo"
:if empty(dict)                 " TRUE if dict is empty
:let l = len(dict)              " number of items in dict
:let big = max(dict)            " maximum value in dict
:let small = min(dict)          " minimum value in dict
:let xs = count(dict, 'x')      " count nr of times 'x' appears in dict
:let s = string(dict)           " String representation of dict
:call map(dict, '">> " . v:val')  " prepend ">> " to each item
```

1.5 More about variables

more-variables

If you need to know the type of a variable or expression, use the type()
function.

When the '!' flag is included in the 'viminfo' option, global variables that
start with an uppercase letter, and don't contain a lowercase letter, are
stored in the viminfo file viminfo-file .

When the 'sessionoptions' option contains "global", global variables that
start with an uppercase letter and contain at least one lowercase letter are
stored in the session file session-file .

variable name	can be stored where
my_var_6	not
My_Var_6	session file
MY_VAR_6	viminfo file

It's possible to form a variable name with curly braces, see
 curly-braces-names .

==

2. Expression syntax

expression-syntax

Expression syntax summary, from least to most significant:

```
 expr1  expr2
        expr2 ? expr1 : expr1   if-then-else
```

```
expr2  expr3
       expr3 || expr3 ..       logical OR

expr3  expr4
       expr4 && expr4 ..       logical AND

expr4  expr5
       expr5 == expr5          equal
       expr5 != expr5          not equal
       expr5 >  expr5          greater than
       expr5 >= expr5          greater than or equal
       expr5 <  expr5          smaller than
       expr5 <= expr5          smaller than or equal
       expr5 =~ expr5          regexp matches
       expr5 !~ expr5          regexp doesn't match

       expr5 ==? expr5         equal, ignoring case
       expr5 ==# expr5         equal, match case
       etc.                    As above, append ? for ignoring case, # for
                               matching case

       expr5 is expr5          same  List  instance
       expr5 isnot expr5       different  List  instance

expr5  expr6
       expr6 +  expr6 ..       number addition or list concatenation
       expr6 -  expr6 ..       number subtraction
       expr6 .  expr6 ..       string concatenation

expr6  expr7
       expr7 *  expr7 ..       number multiplication
       expr7 /  expr7 ..       number division
       expr7 %  expr7 ..       number modulo

expr7  expr8
       ! expr7                 logical NOT
       - expr7                 unary minus
       + expr7                 unary plus

expr8  expr9
       expr8[expr1]            byte of a String or item of a  List
       expr8[expr1 : expr1]    substring of a String or sublist of a  List
       expr8.name              entry in a  Dictionary
       expr8(expr1, ...)       function call with  Funcref  variable

expr9  number                  number constant
       "string"                string constant, backslash is special
       'string'                string constant, ' is doubled
       [expr1, ...]             List
       {expr1: expr1, ...}      Dictionary
       &option                 option value
       (expr1)                 nested expression
       variable                internal variable
       va{ria}ble              internal variable with curly braces
```

```
        $VAR                    environment variable
        @r                      contents of register 'r'
        function(expr1, ...)    function call
        func{ti}on(expr1, ...)  function call with curly braces
        {args -> expr1}         lambda expression
```

".." indicates that the operations in this level can be concatenated.
Example:

```
        &nu || &list && &shell == "csh"
```

All expressions within one level are parsed from left to right.

expr1 expr1 E109

expr2 ? expr1 : expr1

The expression before the '?' is evaluated to a number. If it evaluates to TRUE, the result is the value of the expression between the '?' and ':', otherwise the result is the value of the expression after the ':'.
Example:

```
        :echo lnum == 1 ? "top" : lnum
```

Since the first expression is an "expr2", it cannot contain another ?:. The other two expressions can, thus allow for recursive use of ?:.
Example:

```
        :echo lnum == 1 ? "top" : lnum == 1000 ? "last" : lnum
```

To keep this readable, using line-continuation is suggested:

```
        :echo lnum == 1
        :\      ? "top"
        :\      : lnum == 1000
        :\              ? "last"
        :\              : lnum
```

You should always put a space before the ':', otherwise it can be mistaken for use in a variable such as "a:1".

expr2 and expr3 expr2 expr3

```
expr3 || expr3 ..       logical OR              expr-barbar
expr4 && expr4 ..       logical AND             expr-&&
```

The "||" and "&&" operators take one argument on each side. The arguments are (converted to) Numbers. The result is:

```
    input                       output
n1      n2              n1 || n2        n1 && n2
 FALSE   FALSE           FALSE           FALSE
 FALSE   TRUE            TRUE            FALSE
```

```
 TRUE    FALSE           TRUE            FALSE
 TRUE    TRUE            TRUE            TRUE
```

The operators can be concatenated, for example:

```
        &nu || &list && &shell == "csh"
```

Note that "&&" takes precedence over "||", so this has the meaning of:

```
        &nu || (&list && &shell == "csh")
```

Once the result is known, the expression "short-circuits", that is, further arguments are not evaluated. This is like what happens in C. For example:

```
        let a = 1
        echo a || b
```

This is valid even if there is no variable called "b" because "a" is TRUE , so the result must be TRUE . Similarly below:

```
        echo exists("b") && b == "yes"
```

This is valid whether "b" has been defined or not. The second clause will only be evaluated if "b" has been defined.

expr4   expr4
-----

expr5 {cmp} expr5

Compare two expr5 expressions, resulting in a 0 if it evaluates to false, or 1 if it evaluates to true.

```
                        expr-==    expr-!=    expr->     expr->=
                        expr-<     expr-<=    expr-=~    expr-!~
                        expr-==#   expr-!=#   expr->#    expr->=#
                        expr-<#    expr-<=#   expr-=~#   expr-!~#
                        expr-==?   expr-!=?   expr->?    expr->=?
                        expr-<?    expr-<=?   expr-=~?   expr-!~?
                        expr-is   expr-isnot   expr-is#   expr-isnot#
                        expr-is?   expr-isnot?
                use 'ignorecase'    match case     ignore case
equal                       ==             ==#            ==?
not equal                   !=             !=#            !=?
greater than                >              >#             >?
greater than or equal       >=             >=#            >=?
smaller than                <              <#             <?
smaller than or equal       <=             <=#            <=?
regexp matches              =~             =~#            =~?
regexp doesn't match        !~             !~#            !~?
same instance               is             is#            is?
different instance          isnot          isnot#         isnot?
```

Examples:
"abc" ==# "Abc"   evaluates to 0
"abc" ==? "Abc"   evaluates to 1
"abc" == "Abc"   evaluates to 1 if 'ignorecase' is set, 0 otherwise

E691 E692
A List can only be compared with a List and only "equal", "not equal", "is" and "isnot" can be used. This compares the values of the list, recursively. Ignoring case means case is ignored when comparing item values.

E735 E736
A Dictionary can only be compared with a Dictionary and only "equal", "not equal", "is" and "isnot" can be used. This compares the key/values of the Dictionary recursively. Ignoring case means case is ignored when comparing item values.

E694
A Funcref can only be compared with a Funcref and only "equal", "not equal", "is" and "isnot" can be used. Case is never ignored. Whether arguments or a Dictionary are bound (with a partial) matters. The Dictionaries must also be equal (or the same, in case of "is") and the arguments must be equal (or the same).

To compare Funcrefs to see if they refer to the same function, ignoring bound Dictionary and arguments, use get() to get the function name:
```
if get(Part1, 'name') == get(Part2, 'name')
   " Part1 and Part2 refer to the same function
```

When using "is" or "isnot" with a List or a Dictionary this checks if the expressions are referring to the same List or Dictionary instance. A copy of a List is different from the original List . When using "is" without a List or a Dictionary it is equivalent to using "equal", using "isnot" equivalent to using "not equal". Except that a different type means the values are different:
```
echo 4 == '4'
1
echo 4 is '4'
0
echo 0 is []
0
```
"is#"/"isnot#" and "is?"/"isnot?" can be used to match and ignore case.

When comparing a String with a Number, the String is converted to a Number, and the comparison is done on Numbers. This means that:
```
echo 0 == 'x'
1
```
because 'x' converted to a Number is zero. However:
```
echo [0] == ['x']
0
```
Inside a List or Dictionary this conversion is not used.

When comparing two Strings, this is done with strcmp() or stricmp(). This results in the mathematical difference (comparing byte values), not necessarily the alphabetical difference in the local language.

When using the operators with a trailing '#', or the short version and 'ignorecase' is off, the comparing is done with strcmp(): case matters.

When using the operators with a trailing '?', or the short version and 'ignorecase' is set, the comparing is done with stricmp(): case is ignored.

'smartcase' is not used.

The "=~" and "!~" operators match the lefthand argument with the righthand argument, which is used as a pattern. See pattern for what a pattern is. This matching is always done like 'magic' was set and 'cpoptions' is empty, no matter what the actual value of 'magic' or 'cpoptions' is. This makes scripts portable. To avoid backslashes in the regexp pattern to be doubled, use a single-quote string, see literal-string .
Since a string is considered to be a single line, a multi-line pattern (containing \n, backslash-n) will not match. However, a literal NL character can be matched like an ordinary character. Examples:

```
"foo\nbar" =~ "\n"      evaluates to 1
"foo\nbar" =~ "\\n"     evaluates to 0
```

expr5 and expr6 expr5 expr6

---

expr6 + expr6 ..	Number addition or List concatenation		expr-+
expr6 - expr6 ..	Number subtraction		expr--
expr6 . expr6 ..	String concatenation		expr-.

For Lists only "+" is possible and then both expr6 must be a list. The result is a new list with the two lists Concatenated.

expr7 * expr7 ..	Number multiplication	expr-star
expr7 / expr7 ..	Number division	expr-/
expr7 % expr7 ..	Number modulo	expr-%

For all, except ".", Strings are converted to Numbers.
For bitwise operators see and() , or() and xor() .

Note the difference between "+" and ".":

```
"123" + "456" = 579
"123" . "456" = "123456"
```

Since '.' has the same precedence as '+' and '-', you need to read:

```
1 . 90 + 90.0
```

As:

```
(1 . 90) + 90.0
```

That works, since the String "190" is automatically converted to the Number 190, which can be added to the Float 90.0. However:

```
1 . 90 * 90.0
```

Should be read as:

```
1 . (90 * 90.0)
```

Since '.' has lower precedence than '*'. This does NOT work, since this attempts to concatenate a Float and a String.

When dividing a Number by zero the result depends on the value:
```
          0 / 0  = -0x80000000  (like NaN for Float)
         >0 / 0  =  0x7fffffff  (like positive infinity)
         <0 / 0  = -0x7fffffff  (like negative infinity)
        (before Vim 7.2 it was always 0x7fffffff)
```

When 64-bit Number support is enabled:
```
          0 / 0  = -0x8000000000000000  (like NaN for Float)
         >0 / 0  =  0x7fffffffffffffff  (like positive infinity)
         <0 / 0  = -0x7fffffffffffffff  (like negative infinity)
```

When the righthand side of '%' is zero, the result is 0.

None of these work for Funcref s.

. and % do not work for Float. E804

expr7 expr7

! expr7	logical NOT	expr-!
- expr7	unary minus	expr-unary--
+ expr7	unary plus	expr-unary-+

For '!' TRUE becomes FALSE , FALSE becomes TRUE (one).
For '-' the sign of the number is changed.
For '+' the number is unchanged.

A String will be converted to a Number first.

These three can be repeated and mixed. Examples:
```
        !-1         == 0
        !!8         == 1
        --9         == 9
```

expr8 expr8
-----
expr8[expr1]	item of String or List	expr-[] E111 E909 subscript

If expr8 is a Number or String this results in a String that contains the expr1'th single byte from expr8. expr8 is used as a String, expr1 as a Number. This doesn't recognize multi-byte encodings, see `byteidx()` for an alternative, or use `split()` to turn the string into a list of characters.

Index zero gives the first byte. This is like it works in C. Careful: text column numbers start with one! Example, to get the byte under the cursor:
```
        :let c = getline(".")[col(".") - 1]
```

If the length of the String is less than the index, the result is an empty String. A negative index always results in an empty string (reason: backward compatibility). Use [-1:] to get the last byte.

If expr8 is a List then it results the item at index expr1. See list-index for possible index values. If the index is out of range this results in an error. Example:

```
:let item = mylist[-1]          " get last item
```

Generally, if a List index is equal to or higher than the length of the List , or more negative than the length of the List , this results in an error.

expr8[expr1a : expr1b] substring or sublist expr-[:]

If expr8 is a Number or String this results in the substring with the bytes from expr1a to and including expr1b. expr8 is used as a String, expr1a and expr1b are used as a Number. This doesn't recognize multi-byte encodings, see byteidx() for computing the indexes.

If expr1a is omitted zero is used. If expr1b is omitted the length of the string minus one is used.

A negative number can be used to measure from the end of the string. -1 is the last character, -2 the last but one, etc.

If an index goes out of range for the string characters are omitted. If expr1b is smaller than expr1a the result is an empty string.

Examples:

```
:let c = name[-1:]              " last byte of a string
:let c = name[-2:-2]            " last but one byte of a string
:let s = line(".")[4:]          " from the fifth byte to the end
:let s = s[:-3]                 " remove last two bytes
```

slice

If expr8 is a List this results in a new List with the items indicated by the indexes expr1a and expr1b. This works like with a String, as explained just above. Also see sublist below. Examples:

```
:let l = mylist[:3]             " first four items
:let l = mylist[4:4]            " List with one item
:let l = mylist[:]              " shallow copy of a List
```

Using expr8[expr1] or expr8[expr1a : expr1b] on a Funcref results in an error.

Watch out for confusion between a namespace and a variable followed by a colon for a sublist:

```
mylist[n:]     " uses variable n
mylist[s:]     " uses namespace s:, error!
```

expr8.name entry in a Dictionary expr-entry

If expr8 is a Dictionary and it is followed by a dot, then the following name will be used as a key in the Dictionary . This is just like: expr8[name].

The name must consist of alphanumeric characters, just like a variable name,
but it may start with a number. Curly braces cannot be used.

There must not be white space before or after the dot.

Examples:
```
        :let dict = {"one": 1, 2: "two"}
        :echo dict.one
        :echo dict .2
```

Note that the dot is also used for String concatenation. To avoid confusion
always put spaces around the dot for String concatenation.

expr8(expr1, ...)   Funcref function call

When expr8 is a Funcref type variable, invoke the function it refers to.

expr9

number
------
number   number constant   expr-number
                                hex-number   octal-number   binary-number

Decimal, Hexadecimal (starting with 0x or 0X), Binary (starting with 0b or 0B)
and Octal (starting with 0).

floating-point-format
Floating point numbers can be written in two forms:

```
        [-+]{N}.{M}
        [-+]{N}.{M}[eE][-+]{exp}
```

{N} and {M} are numbers. Both {N} and {M} must be present and can only
contain digits.
[-+] means there is an optional plus or minus sign.
{exp} is the exponent, power of 10.
Only a decimal point is accepted, not a comma. No matter what the current
locale is.
{only when compiled with the |+float| feature}

Examples:
```
        123.456
        +0.0001
        55.0
        -0.123
        1.234e03
        1.0E-6
        -3.1416e+88
```

These are INVALID:

```
        3.              empty {M}
        1e40            missing .{M}
```

float-pi float-e

A few useful values to copy&paste:

```
        :let pi = 3.14159265359
        :let e  = 2.71828182846
```

Rationale:
Before floating point was introduced, the text "123.456" was interpreted as the two numbers "123" and "456", both converted to a string and concatenated, resulting in the string "123456". Since this was considered pointless, and we could not find it intentionally being used in Vim scripts, this backwards incompatibility was accepted in favor of being able to use the normal notation for floating point numbers.

floating-point-precision

The precision and range of floating points numbers depends on what "double" means in the library Vim was compiled with. There is no way to change this at runtime.

The default for displaying a Float is to use 6 decimal places, like using printf("%g", f). You can select something else when using the printf() function. Example:

```
        :echo printf('%.15e', atan(1))
       7.853981633974483e-01
```

string

string String expr-string E114

"string" string constant expr-quote

Note that double quotes are used.

A string constant accepts these special characters:

```
\...    three-digit octal number (e.g., "\316")
\..     two-digit octal number (must be followed by non-digit)
\.      one-digit octal number (must be followed by non-digit)
\x..    byte specified with two hex numbers (e.g., "\x1f")
\x.     byte specified with one hex number (must be followed by non-hex char)
\X..    same as \x..
\X.     same as \x.
\u....  character specified with up to 4 hex numbers, stored according to the
        current value of 'encoding' (e.g., "\u02a4")
\U....  same as \u but allows up to 8 hex numbers.
\b      backspace <BS>
\e      escape <Esc>
\f      formfeed <FF>
\n      newline <NL>
\r      return <CR>
\t      tab <Tab>
\\      backslash
\"      double quote
```

\<xxx> Special key named "xxx". e.g. "\<C-W>" for CTRL-W. This is for use
        in mappings, the 0x80 byte is escaped.
        To use the double quote character it must be escaped: "<M-\">".
        Don't use <Char-xxxx> to get a utf-8 character, use \uxxxx as
        mentioned above.

Note that "\xff" is stored as the byte 255, which may be invalid in some
encodings. Use "\u00ff" to store character 255 according to the current value
of 'encoding'.

Note that "\000" and "\x00" force the end of the string.

literal-string   literal-string   E115

'string'   string constant   expr-'

Note that single quotes are used.

This string is taken as it is. No backslashes are removed or have a special
meaning. The only exception is that two quotes stand for one quote.

Single quoted strings are useful for patterns, so that backslashes do not need
to be doubled. These two commands are equivalent:
        if a =~ "\\s*"
        if a =~ '\s*'

option   expr-option   E112   E113

&option   option value, local value if possible
&g:option   global option value
&l:option   local option value

Examples:
        echo "tabstop is " . &tabstop
        if &insertmode

Any option name can be used here. See options . When using the local value
and there is no buffer-local or window-local value, the global value is used
anyway.

register   expr-register   @r

@r   contents of register 'r'

The result is the contents of the named register, as a single string.
Newlines are inserted where required. To get the contents of the unnamed
register use @" or @@. See registers for an explanation of the available
registers.

When using the '=' register you get the expression itself, not what it
evaluates to. Use eval() to evaluate it.

nesting   expr-nesting   E110

(expr1)   nested expression

environment variable   expr-env

$VAR   environment variable

The String value of any environment variable. When it is not defined, the
result is an empty string.
                                                        expr-env-expand
Note that there is a difference between using $VAR directly and using
expand("$VAR"). Using it directly will only expand environment variables that
are known inside the current Vim session. Using expand() will first try using
the environment variables known inside the current Vim session. If that
fails, a shell will be used to expand the variable. This can be slow, but it
does expand all variables that the shell knows about. Example:
        :echo $shell
        :echo expand("$shell")
The first one probably doesn't echo anything, the second echoes the $shell
variable (if your shell supports it).

internal variable   expr-variable
----
variable   internal variable
See below internal-variables .

function call   expr-function   E116   E118   E119   E120
----
function(expr1, ...)   function call
See below functions .

lambda expression   expr-lambda   lambda

{args -> expr1}   lambda expression

A lambda expression creates a new unnamed function which returns the result of
evaluating expr1 . Lambda expressions differ from user-functions in
the following ways:

1. The body of the lambda expression is an expr1 and not a sequence of Ex
   commands.
2. The prefix "a:" should not be used for arguments. E.g.:
        :let F = {arg1, arg2 -> arg1 - arg2}
        :echo F(5, 2)
       3

The arguments are optional. Example:

```
:let F = {-> 'error function'}
:echo F()
error function
```

closure

Lambda expressions can access outer scope variables and arguments. This is often called a closure. Example where "i" and "a:arg" are used in a lambda while they already exist in the function scope. They remain valid even after the function returns:

```
:function Foo(arg)
:  let i = 3
:  return {x -> x + i - a:arg}
:endfunction
:let Bar = Foo(4)
:echo Bar(6)
5
```

Note that the variables must exist in the outer scope before the lamba is defined for this to work. See also :func-closure .

Lambda and closure support can be checked with:

```
if has('lambda')
```

Examples for using a lambda expression with sort() , map() and filter() :

```
:echo map([1, 2, 3], {idx, val -> val + 1})
[2, 3, 4]
:echo sort([3,7,2,1,4], {a, b -> a - b})
[1, 2, 3, 4, 7]
```

The lambda expression is also useful for Channel, Job and timer:

```
:let timer = timer_start(500,
                \ {-> execute("echo 'Handler called'", "")},
                \ {'repeat': 3})
Handler called
 Handler called
 Handler called
```

Note how execute() is used to execute an Ex command. That's ugly though.

Lambda expressions have internal names like '<lambda>42'. If you get an error for a lambda expression, you can find what it is with the following command:

```
:function {'<lambda>42'}
```

See also: numbered-function

==

3. Internal variable internal-variables E461

An internal variable name can be made up of letters, digits and '_'. But it cannot start with a digit. It's also possible to use curly braces, see curly-braces-names .

An internal variable is created with the ":let" command :let .
An internal variable is explicitly destroyed with the ":unlet" command :unlet .

Using a name that is not an internal variable or refers to a variable that has been destroyed results in an error.

There are several name spaces for variables. Which one is to be used is specified by what is prepended:

```
                (nothing) In a function: local to a function; otherwise: global
 buffer-variable      b:   Local to the current buffer.
 window-variable      w:   Local to the current window.
 tabpage-variable     t:   Local to the current tab page.
 global-variable      g:   Global.
 local-variable       l:   Local to a function.
 script-variable      s:   Local to a  :source 'ed Vim script.
 function-argument    a:   Function argument (only inside a function).
 vim-variable         v:   Global, predefined by Vim.
```

The scope name by itself can be used as a Dictionary . For example, to delete all script-local variables:

```
:for k in keys(s:)
:    unlet s:[k]
:endfor
```

buffer-variable b:var b:

A variable name that is preceded with "b:" is local to the current buffer. Thus you can have several "b:foo" variables, one for each buffer. This kind of variable is deleted when the buffer is wiped out or deleted with :bdelete .

One local buffer variable is predefined:

b:changedtick changetick

b:changedtick The total number of changes to the current buffer. It is incremented for each change. An undo command is also a change in this case. This can be used to perform an action only when the buffer has changed. Example:

```
:if my_changedtick != b:changedtick
:   let my_changedtick = b:changedtick
:   call My_Update()
:endif
```

You cannot change or delete the b:changedtick variable.

window-variable w:var w:

A variable name that is preceded with "w:" is local to the current window. It is deleted when the window is closed.

tabpage-variable t:var t:

A variable name that is preceded with "t:" is local to the current tab page, It is deleted when the tab page is closed. {not available when compiled without the +windows feature}

global-variable g:var g:

Inside functions global variables are accessed with "g:". Omitting this will access a variable local to a function. But "g:" can also be used in any other place if you like.

local-variable l:var l:

Inside functions local variables are accessed without prepending anything. But you can also prepend "l:" if you like. However, without prepending "l:" you may run into reserved variable names. For example "count". By itself it refers to "v:count". Using "l:count" you can have a local variable with the same name.

script-variable s:var

In a Vim script variables starting with "s:" can be used. They cannot be accessed from outside of the scripts, thus are local to the script.

They can be used in:
- commands executed while the script is sourced
- functions defined in the script
- autocommands defined in the script
- functions and autocommands defined in functions and autocommands which were defined in the script (recursively)
- user defined commands defined in the script

Thus not in:
- other scripts sourced from this one
- mappings
- menus
- etc.

Script variables can be used to avoid conflicts with global variable names. Take this example:

```
let s:counter = 0
function MyCounter()
  let s:counter = s:counter + 1
  echo s:counter
endfunction
command Tick call MyCounter()
```

You can now invoke "Tick" from any script, and the "s:counter" variable in that script will not be changed, only the "s:counter" in the script where "Tick" was defined is used.

Another example that does the same:

```
let s:counter = 0
command Tick let s:counter = s:counter + 1 | echo s:counter
```

When calling a function and invoking a user-defined command, the context for script variables is set to the script where the function or command was defined.

The script variables are also available when a function is defined inside a function that is defined in a script. Example:

```
let s:counter = 0
function StartCounting(incr)
  if a:incr
    function MyCounter()
```

```
      let s:counter = s:counter + 1
    endfunction
  else
    function MyCounter()
      let s:counter = s:counter - 1
    endfunction
  endif
endfunction
```

This defines the MyCounter() function either for counting up or counting down when calling StartCounting(). It doesn't matter from where StartCounting() is called, the s:counter variable will be accessible in MyCounter().

When the same script is sourced again it will use the same script variables. They will remain valid as long as Vim is running. This can be used to maintain a counter:

```
if !exists("s:counter")
  let s:counter = 1
  echo "script executed for the first time"
else
  let s:counter = s:counter + 1
  echo "script executed " . s:counter . " times now"
endif
```

Note that this means that filetype plugins don't get a different set of script variables for each buffer. Use local buffer variables instead b:var .

Predefined Vim variables: vim-variable v:var v:

v:beval_col — v:beval_col beval_col-variable

The number of the column, over which the mouse pointer is. This is the byte index in the v:beval_lnum line. Only valid while evaluating the 'balloonexpr' option.

v:beval_bufnr — v:beval_bufnr beval_bufnr-variable

The number of the buffer, over which the mouse pointer is. Only valid while evaluating the 'balloonexpr' option.

v:beval_lnum — v:beval_lnum beval_lnum-variable

The number of the line, over which the mouse pointer is. Only valid while evaluating the 'balloonexpr' option.

v:beval_text — v:beval_text beval_text-variable

The text under or after the mouse pointer. Usually a word as it is useful for debugging a C program. 'iskeyword' applies, but a dot and "->" before the position is included. When on a ']' the text before it is used, including the matching '[' and word before it. When on a Visual area within one line the highlighted text is used. Also see <cexpr> .
Only valid while evaluating the 'balloonexpr' option.

v:beval_winnr — v:beval_winnr beval_winnr-variable

v:beval_winnr	The number of the window, over which the mouse pointer is. Only valid while evaluating the 'balloonexpr' option. The first window has number zero (unlike most other places where a window gets a number).

v:beval_winid	The window-ID of the window, over which the mouse pointer is. Otherwise like v:beval_winnr.

v:char	Argument for evaluating 'formatexpr' and used for the typed character when using <expr> in an abbreviation :map-<expr> . It is also used by the InsertCharPre and InsertEnter events.

v:charconvert_from
	The name of the character encoding of a file to be converted. Only valid while evaluating the 'charconvert' option.

v:charconvert_to
	The name of the character encoding of a file after conversion. Only valid while evaluating the 'charconvert' option.

v:cmdarg	This variable is used for two purposes:
1. The extra arguments given to a file read/write command. Currently these are "++enc=" and "++ff=". This variable is set before an autocommand event for a file read/write command is triggered. There is a leading space to make it possible to append this variable directly after the read/write command. Note: The "+cmd" argument isn't included here, because it will be executed anyway.
2. When printing a PostScript file with ":hardcopy" this is the argument for the ":hardcopy" command. This can be used in 'printexpr'.

v:cmdbang	Set like v:cmdarg for a file read/write command. When a "!" was used the value is 1, otherwise it is 0. Note that this can only be used in autocommands. For user commands <bang> can be used.

v:completed_item
	Dictionary containing the complete-items for the most recently completed word after CompleteDone . The Dictionary is empty if the completion failed.

v:count	The count given for the last Normal mode command. Can be used to get the count before a mapping. Read-only. Example:
```
:map _x :<C-U>echo "the count is " . v:count<CR>
```
Note: The <C-U> is required to remove the line range that you

get when typing ':' after a count.
When there are two counts, as in "3d2w", they are multiplied,
just like what happens in the command, "d6w" for the example.
Also used for evaluating the 'formatexpr' option.
"count" also works, for backwards compatibility.

v:count1 *count1-variable*

v:count1 Just like "v:count", but defaults to one when no count is used.

v:ctype *ctype-variable*

v:ctype The current locale setting for characters of the runtime environment. This allows Vim scripts to be aware of the current locale encoding. Technical: it's the value of LC_CTYPE. When not using a locale the value is "C".
This variable can not be set directly, use the :language command.
See multi-lang .

v:dying *dying-variable*

v:dying Normally zero. When a deadly signal is caught it's set to one. When multiple signals are caught the number increases. Can be used in an autocommand to check if Vim didn't terminate normally. {only works on Unix}
Example:

```
:au VimLeave * if v:dying | echo "\nAAAAaaaarrrgggghhhh!!!\n" | endif
```

Note: if another deadly signal is caught when v:dying is one, VimLeave autocommands will not be executed.

v:errmsg *errmsg-variable*

v:errmsg Last given error message. It's allowed to set this variable.
Example:

```
:let v:errmsg = ""
:silent! next
:if v:errmsg != ""
:  ... handle error
```

"errmsg" also works, for backwards compatibility.

v:errors *errors-variable* *assert-return*

v:errors Errors found by assert functions, such as assert_true() .
This is a list of strings.
The assert functions append an item when an assert fails.
The return value indicates this: a one is returned if an item was added to v:errors, otherwise zero is returned.
To remove old results make it empty:

```
:let v:errors = []
```

If v:errors is set to anything but a list it is made an empty list by the assert function.

v:event *event-variable*

v:event Dictionary containing information about the current autocommand . The dictionary is emptied when the autocommand finishes, please refer to dict-identity for how to get an independent copy of it.

v:exception exception-variable

v:exception The value of the exception most recently caught and not finished. See also v:throwpoint and throw-variables . Example:

```
:try
:  throw "oops"
:catch /.*/
:  echo "caught" v:exception
:endtry
```

Output: "caught oops".

v:false false-variable

v:false A Number with value zero. Used to put "false" in JSON. See json_encode() . When used as a string this evaluates to "v:false".

```
echo v:false
v:false
```

That is so that eval() can parse the string back to the same value. Read-only.

v:fcs_reason fcs_reason-variable

v:fcs_reason The reason why the FileChangedShell event was triggered. Can be used in an autocommand to decide what to do and/or what to set v:fcs_choice to. Possible values:

deleted	file no longer exists
conflict	file contents, mode or timestamp was changed and buffer is modified
changed	file contents has changed
mode	mode of file changed
time	only file timestamp changed

v:fcs_choice fcs_choice-variable

v:fcs_choice What should happen after a FileChangedShell event was triggered. Can be used in an autocommand to tell Vim what to do with the affected buffer:

reload	Reload the buffer (does not work if the file was deleted).
ask	Ask the user what to do, as if there was no autocommand. Except that when only the timestamp changed nothing will happen.
<empty>	Nothing, the autocommand should do everything that needs to be done.

The default is empty. If another (invalid) value is used then Vim behaves like it is empty, there is no warning message.

v:fname_in fname_in-variable

v:fname_in The name of the input file. Valid while evaluating:

option	used for
'charconvert'	file to be converted
'diffexpr'	original file
'patchexpr'	original file
'printexpr'	file to be printed

And set to the swap file name for SwapExists .

v:fname_out — fname_out-variable

v:fname_out — The name of the output file. Only valid while evaluating:

option	used for
'charconvert'	resulting converted file (*)
'diffexpr'	output of diff
'patchexpr'	resulting patched file

(*) When doing conversion for a write command (e.g., ":w file") it will be equal to v:fname_in. When doing conversion for a read command (e.g., ":e file") it will be a temporary file and different from v:fname_in.

v:fname_new — fname_new-variable

v:fname_new — The name of the new version of the file. Only valid while evaluating 'diffexpr'.

v:fname_diff — fname_diff-variable

v:fname_diff — The name of the diff (patch) file. Only valid while evaluating 'patchexpr'.

v:folddashes — folddashes-variable

v:folddashes — Used for 'foldtext': dashes representing foldlevel of a closed fold.
Read-only in the sandbox . fold-foldtext

v:foldlevel — foldlevel-variable

v:foldlevel — Used for 'foldtext': foldlevel of closed fold.
Read-only in the sandbox . fold-foldtext

v:foldend — foldend-variable

v:foldend — Used for 'foldtext': last line of closed fold.
Read-only in the sandbox . fold-foldtext

v:foldstart — foldstart-variable

v:foldstart — Used for 'foldtext': first line of closed fold.
Read-only in the sandbox . fold-foldtext

v:hlsearch — hlsearch-variable

v:hlsearch — Variable that indicates whether search highlighting is on. Setting it makes sense only if 'hlsearch' is enabled which requires +extra_search . Setting this variable to zero acts like the :nohlsearch command, setting it to one acts like

```
let &hlsearch = &hlsearch
```

Note that the value is restored when returning from a function. function-search-undo .

v:insertmode — insertmode-variable

v:insertmode — Used for the InsertEnter and InsertChange autocommand events. Values:

i	Insert mode
r	Replace mode
v	Virtual Replace mode

v:key

v:key Key of the current item of a Dictionary . Only valid while evaluating the expression used with map() and filter() . Read-only.

v:lang

v:lang The current locale setting for messages of the runtime environment. This allows Vim scripts to be aware of the current language. Technical: it's the value of LC_MESSAGES. The value is system dependent.
This variable can not be set directly, use the :language command.
It can be different from v:ctype when messages are desired in a different language than what is used for character encoding. See multi-lang .

v:lc_time

v:lc_time The current locale setting for time messages of the runtime environment. This allows Vim scripts to be aware of the current language. Technical: it's the value of LC_TIME.
This variable can not be set directly, use the :language command. See multi-lang .

v:lnum

v:lnum Line number for the 'foldexpr' fold-expr , 'formatexpr' and 'indentexpr' expressions, tab page number for 'guitablabel' and 'guitabtooltip'. Only valid while one of these expressions is being evaluated. Read-only when in the sandbox .

v:mouse_win

v:mouse_win Window number for a mouse click obtained with getchar() . First window has number 1, like with winnr() . The value is zero when there was no mouse button click.

v:mouse_winid

v:mouse_winid Window ID for a mouse click obtained with getchar() .
The value is zero when there was no mouse button click.

v:mouse_lnum

v:mouse_lnum Line number for a mouse click obtained with getchar() .
This is the text line number, not the screen line number. The value is zero when there was no mouse button click.

v:mouse_col

v:mouse_col Column number for a mouse click obtained with getchar() .
This is the screen column number, like with virtcol() . The value is zero when there was no mouse button click.

v:none

v:none An empty String. Used to put an empty item in JSON. See json_encode() .
When used as a number this evaluates to zero.

When used as a string this evaluates to "v:none".
```
echo v:none
v:none
```
That is so that eval() can parse the string back to the same value. Read-only.

v:null *null-variable*

v:null An empty String. Used to put "null" in JSON. See json_encode() .
When used as a number this evaluates to zero.
When used as a string this evaluates to "v:null".
```
echo v:null
v:null
```
That is so that eval() can parse the string back to the same value. Read-only.

v:oldfiles *oldfiles-variable*

v:oldfiles List of file names that is loaded from the viminfo file on startup. These are the files that Vim remembers marks for. The length of the List is limited by the ' argument of the 'viminfo' option (default is 100).
When the viminfo file is not used the List is empty.
Also see :oldfiles and c_#< .
The List can be modified, but this has no effect on what is stored in the viminfo file later. If you use values other than String this will cause trouble.
{only when compiled with the |+viminfo| feature}

v:option_new

v:option_new New value of the option. Valid while executing an OptionSet autocommand.

v:option_old

v:option_old Old value of the option. Valid while executing an OptionSet autocommand.

v:option_type

v:option_type Scope of the set command. Valid while executing an OptionSet autocommand. Can be either "global" or "local"

v:operator *operator-variable*

v:operator The last operator given in Normal mode. This is a single character except for commands starting with <g> or <z>, in which case it is two characters. Best used alongside v:prevcount and v:register . Useful if you want to cancel Operator-pending mode and then use the operator, e.g.:
```
:omap O <Esc>:call MyMotion(v:operator)<CR>
```
The value remains set until another operator is entered, thus don't expect it to be empty.
v:operator is not set for :delete , :yank or other Ex commands.
Read-only.

v:prevcount *prevcount-variable*

v:prevcount The count given for the last but one Normal mode command. This is the v:count value of the previous command. Useful if you want to cancel Visual or Operator-pending mode and then

use the count, e.g.:
```
:vmap % <Esc>:call MyFilter(v:prevcount)<CR>
```
Read-only.

v:profiling v:profiling profiling-variable

v:profiling Normally zero. Set to one after using ":profile start". See profiling .

v:progname v:progname progname-variable

v:progname Contains the name (with path removed) with which Vim was invoked. Allows you to do special initialisations for view , evim etc., or any other name you might symlink to Vim. Read-only.

v:progpath v:progpath progpath-variable

v:progpath Contains the command with which Vim was invoked, including the path. Useful if you want to message a Vim server using a --remote-expr .
To get the full path use:
```
echo exepath(v:progpath)
```
If the path is relative it will be expanded to the full path, so that it still works after `:cd`. Thus starting "./vim" results in "/home/user/path/to/vim/src/vim".
On MS-Windows the executable may be called "vim.exe", but the ".exe" is not added to v:progpath.
Read-only.

v:register v:register register-variable

v:register The name of the register in effect for the current normal mode command (regardless of whether that command actually used a register). Or for the currently executing normal mode mapping (use this in custom commands that take a register).
If none is supplied it is the default register '"', unless 'clipboard' contains "unnamed" or "unnamedplus", then it is '*' or '+'.
Also see getreg() and setreg()

v:scrollstart v:scrollstart scrollstart-variable

v:scrollstart String describing the script or function that caused the screen to scroll up. It's only set when it is empty, thus the first reason is remembered. It is set to "Unknown" for a typed command.
This can be used to find out why your script causes the hit-enter prompt.

v:servername v:servername servername-variable

v:servername The resulting registered client-server-name if any.
Read-only.

v:searchforward v:searchforward searchforward-variable

Search direction: 1 after a forward search, 0 after a backward search. It is reset to forward when directly setting the last search pattern, see quote/ .

Note that the value is restored when returning from a
function. function-search-undo .
Read-write.

v:shell_error shell_error-variable
v:shell_error Result of the last shell command. When non-zero, the last
shell command had an error. When zero, there was no problem.
This only works when the shell returns the error code to Vim.
The value -1 is often used when the command could not be
executed. Read-only.
Example:

```
:!mv foo bar
:if v:shell_error
:  echo 'could not rename "foo" to "bar"!'
:endif
```

"shell_error" also works, for backwards compatibility.

v:statusmsg statusmsg-variable
v:statusmsg Last given status message. It's allowed to set this variable.

v:swapname swapname-variable
v:swapname Only valid when executing SwapExists autocommands: Name of
the swap file found. Read-only.

v:swapchoice swapchoice-variable
v:swapchoice SwapExists autocommands can set this to the selected choice
for handling an existing swap file:

```
'o'     Open read-only
'e'     Edit anyway
'r'     Recover
'd'     Delete swapfile
'q'     Quit
'a'     Abort
```

The value should be a single-character string. An empty value
results in the user being asked, as would happen when there is
no SwapExists autocommand. The default is empty.

v:swapcommand swapcommand-variable
v:swapcommand Normal mode command to be executed after a file has been
opened. Can be used for a SwapExists autocommand to have
another Vim open the file and jump to the right place. For
example, when jumping to a tag the value is ":tag tagname\r".
For ":edit +cmd file" the value is ":cmd\r".

v:t_TYPE v:t_bool t_bool-variable
v:t_bool Value of Boolean type. Read-only. See: type()
v:t_channel t_channel-variable
v:t_channel Value of Channel type. Read-only. See: type()
v:t_dict t_dict-variable
v:t_dict Value of Dictionary type. Read-only. See: type()
v:t_float t_float-variable
v:t_float Value of Float type. Read-only. See: type()
v:t_func t_func-variable
v:t_func Value of Funcref type. Read-only. See: type()

v:t_job
Value of Job type. Read-only. See: type()

v:t_list
Value of List type. Read-only. See: type()

v:t_none
Value of None type. Read-only. See: type()

v:t_number
Value of Number type. Read-only. See: type()

v:t_string
Value of String type. Read-only. See: type()

v:termresponse
The escape sequence returned by the terminal for the t_RV termcap entry. It is set when Vim receives an escape sequence that starts with ESC [or CSI and ends in a 'c', with only digits, ';' and '.' in between.
When this option is set, the TermResponse autocommand event is fired, so that you can react to the response from the terminal.
The response from a new xterm is: "<Esc>[Pp ; Pv ; Pc c". Pp is the terminal type: 0 for vt100 and 1 for vt220. Pv is the patch level (since this was introduced in patch 95, it's always 95 or bigger). Pc is always zero.
{only when compiled with |+termresponse| feature}

v:termblinkresp
The escape sequence returned by the terminal for the t_RC termcap entry. This is used to find out whether the terminal cursor is blinking. This is used by term_getcursor() .

v:termstyleresp
The escape sequence returned by the terminal for the t_RS termcap entry. This is used to find out what the shape of the cursor is. This is used by term_getcursor() .

v:termrbgresp
The escape sequence returned by the terminal for the t_RB termcap entry. This is used to find out what the terminal background color is, see 'background'.

v:termrfgresp
The escape sequence returned by the terminal for the t_RF termcap entry. This is used to find out what the terminal foreground color is.

v:termu7resp
The escape sequence returned by the terminal for the t_u7 termcap entry. This is used to find out what the terminal does with ambiguous width characters, see 'ambiwidth'.

v:testing
Must be set before using `test_garbagecollect_now()`.
Also, when set certain error messages won't be shown for 2 seconds. (e.g. "'dictionary' option is empty")

v:this_session this_session-variable

v:this_session Full filename of the last loaded or saved session file. See :mksession . It is allowed to set this variable. When no session file has been saved, this variable is empty. "this_session" also works, for backwards compatibility.

v:throwpoint throwpoint-variable

v:throwpoint The point where the exception most recently caught and not finished was thrown. Not set when commands are typed. See also v:exception and throw-variables . Example:

```
:try
:  throw "oops"
:catch /.*/
:  echo "Exception from" v:throwpoint
:endtry
```

Output: "Exception from test.vim, line 2"

v:true true-variable

v:true A Number with value one. Used to put "true" in JSON. See json_encode() . When used as a string this evaluates to "v:true".

```
echo v:true
v:true
```

That is so that eval() can parse the string back to the same value. Read-only.

v:val val-variable

v:val Value of the current item of a List or Dictionary . Only valid while evaluating the expression used with map() and filter() . Read-only.

v:version version-variable

v:version Version number of Vim: Major version number times 100 plus minor version number. Version 5.0 is 500. Version 5.1 (5.01) is 501. Read-only. "version" also works, for backwards compatibility.
Use has() to check if a certain patch was included, e.g.:

```
if has("patch-7.4.123")
```

Note that patch numbers are specific to the version, thus both version 5.0 and 5.1 may have a patch 123, but these are completely different.

v:vim_did_enter vim_did_enter-variable

v:vim_did_enter Zero until most of startup is done. It is set to one just before VimEnter autocommands are triggered.

v:warningmsg warningmsg-variable

v:warningmsg Last given warning message. It's allowed to set this variable.

v:windowid windowid-variable

v:windowid When any X11 based GUI is running or when running in a terminal and Vim connects to the X server (-X) this will be set to the window ID.

When an MS-Windows GUI is running this will be set to the
window handle.
Otherwise the value is zero.
Note: for windows inside Vim use winnr() or win_getid() ,
see window-ID .

==
4. Builtin Functions functions

See function-list for a list grouped by what the function is used for.

(Use CTRL-] on the function name to jump to the full explanation.)

USAGE RESULT DESCRIPTION

abs({expr}) Float or Number absolute value of {expr}
acos({expr}) Float arc cosine of {expr}
add({list}, {item}) List append {item} to List {list}
and({expr}, {expr}) Number bitwise AND
append({lnum}, {string}) Number append {string} below line {lnum}
append({lnum}, {list}) Number append lines {list} below line {lnum}
argc() Number number of files in the argument list
argidx() Number current index in the argument list
arglistid([{winnr} [, {tabnr}]]) Number argument list id
argv({nr}) String {nr} entry of the argument list
argv() List the argument list
assert_beeps({cmd}) Number assert {cmd} causes a beep
assert_equal({exp}, {act} [, {msg}])
Number assert {exp} is equal to {act}
assert_equalfile({fname-one}, {fname-two})
Number assert file contents is equal
assert_exception({error} [, {msg}])
Number assert {error} is in v:exception
assert_fails({cmd} [, {error}]) Number assert {cmd} fails
assert_false({actual} [, {msg}])
Number assert {actual} is false
assert_inrange({lower}, {upper}, {actual} [, {msg}])
Number assert {actual} is inside the range
assert_match({pat}, {text} [, {msg}])
Number assert {pat} matches {text}
assert_notequal({exp}, {act} [, {msg}])
Number assert {exp} is not equal {act}
assert_notmatch({pat}, {text} [, {msg}])
Number assert {pat} not matches {text}
assert_report({msg}) Number report a test failure
assert_true({actual} [, {msg}]) Number assert {actual} is true
asin({expr}) Float arc sine of {expr}
atan({expr}) Float arc tangent of {expr}
atan2({expr1}, {expr2}) Float arc tangent of {expr1} / {expr2}
balloon_show({expr}) none show {expr} inside the balloon
balloon_split({msg}) List split {msg} as used for a balloon
browse({save}, {title}, {initdir}, {default})
String put up a file requester
browsedir({title}, {initdir}) String put up a directory requester

```
bufexists({expr})               Number   TRUE  if buffer {expr} exists
buflisted({expr})               Number   TRUE  if buffer {expr} is listed
bufloaded({expr})               Number   TRUE  if buffer {expr} is loaded
bufname({expr})                 String  Name of the buffer {expr}
bufnr({expr} [, {create}])      Number  Number of the buffer {expr}
bufwinid({expr})                Number  window ID of buffer {expr}
bufwinnr({expr})                Number  window number of buffer {expr}
byte2line({byte})               Number  line number at byte count {byte}
byteidx({expr}, {nr})           Number  byte index of {nr}'th char in {expr}
byteidxcomp({expr}, {nr})       Number  byte index of {nr}'th char in {expr}
call({func}, {arglist} [, {dict}])
                                any     call {func} with arguments {arglist}
ceil({expr})                    Float   round {expr} up
ch_canread({handle})            Number  check if there is something to read
ch_close({handle})              none    close {handle}
ch_close_in({handle})           none    close in part of {handle}
ch_evalexpr({handle}, {expr} [, {options}])
                                any     evaluate {expr} on JSON {handle}
ch_evalraw({handle}, {string} [, {options}])
                                any     evaluate {string} on raw {handle}
ch_getbufnr({handle}, {what})   Number  get buffer number for {handle}/{what}
ch_getjob({channel})            Job     get the Job of {channel}
ch_info({handle})               String  info about channel {handle}
ch_log({msg} [, {handle}])      none    write {msg} in the channel log file
ch_logfile({fname} [, {mode}])  none    start logging channel activity
ch_open({address} [, {options}])
                                Channel open a channel to {address}
ch_read({handle} [, {options}]) String  read from {handle}
ch_readraw({handle} [, {options}])
                                String  read raw from {handle}
ch_sendexpr({handle}, {expr} [, {options}])
                                any     send {expr} over JSON {handle}
ch_sendraw({handle}, {string} [, {options}])
                                any     send {string} over raw {handle}
ch_setoptions({handle}, {options})
                                none    set options for {handle}
ch_status({handle} [, {options}])
                                String  status of channel {handle}
changenr()                      Number  current change number
char2nr({expr} [, {utf8}])      Number  ASCII/UTF8 value of first char in {expr}
cindent({lnum})                 Number  C indent for line {lnum}
clearmatches()                  none    clear all matches
col({expr})                     Number  column nr of cursor or mark
complete({startcol}, {matches}) none    set Insert mode completion
complete_add({expr})            Number  add completion match
complete_check()                Number  check for key typed during completion
confirm({msg} [, {choices} [, {default} [, {type}]]])
                                Number  number of choice picked by user
copy({expr})                    any     make a shallow copy of {expr}
cos({expr})                     Float   cosine of {expr}
cosh({expr})                    Float   hyperbolic cosine of {expr}
count({list}, {expr} [, {ic} [, {start}]])
                                Number  count how many {expr} are in {list}
cscope_connection([{num}, {dbpath} [, {prepend}]])
```

```
                                Number  checks existence of cscope connection
cursor({lnum}, {col} [, {off}])
                                Number  move cursor to {lnum}, {col}, {off}
cursor({list})                  Number  move cursor to position in {list}
debugbreak({pid})               Number  interrupt process being debugged
deepcopy({expr} [, {noref}])    any     make a full copy of {expr}
delete({fname} [, {flags}])     Number  delete the file or directory {fname}
deletebufline({expr}, {first}[, {last}])
                                Number  delete lines from buffer {expr}
did_filetype()                  Number   TRUE  if FileType autocmd event used
diff_filler({lnum})             Number  diff filler lines about {lnum}
diff_hlID({lnum}, {col})        Number  diff highlighting at {lnum}/{col}
empty({expr})                   Number   TRUE  if {expr} is empty
escape({string}, {chars})       String  escape {chars} in {string} with '\'
eval({string})                  any     evaluate {string} into its value
eventhandler()                  Number   TRUE  if inside an event handler
executable({expr})              Number  1 if executable {expr} exists
execute({command})              String  execute {command} and get the output
exepath({expr})                 String  full path of the command {expr}
exists({expr})                  Number   TRUE  if {expr} exists
extend({expr1}, {expr2} [, {expr3}])
                                List/Dict insert items of {expr2} into {expr1}
exp({expr})                     Float   exponential of {expr}
expand({expr} [, {nosuf} [, {list}]])
                                any     expand special keywords in {expr}
feedkeys({string} [, {mode}])   Number  add key sequence to typeahead buffer
filereadable({file})            Number   TRUE  if {file} is a readable file
filewritable({file})            Number   TRUE  if {file} is a writable file
filter({expr1}, {expr2})        List/Dict  remove items from {expr1} where
                                        {expr2} is 0
finddir({name} [, {path} [, {count}]])
                                String  find directory {name} in {path}
findfile({name} [, {path} [, {count}]])
                                String  find file {name} in {path}
float2nr({expr})                Number  convert Float {expr} to a Number
floor({expr})                   Float   round {expr} down
fmod({expr1}, {expr2})          Float   remainder of {expr1} / {expr2}
fnameescape({fname})            String  escape special characters in {fname}
fnamemodify({fname}, {mods})    String  modify file name
foldclosed({lnum})              Number  first line of fold at {lnum} if closed
foldclosedend({lnum})           Number  last line of fold at {lnum} if closed
foldlevel({lnum})               Number  fold level at {lnum}
foldtext()                      String  line displayed for closed fold
foldtextresult({lnum})          String  text for closed fold at {lnum}
foreground()                    Number  bring the Vim window to the foreground
funcref({name} [, {arglist}] [, {dict}])
                                Funcref reference to function {name}
function({name} [, {arglist}] [, {dict}])
                                Funcref named reference to function {name}
garbagecollect([{atexit}])      none    free memory, breaking cyclic references
get({list}, {idx} [, {def}])    any     get item {idx} from {list} or {def}
get({dict}, {key} [, {def}])    any     get item {key} from {dict} or {def}
get({func}, {what})             any     get property of funcref/partial {func}
getbufinfo([{expr}])            List    information about buffers
```

```
getbufline({expr}, {lnum} [, {end}])
                                List    lines {lnum} to {end} of buffer {expr}
getbufvar({expr}, {varname} [, {def}])
                                any     variable {varname} in buffer {expr}
getchangelist({expr})           List    list of change list items
getchar([expr])                 Number  get one character from the user
getcharmod()                    Number  modifiers for the last typed character
getcharsearch()                 Dict    last character search
getcmdline()                    String  return the current command-line
getcmdpos()                     Number  return cursor position in command-line
getcmdtype()                    String  return current command-line type
getcmdwintype()                 String  return current command-line window type
getcompletion({pat}, {type} [, {filtered}])
                                List    list of cmdline completion matches
getcurpos()                     List    position of the cursor
getcwd([{winnr} [, {tabnr}]])   String  get the current working directory
getfontname([{name}])           String  name of font being used
getfperm({fname})               String  file permissions of file {fname}
getfsize({fname})               Number  size in bytes of file {fname}
getftime({fname})               Number  last modification time of file
getftype({fname})               String  description of type of file {fname}
getjumplist([{winnr} [, {tabnr}]])
                                List    list of jump list items
getline({lnum})                 String  line {lnum} of current buffer
getline({lnum}, {end})          List    lines {lnum} to {end} of current buffer
getloclist({nr} [, {what}])     List    list of location list items
getmatches()                    List    list of current matches
getpid()                        Number  process ID of Vim
getpos({expr})                  List    position of cursor, mark, etc.
getqflist([{what}])             List    list of quickfix items
getreg([{regname} [, 1 [, {list}]]])
                                String or List   contents of register
getregtype([{regname}])         String  type of register
gettabinfo([{expr}])            List    list of tab pages
gettabvar({nr}, {varname} [, {def}])
                                any     variable {varname} in tab {nr} or {def}
gettabwinvar({tabnr}, {winnr}, {name} [, {def}])
                                any     {name} in {winnr} in tab page {tabnr}
getwininfo([{winid}])           List    list of info about each window
getwinpos([{timeout}])          List    X and Y coord in pixels of the Vim window
getwinposx()                    Number  X coord in pixels of the Vim window
getwinposy()                    Number  Y coord in pixels of the Vim window
getwinvar({nr}, {varname} [, {def}])
                                any     variable {varname} in window {nr}
glob({expr} [, {nosuf} [, {list} [, {alllinks}]]])
                                any     expand file wildcards in {expr}
glob2regpat({expr})             String  convert a glob pat into a search pat
globpath({path}, {expr} [, {nosuf} [, {list} [, {alllinks}]]])
                                String  do glob({expr}) for all dirs in {path}
has({feature})                  Number   TRUE  if feature {feature} supported
has_key({dict}, {key})          Number   TRUE  if {dict} has entry {key}
haslocaldir([{winnr} [, {tabnr}]])
                                Number   TRUE  if the window executed  :lcd
hasmapto({what} [, {mode} [, {abbr}]])
```

```
                                Number   TRUE  if mapping to {what} exists
histadd({history}, {item})      String  add an item to a history
histdel({history} [, {item}])   String  remove an item from a history
histget({history} [, {index}])  String  get the item {index} from a history
histnr({history})               Number  highest index of a history
hlexists({name})                Number   TRUE  if highlight group {name} exists
hlID({name})                    Number  syntax ID of highlight group {name}
hostname()                      String  name of the machine Vim is running on
iconv({expr}, {from}, {to})     String  convert encoding of {expr}
indent({lnum})                  Number  indent of line {lnum}
index({list}, {expr} [, {start} [, {ic}]])
                                Number  index in {list} where {expr} appears
input({prompt} [, {text} [, {completion}]])
                                String  get input from the user
inputdialog({prompt} [, {text} [, {completion}]])
                                String  like input() but in a GUI dialog
inputlist({textlist})           Number  let the user pick from a choice list
inputrestore()                  Number  restore typeahead
inputsave()                     Number  save and clear typeahead
inputsecret({prompt} [, {text}]) String like input() but hiding the text
insert({list}, {item} [, {idx}]) List   insert {item} in {list} [before {idx}]
invert({expr})                  Number  bitwise invert
isdirectory({directory})        Number   TRUE  if {directory} is a directory
islocked({expr})                Number   TRUE  if {expr} is locked
isnan({expr})                   Number   TRUE  if {expr} is NaN
items({dict})                   List    key-value pairs in {dict}
job_getchannel({job})           Channel get the channel handle for {job}
job_info([{job}])               Dict    get information about {job}
job_setoptions({job}, {options}) none   set options for {job}
job_start({command} [, {options}])
                                Job     start a job
job_status({job})               String  get the status of {job}
job_stop({job} [, {how}])       Number  stop {job}
join({list} [, {sep}])          String  join {list} items into one String
js_decode({string})             any     decode JS style JSON
js_encode({expr})               String  encode JS style JSON
json_decode({string})           any     decode JSON
json_encode({expr})             String  encode JSON
keys({dict})                    List    keys in {dict}
len({expr})                     Number  the length of {expr}
libcall({lib}, {func}, {arg})   String  call {func} in library {lib} with {arg}
libcallnr({lib}, {func}, {arg}) Number  idem, but return a Number
line({expr})                    Number  line nr of cursor, last line or mark
line2byte({lnum})               Number  byte count of line {lnum}
lispindent({lnum})              Number  Lisp indent for line {lnum}
localtime()                     Number  current time
log({expr})                     Float   natural logarithm (base e) of {expr}
log10({expr})                   Float   logarithm of Float {expr} to base 10
luaeval({expr} [, {expr}])      any     evaluate  Lua  expression
map({expr1}, {expr2})           List/Dict  change each item in {expr1} to {expr}
maparg({name} [, {mode} [, {abbr} [, {dict}]])
                                String or Dict
                                        rhs of mapping {name} in mode {mode}
mapcheck({name} [, {mode} [, {abbr}])
```

```
                                String  check for mappings matching {name}
match({expr}, {pat} [, {start} [, {count}]])
                                Number  position where {pat} matches in {expr}
matchadd({group}, {pattern} [, {priority} [, {id} [, {dict}]]])
                                Number  highlight {pattern} with {group}
matchaddpos({group}, {pos} [, {priority} [, {id} [, {dict}]]])
                                Number  highlight positions with {group}
matcharg({nr})                  List    arguments of  :match
matchdelete({id})               Number  delete match identified by {id}
matchend({expr}, {pat} [, {start} [, {count}]])
                                Number  position where {pat} ends in {expr}
matchlist({expr}, {pat} [, {start} [, {count}]])
                                List    match and submatches of {pat} in {expr}
matchstr({expr}, {pat} [, {start} [, {count}]])
                                String  {count}'th match of {pat} in {expr}
matchstrpos({expr}, {pat} [, {start} [, {count}]])
                                List    {count}'th match of {pat} in {expr}
max({expr})                     Number  maximum value of items in {expr}
min({expr})                     Number  minimum value of items in {expr}
mkdir({name} [, {path} [, {prot}]])
                                Number  create directory {name}
mode([expr])                    String  current editing mode
mzeval({expr})                  any     evaluate  MzScheme  expression
nextnonblank({lnum})            Number  line nr of non-blank line >= {lnum}
nr2char({expr} [, {utf8}])      String  single char with ASCII/UTF8 value {expr}
or({expr}, {expr})              Number  bitwise OR
pathshorten({expr})             String  shorten directory names in a path
perleval({expr})                any     evaluate  Perl  expression
pow({x}, {y})                   Float   {x} to the power of {y}
prevnonblank({lnum})            Number  line nr of non-blank line <= {lnum}
printf({fmt}, {expr1}...)       String  format text
prompt_addtext({buf}, {expr})   none    add text to a prompt buffer
prompt_setcallback({buf}, {expr}) none  set prompt callback function
prompt_setinterrupt({buf}, {text}) none set prompt interrupt function
prompt_setprompt({buf}, {text}) none    set prompt text
pumvisible()                    Number  whether popup menu is visible
pyeval({expr})                  any     evaluate  Python  expression
py3eval({expr})                 any     evaluate  python3  expression
pyxeval({expr})                 any     evaluate  python_x  expression
range({expr} [, {max} [, {stride}]])
                                List    items from {expr} to {max}

values({dict})                  List    values in {dict}
virtcol({expr})                 Number  screen column of cursor or mark
visualmode([expr])              String  last visual mode used
wildmenumode()                  Number  whether 'wildmenu' mode is active
win_findbuf({bufnr})            List    find windows containing {bufnr}
win_getid([{win} [, {tab}]])    Number  get window ID for {win} in {tab}
win_gotoid({expr})              Number  go to window with ID {expr}
win_id2tabwin({expr})           List    get tab and window nr from window ID
win_id2win({expr})              Number  get window nr from window ID
win_screenpos({nr})             List    get screen position of window {nr}
winbufnr({nr})                  Number  buffer number of window {nr}
wincol()                        Number  window column of the cursor
winheight({nr})                 Number  height of window {nr}
winline()                       Number  window line of the cursor
winnr([{expr}])                 Number  number of current window
winrestcmd()                    String  returns command to restore window sizes
winrestview({dict})             none    restore view of current window
winsaveview()                   Dict    save view of current window
winwidth({nr})                  Number  width of window {nr}
wordcount()                     Dict    get byte/char/word statistics
writefile({list}, {fname} [, {flags}])
                                Number  write list of lines to file {fname}
xor({expr}, {expr})             Number  bitwise XOR
```

```
abs({expr})                                                       abs()
```
Return the absolute value of {expr}. When {expr} evaluates to a Float abs() returns a Float . When {expr} can be converted to a Number abs() returns a Number . Otherwise abs() gives an error message and returns -1.
Examples:

```
:echo abs(1.456)
1.456
:echo abs(-5.456)
5.456
:echo abs(-4)
4
```

{only available when compiled with the |+float| feature}

```
acos({expr})                                                      acos()
```
Return the arc cosine of {expr} measured in radians, as a Float in the range of [0, pi].
{expr} must evaluate to a Float or a Number in the range [-1, 1].
Examples:

```
:echo acos(0)
1.570796
:echo acos(-0.5)
2.094395
```

{only available when compiled with the |+float| feature}

add({list}, {expr}) add()
Append the item {expr} to List {list}. Returns the resulting List. Examples:
```
:let alist = add([1, 2, 3], item)
:call add(mylist, "woodstock")
```
Note that when {expr} is a List it is appended as a single item. Use extend() to concatenate Lists. Use insert() to add an item at another position.

and({expr}, {expr}) and()
Bitwise AND on the two arguments. The arguments are converted to a number. A List, Dict or Float argument causes an error. Example:
```
:let flag = and(bits, 0x80)
```

append({lnum}, {expr}) append()
When {expr} is a List: Append each item of the List as a text line below line {lnum} in the current buffer. Otherwise append {expr} as one text line below line {lnum} in the current buffer. {lnum} can be zero to insert a line before the first one. Returns 1 for failure ({lnum} out of range or out of memory), 0 for success. Example:
```
:let failed = append(line('$'), "# THE END")
:let failed = append(0, ["Chapter 1", "the beginning"])
```

appendbufline({expr}, {lnum}, {text}) appendbufline()
Like append() but append the text in buffer {expr}.

For the use of {expr}, see bufname().

{lnum} is used like with append(). Note that using line() would use the current buffer, not the one appending to. Use "$" to append at the end of the buffer.

On success 0 is returned, on failure 1 is returned.

If {expr} is not a valid buffer or {lnum} is not valid, an error message is given. Example:
```
:let failed = appendbufline(13, 0, "# THE START")
```

argc() argc()
The result is the number of files in the argument list of the current window. See arglist.

argidx() argidx()
The result is the current index in the argument list. 0 is the first file. argc() - 1 is the last one. See arglist.

arglistid([{winnr} [, {tabnr}]]) arglistid()

Return the argument list ID. This is a number which identifies the argument list being used. Zero is used for the global argument list. See arglist .
Return -1 if the arguments are invalid.

Without arguments use the current window.
With {winnr} only use this window in the current tab page.
With {winnr} and {tabnr} use the window in the specified tab page.
{winnr} can be the window number or the window-ID .

argv()
argv([{nr}]) The result is the {nr}th file in the argument list of the current window. See arglist . "argv(0)" is the first one. Example:

```
:let i = 0
:while i < argc()
:  let f = escape(fnameescape(argv(i)), '.')
:  exe 'amenu Arg.' . f . ' :e ' . f . '<CR>'
:  let i = i + 1
:endwhile
```

Without the {nr} argument a List with the whole arglist is returned.

assert_beeps({cmd}) assert_beeps()
Run {cmd} and add an error message to v:errors if it does NOT produce a beep or visual bell.
Also see assert_fails() and assert-return .

assert_equal()
assert_equal({expected}, {actual} [, {msg}])
When {expected} and {actual} are not equal an error message is added to v:errors and 1 is returned. Otherwise zero is returned assert-return .
There is no automatic conversion, the String "4" is different from the Number 4. And the number 4 is different from the Float 4.0. The value of 'ignorecase' is not used here, case always matters.
When {msg} is omitted an error in the form "Expected {expected} but got {actual}" is produced.
Example:

```
assert_equal('foo', 'bar')
```

Will result in a string to be added to v:errors :

```
test.vim line 12: Expected 'foo' but got 'bar'
```

assert_equalfile()
assert_equalfile({fname-one}, {fname-two})
When the files {fname-one} and {fname-two} do not contain exactly the same text an error message is added to v:errors .
Also see assert-return .
When {fname-one} or {fname-two} does not exist the error will mention that.
Mainly useful with terminal-diff .

```
assert_exception({error} [, {msg}])                    assert_exception()
                When v:exception does not contain the string {error} an error
                message is added to  v:errors .  Also see  assert-return .
                This can be used to assert that a command throws an exception.
                Using the error number, followed by a colon, avoids problems
                with translations:
                        try
                          commandthatfails
                          call assert_false(1, 'command should have failed')
                        catch
                          call assert_exception('E492:')
                        endtry

assert_fails({cmd} [, {error}])                              assert_fails()
                Run {cmd} and add an error message to  v:errors  if it does
                NOT produce an error.  Also see  assert-return .
                When {error} is given it must match in  v:errmsg .
                Note that beeping is not considered an error, and some failing
                commands only beep.  Use  assert_beeps()  for those.

assert_false({actual} [, {msg}])                             assert_false()
                When {actual} is not false an error message is added to
                 v:errors , like with  assert_equal() .
                Also see  assert-return .
                A value is false when it is zero. When {actual} is not a
                number the assert fails.
                When {msg} is omitted an error in the form
                "Expected False but got {actual}" is produced.

assert_inrange({lower}, {upper}, {actual} [, {msg}])      assert_inrange()
                This asserts number values.  When {actual}  is lower than
                {lower} or higher than {upper} an error message is added to
                 v:errors .  Also see  assert-return .
                When {msg} is omitted an error in the form
                "Expected range {lower} - {upper}, but got {actual}" is
                produced.

                                                             assert_match()
assert_match({pattern}, {actual} [, {msg}])
                When {pattern} does not match {actual} an error message is
                added to  v:errors .  Also see  assert-return .

                {pattern} is used as with  =~ : The matching is always done
                like 'magic' was set and 'cpoptions' is empty, no matter what
                the actual value of 'magic' or 'cpoptions' is.

                {actual} is used as a string, automatic conversion applies.
                Use "^" and "$" to match with the start and end of the text.
                Use both to match the whole text.

                When {msg} is omitted an error in the form
                "Pattern {pattern} does not match {actual}" is produced.
                Example:
        assert_match('^f.*o$', 'foobar')
```

Will result in a string to be added to v:errors :
test.vim line 12: Pattern '^f.*o$' does not match 'foobar'

assert_notequal()
assert_notequal({expected}, {actual} [, {msg}])
The opposite of `assert_equal()`: add an error message to v:errors when {expected} and {actual} are equal.
Also see assert-return .

assert_notmatch()
assert_notmatch({pattern}, {actual} [, {msg}])
The opposite of `assert_match()`: add an error message to v:errors when {pattern} matches {actual}.
Also see assert-return .

assert_report({msg}) assert_report()
Report a test failure directly, using {msg}.
Always returns one.

assert_true({actual} [, {msg}]) assert_true()
When {actual} is not true an error message is added to v:errors , like with assert_equal() .
Also see assert-return .
A value is TRUE when it is a non-zero number. When {actual} is not a number the assert fails.
When {msg} is omitted an error in the form "Expected True but got {actual}" is produced.

asin({expr}) asin()
Return the arc sine of {expr} measured in radians, as a Float in the range of [-pi/2, pi/2].
{expr} must evaluate to a Float or a Number in the range [-1, 1].
Examples:
```
:echo asin(0.8)
0.927295
:echo asin(-0.5)
-0.523599
```
{only available when compiled with the |+float| feature}

atan({expr}) atan()
Return the principal value of the arc tangent of {expr}, in the range [-pi/2, +pi/2] radians, as a Float .
{expr} must evaluate to a Float or a Number .
Examples:
```
:echo atan(100)
1.560797
:echo atan(-4.01)
-1.326405
```
{only available when compiled with the |+float| feature}

atan2({expr1}, {expr2}) atan2()

Return the arc tangent of {expr1} / {expr2}, measured in radians, as a Float in the range [-pi, pi]. {expr1} and {expr2} must evaluate to a Float or a Number. Examples:

```
:echo atan2(-1, 1)
-0.785398
:echo atan2(1, -1)
2.356194
```

{only available when compiled with the |+float| feature}

balloon_show({expr}) balloon_show()

Show {expr} inside the balloon. For the GUI {expr} is used as a string. For a terminal {expr} can be a list, which contains the lines of the balloon. If {expr} is not a list it will be split with balloon_split().

Example:

```
func GetBalloonContent()
  " initiate getting the content
  return ''
endfunc
set balloonexpr=GetBalloonContent()

func BalloonCallback(result)
  call balloon_show(a:result)
endfunc
```

The intended use is that fetching the content of the balloon is initiated from 'balloonexpr'. It will invoke an asynchronous method, in which a callback invokes balloon_show(). The 'balloonexpr' itself can return an empty string or a placeholder.

When showing a balloon is not possible nothing happens, no error message.
{only available when compiled with the +balloon_eval or +balloon_eval_term feature}

balloon_split({msg}) balloon_split()

Split {msg} into lines to be displayed in a balloon. The splits are made for the current window size and optimize to show debugger output.
Returns a List with the split lines.
{only available when compiled with the +balloon_eval_term feature}

browse() browse()

browse({save}, {title}, {initdir}, {default})

Put up a file requester. This only works when "has("browse")" returns TRUE (only in some GUI versions).
The input fields are:

{save}	when TRUE, select file to write
{title}	title for the requester
{initdir}	directory to start browsing in

{default}   default file name
When the "Cancel" button is hit, something went wrong, or
browsing is not possible, an empty string is returned.

browsedir()
browsedir({title}, {initdir})
Put up a directory requester. This only works when
"has("browse")" returns TRUE (only in some GUI versions).
On systems where a directory browser is not supported a file
browser is used. In that case: select a file in the directory
to be used.
The input fields are:
{title}   title for the requester
{initdir}   directory to start browsing in
When the "Cancel" button is hit, something went wrong, or
browsing is not possible, an empty string is returned.

bufexists({expr}) bufexists()
The result is a Number, which is TRUE if a buffer called
{expr} exists.
If the {expr} argument is a number, buffer numbers are used.
Number zero is the alternate buffer for the current window.

If the {expr} argument is a string it must match a buffer name
exactly. The name can be:
- Relative to the current directory.
- A full path.
- The name of a buffer with 'buftype' set to "nofile".
- A URL name.
Unlisted buffers will be found.
Note that help files are listed by their short name in the
output of :buffers , but bufexists() requires using their
long name to be able to find them.
bufexists() may report a buffer exists, but to use the name
with a :buffer command you may need to use expand() . Esp
for MS-Windows 8.3 names in the form "c:\DOCUME~1"
Use "bufexists(0)" to test for the existence of an alternate
file name.
buffer_exists()
Obsolete name: buffer_exists().

buflisted({expr}) buflisted()
The result is a Number, which is TRUE if a buffer called
{expr} exists and is listed (has the 'buflisted' option set).
The {expr} argument is used like with bufexists() .

bufloaded({expr}) bufloaded()
The result is a Number, which is TRUE if a buffer called
{expr} exists and is loaded (shown in a window or hidden).
The {expr} argument is used like with bufexists() .

bufname({expr}) bufname()
The result is the name of a buffer, as it is displayed by the
":ls" command.

If {expr} is a Number, that buffer number's name is given.
Number zero is the alternate buffer for the current window.
If {expr} is a String, it is used as a file-pattern to match
with the buffer names. This is always done like 'magic' is
set and 'cpoptions' is empty. When there is more than one
match an empty string is returned.
"" or "%" can be used for the current buffer, "#" for the
alternate buffer.
A full match is preferred, otherwise a match at the start, end
or middle of the buffer name is accepted. If you only want a
full match then put "^" at the start and "$" at the end of the
pattern.
Listed buffers are found first. If there is a single match
with a listed buffer, that one is returned. Next unlisted
buffers are searched for.
If the {expr} is a String, but you want to use it as a buffer
number, force it to be a Number by adding zero to it:

```
:echo bufname("3" + 0)
```

If the buffer doesn't exist, or doesn't have a name, an empty
string is returned.

```
bufname("#")            alternate buffer name
bufname(3)              name of buffer 3
bufname("%")            name of current buffer
bufname("file2")        name of buffer where "file2" matches.
```

buffer_name()
Obsolete name: buffer_name().

bufnr()

bufnr({expr} [, {create}])
The result is the number of a buffer, as it is displayed by
the ":ls" command. For the use of {expr}, see bufname()
above.
If the buffer doesn't exist, -1 is returned. Or, if the
{create} argument is present and not zero, a new, unlisted,
buffer is created and its number is returned.
bufnr("$") is the last buffer:

```
:let last_buffer = bufnr("$")
```

The result is a Number, which is the highest buffer number
of existing buffers. Note that not all buffers with a smaller
number necessarily exist, because ":bwipeout" may have removed
them. Use bufexists() to test for the existence of a buffer.

buffer_number()
Obsolete name: buffer_number().

last_buffer_nr()
Obsolete name for bufnr("$"): last_buffer_nr().

bufwinid({expr})

bufwinid()
The result is a Number, which is the window-ID of the first
window associated with buffer {expr}. For the use of {expr},
see bufname() above. If buffer {expr} doesn't exist or
there is no such window, -1 is returned. Example:

```
echo "A window containing buffer 1 is " . (bufwinid(1))
```

Only deals with the current tab page.

bufwinnr({expr}) bufwinnr()
The result is a Number, which is the number of the first window associated with buffer {expr}. For the use of {expr}, see bufname() above. If buffer {expr} doesn't exist or there is no such window, -1 is returned. Example:

```
echo "A window containing buffer 1 is " . (bufwinnr(1))
```

The number can be used with CTRL-W_w and ":wincmd w" :wincmd .
Only deals with the current tab page.

byte2line({byte}) byte2line()
Return the line number that contains the character at byte count {byte} in the current buffer. This includes the end-of-line character, depending on the 'fileformat' option for the current buffer. The first character has byte count one.
Also see line2byte() , go and :goto .
{not available when compiled without the +byte_offset feature}

byteidx({expr}, {nr}) byteidx()
Return byte index of the {nr}'th character in the string {expr}. Use zero for the first character, it returns zero. This function is only useful when there are multibyte characters, otherwise the returned value is equal to {nr}. Composing characters are not counted separately, their byte length is added to the preceding base character. See byteidxcomp() below for counting composing characters separately.
Example :

```
echo matchstr(str, ".", byteidx(str, 3))
```

will display the fourth character. Another way to do the same:

```
let s = strpart(str, byteidx(str, 3))
echo strpart(s, 0, byteidx(s, 1))
```

Also see strgetchar() and strcharpart() .

If there are less than {nr} characters -1 is returned.
If there are exactly {nr} characters the length of the string in bytes is returned.

byteidxcomp({expr}, {nr}) byteidxcomp()
Like byteidx(), except that a composing character is counted as a separate character. Example:

```
let s = 'e' . nr2char(0x301)
echo byteidx(s, 1)
echo byteidxcomp(s, 1)
echo byteidxcomp(s, 2)
```

The first and third echo result in 3 ('e' plus composing character is 3 bytes), the second echo results in 1 ('e' is

one byte).
Only works different from byteidx() when 'encoding' is set to
a Unicode encoding.

call({func}, {arglist} [, {dict}]) call() E699
Call function {func} with the items in List {arglist} as
arguments.
{func} can either be a Funcref or the name of a function.
a:firstline and a:lastline are set to the cursor line.
Returns the return value of the called function.
{dict} is for functions with the "dict" attribute. It will be
used to set the local variable "self". Dictionary-function

ceil({expr}) ceil()
Return the smallest integral value greater than or equal to
{expr} as a Float (round up).
{expr} must evaluate to a Float or a Number .
Examples:
```
echo ceil(1.456)
2.0
echo ceil(-5.456)
-5.0
echo ceil(4.0)
4.0
```
{only available when compiled with the |+float| feature}

ch_canread({handle}) ch_canread()
Return non-zero when there is something to read from {handle}.
{handle} can be a Channel or a Job that has a Channel.

This is useful to read from a channel at a convenient time,
e.g. from a timer.

Note that messages are dropped when the channel does not have
a callback. Add a close callback to avoid that.

{only available when compiled with the |+channel| feature}

ch_close({handle}) ch_close()
Close {handle}. See channel-close .
{handle} can be a Channel or a Job that has a Channel.
A close callback is not invoked.

{only available when compiled with the |+channel| feature}

ch_close_in({handle}) ch_close_in()
Close the "in" part of {handle}. See channel-close-in .
{handle} can be a Channel or a Job that has a Channel.
A close callback is not invoked.

{only available when compiled with the |+channel| feature}

ch_evalexpr({handle}, {expr} [, {options}]) ch_evalexpr()
Send {expr} over {handle}. The {expr} is encoded

according to the type of channel. The function cannot be used with a raw channel. See channel-use .
{handle} can be a Channel or a Job that has a Channel.
E917
{options} must be a Dictionary. It must not have a "callback" entry. It can have a "timeout" entry to specify the timeout for this specific request.

ch_evalexpr() waits for a response and returns the decoded expression. When there is an error or timeout it returns an empty string.

{only available when compiled with the |+channel| feature}

ch_evalraw({handle}, {string} [, {options}]) ch_evalraw()
Send {string} over {handle}.
{handle} can be a Channel or a Job that has a Channel.

Works like ch_evalexpr() , but does not encode the request or decode the response. The caller is responsible for the correct contents. Also does not add a newline for a channel in NL mode, the caller must do that. The NL in the response is removed.
Note that Vim does not know when the text received on a raw channel is complete, it may only return the first part and you need to use ch_readraw() to fetch the rest.
See channel-use .

{only available when compiled with the |+channel| feature}

ch_getbufnr({handle}, {what}) ch_getbufnr()
Get the buffer number that {handle} is using for {what}.
{handle} can be a Channel or a Job that has a Channel.
{what} can be "err" for stderr, "out" for stdout or empty for socket output.
Returns -1 when there is no buffer.
{only available when compiled with the |+channel| feature}

ch_getjob({channel}) ch_getjob()
Get the Job associated with {channel}.
If there is no job calling job_status() on the returned Job will result in "fail".

{only available when compiled with the +channel and +job features}

ch_info({handle}) ch_info()
Returns a Dictionary with information about {handle}. The items are:
"id" number of the channel
"status" "open", "buffered" or "closed", like ch_status()
When opened with ch_open():
"hostname" the hostname of the address

```
                "port"         the port of the address
                "sock_status"  "open" or "closed"
                "sock_mode"    "NL", "RAW", "JSON" or "JS"
                "sock_io"      "socket"
                "sock_timeout" timeout in msec
              When opened with job_start():
                "out_status"   "open", "buffered" or "closed"
                "out_mode"     "NL", "RAW", "JSON" or "JS"
                "out_io"       "null", "pipe", "file" or "buffer"
                "out_timeout"  timeout in msec
                "err_status"   "open", "buffered" or "closed"
                "err_mode"     "NL", "RAW", "JSON" or "JS"
                "err_io"       "out", "null", "pipe", "file" or "buffer"
                "err_timeout"  timeout in msec
                "in_status"    "open" or "closed"
                "in_mode"      "NL", "RAW", "JSON" or "JS"
                "in_io"        "null", "pipe", "file" or "buffer"
                "in_timeout"   timeout in msec

ch_log({msg} [, {handle}])                                        ch_log()
              Write {msg} in the channel log file, if it was opened with
               ch_logfile() .
              When {handle} is passed the channel number is used for the
              message.
              {handle} can be a Channel or a Job that has a Channel.  The
              Channel must be open for the channel number to be used.

ch_logfile({fname} [, {mode}])                                    ch_logfile()
              Start logging channel activity to {fname}.
              When {fname} is an empty string: stop logging.

              When {mode} is omitted or "a" append to the file.
              When {mode} is "w" start with an empty file.

              The file is flushed after every message, on Unix you can use
              "tail -f" to see what is going on in real time.

              This function is not available in the  sandbox .
              NOTE: the channel communication is stored in the file, be
              aware that this may contain confidential and privacy sensitive
              information, e.g. a password you type in a terminal window.

ch_open({address} [, {options}])                                  ch_open()
              Open a channel to {address}.  See  channel .
              Returns a Channel.  Use  ch_status()  to check for failure.

              {address} has the form "hostname:port", e.g.,
              "localhost:8765".

              If {options} is given it must be a  Dictionary .
              See  channel-open-options .

              {only available when compiled with the |+channel| feature}
```

ch_read({handle} [, {options}]) ch_read()
Read from {handle} and return the received message.
{handle} can be a Channel or a Job that has a Channel.
For a NL channel this waits for a NL to arrive, except when
there is nothing more to read (channel was closed).
See channel-more .
{only available when compiled with the |+channel| feature}

ch_readraw({handle} [, {options}]) ch_readraw()
Like ch_read() but for a JS and JSON channel does not decode
the message. For a NL channel it does not block waiting for
the NL to arrive, but otherwise works like ch_read().
See channel-more .
{only available when compiled with the |+channel| feature}

ch_sendexpr({handle}, {expr} [, {options}]) ch_sendexpr()
Send {expr} over {handle}. The {expr} is encoded
according to the type of channel. The function cannot be used
with a raw channel.
See channel-use . E912
{handle} can be a Channel or a Job that has a Channel.

{only available when compiled with the |+channel| feature}

ch_sendraw({handle}, {string} [, {options}]) ch_sendraw()
Send {string} over {handle}.
Works like ch_sendexpr() , but does not encode the request or
decode the response. The caller is responsible for the
correct contents. Also does not add a newline for a channel
in NL mode, the caller must do that. The NL in the response
is removed.
See channel-use .

{only available when compiled with the |+channel| feature}

ch_setoptions({handle}, {options}) ch_setoptions()
Set options on {handle}:
"callback" the channel callback
"timeout" default read timeout in msec
"mode" mode for the whole channel
See ch_open() for more explanation.
{handle} can be a Channel or a Job that has a Channel.

Note that changing the mode may cause queued messages to be
lost.

These options cannot be changed:
"waittime" only applies to ch_open()

ch_status({handle} [, {options}]) ch_status()
Return the status of {handle}:
"fail" failed to open the channel
"open" channel can be used

```
                "buffered"      channel can be read, not written to
                "closed"        channel can not be used
            {handle} can be a Channel or a Job that has a Channel.
            "buffered" is used when the channel was closed but there is
            still data that can be obtained with  ch_read() .

            If {options} is given it can contain a "part" entry to specify
            the part of the channel to return the status for: "out" or
            "err".  For example, to get the error status:
                ch_status(job, {"part": "err"})

changenr()                                                  changenr()
            Return the number of the most recent change.  This is the same
            number as what is displayed with  :undolist  and can be used
            with the  :undo  command.
            When a change was made it is the number of that change.  After
            redo it is the number of the redone change.  After undo it is
            one less than the number of the undone change.

char2nr({expr} [, {utf8}])                                  char2nr()
            Return number value of the first char in {expr}.  Examples:
                char2nr(" ")            returns 32
                char2nr("ABC")          returns 65
            When {utf8} is omitted or zero, the current 'encoding' is used.
            Example for "utf-8":
                char2nr("á")            returns 225
                char2nr("á"[0])         returns 195
            With {utf8} set to 1, always treat as utf-8 characters.
            A combining character is a separate character.
             nr2char()  does the opposite.

cindent({lnum})                                             cindent()
            Get the amount of indent for line {lnum} according the C
            indenting rules, as with 'cindent'.
            The indent is counted in spaces, the value of 'tabstop' is
            relevant.  {lnum} is used just like in  getline() .
            When {lnum} is invalid or Vim was not compiled the  +cindent
            feature, -1 is returned.
            See  C-indenting .

clearmatches()                                              clearmatches()
            Clears all matches previously defined by  matchadd()  and the
             :match  commands.

                                                            col()
col({expr})     The result is a Number, which is the byte index of the column
            position given with {expr}.  The accepted positions are:
                .       the cursor position
                $       the end of the cursor line (the result is the
                        number of bytes in the cursor line plus one)
                'x      position of mark x (if the mark is not set, 0 is
                        returned)
                v       In Visual mode: the start of the Visual area (the
                        cursor is the end).  When not in Visual mode
```

```
                        returns the cursor position.  Differs from  '<  in
                        that it's updated right away.
                Additionally {expr} can be [lnum, col]: a  List  with the line
                and column number. Most useful when the column is "$", to get
                the last column of a specific line.  When "lnum" or "col" is
                out of range then col() returns zero.
                To get the line number use  line() .  To get both use
                 getpos() .
                For the screen column position use  virtcol() .
                Note that only marks in the current file can be used.
                Examples:
                        col(".")                column of cursor
                        col("$")                length of cursor line plus one
                        col("'t")               column of mark t
                        col("'" . markname)     column of mark markname
               The first column is 1.  0 is returned for an error.
                For an uppercase mark the column may actually be in another
                buffer.
                For the cursor position, when 'virtualedit' is active, the
                column is one higher if the cursor is after the end of the
                line.  This can be used to obtain the column in Insert mode:
                        :imap <F2> <C-O>:let save_ve = &ve<CR>
                                \<C-O>:set ve=all<CR>
                                \<C-O>:echo col(".") . "\n" <Bar>
                                \let &ve = save_ve<CR>

complete({startcol}, {matches})                 complete()   E785
                Set the matches for Insert mode completion.
                Can only be used in Insert mode.  You need to use a mapping
                with CTRL-R = (see  i_CTRL-R ).  It does not work after CTRL-O
                or with an expression mapping.
                {startcol} is the byte offset in the line where the completed
                text start.  The text up to the cursor is the original text
                that will be replaced by the matches.  Use col('.') for an
                empty string.  "col('.') - 1" will replace one character by a
                match.
                {matches} must be a  List .  Each  List  item is one match.
                See  complete-items  for the kind of items that are possible.
                Note that the after calling this function you need to avoid
                inserting anything that would cause completion to stop.
                The match can be selected with CTRL-N and CTRL-P as usual with
                Insert mode completion.  The popup menu will appear if
                specified, see  ins-completion-menu .
                Example:
        inoremap <F5> <C-R>=ListMonths()<CR>

        func! ListMonths()
          call complete(col('.'), ['January', 'February', 'March',
                \ 'April', 'May', 'June', 'July', 'August', 'September',
                \ 'October', 'November', 'December'])
          return ''
        endfunc
               This isn't very useful, but it shows how it works.  Note that
```

an empty string is returned to avoid a zero being inserted.

complete_add({expr}) complete_add()
Add {expr} to the list of matches. Only to be used by the function specified with the 'completefunc' option. Returns 0 for failure (empty string or out of memory), 1 when the match was added, 2 when the match was already in the list.
See complete-functions for an explanation of {expr}. It is the same as one item in the list that 'omnifunc' would return.

complete_check() complete_check()
Check for a key typed while looking for completion matches. This is to be used when looking for matches takes some time. Returns TRUE when searching for matches is to be aborted, zero otherwise.
Only to be used by the function specified with the 'completefunc' option.

confirm() confirm({msg} [, {choices} [, {default} [, {type}]]])
Confirm() offers the user a dialog, from which a choice can be made. It returns the number of the choice. For the first choice this is 1.
Note: confirm() is only supported when compiled with dialog support, see +dialog_con and +dialog_gui .

{msg} is displayed in a dialog with {choices} as the alternatives. When {choices} is missing or empty, "&OK" is used (and translated).
{msg} is a String, use '\n' to include a newline. Only on some systems the string is wrapped when it doesn't fit.

{choices} is a String, with the individual choices separated by '\n', e.g.
confirm("Save changes?", "&Yes\n&No\n&Cancel")
The letter after the '&' is the shortcut key for that choice. Thus you can type 'c' to select "Cancel". The shortcut does not need to be the first letter:
confirm("file has been modified", "&Save\nSave &All")
For the console, the first letter of each choice is used as the default shortcut key.

The optional {default} argument is the number of the choice that is made if the user hits <CR>. Use 1 to make the first choice the default one. Use 0 to not set a default. If {default} is omitted, 1 is used.

The optional {type} argument gives the type of dialog. This is only used for the icon of the GTK, Mac, Motif and Win32 GUI. It can be one of these values: "Error", "Question", "Info", "Warning" or "Generic". Only the first character is relevant. When {type} is omitted, "Generic" is used.

If the user aborts the dialog by pressing <Esc>, CTRL-C, or another valid interrupt key, confirm() returns 0.

An example:

```
:let choice = confirm("What do you want?", "&Apples\n&Oranges\n&Bananas", 2)
:if choice == 0
:    echo "make up your mind!"
:elseif choice == 3
:    echo "tasteful"
:else
:    echo "I prefer bananas myself."
:endif
```

In a GUI dialog, buttons are used. The layout of the buttons depends on the 'v' flag in 'guioptions'. If it is included, the buttons are always put vertically. Otherwise, confirm() tries to put the buttons in one horizontal line. If they don't fit, a vertical layout is used anyway. For some systems the horizontal layout is always used.

copy({expr}) copy()

Make a copy of {expr}. For Numbers and Strings this isn't different from using {expr} directly.
When {expr} is a List a shallow copy is created. This means that the original List can be changed without changing the copy, and vice versa. But the items are identical, thus changing an item changes the contents of both Lists.
A Dictionary is copied in a similar way as a List.
Also see deepcopy().

cos({expr}) cos()

Return the cosine of {expr}, measured in radians, as a Float. {expr} must evaluate to a Float or a Number.
Examples:

```
:echo cos(100)
0.862319
:echo cos(-4.01)
-0.646043
```

{only available when compiled with the |+float| feature}

cosh({expr}) cosh()

Return the hyperbolic cosine of {expr} as a Float in the range [1, inf]. {expr} must evaluate to a Float or a Number.
Examples:

```
:echo cosh(0.5)
1.127626
:echo cosh(-0.5)
-1.127626
```

{only available when compiled with the |+float| feature}

count({comp}, {expr} [, {ic} [, {start}]]) count()

Return the number of times an item with value {expr} appears

in String , List or Dictionary {comp}.

If {start} is given then start with the item with this index. {start} can only be used with a List .

When {ic} is given and it's TRUE then case is ignored.

When {comp} is a string then the number of not overlapping occurrences of {expr} is returned. Zero is returned when {expr} is an empty string.

cscope_connection() cscope_connection()

cscope_connection([{num} , {dbpath} [, {prepend}]])
Checks for the existence of a cscope connection. If no parameters are specified, then the function returns:
0, if cscope was not available (not compiled in), or if there are no cscope connections;
1, if there is at least one cscope connection.

If parameters are specified, then the value of {num} determines how existence of a cscope connection is checked:

{num}	Description of existence check
0	Same as no parameters (e.g., "cscope_connection()").
1	Ignore {prepend}, and use partial string matches for {dbpath}.
2	Ignore {prepend}, and use exact string matches for {dbpath}.
3	Use {prepend}, use partial string matches for both {dbpath} and {prepend}.
4	Use {prepend}, use exact string matches for both {dbpath} and {prepend}.

Note: All string comparisons are case sensitive!

Examples. Suppose we had the following (from ":cs show"):

```
  # pid    database name                       prepend path
  0 27664  cscope.out                          /usr/local
```

Invocation	Return Val
cscope_connection()	1
cscope_connection(1, "out")	1
cscope_connection(2, "out")	0
cscope_connection(3, "out")	0
cscope_connection(3, "out", "local")	1
cscope_connection(4, "out")	0
cscope_connection(4, "out", "local")	0
cscope_connection(4, "cscope.out", "/usr/local")	1

cursor({lnum}, {col} [, {off}]) cursor()
cursor({list})

Positions the cursor at the column (byte count) {col} in the
line {lnum}. The first column is one.

When there is one argument {list} this is used as a List
with two, three or four item:
        [{lnum}, {col}]
        [{lnum}, {col}, {off}]
        [{lnum}, {col}, {off}, {curswant}]
This is like the return value of getpos() or getcurpos() ,
but without the first item.

Does not change the jumplist.
If {lnum} is greater than the number of lines in the buffer,
the cursor will be positioned at the last line in the buffer.
If {lnum} is zero, the cursor will stay in the current line.
If {col} is greater than the number of bytes in the line,
the cursor will be positioned at the last character in the
line.
If {col} is zero, the cursor will stay in the current column.
If {curswant} is given it is used to set the preferred column
for vertical movement. Otherwise {col} is used.

When 'virtualedit' is used {off} specifies the offset in
screen columns from the start of the character. E.g., a
position within a <Tab> or after the last character.
Returns 0 when the position could be set, -1 otherwise.

debugbreak({pid})   debugbreak()
Specifically used to interrupt a program being debugged. It
will cause process {pid} to get a SIGTRAP. Behavior for other
processes is undefined. See terminal-debugger .
{only available on MS-Windows}

deepcopy({expr} [, {noref}])   deepcopy() E698
Make a copy of {expr}. For Numbers and Strings this isn't
different from using {expr} directly.
When {expr} is a List a full copy is created. This means
that the original List can be changed without changing the
copy, and vice versa. When an item is a List or
 Dictionary , a copy for it is made, recursively. Thus
changing an item in the copy does not change the contents of
the original List .
A Dictionary is copied in a similar way as a List .
When {noref} is omitted or zero a contained List or
 Dictionary is only copied once. All references point to
this single copy. With {noref} set to 1 every occurrence of a
 List or Dictionary results in a new copy. This also means
that a cyclic reference causes deepcopy() to fail.
                                                      E724
Nesting is possible up to 100 levels. When there is an item
that refers back to a higher level making a deep copy with
{noref} set to 1 will fail.
Also see copy() .

delete({fname} [, {flags}]) delete()
Without {flags} or with {flags} empty: Deletes the file by the name {fname}. This also works when {fname} is a symbolic link.

When {flags} is "d": Deletes the directory by the name {fname}. This fails when directory {fname} is not empty.

When {flags} is "rf": Deletes the directory by the name {fname} and everything in it, recursively. BE CAREFUL! Note: on MS-Windows it is not possible to delete a directory that is being used.

A symbolic link itself is deleted, not what it points to.

The result is a Number, which is 0 if the delete operation was successful and -1 when the deletion failed or partly failed.

Use remove() to delete an item from a List. To delete a line from the buffer use :delete or deletebufline().

deletebufline({expr}, {first}[, {last}]) deletebufline()
Delete lines {first} to {last} (inclusive) from buffer {expr}. If {last} is omitted then delete line {first} only. On success 0 is returned, on failure 1 is returned.

For the use of {expr}, see bufname() above.

{first} and {last} are used like with setline(). Note that when using line() this refers to the current buffer. Use "$" to refer to the last line in buffer {expr}.

did_filetype() did_filetype()
Returns TRUE when autocommands are being executed and the FileType event has been triggered at least once. Can be used to avoid triggering the FileType event again in the scripts that detect the file type. FileType
Returns FALSE when `:setf FALLBACK` was used.
When editing another file, the counter is reset, thus this really checks if the FileType event has been triggered for the current buffer. This allows an autocommand that starts editing another buffer to set 'filetype' and load a syntax file.

diff_filler({lnum}) diff_filler()
Returns the number of filler lines above line {lnum}. These are the lines that were inserted at this point in another diff'ed window. These filler lines are shown in the display but don't exist in the buffer.
{lnum} is used like with getline(). Thus "." is the current line, "'m" mark m, etc.
Returns 0 if the current window is not in diff mode.

diff_hlID({lnum}, {col}) diff_hlID()

Returns the highlight ID for diff mode at line {lnum} column {col} (byte index). When the current line does not have a diff change zero is returned.
{lnum} is used like with getline() . Thus "." is the current line, "'m" mark m, etc.
{col} is 1 for the leftmost column, {lnum} is 1 for the first line.
The highlight ID can be used with synIDattr() to obtain syntax information about the highlighting.

empty({expr}) empty()
Return the Number 1 if {expr} is empty, zero otherwise.
- A List or Dictionary is empty when it does not have any items.
- A String is empty when its length is zero.
- A Number and Float is empty when its value is zero.
- v:false , v:none and v:null are empty, v:true is not.
- A Job is empty when it failed to start.
- A Channel is empty when it is closed.

For a long List this is much faster than comparing the length with zero.

escape({string}, {chars}) escape()
Escape the characters in {chars} that occur in {string} with a backslash. Example:
```
:echo escape('c:\program files\vim', ' \')
```
results in:
```
c:\\program\ files\\vim
```
Also see shellescape() and fnameescape() .

eval({string}) eval()
Evaluate {string} and return the result. Especially useful to turn the result of string() back into the original value. This works for Numbers, Floats, Strings and composites of them. Also works for Funcref s that refer to existing functions.

eventhandler() eventhandler()
Returns 1 when inside an event handler. That is that Vim got interrupted while waiting for the user to type a character, e.g., when dropping a file on Vim. This means interactive commands cannot be used. Otherwise zero is returned.

executable({expr}) executable()
This function checks if an executable with the name {expr} exists. {expr} must be the name of the program without any arguments.
executable() uses the value of $PATH and/or the normal searchpath for programs. PATHEXT
On MS-DOS and MS-Windows the ".exe", ".bat", etc. can optionally be included. Then the extensions in $PATHEXT are tried. Thus if "foo.exe" does not exist, "foo.exe.bat" can be found. If $PATHEXT is not set then ".exe;.com;.bat;.cmd" is

used. A dot by itself can be used in $PATHEXT to try using
the name without an extension. When 'shell' looks like a
Unix shell, then the name is also tried without adding an
extension.
On MS-DOS and MS-Windows it only checks if the file exists and
is not a directory, not if it's really executable.
On MS-Windows an executable in the same directory as Vim is
always found. Since this directory is added to $PATH it
should also work to execute it win32-PATH .
The result is a Number:
        1   exists
        0   does not exist
        -1   not implemented on this system
 exepath() can be used to get the full path of an executable.

execute({command} [, {silent}])   execute()
Execute an Ex command or commands and return the output as a
string.
{command} can be a string or a List. In case of a List the
lines are executed one by one.
This is equivalent to:
        redir => var
        {command}
        redir END

The optional {silent} argument can have these values:
        ""   no `:silent` used
        "silent"   `:silent` used
        "silent!"   `:silent!` used
The default is "silent". Note that with "silent!", unlike
`:redir`, error messages are dropped. When using an external
command the screen may be messed up, use `system()` instead.
                                                 E930
It is not possible to use `:redir` anywhere in {command}.

To get a list of lines use split() on the result:
        split(execute('args'), "\n")

When used recursively the output of the recursive call is not
included in the output of the higher level call.

exepath({expr})   exepath()
If {expr} is an executable and is either an absolute path, a
relative path or found in $PATH, return the full path.
Note that the current directory is used when {expr} starts
with "./", which may be a problem for Vim:
        echo exepath(v:progpath)
If {expr} cannot be found in $PATH or is not executable then
an empty string is returned.

                                                                 exists()
exists({expr}) The result is a Number, which is TRUE if {expr} is defined,
zero otherwise.

```
For checking for a supported feature use  has() .
For checking if a file exists use  filereadable() .

The {expr} argument is a string, which contains one of these:
        &option-name    Vim option (only checks if it exists,
                        not if it really works)
        +option-name    Vim option that works.
        $ENVNAME        environment variable (could also be
                        done by comparing with an empty
                        string)
        *funcname       built-in function (see  functions )
                        or user defined function (see
                         user-functions ). Also works for a
                        variable that is a Funcref.
        varname         internal variable (see
                         internal-variables ).  Also works
                        for  curly-braces-names ,  Dictionary
                        entries,  List  items, etc.  Beware
                        that evaluating an index may cause an
                        error message for an invalid
                        expression.  E.g.:
                           :let l = [1, 2, 3]
                           :echo exists("l[5]")
                          0
                           :echo exists("l[xx]")
                          E121: Undefined variable: xx
                           0
        :cmdname        Ex command: built-in command, user
                        command or command modifier  :command .
                        Returns:
                        1  for match with start of a command
                        2  full match with a command
                        3  matches several user commands
                        To check for a supported command
                        always check the return value to be 2.
        :2match         The  :2match  command.
        :3match         The  :3match  command.
        #event          autocommand defined for this event
        #event#pattern  autocommand defined for this event and
                        pattern (the pattern is taken
                        literally and compared to the
                        autocommand patterns character by
                        character)
        #group          autocommand group exists
        #group#event    autocommand defined for this group and
                        event.
        #group#event#pattern
                        autocommand defined for this group,
                        event and pattern.
        ##event         autocommand for this event is
                        supported.

Examples:
        exists("&shortname")
```

```
		exists("$HOSTNAME")
		exists("*strftime")
		exists("*s:MyFunc")
		exists("bufcount")
		exists(":Make")
		exists("#CursorHold")
		exists("#BufReadPre#*.gz")
		exists("#filetypeindent")
		exists("#filetypeindent#FileType")
		exists("#filetypeindent#FileType#*")
		exists("##ColorScheme")
	There must be no space between the symbol (&/$/*/#) and the
	 name.
	 There must be no extra characters after the name, although in
	 a few cases this is ignored.  That may become more strict in
	 the future, thus don't count on it!
	 Working example:
		exists(":make")
	NOT working example:
		exists(":make install")

	Note that the argument must be a string, not the name of the
	 variable itself.  For example:
		exists(bufcount)
	This doesn't check for existence of the "bufcount" variable,
	 but gets the value of "bufcount", and checks if that exists.

exp({expr})                                                  exp()
	 Return the exponential of {expr} as a  Float  in the range
	 [0, inf].
	 {expr} must evaluate to a  Float  or a  Number .
	 Examples:
		:echo exp(2)
	       7.389056
		:echo exp(-1)
	       0.367879
	 {only available when compiled with the |+float| feature}

expand({expr} [, {nosuf} [, {list}]])                        expand()
	 Expand wildcards and the following special keywords in {expr}.
	 'wildignorecase' applies.

	 If {list} is given and it is  TRUE , a List will be returned.
	 Otherwise the result is a String and when there are several
	 matches, they are separated by <NL> characters.  [Note: in
	 version 5.0 a space was used, which caused problems when a
	 file name contains a space]

	 If the expansion fails, the result is an empty string.  A name
	 for a non-existing file is not included, unless {expr} does
	 not start with '%', '#' or '<', see below.

	 When {expr} starts with '%', '#' or '<', the expansion is done
```

like for the cmdline-special variables with their associated modifiers. Here is a short overview:

```
        %               current file name
        #               alternate file name
        #n              alternate file name n
        <cfile>         file name under the cursor
        <afile>         autocmd file name
        <abuf>          autocmd buffer number (as a String!)
        <amatch>        autocmd matched name
        <sfile>         sourced script file or function name
        <slnum>         sourced script file line number
        <cword>         word under the cursor
        <cWORD>         WORD under the cursor
        <client>        the {clientid} of the last received
                        message server2client()
Modifiers:
        :p              expand to full path
        :h              head (last path component removed)
        :t              tail (last path component only)
        :r              root (one extension removed)
        :e              extension only

Example:
        :let &tags = expand("%:p:h") . "/tags"
```

Note that when expanding a string that starts with '%', '#' or '<', any following text is ignored. This does NOT work:

```
        :let doesntwork = expand("%:h.bak")
```

Use this:

```
        :let doeswork = expand("%:h") . ".bak"
```

Also note that expanding "<cfile>" and others only returns the referenced file name without further expansion. If "<cfile>" is "~/.cshrc", you need to do another expand() to have the "~/" expanded into the path of the home directory:

```
        :echo expand(expand("<cfile>"))
```

There cannot be white space between the variables and the following modifier. The fnamemodify() function can be used to modify normal file names.

When using '%' or '#', and the current or alternate file name is not defined, an empty string is used. Using "%:p" in a buffer with no name, results in the current directory, with a '/' added.

When {expr} does not start with '%', '#' or '<', it is expanded like a file name is expanded on the command line. 'suffixes' and 'wildignore' are used, unless the optional {nosuf} argument is given and it is TRUE .
Names for non-existing files are included. The "**" item can be used to search in a directory tree. For example, to find all "README" files in the current directory and below:

```
        :echo expand("**/README")
```

Expand() can also be used to expand variables and environment variables that are only known in a shell. But this can be slow, because a shell may be used to do the expansion. See expr-env-expand .
The expanded variable is still handled like a list of file names. When an environment variable cannot be expanded, it is left unchanged. Thus ":echo expand('$FOOBAR')" results in "$FOOBAR".

See glob() for finding existing files. See system() for getting the raw output of an external command.

extend({expr1}, {expr2} [, {expr3}]) extend()
{expr1} and {expr2} must be both Lists or both Dictionaries .

If they are Lists : Append {expr2} to {expr1}.
If {expr3} is given insert the items of {expr2} before item {expr3} in {expr1}. When {expr3} is zero insert before the first item. When {expr3} is equal to len({expr1}) then {expr2} is appended.
Examples:
```
:echo sort(extend(mylist, [7, 5]))
:call extend(mylist, [2, 3], 1)
```
When {expr1} is the same List as {expr2} then the number of items copied is equal to the original length of the List. E.g., when {expr3} is 1 you get N new copies of the first item (where N is the original length of the List).
Use add() to concatenate one item to a list. To concatenate two lists into a new list use the + operator:
```
:let newlist = [1, 2, 3] + [4, 5]
```

If they are Dictionaries :
Add all entries from {expr2} to {expr1}.
If a key exists in both {expr1} and {expr2} then {expr3} is used to decide what to do:
{expr3} = "keep": keep the value of {expr1}
{expr3} = "force": use the value of {expr2}
{expr3} = "error": give an error message E737
When {expr3} is omitted then "force" is assumed.

{expr1} is changed when {expr2} is not empty. If necessary make a copy of {expr1} first.
{expr2} remains unchanged.
When {expr1} is locked and {expr2} is not empty the operation fails.
Returns {expr1}.

feedkeys({string} [, {mode}]) feedkeys()
Characters in {string} are queued for processing as if they come from a mapping or were typed by the user.
By default the string is added to the end of the typeahead buffer, thus if a mapping is still being executed the

characters come after them. Use the 'i' flag to insert before other characters, they will be executed next, before any characters from a mapping.
The function does not wait for processing of keys contained in {string}.
To include special keys into {string}, use double-quotes and "\..." notation expr-quote . For example, feedkeys("\<CR>") simulates pressing of the <Enter> key. But feedkeys('\<CR>') pushes 5 characters.
If {mode} is absent, keys are remapped.
{mode} is a String, which can contain these character flags:
'm'	Remap keys. This is default.
'n'	Do not remap keys.
't'	Handle keys as if typed; otherwise they are handled as if coming from a mapping. This matters for undo, opening folds, etc.
'i'	Insert the string instead of appending (see above).
'x'	Execute commands until typeahead is empty. This is similar to using ":normal!". You can call feedkeys() several times without 'x' and then one time with 'x' (possibly with an empty {string}) to execute all the typeahead. Note that when Vim ends in Insert mode it will behave as if <Esc> is typed, to avoid getting stuck, waiting for a character to be typed before the script continues.
'!'	When used with 'x' will not end Insert mode. Can be used in a test when a timer is set to exit Insert mode a little later. Useful for testing CursorHoldI.

Return value is always 0.

filereadable({file}) filereadable()
The result is a Number, which is TRUE when a file with the name {file} exists, and can be read. If {file} doesn't exist, or is a directory, the result is FALSE . {file} is any expression, which is used as a String.
If you don't care about the file being readable you can use glob() .
file_readable()
Obsolete name: file_readable().

filewritable({file}) filewritable()
The result is a Number, which is 1 when a file with the name {file} exists, and can be written. If {file} doesn't exist, or is not writable, the result is 0. If {file} is a directory, and we can write to it, the result is 2.

filter({expr1}, {expr2}) filter()
{expr1} must be a List or a Dictionary .
For each item in {expr1} evaluate {expr2} and when the result is zero remove the item from the List or Dictionary .
{expr2} must be a string or Funcref .

If {expr2} is a string, inside {expr2} v:val has the value of the current item. For a Dictionary v:key has the key of the current item and for a List v:key has the index of the current item.
Examples:

```
call filter(mylist, 'v:val !~ "OLD"')
```

Removes the items where "OLD" appears.

```
call filter(mydict, 'v:key >= 8')
```

Removes the items with a key below 8.

```
call filter(var, 0)
```

Removes all the items, thus clears the List or Dictionary.

Note that {expr2} is the result of expression and is then used as an expression again. Often it is good to use a literal-string to avoid having to double backslashes.

If {expr2} is a Funcref it must take two arguments:
1. the key or the index of the current item.
2. the value of the current item.

The function must return TRUE if the item should be kept.
Example that keeps the odd items of a list:

```
func Odd(idx, val)
  return a:idx % 2 == 1
endfunc
call filter(mylist, function('Odd'))
```

It is shorter when using a lambda:

```
call filter(myList, {idx, val -> idx * val <= 42})
```

If you do not use "val" you can leave it out:

```
call filter(myList, {idx -> idx % 2 == 1})
```

The operation is done in-place. If you want a List or Dictionary to remain unmodified make a copy first:

```
:let l = filter(copy(mylist), 'v:val =~ "KEEP"')
```

Returns {expr1}, the List or Dictionary that was filtered. When an error is encountered while evaluating {expr2} no further items in {expr1} are processed. When {expr2} is a Funcref errors inside a function are ignored, unless it was defined with the "abort" flag.

finddir({name} [, {path} [, {count}]]) finddir()

Find directory {name} in {path}. Supports both downwards and upwards recursive directory searches. See file-searching for the syntax of {path}.
Returns the path of the first found match. When the found directory is below the current directory a relative path is returned. Otherwise a full path is returned.
If {path} is omitted or empty then 'path' is used.
If the optional {count} is given, find {count}'s occurrence of {name} in {path} instead of the first one.
When {count} is negative return all the matches in a List.
This is quite similar to the ex-command :find.

{only available when compiled with the +file_in_path feature}

findfile({name} [, {path} [, {count}]]) findfile()
Just like finddir() , but find a file instead of a directory.
Uses 'suffixesadd'.
Example:
```
:echo findfile("tags.vim", ".;")
```
Searches from the directory of the current file upwards until it finds the file "tags.vim".

float2nr({expr}) float2nr()
Convert {expr} to a Number by omitting the part after the decimal point.
{expr} must evaluate to a Float or a Number.
When the value of {expr} is out of range for a Number the result is truncated to 0x7fffffff or -0x7fffffff (or when 64-bit Number support is enabled, 0x7fffffffffffffff or -0x7fffffffffffffff). NaN results in -0x80000000 (or when 64-bit Number support is enabled, -0x8000000000000000).
Examples:
```
echo float2nr(3.95)
3
echo float2nr(-23.45)
-23
echo float2nr(1.0e100)
2147483647  (or 9223372036854775807)
echo float2nr(-1.0e150)
-2147483647 (or -9223372036854775807)
echo float2nr(1.0e-100)
0
```
{only available when compiled with the |+float| feature}

floor({expr}) floor()
Return the largest integral value less than or equal to {expr} as a Float (round down).
{expr} must evaluate to a Float or a Number .
Examples:
```
echo floor(1.856)
1.0
echo floor(-5.456)
-6.0
echo floor(4.0)
4.0
```
{only available when compiled with the |+float| feature}

fmod({expr1}, {expr2}) fmod()
Return the remainder of {expr1} / {expr2}, even if the division is not representable. Returns {expr1} - i * {expr2} for some integer i such that if {expr2} is non-zero, the result has the same sign as {expr1} and magnitude less than the magnitude of {expr2}. If {expr2} is zero, the value

returned is zero. The value returned is a Float .
{expr1} and {expr2} must evaluate to a Float or a Number .
Examples:

```
:echo fmod(12.33, 1.22)
0.13
:echo fmod(-12.33, 1.22)
-0.13
```

{only available when compiled with |+float| feature}

fnameescape({string}) fnameescape()

Escape {string} for use as file name command argument. All characters that have a special meaning, such as '%' and '|' are escaped with a backslash.
For most systems the characters escaped are " \t\n*?[{`$\\%#'\"|!<". For systems where a backslash appears in a filename, it depends on the value of 'isfname'. A leading '+' and '>' is also escaped (special after :edit and :write). And a "-" by itself (special after :cd).
Example:

```
:let fname = '+some str%nge|name'
:exe "edit " . fnameescape(fname)
```

results in executing:

```
edit \+some\ str\%nge\|name
```

fnamemodify({fname}, {mods}) fnamemodify()

Modify file name {fname} according to {mods}. {mods} is a string of characters like it is used for file names on the command line. See filename-modifiers .
Example:

```
:echo fnamemodify("main.c", ":p:h")
```

results in:

```
/home/mool/vim/vim/src
```

Note: Environment variables don't work in {fname}, use expand() first then.

foldclosed({lnum}) foldclosed()

The result is a Number. If the line {lnum} is in a closed fold, the result is the number of the first line in that fold. If the line {lnum} is not in a closed fold, -1 is returned.

foldclosedend({lnum}) foldclosedend()

The result is a Number. If the line {lnum} is in a closed fold, the result is the number of the last line in that fold. If the line {lnum} is not in a closed fold, -1 is returned.

foldlevel({lnum}) foldlevel()

The result is a Number, which is the foldlevel of line {lnum} in the current buffer. For nested folds the deepest level is returned. If there is no fold at line {lnum}, zero is returned. It doesn't matter if the folds are open or closed. When used while updating folds (from 'foldexpr') -1 is returned for lines where folds are still to be updated and the foldlevel is unknown. As a special case the level of the

previous line is usually available.

foldtext()

foldtext()	Returns a String, to be displayed for a closed fold. This is the default function used for the 'foldtext' option and should only be called from evaluating 'foldtext'. It uses the v:foldstart , v:foldend and v:folddashes variables. The returned string looks like this:

```
+-- 45 lines: abcdef
```

The number of leading dashes depends on the foldlevel. The "45" is the number of lines in the fold. "abcdef" is the text in the first non-blank line of the fold. Leading white space, "//" or "/*" and the text from the 'foldmarker' and 'commentstring' options is removed.
When used to draw the actual foldtext, the rest of the line will be filled with the fold char from the 'fillchars' setting.
{not available when compiled without the |+folding| feature}

foldtextresult({lnum}) foldtextresult()

Returns the text that is displayed for the closed fold at line {lnum}. Evaluates 'foldtext' in the appropriate context. When there is no closed fold at {lnum} an empty string is returned.
{lnum} is used like with getline() . Thus "." is the current line, "'m" mark m, etc.
Useful when exporting folded text, e.g., to HTML.
{not available when compiled without the |+folding| feature}

foreground() foreground()

Move the Vim window to the foreground. Useful when sent from a client to a Vim server. remote_send()
On Win32 systems this might not work, the OS does not always allow a window to bring itself to the foreground. Use remote_foreground() instead.
{only in the Win32, Athena, Motif and GTK GUI versions and the Win32 console version}

funcref({name} [, {arglist}] [, {dict}]) funcref()

Just like function() , but the returned Funcref will lookup the function by reference, not by name. This matters when the function {name} is redefined later.

Unlike function() , {name} must be an existing user function. Also for autoloaded functions. {name} cannot be a builtin function.

function({name} [, {arglist}] [, {dict}]) function() E700 E922 E923

Return a Funcref variable that refers to function {name}. {name} can be the name of a user defined function or an internal function.

{name} can also be a Funcref or a partial. When it is a
partial the dict stored in it will be used and the {dict}
argument is not allowed. E.g.:

```
let FuncWithArg = function(dict.Func, [arg])
let Broken = function(dict.Func, [arg], dict)
```

When using the Funcref the function will be found by {name},
also when it was redefined later. Use funcref() to keep the
same function.

When {arglist} or {dict} is present this creates a partial.
That means the argument list and/or the dictionary is stored in
the Funcref and will be used when the Funcref is called.

The arguments are passed to the function in front of other
arguments. Example:

```
func Callback(arg1, arg2, name)
...
let Func = function('Callback', ['one', 'two'])
...
call Func('name')
```

Invokes the function as with:

```
call Callback('one', 'two', 'name')
```

The function() call can be nested to add more arguments to the
Funcref. The extra arguments are appended to the list of
arguments. Example:

```
func Callback(arg1, arg2, name)
...
let Func = function('Callback', ['one'])
let Func2 = function(Func, ['two'])
...
call Func2('name')
```

Invokes the function as with:

```
call Callback('one', 'two', 'name')
```

The Dictionary is only useful when calling a "dict" function.
In that case the {dict} is passed in as "self". Example:

```
function Callback() dict
   echo "called for " . self.name
endfunction
...
let context = {"name": "example"}
let Func = function('Callback', context)
...
call Func()     " will echo: called for example
```

The use of function() is not needed when there are no extra
arguments, these two are equivalent:

```
let Func = function('Callback', context)
let Func = context.Callback
```

The argument list and the Dictionary can be combined:

```
function Callback(arg1, count) dict
...
```

```
		let context = {"name": "example"}
		let Func = function('Callback', ['one'], context)
		...
		call Func(500)
	Invokes the function as with:
		call context.Callback('one', 500)
```

garbagecollect([{atexit}]) garbagecollect()

Cleanup unused Lists , Dictionaries , Channels and Jobs that have circular references.

There is hardly ever a need to invoke this function, as it is automatically done when Vim runs out of memory or is waiting for the user to press a key after 'updatetime'. Items without circular references are always freed when they become unused. This is useful if you have deleted a very big List and/or Dictionary with circular references in a script that runs for a long time.

When the optional {atexit} argument is one, garbage collection will also be done when exiting Vim, if it wasn't done before. This is useful when checking for memory leaks.

The garbage collection is not done immediately but only when it's safe to perform. This is when waiting for the user to type a character. To force garbage collection immediately use test_garbagecollect_now() .

get({list}, {idx} [, {default}]) get()

Get item {idx} from List {list}. When this item is not available return {default}. Return zero when {default} is omitted.

get({dict}, {key} [, {default}])

Get item with key {key} from Dictionary {dict}. When this item is not available return {default}. Return zero when {default} is omitted.

get({func}, {what})

Get an item with from Funcref {func}. Possible values for {what} are:

```
	"name"	The function name
	"func"	The function
	"dict"	The dictionary
	"args"	The list with arguments
```

getbufinfo()

getbufinfo([{expr}])
getbufinfo([{dict}])

Get information about buffers as a List of Dictionaries.

Without an argument information about all the buffers is returned.

When the argument is a Dictionary only the buffers matching

the specified criteria are returned. The following keys can be specified in {dict}:

buflisted	include only listed buffers.
bufloaded	include only loaded buffers.
bufmodified	include only modified buffers.

Otherwise, {expr} specifies a particular buffer to return information for. For the use of {expr}, see bufname() above. If the buffer is found the returned List has one item. Otherwise the result is an empty list.

Each returned List item is a dictionary with the following entries:

bufnr	buffer number.
changed	TRUE if the buffer is modified.
changedtick	number of changes made to the buffer.
hidden	TRUE if the buffer is hidden.
listed	TRUE if the buffer is listed.
lnum	current line number in buffer.
loaded	TRUE if the buffer is loaded.
name	full path to the file in the buffer.
signs	list of signs placed in the buffer. Each list item is a dictionary with the following fields: id sign identifier lnum line number name sign name
variables	a reference to the dictionary with buffer-local variables.
windows	list of window-ID s that display this buffer

Examples:

```
for buf in getbufinfo()
    echo buf.name
endfor
for buf in getbufinfo({'buflisted':1})
    if buf.changed
        ....
    endif
endfor
```

To get buffer-local options use:

```
getbufvar({bufnr}, '&')
```

getbufline()

getbufline({expr}, {lnum} [, {end}])

Return a List with the lines starting from {lnum} to {end} (inclusive) in the buffer {expr}. If {end} is omitted, a List with only the line {lnum} is returned.

For the use of {expr}, see bufname() above.

For {lnum} and {end} "$" can be used for the last line of the buffer. Otherwise a number must be used.

When {lnum} is smaller than 1 or bigger than the number of lines in the buffer, an empty List is returned.

When {end} is greater than the number of lines in the buffer, it is treated as {end} is set to the number of lines in the buffer. When {end} is before {lnum} an empty List is returned.

This function works only for loaded buffers. For unloaded and non-existing buffers, an empty List is returned.

Example:
```
:let lines = getbufline(bufnr("myfile"), 1, "$")
```

getbufvar({expr}, {varname} [, {def}]) getbufvar()

The result is the value of option or local buffer variable {varname} in buffer {expr}. Note that the name without "b:" must be used.
When {varname} is empty returns a dictionary with all the buffer-local variables.
When {varname} is equal to "&" returns a dictionary with all the buffer-local options.
Otherwise, when {varname} starts with "&" returns the value of a buffer-local option.
This also works for a global or buffer-local option, but it doesn't work for a global variable, window-local variable or window-local option.
For the use of {expr}, see bufname() above.
When the buffer or variable doesn't exist {def} or an empty string is returned, there is no error message.
Examples:
```
:let bufmodified = getbufvar(1, "&mod")
:echo "todo myvar = " . getbufvar("todo", "myvar")
```

getchangelist({expr}) getchangelist()

Returns the changelist for the buffer {expr}. For the use of {expr}, see bufname() above. If buffer {expr} doesn't exist, an empty list is returned.

The returned list contains two entries: a list with the change locations and the current position in the list. Each entry in the change list is a dictionary with the following entries:

col	column number
coladd	column offset for 'virtualedit'
lnum	line number

If buffer {expr} is the current buffer, then the current position refers to the position in the list. For other buffers, it is set to the length of the list.

getchar([expr]) getchar()

Get a single character from the user or input stream.
If [expr] is omitted, wait until a character is available.
If [expr] is 0, only get a character when one is available.
	Return zero otherwise.
If [expr] is 1, only check if a character is available, it is
	not consumed. Return zero if no character available.

Without [expr] and when [expr] is 0 a whole character or
special key is returned. If it is a single character, the
result is a number. Use nr2char() to convert it to a String.
Otherwise a String is returned with the encoded character.
For a special key it's a String with a sequence of bytes
starting with 0x80 (decimal: 128). This is the same value as
the String "\<Key>", e.g., "\<Left>". The returned value is
also a String when a modifier (shift, control, alt) was used
that is not included in the character.

When [expr] is 0 and Esc is typed, there will be a short delay
while Vim waits to see if this is the start of an escape
sequence.

When [expr] is 1 only the first byte is returned. For a
one-byte character it is the character itself as a number.
Use nr2char() to convert it to a String.

Use getcharmod() to obtain any additional modifiers.

When the user clicks a mouse button, the mouse event will be
returned. The position can then be found in v:mouse_col ,
 v:mouse_lnum , v:mouse_winid and v:mouse_win . This
example positions the mouse as it would normally happen:
```
	let c = getchar()
	if c == "\<LeftMouse>" && v:mouse_win > 0
	  exe v:mouse_win . "wincmd w"
	  exe v:mouse_lnum
	  exe "normal " . v:mouse_col . "|"
	endif
```

When using bracketed paste only the first character is
returned, the rest of the pasted text is dropped.
 xterm-bracketed-paste .

There is no prompt, you will somehow have to make clear to the
user that a character has to be typed.
There is no mapping for the character.
Key codes are replaced, thus when the user presses the <Del>
key you get the code for the <Del> key, not the raw character
sequence. Examples:
```
	getchar() == "\<Del>"
	getchar() == "\<S-Left>"
```
This example redefines "f" to ignore case:
```
	:nmap f :call FindChar()<CR>
	:function FindChar()
	:  let c = nr2char(getchar())
```

```
:  while col('.') < col('$') - 1
:    normal l
:    if getline('.')[col('.') - 1] ==? c
:      break
:    endif
:  endwhile
:endfunction
```

You may also receive synthetic characters, such as <CursorHold> . Often you will want to ignore this and get another character:

```
:function GetKey()
:  let c = getchar()
:  while c == "\<CursorHold>"
:    let c = getchar()
:  endwhile
:  return c
:endfunction
```

getcharmod() getcharmod()

The result is a Number which is the state of the modifiers for the last obtained character with getchar() or in another way. These values are added together:

2	shift
4	control
8	alt (meta)
16	meta (when it's different from ALT)
32	mouse double click
64	mouse triple click
96	mouse quadruple click (== 32 + 64)
128	command (Macintosh only)

Only the modifiers that have not been included in the character itself are obtained. Thus Shift-a results in "A" without a modifier.

getcharsearch() getcharsearch()

Return the current character search information as a {dict} with the following entries:

char	character previously used for a character search (t , f , T , or F); empty string if no character search has been performed
forward	direction of character search; 1 for forward, 0 for backward
until	type of character search; 1 for a t or T character search, 0 for an f or F character search

This can be useful to always have ; and , search forward/backward regardless of the direction of the previous character search:

```
:nnoremap <expr> ; getcharsearch().forward ? ';' : ','
:nnoremap <expr> , getcharsearch().forward ? ',' : ';'
```

Also see setcharsearch() .

getcmdline() getcmdline()

Return the current command-line. Only works when the command line is being edited, thus requires use of c_CTRL-_e or c_CTRL-R_= .
Example:

```
:cmap <F7> <C-\>eescape(getcmdline(), ' \')<CR>
```

Also see getcmdtype() , getcmdpos() and setcmdpos() .

getcmdpos() getcmdpos()

Return the position of the cursor in the command line as a byte count. The first column is 1.
Only works when editing the command line, thus requires use of c_CTRL-_e or c_CTRL-R_= or an expression mapping.
Returns 0 otherwise.
Also see getcmdtype() , setcmdpos() and getcmdline() .

getcmdtype() getcmdtype()

Return the current command-line type. Possible return values are:

```
:   normal Ex command
>   debug mode command  debug-mode
/   forward search command
?   backward search command
@    input()  command
-    :insert  or  :append  command
=    i_CTRL-R_=
```

Only works when editing the command line, thus requires use of c_CTRL-_e or c_CTRL-R_= or an expression mapping.
Returns an empty string otherwise.
Also see getcmdpos() , setcmdpos() and getcmdline() .

getcmdwintype() getcmdwintype()

Return the current command-line-window type. Possible return values are the same as getcmdtype() . Returns an empty string when not in the command-line window.

getcompletion({pat}, {type} [, {filtered}]) getcompletion()

Return a list of command-line completion matches. {type} specifies what for. The following completion types are supported:

```
arglist         file names in argument list
augroup         autocmd groups
buffer          buffer names
behave          :behave suboptions
color           color schemes
command         Ex command (and arguments)
compiler        compilers
cscope           :cscope  suboptions
dir             directory names
environment     environment variable names
event           autocommand events
expression      Vim expression
```

```
                file            file and directory names
                file_in_path    file and directory names in  'path'
                filetype        filetype names  'filetype'
                function        function name
                help            help subjects
                highlight       highlight groups
                history         :history suboptions
                locale          locale names (as output of locale -a)
                mapclear        buffer argument
                mapping         mapping name
                menu            menus
                messages         :messages  suboptions
                option          options
                packadd         optional package  pack-add  names
                shellcmd        Shell command
                sign             :sign  suboptions
                syntax          syntax file names  'syntax'
                syntime          :syntime  suboptions
                tag             tags
                tag_listfiles   tags, file names
                user            user names
                var             user variables

                If {pat} is an empty string, then all the matches are returned.
                Otherwise only items matching {pat} are returned. See
                 wildcards  for the use of special characters in {pat}.

                If the optional {filtered} flag is set to 1, then 'wildignore'
                is applied to filter the results.  Otherwise all the matches
                are returned. The 'wildignorecase' option always applies.

                If there are no matches, an empty list is returned.  An
                invalid value for {type} produces an error.

                                                              getcurpos()
getcurpos()     Get the position of the cursor.  This is like getpos('.'), but
                includes an extra item in the list:
                    [bufnum, lnum, col, off, curswant]
                The "curswant" number is the preferred column when moving the
                cursor vertically.  Also see  getpos() .

                This can be used to save and restore the cursor position:
                        let save_cursor = getcurpos()
                        MoveTheCursorAround
                        call setpos('.', save_cursor)
              Note that this only works within the window.  See
                winrestview()  for restoring more state.
                                                              getcwd()
getcwd([{winnr} [, {tabnr}]])
                The result is a String, which is the name of the current
                working directory.
                Without arguments, for the current window.

                With {winnr} return the local current directory of this window
```

in the current tab page. {winnr} can be the window number or the window-ID .
If {winnr} is -1 return the name of the global working directory. See also haslocaldir() .

With {winnr} and {tabnr} return the local current directory of the window in the specified tab page.
Return an empty string if the arguments are invalid.

getfsize({fname}) getfsize()
The result is a Number, which is the size in bytes of the given file {fname}.
If {fname} is a directory, 0 is returned.
If the file {fname} can't be found, -1 is returned.
If the size of {fname} is too big to fit in a Number then -2 is returned.

getfontname([{name}]) getfontname()
Without an argument returns the name of the normal font being used. Like what is used for the Normal highlight group hl-Normal .
With an argument a check is done whether {name} is a valid font name. If not then an empty string is returned.
Otherwise the actual font name is returned, or {name} if the GUI does not support obtaining the real name.
Only works when the GUI is running, thus not in your vimrc or gvimrc file. Use the GUIEnter autocommand to use this function just after the GUI has started.
Note that the GTK GUI accepts any font name, thus checking for a valid name does not work.

getfperm({fname}) getfperm()
The result is a String, which is the read, write, and execute permissions of the given file {fname}.
If {fname} does not exist or its directory cannot be read, an empty string is returned.
The result is of the form "rwxrwxrwx", where each group of "rwx" flags represent, in turn, the permissions of the owner of the file, the group the file belongs to, and other users.
If a user does not have a given permission the flag for this is replaced with the string "-". Examples:
```
:echo getfperm("/etc/passwd")
:echo getfperm(expand("~/.vimrc"))
```
This will hopefully (from a security point of view) display the string "rw-r--r--" or even "rw-------".

For setting permissions use setfperm() .

getftime({fname}) getftime()
The result is a Number, which is the last modification time of the given file {fname}. The value is measured as seconds since 1st Jan 1970, and may be passed to strftime(). See also localtime() and strftime() .
If the file {fname} can't be found -1 is returned.

getftype({fname}) getftype()
The result is a String, which is a description of the kind of file of the given file {fname}.
If {fname} does not exist an empty string is returned.
Here is a table over different kinds of files and their results:

Normal file	"file"
Directory	"dir"
Symbolic link	"link"
Block device	"bdev"
Character device	"cdev"
Socket	"socket"
FIFO	"fifo"
All other	"other"

Example:
```
getftype("/home")
```
Note that a type such as "link" will only be returned on systems that support it. On some systems only "dir" and "file" are returned. On MS-Windows a symbolic link to a directory returns "dir" instead of "link".

getjumplist([{winnr} [, {tabnr}]]) getjumplist()
Returns the jumplist for the specified window.

Without arguments use the current window.
With {winnr} only use this window in the current tab page.
{winnr} can also be a window-ID.
With {winnr} and {tabnr} use the window in the specified tab page.

The returned list contains two entries: a list with the jump locations and the last used jump position number in the list.
Each entry in the jump location list is a dictionary with the following entries:

bufnr	buffer number
col	column number
coladd	column offset for 'virtualedit'
filename	filename if available
lnum	line number

getline({lnum} [, {end}]) getline()
Without {end} the result is a String, which is line {lnum} from the current buffer. Example:
```
getline(1)
```
When {lnum} is a String that doesn't start with a digit, line() is called to translate the String into a Number.
To get the line under the cursor:
```
getline(".")
```
When {lnum} is smaller than 1 or bigger than the number of lines in the buffer, an empty string is returned.

When {end} is given the result is a List where each item is

a line from the current buffer in the range {lnum} to {end},
including line {end}.
{end} is used in the same way as {lnum}.
Non-existing lines are silently omitted.
When {end} is before {lnum} an empty List is returned.
Example:

```
:let start = line('.')
:let end = search("^$") - 1
:let lines = getline(start, end)
```

To get lines from another buffer see getbufline()

getloclist({nr} [, {what}]) getloclist()
Returns a list with all the entries in the location list for
window {nr}. {nr} can be the window number or the window-ID .
When {nr} is zero the current window is used.

For a location list window, the displayed location list is
returned. For an invalid window number {nr}, an empty list is
returned. Otherwise, same as getqflist() .

If the optional {what} dictionary argument is supplied, then
returns the items listed in {what} as a dictionary. Refer to
getqflist() for the supported items in {what}.

getmatches() getmatches()
Returns a List with all matches previously defined by
matchadd() and the :match commands. getmatches() is
useful in combination with setmatches() , as setmatches()
can restore a list of matches saved by getmatches() .
Example:

```
:echo getmatches()
[{'group': 'MyGroup1', 'pattern': 'TODO',
 'priority': 10, 'id': 1}, {'group': 'MyGroup2',
 'pattern': 'FIXME', 'priority': 10, 'id': 2}]
:let m = getmatches()
:call clearmatches()
:echo getmatches()
[]
:call setmatches(m)
:echo getmatches()
[{'group': 'MyGroup1', 'pattern': 'TODO',
 'priority': 10, 'id': 1}, {'group': 'MyGroup2',
 'pattern': 'FIXME', 'priority': 10, 'id': 2}]
:unlet m
```

getpid() getpid()
Return a Number which is the process ID of the Vim process.
On Unix and MS-Windows this is a unique number, until Vim
exits. On MS-DOS it's always zero.

getpos({expr}) getpos()
Get the position for {expr}. For possible values of {expr}
see line() . For getting the cursor position see

getcurpos() .
The result is a List with four numbers:
    [bufnum, lnum, col, off]
"bufnum" is zero, unless a mark like '0 or 'A is used, then it is the buffer number of the mark.
"lnum" and "col" are the position in the buffer. The first column is 1.
The "off" number is zero, unless 'virtualedit' is used. Then it is the offset in screen columns from the start of the character. E.g., a position within a <Tab> or after the last character.
Note that for '< and '> Visual mode matters: when it is "V" (visual line mode) the column of '< is zero and the column of '> is a large number.
This can be used to save and restore the position of a mark:

```
let save_a_mark = getpos("'a")
...
call setpos("'a", save_a_mark)
```

Also see getcurpos() and setpos() .

getqflist([{what}]) getqflist()

Returns a list with all the current quickfix errors. Each list item is a dictionary with these entries:

bufnr	number of buffer that has the file name, use bufname() to get the name
module	module name
lnum	line number in the buffer (first line is 1)
col	column number (first column is 1)
vcol	TRUE : "col" is visual column FALSE : "col" is byte index
nr	error number
pattern	search pattern used to locate the error
text	description of the error
type	type of the error, 'E', '1', etc.
valid	TRUE : recognized error message

When there is no error list or it's empty, an empty list is returned. Quickfix list entries with non-existing buffer number are returned with "bufnr" set to zero.

Useful application: Find pattern matches in multiple files and do something with them:

```
:vimgrep /theword/jg *.c
:for d in getqflist()
:   echo bufname(d.bufnr) ':' d.lnum '=' d.text
:endfor
```

If the optional {what} dictionary argument is supplied, then returns only the items listed in {what} as a dictionary. The following string items are supported in {what}:

changedtick	get the total number of changes made to the list quickfix-changedtick
context	get the quickfix-context

```
        efm     errorformat to use when parsing "lines". If
                not present, then the 'errorformat' option
                value is used.
        id      get information for the quickfix list with
                 quickfix-ID ; zero means the id for the
                current list or the list specified by "nr"
        idx     index of the current entry in the list
        items   quickfix list entries
        lines   parse a list of lines using 'efm' and return
                the resulting entries.  Only a  List  type is
                accepted.  The current quickfix list is not
                modified. See  quickfix-parse .
        nr      get information for this quickfix list; zero
                means the current quickfix list and "$" means
                the last quickfix list
        size    number of entries in the quickfix list
        title   get the list title  quickfix-title
        winid   get the quickfix  window-ID
        all     all of the above quickfix properties
Non-string items in {what} are ignored. To get the value of a
particular item, set it to zero.
If "nr" is not present then the current quickfix list is used.
If both "nr" and a non-zero "id" are specified, then the list
specified by "id" is used.
To get the number of lists in the quickfix stack, set "nr" to
"$" in {what}. The "nr" value in the returned dictionary
contains the quickfix stack size.
When "lines" is specified, all the other items except "efm"
are ignored.  The returned dictionary contains the entry
"items" with the list of entries.

The returned dictionary contains the following entries:
        changedtick     total number of changes made to the
                        list  quickfix-changedtick
        context quickfix list context. See  quickfix-context
                If not present, set to "".
        id      quickfix list ID  quickfix-ID . If not
                present, set to 0.
        idx     index of the current entry in the list. If not
                present, set to 0.
        items   quickfix list entries. If not present, set to
                an empty list.
        nr      quickfix list number. If not present, set to 0
        size    number of entries in the quickfix list. If not
                present, set to 0.
        title   quickfix list title text. If not present, set
                to "".
        winid   quickfix  window-ID . If not present, set to 0

Examples (See also  getqflist-examples ):
        :echo getqflist({'all': 1})
        :echo getqflist({'nr': 2, 'title': 1})
        :echo getqflist({'lines' : ["F1:10:L10"]})
```

getreg([{regname} [, 1 [, {list}]]]) getreg()
The result is a String, which is the contents of register {regname}. Example:

```
:let cliptext = getreg('*')
```

When {regname} was not set the result is an empty string.

getreg('=') returns the last evaluated value of the expression register. (For use in maps.)
getreg('=', 1) returns the expression itself, so that it can be restored with setreg(). For other registers the extra argument is ignored, thus you can always give it.

If {list} is present and TRUE, the result type is changed to List. Each list item is one text line. Use it if you care about zero bytes possibly present inside register: without third argument both NLs and zero bytes are represented as NLs (see NL-used-for-Nul).
When the register was not set an empty list is returned.

If {regname} is not specified, v:register is used.

getregtype([{regname}]) getregtype()
The result is a String, which is type of register {regname}. The value will be one of:

"v"	for characterwise text
"V"	for linewise text
"<CTRL-V>{width}"	for blockwise-visual text
""	for an empty or unknown register

<CTRL-V> is one character with value 0x16.
If {regname} is not specified, v:register is used.

gettabinfo([{arg}]) gettabinfo()
If {arg} is not specified, then information about all the tab pages is returned as a List. Each List item is a Dictionary. Otherwise, {arg} specifies the tab page number and information about that one is returned. If the tab page does not exist an empty List is returned.

Each List item is a Dictionary with the following entries:

tabnr	tab page number.
variables	a reference to the dictionary with tabpage-local variables
windows	List of window-ID s in the tag page.

gettabvar({tabnr}, {varname} [, {def}]) gettabvar()
Get the value of a tab-local variable {varname} in tab page {tabnr}. t:var
Tabs are numbered starting with one.
When {varname} is empty a dictionary with all tab-local variables is returned.
Note that the name without "t:" must be used.
When the tab or variable doesn't exist {def} or an empty string is returned, there is no error message.

gettabwinvar({tabnr}, {winnr}, {varname} [, {def}]) gettabwinvar()
Get the value of window-local variable {varname} in window
{winnr} in tab page {tabnr}.
When {varname} is empty a dictionary with all window-local
variables is returned.
When {varname} is equal to "&" get the values of all
window-local options in a Dictionary.
Otherwise, when {varname} starts with "&" get the value of a
window-local option.
Note that {varname} must be the name without "w:".
Tabs are numbered starting with one. For the current tabpage
use getwinvar() .
{winnr} can be the window number or the window-ID .
When {winnr} is zero the current window is used.
This also works for a global option, buffer-local option and
window-local option, but it doesn't work for a global variable
or buffer-local variable.
When the tab, window or variable doesn't exist {def} or an
empty string is returned, there is no error message.
Examples:
```
:let list_is_on = gettabwinvar(1, 2, '&list')
:echo "myvar = " . gettabwinvar(3, 1, 'myvar')
```

To obtain all window-local variables use:
```
gettabwinvar({tabnr}, {winnr}, '&')
```

getwininfo([{winid}]) getwininfo()
Returns information about windows as a List with Dictionaries.

If {winid} is given Information about the window with that ID
is returned. If the window does not exist the result is an
empty list.

Without {winid} information about all the windows in all the
tab pages is returned.

Each List item is a Dictionary with the following entries:

bufnr	number of buffer in the window
height	window height (excluding winbar)
loclist	1 if showing a location list {only with the +quickfix feature}
quickfix	1 if quickfix or location list window {only with the +quickfix feature}
terminal	1 if a terminal window {only with the +terminal feature}
tabnr	tab page number
variables	a reference to the dictionary with window-local variables
width	window width
winbar	1 if the window has a toolbar, 0 otherwise
wincol	leftmost screen column of the window, col from win_screenpos()

```
                        winid           window-ID
                        winnr           window number
                        winrow          topmost screen column of the window,
                                        row from  win_screenpos()

getwinpos([{timeout}])                                          getwinpos()
                The result is a list with two numbers, the result of
                getwinposx() and getwinposy() combined:
                        [x-pos, y-pos]
                {timeout} can be used to specify how long to wait in msec for
                a response from the terminal.  When omitted 100 msec is used.
                Use a longer time for a remote terminal.
                When using a value less than 10 and no response is received
                within that time, a previously reported position is returned,
                if available.  This can be used to poll for the position and
                do some work in the mean time:
                        while 1
                          let res = getwinpos(1)
                          if res[0] >= 0
                            break
                          endif
                          " Do some work here
                        endwhile

                                                                getwinposx()
getwinposx()    The result is a Number, which is the X coordinate in pixels of
                the left hand side of the GUI Vim window. Also works for an
                xterm (uses a timeout of 100 msec).
                The result will be -1 if the information is not available.
                The value can be used with `:winpos`.

                                                                getwinposy()
getwinposy()    The result is a Number, which is the Y coordinate in pixels of
                the top of the GUI Vim window.  Also works for an xterm (uses
                a timeout of 100 msec).
                The result will be -1 if the information is not available.
                The value can be used with `:winpos`.

getwinvar({winnr}, {varname} [, {def}])                         getwinvar()
                Like  gettabwinvar()  for the current tabpage.
                Examples:
                        :let list_is_on = getwinvar(2, '&list')
                        :echo "myvar = " . getwinvar(1, 'myvar')

glob({expr} [, {nosuf} [, {list} [, {alllinks}]]])                  glob()
                Expand the file wildcards in {expr}.  See  wildcards  for the
                use of special characters.

                Unless the optional {nosuf} argument is given and is  TRUE ,
                the 'suffixes' and 'wildignore' options apply: Names matching
                one of the patterns in 'wildignore' will be skipped and
                'suffixes' affect the ordering of matches.
                'wildignorecase' always applies.
```

When {list} is present and it is TRUE the result is a List with all matching files. The advantage of using a List is, you also get filenames containing newlines correctly. Otherwise the result is a String and when there are several matches, they are separated by <NL> characters.

If the expansion fails, the result is an empty String or List.

A name for a non-existing file is not included. A symbolic link is only included if it points to an existing file. However, when the {alllinks} argument is present and it is TRUE then all symbolic links are included.

For most systems backticks can be used to get files names from any external command. Example:

```
:let tagfiles = glob("`find . -name tags -print`")
:let &tags = substitute(tagfiles, "\n", ",", "g")
```

The result of the program inside the backticks should be one item per line. Spaces inside an item are allowed.

See expand() for expanding special Vim variables. See system() for getting the raw output of an external command.

glob2regpat({expr}) glob2regpat()

Convert a file pattern, as used by glob(), into a search pattern. The result can be used to match with a string that is a file name. E.g.

```
if filename =~ glob2regpat('Make*.mak')
```

This is equivalent to:

```
if filename =~ '^Make.*\.mak$'
```

When {expr} is an empty string the result is "^$", match an empty string.
Note that the result depends on the system. On MS-Windows a backslash usually means a path separator.

globpath() globpath({path}, {expr} [, {nosuf} [, {list} [, {alllinks}]]])

Perform glob() on all directories in {path} and concatenate the results. Example:

```
:echo globpath(&rtp, "syntax/c.vim")
```

{path} is a comma-separated list of directory names. Each directory name is prepended to {expr} and expanded like with glob() . A path separator is inserted when needed.
To add a comma inside a directory name escape it with a backslash. Note that on MS-Windows a directory may have a trailing backslash, remove it if you put a comma after it.
If the expansion fails for one of the directories, there is no error message.

Unless the optional {nosuf} argument is given and is TRUE , the 'suffixes' and 'wildignore' options apply: Names matching one of the patterns in 'wildignore' will be skipped and 'suffixes' affect the ordering of matches.

When {list} is present and it is TRUE the result is a List with all matching files. The advantage of using a List is, you also get filenames containing newlines correctly. Otherwise the result is a String and when there are several matches, they are separated by <NL> characters. Example:

```
:echo globpath(&rtp, "syntax/c.vim", 0, 1)
```

{alllinks} is used as with glob() .

The "**" item can be used to search in a directory tree. For example, to find all "README.txt" files in the directories in 'runtimepath' and below:

```
:echo globpath(&rtp, "**/README.txt")
```

Upwards search and limiting the depth of "**" is not supported, thus using 'path' will not always work properly.

has()

has({feature}) The result is a Number, which is 1 if the feature {feature} is supported, zero otherwise. The {feature} argument is a string. See feature-list below.
Also see exists() .

has_key({dict}, {key}) has_key()

The result is a Number, which is 1 if Dictionary {dict} has an entry with key {key}. Zero otherwise.

haslocaldir([{winnr} [, {tabnr}]]) haslocaldir()

The result is a Number, which is 1 when the window has set a local path via :lcd , and 0 otherwise.

Without arguments use the current window.
With {winnr} use this window in the current tab page.
With {winnr} and {tabnr} use the window in the specified tab page.
{winnr} can be the window number or the window-ID .
Return 0 if the arguments are invalid.

hasmapto({what} [, {mode} [, {abbr}]]) hasmapto()

The result is a Number, which is 1 if there is a mapping that contains {what} in somewhere in the rhs (what it is mapped to) and this mapping exists in one of the modes indicated by {mode}.
When {abbr} is there and it is TRUE use abbreviations instead of mappings. Don't forget to specify Insert and/or Command-line mode.
Both the global mappings and the mappings local to the current buffer are checked for a match.
If no matching mapping is found 0 is returned.
The following characters are recognized in {mode}:

```
n       Normal mode
v       Visual mode
o       Operator-pending mode
```

```
                i       Insert mode
                l       Language-Argument ("r", "f", "t", etc.)
                c       Command-line mode
            When {mode} is omitted, "nvo" is used.

            This function is useful to check if a mapping already exists
            to a function in a Vim script.  Example:
                :if !hasmapto('\ABCdoit')
                :   map <Leader>d \ABCdoit
                :endif
           This installs the mapping to "\ABCdoit" only if there isn't
            already a mapping to "\ABCdoit".

histadd({history}, {item})                                  histadd()
            Add the String {item} to the history {history} which can be
            one of:                                         hist-names
                "cmd"    or ":"   command line history
                "search" or "/"   search pattern history
                "expr"   or "="   typed expression history
                "input"  or "@"   input line history
                "debug"  or ">"   debug command history
                empty             the current or last used history
            The {history} string does not need to be the whole name, one
            character is sufficient.
            If {item} does already exist in the history, it will be
            shifted to become the newest entry.
            The result is a Number: 1 if the operation was successful,
            otherwise 0 is returned.

            Example:
                :call histadd("input", strftime("%Y %b %d"))
                :let date=input("Enter date: ")
           This function is not available in the  sandbox .

histdel({history} [, {item}])                               histdel()
            Clear {history}, i.e. delete all its entries.  See  hist-names
            for the possible values of {history}.

            If the parameter {item} evaluates to a String, it is used as a
            regular expression.  All entries matching that expression will
            be removed from the history (if there are any).
            Upper/lowercase must match, unless "\c" is used  /\c .
            If {item} evaluates to a Number, it will be interpreted as
            an index, see  :history-indexing .  The respective entry will
            be removed if it exists.

            The result is a Number: 1 for a successful operation,
            otherwise 0 is returned.

            Examples:
            Clear expression register history:
                :call histdel("expr")

            Remove all entries starting with "*" from the search history:
```

```
		:call histdel("/", '^\*')

	The following three are equivalent:
		:call histdel("search", histnr("search"))
		:call histdel("search", -1)
		:call histdel("search", '^'.histget("search", -1).'$')

	To delete the last search pattern and use the last-but-one for
	the "n" command and 'hlsearch':
		:call histdel("search", -1)
		:let @/ = histget("search", -1)

histget({history} [, {index}])                              histget()
	The result is a String, the entry with Number {index} from
	{history}.  See  hist-names  for the possible values of
	{history}, and  :history-indexing  for {index}.  If there is
	no such entry, an empty String is returned.  When {index} is
	omitted, the most recent item from the history is used.

	Examples:
	Redo the second last search from history.
		:execute '/' . histget("search", -2)

       Define an Ex command ":H {num}" that supports re-execution of
	the {num}th entry from the output of  :history .
		:command -nargs=1 H execute histget("cmd", 0+<args>)

histnr({history})                                           histnr()
	The result is the Number of the current entry in {history}.
	See  hist-names  for the possible values of {history}.
	If an error occurred, -1 is returned.

	Example:
		:let inp_index = histnr("expr")

hlexists({name})                                            hlexists()
	The result is a Number, which is non-zero if a highlight group
	called {name} exists.  This is when the group has been
	defined in some way.  Not necessarily when highlighting has
	been defined for it, it may also have been used for a syntax
	item.
                                                            highlight_exists()
	Obsolete name: highlight_exists().

                                                            hlID()
hlID({name})    The result is a Number, which is the ID of the highlight group
	with name {name}.  When the highlight group doesn't exist,
	zero is returned.
	This can be used to retrieve information about the highlight
	group.  For example, to get the background color of the
	"Comment" group:
	:echo synIDattr(synIDtrans(hlID("Comment")), "bg")
                                                            highlightID()
	Obsolete name: highlightID().
```

hostname() hostname()
The result is a String, which is the name of the machine on which Vim is currently running. Machine names greater than 256 characters long are truncated.

iconv({expr}, {from}, {to}) iconv()
The result is a String, which is the text {expr} converted from encoding {from} to encoding {to}.
When the conversion completely fails an empty string is returned. When some characters could not be converted they are replaced with "?".
The encoding names are whatever the iconv() library function can accept, see ":!man 3 iconv".
Most conversions require Vim to be compiled with the +iconv feature. Otherwise only UTF-8 to latin1 conversion and back can be done.
This can be used to display messages with special characters, no matter what 'encoding' is set to. Write the message in UTF-8 and use:

```
echo iconv(utf8_str, "utf-8", &enc)
```

Note that Vim uses UTF-8 for all Unicode encodings, conversion from/to UCS-2 is automatically changed to use UTF-8. You cannot use UCS-2 in a string anyway, because of the NUL bytes.
{only available when compiled with the |+multi_byte| feature}

indent()
indent({lnum}) The result is a Number, which is indent of line {lnum} in the current buffer. The indent is counted in spaces, the value of 'tabstop' is relevant. {lnum} is used just like in getline() .
When {lnum} is invalid -1 is returned.

index({list}, {expr} [, {start} [, {ic}]]) index()
Return the lowest index in List {list} where the item has a value equal to {expr}. There is no automatic conversion, so the String "4" is different from the Number 4. And the number 4 is different from the Float 4.0. The value of 'ignorecase' is not used here, case always matters.
If {start} is given then start looking at the item with index {start} (may be negative for an item relative to the end).
When {ic} is given and it is TRUE , ignore case. Otherwise case must match.
-1 is returned when {expr} is not found in {list}.
Example:

```
:let idx = index(words, "the")
:if index(numbers, 123) >= 0
```

input({prompt} [, {text} [, {completion}]]) input()
The result is a String, which is whatever the user typed on the command-line. The {prompt} argument is either a prompt string, or a blank string (for no prompt). A '\n' can be used

in the prompt to start a new line.
The highlighting set with :echohl is used for the prompt.
The input is entered just like a command-line, with the same
editing commands and mappings. There is a separate history
for lines typed for input().
Example:

```
:if input("Coffee or beer? ") == "beer"
:  echo "Cheers!"
:endif
```

If the optional {text} argument is present and not empty, this
is used for the default reply, as if the user typed this.
Example:

```
:let color = input("Color? ", "white")
```

The optional {completion} argument specifies the type of
completion supported for the input. Without it completion is
not performed. The supported completion types are the same as
that can be supplied to a user-defined command using the
"-complete=" argument. Refer to :command-completion for
more information. Example:

```
let fname = input("File: ", "", "file")
```

NOTE: This function must not be used in a startup file, for
the versions that only run in GUI mode (e.g., the Win32 GUI).
Note: When input() is called from within a mapping it will
consume remaining characters from that mapping, because a
mapping is handled like the characters were typed.
Use inputsave() before input() and inputrestore()
after input() to avoid that. Another solution is to avoid
that further characters follow in the mapping, e.g., by using
:execute or :normal .

Example with a mapping:

```
:nmap \x :call GetFoo()<CR>:exe "/" . Foo<CR>
:function GetFoo()
:  call inputsave()
:  let g:Foo = input("enter search pattern: ")
:  call inputrestore()
:endfunction
```

inputdialog({prompt} [, {text} [, {cancelreturn}]]) inputdialog()
Like input() , but when the GUI is running and text dialogs
are supported, a dialog window pops up to input the text.
Example:

```
:let n = inputdialog("value for shiftwidth", shiftwidth())
:if n != ""
:  let &sw = n
:endif
```

When the dialog is cancelled {cancelreturn} is returned. When
omitted an empty string is returned.
Hitting <Enter> works like pressing the OK button. Hitting
<Esc> works like pressing the Cancel button.
NOTE: Command-line completion is not supported.

inputlist({textlist}) inputlist()
{textlist} must be a List of strings. This List is displayed, one string per line. The user will be prompted to enter a number, which is returned.
The user can also select an item by clicking on it with the mouse. For the first string 0 is returned. When clicking above the first item a negative number is returned. When clicking on the prompt one more than the length of {textlist} is returned.
Make sure {textlist} has less than 'lines' entries, otherwise it won't work. It's a good idea to put the entry number at the start of the string. And put a prompt in the first item.
Example:
```
let color = inputlist(['Select color:', '1. red',
\ '2. green', '3. blue'])
```

inputrestore() inputrestore()
Restore typeahead that was saved with a previous inputsave() . Should be called the same number of times inputsave() is called. Calling it more often is harmless though.
Returns 1 when there is nothing to restore, 0 otherwise.

inputsave() inputsave()
Preserve typeahead (also from mappings) and clear it, so that a following prompt gets input from the user. Should be followed by a matching inputrestore() after the prompt. Can be used several times, in which case there must be just as many inputrestore() calls.
Returns 1 when out of memory, 0 otherwise.

inputsecret({prompt} [, {text}]) inputsecret()
This function acts much like the input() function with but two exceptions:
a) the user's response will be displayed as a sequence of asterisks ("*") thereby keeping the entry secret, and
b) the user's response will not be recorded on the input history stack.
The result is a String, which is whatever the user actually typed on the command-line in response to the issued prompt.
NOTE: Command-line completion is not supported.

insert({list}, {item} [, {idx}]) insert()
Insert {item} at the start of List {list}.
If {idx} is specified insert {item} before the item with index {idx}. If {idx} is zero it goes before the first item, just like omitting {idx}. A negative {idx} is also possible, see list-index . -1 inserts just before the last item.
Returns the resulting List . Examples:
```
:let mylist = insert([2, 3, 5], 1)
:call insert(mylist, 4, -1)
:call insert(mylist, 6, len(mylist))
```
The last example can be done simpler with add() .
Note that when {item} is a List it is inserted as a single

item. Use extend() to concatenate Lists .

invert({expr}) invert()
Bitwise invert. The argument is converted to a number. A List, Dict or Float argument causes an error. Example:

```
:let bits = invert(bits)
```

isdirectory({directory}) isdirectory()
The result is a Number, which is TRUE when a directory with the name {directory} exists. If {directory} doesn't exist, or isn't a directory, the result is FALSE . {directory} is any expression, which is used as a String.

islocked({expr}) islocked() E786
The result is a Number, which is TRUE when {expr} is the name of a locked variable.
{expr} must be the name of a variable, List item or Dictionary entry, not the variable itself! Example:

```
:let alist = [0, ['a', 'b'], 2, 3]
:lockvar 1 alist
:echo islocked('alist')         " 1
:echo islocked('alist[1]')      " 0
```

When {expr} is a variable that does not exist you get an error message. Use exists() to check for existence.

isnan({expr}) isnan()
Return TRUE if {expr} is a float with value NaN.

```
echo isnan(0.0 / 0.0)
1
```

{only available when compiled with the |+float| feature}

items({dict}) items()
Return a List with all the key-value pairs of {dict}. Each List item is a list with two items: the key of a {dict} entry and the value of this entry. The List is in arbitrary order.

job_getchannel({job}) job_getchannel()
Get the channel handle that {job} is using.
To check if the job has no channel:

```
if string(job_getchannel()) == 'channel fail'
```

{only available when compiled with the |+job| feature}

job_info([{job}]) job_info()
Returns a Dictionary with information about {job}:

"status"	what job_status() returns
"channel"	what job_getchannel() returns
"cmd"	List of command arguments used to start the job
"process"	process ID
"tty_in"	terminal input name, empty when none
"tty_out"	terminal output name, empty when none

```
                "exitval"    only valid when "status" is "dead"
                "exit_cb"    function to be called on exit
                "stoponexit"  job-stoponexit

            Without any arguments, returns a List with all Job objects.

job_setoptions({job}, {options})                          job_setoptions()
            Change options for {job}.  Supported are:
                "stoponexit"  job-stoponexit
                "exit_cb"     job-exit_cb

job_start({command} [, {options}])                        job_start()
            Start a job and return a Job object.  Unlike  system()  and
             :!cmd  this does not wait for the job to finish.
            To start a job in a terminal window see  term_start() .

            {command} can be a String.  This works best on MS-Windows.  On
            Unix it is split up in white-separated parts to be passed to
            execvp().  Arguments in double quotes can contain white space.

            {command} can be a List, where the first item is the executable
            and further items are the arguments.  All items are converted
            to String.  This works best on Unix.

            On MS-Windows, job_start() makes a GUI application hidden. If
            want to show it, Use  :!start  instead.

            The command is executed directly, not through a shell, the
            'shell' option is not used.  To use the shell:
        let job = job_start(["/bin/sh", "-c", "echo hello"])
              Or:
        let job = job_start('/bin/sh -c "echo hello"')
              Note that this will start two processes, the shell and the
              command it executes.  If you don't want this use the "exec"
              shell command.

              On Unix $PATH is used to search for the executable only when
              the command does not contain a slash.

              The job will use the same terminal as Vim.  If it reads from
              stdin the job and Vim will be fighting over input, that
              doesn't work.  Redirect stdin and stdout to avoid problems:
        let job = job_start(['sh', '-c', "myserver </dev/null >/dev/null"])

              The returned Job object can be used to get the status with
               job_status()  and stop the job with  job_stop() .

              Note that the job object will be deleted if there are no
              references to it.  This closes the stdin and stderr, which may
              cause the job to fail with an error.  To avoid this keep a
              reference to the job.  Thus instead of:
        call job_start('my-command')
              use:
        let myjob = job_start('my-command')
```

```
            and unlet "myjob" once the job is not needed or is past the
            point where it would fail (e.g. when it prints a message on
            startup).  Keep in mind that variables local to a function
            will cease to exist if the function returns.  Use a
            script-local variable if needed:
        let s:myjob = job_start('my-command')

            {options} must be a Dictionary.  It can contain many optional
            items, see  job-options .

            {only available when compiled with the |+job| feature}

job_status({job})                                          job_status()   E916
            Returns a String with the status of {job}:
                    "run"   job is running
                    "fail"  job failed to start
                    "dead"  job died or was stopped after running

            On Unix a non-existing command results in "dead" instead of
            "fail", because a fork happens before the failure can be
            detected.

            If an exit callback was set with the "exit_cb" option and the
            job is now detected to be "dead" the callback will be invoked.

            For more information see  job_info() .

            {only available when compiled with the |+job| feature}

job_stop({job} [, {how}])                                          job_stop()
            Stop the {job}.  This can also be used to signal the job.

            When {how} is omitted or is "term" the job will be terminated.
            For Unix SIGTERM is sent.  On MS-Windows the job will be
            terminated forcedly (there is no "gentle" way).
            This goes to the process group, thus children may also be
            affected.

            Effect for Unix:
                    "term"   SIGTERM (default)
                    "hup"    SIGHUP
                    "quit"   SIGQUIT
                    "int"    SIGINT
                    "kill"   SIGKILL (strongest way to stop)
                    number   signal with that number

            Effect for MS-Windows:
                    "term"   terminate process forcedly (default)
                    "hup"    CTRL_BREAK
                    "quit"   CTRL_BREAK
                    "int"    CTRL_C
                    "kill"   terminate process forcedly
                    Others   CTRL_BREAK
```

On Unix the signal is sent to the process group. This means
that when the job is "sh -c command" it affects both the shell
and the command.

The result is a Number: 1 if the operation could be executed,
0 if "how" is not supported on the system.
Note that even when the operation was executed, whether the
job was actually stopped needs to be checked with
job_status() .

If the status of the job is "dead", the signal will not be
sent. This is to avoid to stop the wrong job (esp. on Unix,
where process numbers are recycled).

When using "kill" Vim will assume the job will die and close
the channel.

{only available when compiled with the |+job| feature}

join({list} [, {sep}]) join()
Join the items in {list} together into one String.
When {sep} is specified it is put in between the items. If
{sep} is omitted a single space is used.
Note that {sep} is not added at the end. You might want to
add it there too:
let lines = join(mylist, "\n") . "\n"
String items are used as-is. Lists and Dictionaries are
converted into a string like with string() .
The opposite function is split() .

js_decode({string}) js_decode()
This is similar to json_decode() with these differences:
- Object key names do not have to be in quotes.
- Strings can be in single quotes.
- Empty items in an array (between two commas) are allowed and
result in v:none items.

js_encode({expr}) js_encode()
This is similar to json_encode() with these differences:
- Object key names are not in quotes.
- v:none items in an array result in an empty item between
commas.
For example, the Vim object:
[1,v:none,{"one":1},v:none]
Will be encoded as:
[1,,{one:1},,]
While json_encode() would produce:
[1,null,{"one":1},null]
This encoding is valid for JavaScript. It is more efficient
than JSON, especially when using an array with optional items.

json_decode({string}) json_decode()
This parses a JSON formatted string and returns the equivalent

in Vim values. See json_encode() for the relation between JSON and Vim values.
The decoding is permissive:
- A trailing comma in an array and object is ignored, e.g. "[1, 2,]" is the same as "[1, 2]".
- More floating point numbers are recognized, e.g. "1." for "1.0", or "001.2" for "1.2". Special floating point values "Infinity" and "NaN" (capitalization ignored) are accepted.
- Leading zeroes in integer numbers are ignored, e.g. "012" for "12" or "-012" for "-12".
- Capitalization is ignored in literal names null, true or false, e.g. "NULL" for "null", "True" for "true".
- Control characters U+0000 through U+001F which are not escaped in strings are accepted, e.g. "	" (tab character in string) for "\t".
- Backslash in an invalid 2-character sequence escape is ignored, e.g. "\a" is decoded as "a".
- A correct surrogate pair in JSON strings should normally be a 12 character sequence such as "\uD834\uDD1E", but json_decode() silently accepts truncated surrogate pairs such as "\uD834" or "\uD834\u"
E938
A duplicate key in an object, valid in rfc7159, is not accepted by json_decode() as the result must be a valid Vim type, e.g. this fails: {"a":"b", "a":"c"}

json_encode({expr}) json_encode()
Encode {expr} as JSON and return this as a string.
The encoding is specified in:
https://tools.ietf.org/html/rfc7159.html
Vim values are converted as follows:

Number	decimal number
Float	floating point number
Float nan	"NaN"
Float inf	"Infinity"
String	in double quotes (possibly null)
Funcref	not possible, error
List	as an array (possibly null); when used recursively: []
Dict	as an object (possibly null); when used recursively: {}
v:false	"false"
v:true	"true"
v:none	"null"
v:null	"null"

Note that NaN and Infinity are passed on as values. This is missing in the JSON standard, but several implementations do allow it. If not then you will get an error.

keys({dict}) keys()
Return a List with all the keys of {dict}. The List is in arbitrary order.

len() E701

len({expr}) The result is a Number, which is the length of the argument.
When {expr} is a String or a Number the length in bytes is used, as with strlen() .
When {expr} is a List the number of items in the List is returned.
When {expr} is a Dictionary the number of entries in the Dictionary is returned.
Otherwise an error is given.

libcall() E364 E368

libcall({libname}, {funcname}, {argument})
Call function {funcname} in the run-time library {libname} with single argument {argument}.
This is useful to call functions in a library that you especially made to be used with Vim. Since only one argument is possible, calling standard library functions is rather limited.
The result is the String returned by the function. If the function returns NULL, this will appear as an empty string "" to Vim.
If the function returns a number, use libcallnr()!
If {argument} is a number, it is passed to the function as an int; if {argument} is a string, it is passed as a null-terminated string.
This function will fail in restricted-mode .

libcall() allows you to write your own 'plug-in' extensions to Vim without having to recompile the program. It is NOT a means to call system functions! If you try to do so Vim will very probably crash.

For Win32, the functions you write must be placed in a DLL and use the normal C calling convention (NOT Pascal which is used in Windows System DLLs). The function must take exactly one parameter, either a character pointer or a long integer, and must return a character pointer or NULL. The character pointer returned must point to memory that will remain valid after the function has returned (e.g. in static data in the DLL). If it points to allocated memory, that memory will leak away. Using a static buffer in the function should work, it's then freed when the DLL is unloaded.

WARNING: If the function returns a non-valid pointer, Vim may crash! This also happens if the function returns a number, because Vim thinks it's a pointer.
For Win32 systems, {libname} should be the filename of the DLL without the ".DLL" suffix. A full path is only required if the DLL is not in the usual places.
For Unix: When compiling your own plugins, remember that the object code must be compiled as position-independent ('PIC').
{only in Win32 and some Unix versions, when the +libcall feature is present}
Examples:

```
                        :echo libcall("libc.so", "getenv", "HOME")

                                                        libcallnr()
libcallnr({libname}, {funcname}, {argument})
                Just like  libcall() , but used for a function that returns an
                int instead of a string.
                {only in Win32 on some Unix versions, when the  +libcall
                feature is present}
                Examples:
                        :echo libcallnr("/usr/lib/libc.so", "getpid", "")
                        :call libcallnr("libc.so", "printf", "Hello World!\n")
                        :call libcallnr("libc.so", "sleep", 10)

                                                        line()
line({expr})    The result is a Number, which is the line number of the file
                position given with {expr}.  The accepted positions are:
                    .       the cursor position
                    $       the last line in the current buffer
                    'x      position of mark x (if the mark is not set, 0 is
                            returned)
                    w0      first line visible in current window (one if the
                            display isn't updated, e.g. in silent Ex mode)
                    w$      last line visible in current window (this is one
                            less than "w0" if no lines are visible)
                    v       In Visual mode: the start of the Visual area (the
                            cursor is the end).  When not in Visual mode
                            returns the cursor position.  Differs from  '<  in
                            that it's updated right away.
                Note that a mark in another file can be used.  The line number
                then applies to another buffer.
                To get the column number use  col() .  To get both use
                 getpos() .
                Examples:
                        line(".")               line number of the cursor
                        line("'t")              line number of mark t
                        line("'" . marker)      line number of mark marker
                                                        last-position-jump
                This autocommand jumps to the last known position in a file
                just after opening it, if the '" mark is set:
    :au BufReadPost *
        \ if line("'\"") > 1 && line("'\"") <= line("$") && &ft !~# 'commit'
        \ |   exe "normal! g`\""
        \ | endif

line2byte({lnum})                                       line2byte()
                Return the byte count from the start of the buffer for line
                {lnum}.  This includes the end-of-line character, depending on
                the 'fileformat' option for the current buffer.  The first
                line returns 1. 'encoding' matters, 'fileencoding' is ignored.
                This can also be used to get the byte count for the line just
                below the last line:
                        line2byte(line("$") + 1)
               This is the buffer size plus one.  If 'fileencoding' is empty
                it is the file size plus one.
```

When {lnum} is invalid, or the +byte_offset feature has been disabled at compile time, -1 is returned.
Also see byte2line(), go and :goto.

lispindent({lnum}) lispindent()
Get the amount of indent for line {lnum} according the lisp indenting rules, as with 'lisp'.
The indent is counted in spaces, the value of 'tabstop' is relevant. {lnum} is used just like in getline().
When {lnum} is invalid or Vim was not compiled the +lispindent feature, -1 is returned.

localtime() localtime()
Return the current time, measured as seconds since 1st Jan 1970. See also strftime() and getftime().

log({expr}) log()
Return the natural logarithm (base e) of {expr} as a Float. {expr} must evaluate to a Float or a Number in the range (0, inf].
Examples:
```
:echo log(10)
2.302585
:echo log(exp(5))
5.0
```
{only available when compiled with the |+float| feature}

log10({expr}) log10()
Return the logarithm of Float {expr} to base 10 as a Float. {expr} must evaluate to a Float or a Number.
Examples:
```
:echo log10(1000)
3.0
:echo log10(0.01)
-2.0
```
{only available when compiled with the |+float| feature}

luaeval({expr} [, {expr}]) luaeval()
Evaluate Lua expression {expr} and return its result converted to Vim data structures. Second {expr} may hold additional argument accessible as _A inside first {expr}.
Strings are returned as they are.
Boolean objects are converted to numbers.
Numbers are converted to Float values if vim was compiled with +float and to numbers otherwise.
Dictionaries and lists obtained by vim.eval() are returned as-is.
Other objects are returned as zero without any errors.
See lua-luaeval for more details.
{only available when compiled with the |+lua| feature}

map({expr1}, {expr2}) map()

{expr1} must be a List or a Dictionary .
Replace each item in {expr1} with the result of evaluating
{expr2}. {expr2} must be a string or Funcref .

If {expr2} is a string , inside {expr2} v:val has the value
of the current item. For a Dictionary v:key has the key
of the current item and for a List v:key has the index of
the current item.
Example:

```
:call map(mylist, '"> " . v:val . " <"')
```

This puts "> " before and " <" after each item in "mylist".

Note that {expr2} is the result of an expression and is then
used as an expression again. Often it is good to use a
literal-string to avoid having to double backslashes. You
still have to double ' quotes

If {expr2} is a Funcref it is called with two arguments:

1. The key or the index of the current item.
2. the value of the current item.

The function must return the new value of the item. Example
that changes each value by "key-value":

```
func KeyValue(key, val)
  return a:key . '-' . a:val
endfunc
call map(myDict, function('KeyValue'))
```

It is shorter when using a lambda :

```
call map(myDict, {key, val -> key . '-' . val})
```

If you do not use "val" you can leave it out:

```
call map(myDict, {key -> 'item: ' . key})
```

The operation is done in-place. If you want a List or
Dictionary to remain unmodified make a copy first:

```
:let tlist = map(copy(mylist), ' v:val . "\t"')
```

Returns {expr1}, the List or Dictionary that was filtered.
When an error is encountered while evaluating {expr2} no
further items in {expr1} are processed. When {expr2} is a
Funcref errors inside a function are ignored, unless it was
defined with the "abort" flag.

maparg({name} [, {mode} [, {abbr} [, {dict}]]]) maparg()

When {dict} is omitted or zero: Return the rhs of mapping
{name} in mode {mode}. The returned String has special
characters translated like in the output of the ":map" command
listing.

When there is no mapping for {name}, an empty String is
returned. When the mapping for {name} is empty, then "<Nop>"
is returned.

The {name} can have special key names, like in the ":map"
command.

{mode} can be one of these strings:
        "n"   Normal
        "v"   Visual (including Select)
        "o"   Operator-pending
        "i"   Insert
        "c"   Cmd-line
        "s"   Select
        "x"   Visual
        "l"   langmap language-mapping
        "t"   Terminal-Job
        ""   Normal, Visual and Operator-pending
When {mode} is omitted, the modes for "" are used.

When {abbr} is there and it is TRUE use abbreviations
instead of mappings.

When {dict} is there and it is TRUE return a dictionary
containing all the information of the mapping with the
following items:
  "lhs"   The {lhs} of the mapping.
  "rhs"   The {rhs} of the mapping as typed.
  "silent"   1 for a :map-silent mapping, else 0.
  "noremap" 1 if the {rhs} of the mapping is not remappable.
  "expr"   1 for an expression mapping (:map-<expr>).
  "buffer"   1 for a buffer local mapping (:map-local).
  "mode"   Modes for which the mapping is defined. In
             addition to the modes mentioned above, these
             characters will be used:
             " "   Normal, Visual and Operator-pending
             "!"   Insert and Commandline mode
                     (mapmode-ic)
  "sid"   The script local ID, used for <sid> mappings
             (<SID>).
  "nowait"   Do not wait for other, longer mappings.
             (:map-<nowait>).

The mappings local to the current buffer are checked first,
then the global mappings.
This function can be used to map a key even when it's already
mapped, and have it do the original mapping too. Sketch:
        exe 'nnoremap <Tab> ==' . maparg('<Tab>', 'n')

mapcheck({name} [, {mode} [, {abbr}]])   mapcheck()
Check if there is a mapping that matches with {name} in mode
{mode}. See maparg() for {mode} and special names in
{name}.
When {abbr} is there and it is TRUE use abbreviations
instead of mappings.
A match happens with a mapping that starts with {name} and
with a mapping which is equal to the start of {name}.

        matches mapping "a"   "ab"   "abc"

```
                mapcheck("a")        yes     yes      yes
                mapcheck("abc")      yes     yes      yes
                mapcheck("ax")       yes     no       no
                mapcheck("b")        no      no       no
```

The difference with maparg() is that mapcheck() finds a mapping that matches with {name}, while maparg() only finds a mapping for {name} exactly.
When there is no mapping that starts with {name}, an empty String is returned. If there is one, the RHS of that mapping is returned. If there are several mappings that start with {name}, the RHS of one of them is returned. This will be "<Nop>" if the RHS is empty.
The mappings local to the current buffer are checked first, then the global mappings.
This function can be used to check if a mapping can be added without being ambiguous. Example:

```
:if mapcheck("_vv") == ""
:   map _vv :set guifont=7x13<CR>
:endif
```

This avoids adding the "_vv" mapping when there already is a mapping for "_v" or for "_vvv".

match({expr}, {pat} [, {start} [, {count}]]) match()
When {expr} is a List then this returns the index of the first item where {pat} matches. Each item is used as a String, Lists and Dictionaries are used as echoed.
Otherwise, {expr} is used as a String. The result is a Number, which gives the index (byte offset) in {expr} where {pat} matches.
A match at the first character or List item returns zero.
If there is no match -1 is returned.
For getting submatches see matchlist() .
Example:

```
:echo match("testing", "ing")   " results in 4
:echo match([1, 'x'], '\a')     " results in 1
```

See string-match for how {pat} is used.
strpbrk()
Vim doesn't have a strpbrk() function. But you can do:

```
:let sepidx = match(line, '[.,;: \t]')
```

strcasestr()
Vim doesn't have a strcasestr() function. But you can add "\c" to the pattern to ignore case:

```
:let idx = match(haystack, '\cneedle')
```

If {start} is given, the search starts from byte index {start} in a String or item {start} in a List .
The result, however, is still the index counted from the first character/item. Example:

```
:echo match("testing", "ing", 2)
```

result is again "4".

```
:echo match("testing", "ing", 4)
```

result is again "4".

```
:echo match("testing", "t", 2)
```

result is "3".
For a String, if {start} > 0 then it is like the string starts {start} bytes later, thus "^" will match at {start}. Except when {count} is given, then it's like matches before the {start} byte are ignored (this is a bit complicated to keep it backwards compatible).
For a String, if {start} < 0, it will be set to 0. For a list the index is counted from the end.
If {start} is out of range ({start} > strlen({expr}) for a String or {start} > len({expr}) for a List) -1 is returned.

When {count} is given use the {count}'th match. When a match is found in a String the search for the next one starts one character further. Thus this example results in 1:
```
echo match("testing", "..", 0, 2)
```
In a List the search continues in the next item.
Note that when {count} is added the way {start} works changes, see above.

See pattern for the patterns that are accepted.
The 'ignorecase' option is used to set the ignore-caseness of the pattern. 'smartcase' is NOT used. The matching is always done like 'magic' is set and 'cpoptions' is empty.

matchadd() E798 E799 E801 E957

matchadd({group}, {pattern} [, {priority} [, {id} [, {dict}]]])
Defines a pattern to be highlighted in the current window (a "match"). It will be highlighted with {group}. Returns an identification number (ID), which can be used to delete the match using matchdelete() .
Matching is case sensitive and magic, unless case sensitivity or magicness are explicitly overridden in {pattern}. The 'magic', 'smartcase' and 'ignorecase' options are not used. The "Conceal" value is special, it causes the match to be concealed.

The optional {priority} argument assigns a priority to the match. A match with a high priority will have its highlighting overrule that of a match with a lower priority. A priority is specified as an integer (negative numbers are no exception). If the {priority} argument is not specified, the default priority is 10. The priority of 'hlsearch' is zero, hence all matches with a priority greater than zero will overrule it. Syntax highlighting (see 'syntax') is a separate mechanism, and regardless of the chosen priority a match will always overrule syntax highlighting.

The optional {id} argument allows the request for a specific match ID. If a specified ID is already taken, an error message will appear and the match will not be added. An ID is specified as a positive integer (zero excluded). IDs 1, 2 and 3 are reserved for :match , :2match and :3match , respectively. If the {id} argument is not specified or -1, matchadd() automatically chooses a free ID.

The optional {dict} argument allows for further custom values. Currently this is used to specify a match specific conceal character that will be shown for hl-Conceal highlighted matches. The dict can have the following members:

conceal	Special character to show instead of the match (only for hl-Conceal highlighted matches, see :syn-cchar)
window	Instead of the current window use the window with this number or window ID.

The number of matches is not limited, as it is the case with the :match commands.

Example:

```
:highlight MyGroup ctermbg=green guibg=green
:let m = matchadd("MyGroup", "TODO")
```

Deletion of the pattern:

```
:call matchdelete(m)
```

A list of matches defined by matchadd() and :match are available from getmatches() . All matches can be deleted in one operation by clearmatches() .

matchaddpos()

matchaddpos({group}, {pos} [, {priority} [, {id} [, {dict}]]])

Same as matchadd() , but requires a list of positions {pos} instead of a pattern. This command is faster than matchadd() because it does not require to handle regular expressions and sets buffer line boundaries to redraw screen. It is supposed to be used when fast match additions and deletions are required, for example to highlight matching parentheses.

The list {pos} can contain one of these items:

- A number. This whole line will be highlighted. The first line has number 1.
- A list with one number, e.g., [23]. The whole line with this number will be highlighted.
- A list with two numbers, e.g., [23, 11]. The first number is the line number, the second one is the column number (first column is 1, the value must correspond to the byte index as col() would return). The character at this position will be highlighted.
- A list with three numbers, e.g., [23, 11, 3]. As above, but the third number gives the length of the highlight in bytes.

The maximum number of positions is 8.

Example:

```
:highlight MyGroup ctermbg=green guibg=green
:let m = matchaddpos("MyGroup", [[23, 24], 34])
```

Deletion of the pattern:

```
:call matchdelete(m)
```

Matches added by matchaddpos() are returned by
getmatches() with an entry "pos1", "pos2", etc., with the
value a list like the {pos} item.

matcharg({nr}) matcharg()
Selects the {nr} match item, as set with a :match ,
:2match or :3match command.
Return a List with two elements:
The name of the highlight group used
The pattern used.
When {nr} is not 1, 2 or 3 returns an empty List .
When there is no match item set returns ['', ''].
This is useful to save and restore a :match .
Highlighting matches using the :match commands are limited
to three matches. matchadd() does not have this limitation.

matchdelete({id}) matchdelete() E802 E803
Deletes a match with ID {id} previously defined by matchadd()
or one of the :match commands. Returns 0 if successful,
otherwise -1. See example for matchadd() . All matches can
be deleted in one operation by clearmatches() .

matchend({expr}, {pat} [, {start} [, {count}]]) matchend()
Same as match() , but return the index of first character
after the match. Example:
:echo matchend("testing", "ing")
results in "7".
strspn() strcspn()
Vim doesn't have a strspn() or strcspn() function, but you can
do it with matchend():
:let span = matchend(line, '[a-zA-Z]')
:let span = matchend(line, '[^a-zA-Z]')
Except that -1 is returned when there are no matches.

The {start}, if given, has the same meaning as for match() .
:echo matchend("testing", "ing", 2)
results in "7".
:echo matchend("testing", "ing", 5)
result is "-1".
When {expr} is a List the result is equal to match() .

matchlist({expr}, {pat} [, {start} [, {count}]]) matchlist()
Same as match() , but return a List . The first item in the
list is the matched string, same as what matchstr() would
return. Following items are submatches, like "\1", "\2", etc.
in :substitute . When an optional submatch didn't match an
empty string is used. Example:
echo matchlist('acd', '\(a\)\?\(b\)\?\(c\)\?\(.*\)')
Results in: ['acd', 'a', '', 'c', 'd', '', '', '', '', '']
When there is no match an empty list is returned.

matchstr({expr}, {pat} [, {start} [, {count}]]) matchstr()
Same as match() , but return the matched string. Example:

```
                :echo matchstr("testing", "ing")
            results in "ing".
             When there is no match "" is returned.
             The {start}, if given, has the same meaning as for  match() .
                :echo matchstr("testing", "ing", 2)
            results in "ing".
                :echo matchstr("testing", "ing", 5)
            result is "".
             When {expr} is a  List  then the matching item is returned.
             The type isn't changed, it's not necessarily a String.

matchstrpos({expr}, {pat} [, {start} [, {count}]])              matchstrpos()
             Same as  matchstr() , but return the matched string, the start
             position and the end position of the match.  Example:
                :echo matchstrpos("testing", "ing")
            results in ["ing", 4, 7].
             When there is no match ["", -1, -1] is returned.
             The {start}, if given, has the same meaning as for  match() .
                :echo matchstrpos("testing", "ing", 2)
            results in ["ing", 4, 7].
                :echo matchstrpos("testing", "ing", 5)
            result is ["", -1, -1].
             When {expr} is a  List  then the matching item, the index
             of first item where {pat} matches, the start position and the
             end position of the match are returned.
                :echo matchstrpos([1, '__x'], '\a')
            result is ["x", 1, 2, 3].
             The type isn't changed, it's not necessarily a String.

                                                             max()
max({expr})     Return the maximum value of all items in {expr}.
             {expr} can be a list or a dictionary.  For a dictionary,
             it returns the maximum of all values in the dictionary.
             If {expr} is neither a list nor a dictionary, or one of the
             items in {expr} cannot be used as a Number this results in
             an error.  An empty  List  or  Dictionary  results in zero.

                                                             min()
min({expr})     Return the minimum value of all items in {expr}.
             {expr} can be a list or a dictionary.  For a dictionary,
             it returns the minimum of all values in the dictionary.
             If {expr} is neither a list nor a dictionary, or one of the
             items in {expr} cannot be used as a Number this results in
             an error.  An empty  List  or  Dictionary  results in zero.

                                                             mkdir()   E739
mkdir({name} [, {path} [, {prot}]])
             Create directory {name}.
             If {path} is "p" then intermediate directories are created as
             necessary.  Otherwise it must be "".
             If {prot} is given it is used to set the protection bits of
             the new directory.  The default is 0755 (rwxr-xr-x: r/w for
             the user readable for others).  Use 0700 to make it unreadable
             for others.  This is only used for the last part of {name}.
```

Thus if you create /tmp/foo/bar then /tmp/foo will be created
with 0755.
Example:
```
:call mkdir($HOME . "/tmp/foo/bar", "p", 0700)
```
This function is not available in the sandbox .
There is no error if the directory already exists and the "p"
flag is passed (since patch 8.0.1708).
Not available on all systems. To check use:
```
:if exists("*mkdir")
```

mode()

mode([expr]) Return a string that indicates the current mode.
If [expr] is supplied and it evaluates to a non-zero Number or
a non-empty String (non-zero-arg), then the full mode is
returned, otherwise only the first letter is returned.

n	Normal, Terminal-Normal
no	Operator-pending
niI	Normal using i_CTRL-O in Insert-mode
niR	Normal using i_CTRL-O in Replace-mode
niV	Normal using i_CTRL-O in Virtual-Replace-mode
v	Visual by character
V	Visual by line
CTRL-V	Visual blockwise
s	Select by character
S	Select by line
CTRL-S	Select blockwise
i	Insert
ic	Insert mode completion compl-generic
ix	Insert mode i_CTRL-X completion
R	Replace R
Rc	Replace mode completion compl-generic
Rv	Virtual Replace gR
Rx	Replace mode i_CTRL-X completion
c	Command-line editing
cv	Vim Ex mode gQ
ce	Normal Ex mode Q
r	Hit-enter prompt
rm	The -- more -- prompt
r?	A :confirm query of some sort
!	Shell or external command is executing
t	Terminal-Job mode: keys go to the job

This is useful in the 'statusline' option or when used
with remote_expr() In most other places it always returns
"c" or "n".
Note that in the future more modes and more specific modes may
be added. It's better not to compare the whole string but only
the leading character(s).
Also see visualmode() .

mzeval({expr}) mzeval()
Evaluate MzScheme expression {expr} and return its result
converted to Vim data structures.
Numbers and strings are returned as they are.

Pairs (including lists and improper lists) and vectors are
returned as Vim Lists .
Hash tables are represented as Vim Dictionary type with keys
converted to strings.
All other types are converted to string with display function.
Examples:

```
:mz (define l (list 1 2 3))
:mz (define h (make-hash)) (hash-set! h "list" l)
:echo mzeval("l")
:echo mzeval("h")
```

{only available when compiled with the |+mzscheme| feature}

nextnonblank({lnum}) nextnonblank()
Return the line number of the first line at or below {lnum}
that is not blank. Example:

```
if getline(nextnonblank(1)) =~ "Java"
```

When {lnum} is invalid or there is no non-blank line at or
below it, zero is returned.
See also prevnonblank() .

nr2char({expr} [, {utf8}]) nr2char()
Return a string with a single character, which has the number
value {expr}. Examples:

```
nr2char(64)             returns "@"
nr2char(32)             returns " "
```

When {utf8} is omitted or zero, the current 'encoding' is used.
Example for "utf-8":

```
nr2char(300)            returns I with bow character
```

With {utf8} set to 1, always return utf-8 characters.
Note that a NUL character in the file is specified with
nr2char(10), because NULs are represented with newline
characters. nr2char(0) is a real NUL and terminates the
string, thus results in an empty string.

or({expr}, {expr}) or()
Bitwise OR on the two arguments. The arguments are converted
to a number. A List, Dict or Float argument causes an error.
Example:

```
:let bits = or(bits, 0x80)
```

pathshorten({expr}) pathshorten()
Shorten directory names in the path {expr} and return the
result. The tail, the file name, is kept as-is. The other
components in the path are reduced to single letters. Leading
'~' and '.' characters are kept. Example:

```
:echo pathshorten('~/.vim/autoload/myfile.vim')
~/.v/a/myfile.vim
```

It doesn't matter if the path exists or not.

perleval({expr}) perleval()
Evaluate Perl expression {expr} in scalar context and return
its result converted to Vim data structures. If value can't be

converted, it is returned as a string Perl representation.
Note: If you want an array or hash, {expr} must return a
reference to it.
Example:
```
:echo perleval('[1 .. 4]')
[1, 2, 3, 4]
```
{only available when compiled with the |+perl| feature}

pow({x}, {y}) pow()
Return the power of {x} to the exponent {y} as a Float .
{x} and {y} must evaluate to a Float or a Number .
Examples:
```
:echo pow(3, 3)
27.0
:echo pow(2, 16)
65536.0
:echo pow(32, 0.20)
2.0
```
{only available when compiled with the |+float| feature}

prevnonblank({lnum}) prevnonblank()
Return the line number of the first line at or above {lnum}
that is not blank. Example:
```
let ind = indent(prevnonblank(v:lnum - 1))
```
When {lnum} is invalid or there is no non-blank line at or
above it, zero is returned.
Also see nextnonblank() .

printf({fmt}, {expr1} ...) printf()
Return a String with {fmt}, where "%" items are replaced by
the formatted form of their respective arguments. Example:
```
printf("%4d: E%d %.30s", lnum, errno, msg)
```
May result in:
```
"  99: E42 asdfasdfasdfasdfasdfasdfasdfas"
```

Often used items are:

%s	string
%6S	string right-aligned in 6 display cells
%6s	string right-aligned in 6 bytes
%.9s	string truncated to 9 bytes
%c	single byte
%d	decimal number
%5d	decimal number padded with spaces to 5 characters
%x	hex number
%04x	hex number padded with zeros to at least 4 characters
%X	hex number using upper case letters
%o	octal number
%08b	binary number padded with zeros to at least 8 chars
%f	floating point number as 12.23, inf, -inf or nan
%F	floating point number as 12.23, INF, -INF or NAN
%e	floating point number as 1.23e3, inf, -inf or nan
%E	floating point number as 1.23E3, INF, -INF or NAN
%g	floating point number, as %f or %e depending on value

```
  %G    floating point number, as %F or %E depending on value
  %%    the % character itself

Conversion specifications start with '%' and end with the
conversion type.  All other characters are copied unchanged to
the result.

The "%" starts a conversion specification.  The following
arguments appear in sequence:

        %  [flags]  [field-width]  [.precision]  type

flags
        Zero or more of the following flags:

    #         The value should be converted to an "alternate
              form".  For c, d, and s conversions, this option
              has no effect.  For o conversions, the precision
              of the number is increased to force the first
              character of the output string to a zero (except
              if a zero value is printed with an explicit
              precision of zero).
              For b and B conversions, a non-zero result has
              the string "0b" (or "0B" for B conversions)
              prepended to it.
              For x and X conversions, a non-zero result has
              the string "0x" (or "0X" for X conversions)
              prepended to it.

    0 (zero)  Zero padding.  For all conversions the converted
              value is padded on the left with zeros rather
              than blanks.  If a precision is given with a
              numeric conversion (d, b, B, o, x, and X), the 0
              flag is ignored.

    -         A negative field width flag; the converted value
              is to be left adjusted on the field boundary.
              The converted value is padded on the right with
              blanks, rather than on the left with blanks or
              zeros.  A - overrides a 0 if both are given.

    ' ' (space)  A blank should be left before a positive
              number produced by a signed conversion (d).

    +         A sign must always be placed before a number
              produced by a signed conversion.  A + overrides
              a space if both are used.

field-width
        An optional decimal digit string specifying a minimum
        field width.  If the converted value has fewer bytes
        than the field width, it will be padded with spaces on
        the left (or right, if the left-adjustment flag has
        been given) to fill out the field width.
```

.precision
	An optional precision, in the form of a period '.'
	followed by an optional digit string. If the digit
	string is omitted, the precision is taken as zero.
	This gives the minimum number of digits to appear for
	d, o, x, and X conversions, or the maximum number of
	bytes to be printed from a string for s conversions.
	For floating point it is the number of digits after
	the decimal point.

type
	A character that specifies the type of conversion to
	be applied, see below.

A field width or precision, or both, may be indicated by an
asterisk '*' instead of a digit string. In this case, a
Number argument supplies the field width or precision. A
negative field width is treated as a left adjustment flag
followed by a positive field width; a negative precision is
treated as though it were missing. Example:
	:echo printf("%d: %.*s", nr, width, line)
This limits the length of the text used from "line" to
"width" bytes.

The conversion specifiers and their meanings are:

printf-d printf-b printf-B printf-o
printf-x printf-X

dbBoxX	The Number argument is converted to signed decimal
	(d), unsigned binary (b and B), unsigned octal (o), or
	unsigned hexadecimal (x and X) notation. The letters
	"abcdef" are used for x conversions; the letters
	"ABCDEF" are used for X conversions.
	The precision, if any, gives the minimum number of
	digits that must appear; if the converted value
	requires fewer digits, it is padded on the left with
	zeros.
	In no case does a non-existent or small field width
	cause truncation of a numeric field; if the result of
	a conversion is wider than the field width, the field
	is expanded to contain the conversion result.
	The 'h' modifier indicates the argument is 16 bits.
	The 'l' modifier indicates the argument is 32 bits.
	The 'L' modifier indicates the argument is 64 bits.
	Generally, these modifiers are not useful. They are
	ignored when type is known from the argument.

i	alias for d
D	alias for ld
U	alias for lu
O	alias for lo

printf-c

c	The Number argument is converted to a byte, and the
	resulting character is written.

printf-s
s	The text of the String argument is used. If a
	precision is specified, no more bytes than the number
	specified are used.
	If the argument is not a String type, it is
	automatically converted to text with the same format
	as ":echo".
printf-S
S	The text of the String argument is used. If a
	precision is specified, no more display cells than the
	number specified are used. Without the +multi_byte
	feature works just like 's'.

printf-f E807
f F	The Float argument is converted into a string of the
	form 123.456. The precision specifies the number of
	digits after the decimal point. When the precision is
	zero the decimal point is omitted. When the precision
	is not specified 6 is used. A really big number
	(out of range or dividing by zero) results in "inf"
	or "-inf" with %f (INF or -INF with %F).
	"0.0 / 0.0" results in "nan" with %f (NAN with %F).
	Example:
		echo printf("%.2f", 12.115)
		12.12
	Note that roundoff depends on the system libraries.
	Use round() when in doubt.

printf-e printf-E
e E	The Float argument is converted into a string of the
	form 1.234e+03 or 1.234E+03 when using 'E'. The
	precision specifies the number of digits after the
	decimal point, like with 'f'.

printf-g printf-G
g G	The Float argument is converted like with 'f' if the
	value is between 0.001 (inclusive) and 10000000.0
	(exclusive). Otherwise 'e' is used for 'g' and 'E'
	for 'G'. When no precision is specified superfluous
	zeroes and '+' signs are removed, except for the zero
	immediately after the decimal point. Thus 10000000.0
	results in 1.0e7.

printf-%
%	A '%' is written. No argument is converted. The
	complete conversion specification is "%%".

When a Number argument is expected a String argument is also
accepted and automatically converted.
When a Float or String argument is expected a Number argument
is also accepted and automatically converted.

Any other argument type results in an error message.

E766 E767
The number of {exprN} arguments must exactly match the number of "%" items. If there are not sufficient or too many arguments an error is given. Up to 18 arguments can be used.

prompt_setcallback({buf}, {expr}) prompt_setcallback()
Set prompt callback for buffer {buf} to {expr}. When {expr} is an empty string the callback is removed. This has only effect if {buf} has 'buftype' set to "prompt".

The callback is invoked when pressing Enter. The current buffer will always be the prompt buffer. A new line for a prompt is added before invoking the callback, thus the prompt for which the callback was invoked will be in the last but one line.
If the callback wants to add text to the buffer, it must insert it above the last line, since that is where the current prompt is. This can also be done asynchronously.
The callback is invoked with one argument, which is the text that was entered at the prompt. This can be an empty string if the user only typed Enter.
Example:

```
call prompt_setcallback(bufnr(''), function('s:TextEntered'))
func s:TextEntered(text)
  if a:text == 'exit' || a:text == 'quit'
    stopinsert
    close
  else
    call append(line('$') - 1, 'Entered: "' . a:text . '"')
    " Reset 'modified' to allow the buffer to be closed.
    set nomodified
  endif
endfunc
```

prompt_setinterrupt({buf}, {expr}) prompt_setinterrupt()
Set a callback for buffer {buf} to {expr}. When {expr} is an empty string the callback is removed. This has only effect if {buf} has 'buftype' set to "prompt".

This callback will be invoked when pressing CTRL-C in Insert mode. Without setting a callback Vim will exit Insert mode, as in any buffer.

prompt_setprompt({buf}, {text}) prompt_setprompt()
Set prompt for buffer {buf} to {text}. You most likely want {text} to end in a space.
The result is only visible if {buf} has 'buftype' set to "prompt". Example:

```
call prompt_setprompt(bufnr(''), 'command: ')
```

pumvisible() pumvisible()

Returns non-zero when the popup menu is visible, zero otherwise. See ins-completion-menu . This can be used to avoid some things that would remove the popup menu.

py3eval({expr}) py3eval()

Evaluate Python expression {expr} and return its result converted to Vim data structures. Numbers and strings are returned as they are (strings are copied though, Unicode strings are additionally converted to 'encoding'). Lists are represented as Vim List type. Dictionaries are represented as Vim Dictionary type with keys converted to strings. {only available when compiled with the |+python3| feature}

E858 E859

pyeval({expr}) pyeval()

Evaluate Python expression {expr} and return its result converted to Vim data structures. Numbers and strings are returned as they are (strings are copied though). Lists are represented as Vim List type. Dictionaries are represented as Vim Dictionary type, non-string keys result in error. {only available when compiled with the |+python| feature}

pyxeval({expr}) pyxeval()

Evaluate Python expression {expr} and return its result converted to Vim data structures. Uses Python 2 or 3, see python_x and 'pyxversion'. See also: pyeval() , py3eval() {only available when compiled with the +python or the +python3 feature}

E726 E727

range({expr} [, {max} [, {stride}]]) range()

Returns a List with Numbers:
- If only {expr} is specified: [0, 1, ..., {expr} - 1]
- If {max} is specified: [{expr}, {expr} + 1, ..., {max}]
- If {stride} is specified: [{expr}, {expr} + {stride}, ..., {max}] (increasing {expr} with {stride} each time, not producing a value past {max}).

When the maximum is one before the start the result is an empty list. When the maximum is more than one before the start this is an error.

Examples:

```
range(4)                " [0, 1, 2, 3]
range(2, 4)             " [2, 3, 4]
range(2, 9, 3)          " [2, 5, 8]
range(2, -2, -1)        " [2, 1, 0, -1, -2]
range(0)                " []
range(2, 0)             " error!
```

readfile()

readfile({fname} [, {binary} [, {max}]])
Read file {fname} and return a List , each line of the file as an item. Lines are broken at NL characters. Macintosh files separated with CR will result in a single long line (unless a NL appears somewhere).
All NUL characters are replaced with a NL character.
When {binary} contains "b" binary mode is used:
- When the last line ends in a NL an extra empty list item is added.
- No CR characters are removed.
Otherwise:
- CR characters that appear before a NL are removed.
- Whether the last line ends in a NL or not does not matter.
- When 'encoding' is Unicode any UTF-8 byte order mark is removed from the text.
When {max} is given this specifies the maximum number of lines to be read. Useful if you only want to check the first ten lines of a file:

```
:for line in readfile(fname, '', 10)
:  if line =~ 'Date' | echo line | endif
:endfor
```

When {max} is negative -{max} lines from the end of the file are returned, or as many as there are.
When {max} is zero the result is an empty list.
Note that without {max} the whole file is read into memory.
Also note that there is no recognition of encoding. Read a file into a buffer if you need to.
When the file can't be opened an error message is given and the result is an empty list.
Also see writefile() .

reg_executing() reg_executing()
Returns the single letter name of the register being executed.
Returns an empty string when no register is being executed.
See @ .

reg_recording() reg_recording()
Returns the single letter name of the register being recorded.
Returns an empty string string when not recording. See q .

reltime([{start} [, {end}]]) reltime()
Return an item that represents a time value. The format of the item depends on the system. It can be passed to reltimestr() to convert it to a string or reltimefloat() to convert to a Float.
Without an argument it returns the current time.
With one argument is returns the time passed since the time specified in the argument.
With two arguments it returns the time passed between {start} and {end}.
The {start} and {end} arguments must be values returned by reltime().

{only available when compiled with the |+reltime| feature}

reltimefloat({time}) reltimefloat()
Return a Float that represents the time value of {time}.
Example:
```
let start = reltime()
call MyFunction()
let seconds = reltimefloat(reltime(start))
```
See the note of reltimestr() about overhead.
Also see profiling .
{only available when compiled with the |+reltime| feature}

reltimestr({time}) reltimestr()
Return a String that represents the time value of {time}.
This is the number of seconds, a dot and the number of
microseconds. Example:
```
let start = reltime()
call MyFunction()
echo reltimestr(reltime(start))
```
Note that overhead for the commands will be added to the time.
The accuracy depends on the system.
Leading spaces are used to make the string align nicely. You
can use split() to remove it.
```
echo split(reltimestr(reltime(start)))[0]
```
Also see profiling .
{only available when compiled with the |+reltime| feature}

remote_expr() E449
remote_expr({server}, {string} [, {idvar} [, {timeout}]])
Send the {string} to {server}. The string is sent as an
expression and the result is returned after evaluation.
The result must be a String or a List . A List is turned
into a String by joining the items with a line break in
between (not at the end), like with join(expr, "\n").
If {idvar} is present and not empty, it is taken as the name
of a variable and a {serverid} for later use with
remote_read() is stored there.
If {timeout} is given the read times out after this many
seconds. Otherwise a timeout of 600 seconds is used.
See also clientserver RemoteReply .
This function is not available in the sandbox .
{only available when compiled with the |+clientserver| feature}
Note: Any errors will cause a local error message to be issued
and the result will be the empty string.

Variables will be evaluated in the global namespace,
independent of a function currently being active. Except
when in debug mode, then local function variables and
arguments can be evaluated.

Examples:
```
:echo remote_expr("gvim", "2+2")
:echo remote_expr("gvim1", "b:current_syntax")
```

remote_foreground({server})   remote_foreground()
Move the Vim server with the name {server} to the foreground.
This works like:
	remote_expr({server}, "foreground()")
Except that on Win32 systems the client does the work, to work
around the problem that the OS doesn't always allow the server
to bring itself to the foreground.
Note: This does not restore the window if it was minimized,
like foreground() does.
This function is not available in the sandbox .
{only in the Win32, Athena, Motif and GTK GUI versions and the
Win32 console version}

remote_peek({serverid} [, {retvar}])   remote_peek()
Returns a positive number if there are available strings
from {serverid}. Copies any reply string into the variable
{retvar} if specified. {retvar} must be a string with the
name of a variable.
Returns zero if none are available.
Returns -1 if something is wrong.
See also clientserver .
This function is not available in the sandbox .
{only available when compiled with the |+clientserver| feature}
Examples:
	:let repl = ""
	:echo "PEEK: ".remote_peek(id, "repl").": ".repl

remote_read({serverid}, [{timeout}])   remote_read()
Return the oldest available reply from {serverid} and consume
it. Unless a {timeout} in seconds is given, it blocks until a
reply is available.
See also clientserver .
This function is not available in the sandbox .
{only available when compiled with the |+clientserver| feature}
Example:
	:echo remote_read(id)

                                                  remote_send() E241
remote_send({server}, {string} [, {idvar}])
Send the {string} to {server}. The string is sent as input
keys and the function returns immediately. At the Vim server
the keys are not mapped :map .
If {idvar} is present, it is taken as the name of a variable
and a {serverid} for later use with remote_read() is stored
there.
See also clientserver   RemoteReply .
This function is not available in the sandbox .
{only available when compiled with the |+clientserver| feature}

Note: Any errors will be reported in the server and may mess
up the display.
Examples:

```
:echo remote_send("gvim", ":DropAndReply ".file, "serverid").
 \ remote_read(serverid)

:autocmd NONE RemoteReply *
 \ echo remote_read(expand("<amatch>"))
:echo remote_send("gvim", ":sleep 10 | echo ".
 \ 'server2client(expand("<client>"), "HELLO")<CR>')
```

remote_startserver() E941 E942

remote_startserver({name})
Become the server {name}. This fails if already running as a server, when v:servername is not empty.
{only available when compiled with the |+clientserver| feature}

remove({list}, {idx} [, {end}]) remove()
Without {end}: Remove the item at {idx} from List {list} and return the item.
With {end}: Remove items from {idx} to {end} (inclusive) and return a List with these items. When {idx} points to the same item as {end} a list with one item is returned. When {end} points to an item before {idx} this is an error.
See list-index for possible values of {idx} and {end}.
Example:
```
:echo "last item: " . remove(mylist, -1)
:call remove(mylist, 0, 9)
```
remove({dict}, {key})
Remove the entry from {dict} with key {key}. Example:
```
:echo "removed " . remove(dict, "one")
```
If there is no {key} in {dict} this is an error.

Use delete() to remove a file.

rename({from}, {to}) rename()
Rename the file by the name {from} to the name {to}. This should also work to move files across file systems. The result is a Number, which is 0 if the file was renamed successfully, and non-zero when the renaming failed.
NOTE: If {to} exists it is overwritten without warning.
This function is not available in the sandbox .

repeat({expr}, {count}) repeat()
Repeat {expr} {count} times and return the concatenated result. Example:
```
:let separator = repeat('-', 80)
```
When {count} is zero or negative the result is empty.
When {expr} is a List the result is {expr} concatenated {count} times. Example:
```
:let longlist = repeat(['a', 'b'], 3)
```
Results in ['a', 'b', 'a', 'b', 'a', 'b'].

resolve({filename}) resolve() E655
On MS-Windows, when {filename} is a shortcut (a .lnk file), returns the path the shortcut points to in a simplified form.

On Unix, repeat resolving symbolic links in all path components of {filename} and return the simplified result. To cope with link cycles, resolving of symbolic links is stopped after 100 iterations.
On other systems, return the simplified {filename}. The simplification step is done as by simplify() . resolve() keeps a leading path component specifying the current directory (provided the result is still a relative path name) and also keeps a trailing path separator.

reverse({list}) reverse() Reverse the order of items in {list} in-place. Returns {list}.
If you want a list to remain unmodified make a copy first:

```
:let revlist = reverse(copy(mylist))
```

round({expr}) round()
Round off {expr} to the nearest integral value and return it as a Float . If {expr} lies halfway between two integral values, then use the larger one (away from zero).
{expr} must evaluate to a Float or a Number .
Examples:

```
echo round(0.456)
0.0
echo round(4.5)
5.0
echo round(-4.5)
-5.0
```

{only available when compiled with the |+float| feature}

screenattr({row}, {col}) screenattr()
Like screenchar() , but return the attribute. This is a rather arbitrary number that can only be used to compare to the attribute at other positions.

screenchar({row}, {col}) screenchar()
The result is a Number, which is the character at position [row, col] on the screen. This works for every possible screen position, also status lines, window separators and the command line. The top left position is row one, column one
The character excludes composing characters. For double-byte encodings it may only be the first byte.
This is mainly to be used for testing.
Returns -1 when row or col is out of range.

screencol() screencol()
The result is a Number, which is the current screen column of the cursor. The leftmost column has number 1.
This function is mainly used for testing.

Note: Always returns the current screen column, thus if used in a command (e.g. ":echo screencol()") it will return the column inside the command line, which is 1 when the command is executed. To get the cursor position in the file use one of

the following mappings:
```
nnoremap <expr> GG ":echom ".screencol()."\n"
nnoremap <silent> GG :echom screencol()<CR>
```

screenrow() screenrow()

The result is a Number, which is the current screen row of the cursor. The top line has number one.
This function is mainly used for testing.
Alternatively you can use `winline()`.

Note: Same restrictions as with `screencol()`.

search({pattern} [, {flags} [, {stopline} [, {timeout}]]]) search()

Search for regexp pattern {pattern}. The search starts at the cursor position (you can use `cursor()` to set it).

When a match has been found its line number is returned.
If there is no match a 0 is returned and the cursor doesn't move. No error message is given.

{flags} is a String, which can contain these character flags:
'b' search Backward instead of forward
'c' accept a match at the Cursor position
'e' move to the End of the match
'n' do Not move the cursor
'p' return number of matching sub-Pattern (see below)
's' Set the ' mark at the previous location of the cursor
'w' Wrap around the end of the file
'W' don't Wrap around the end of the file
'z' start searching at the cursor column instead of zero
If neither 'w' or 'W' is given, the 'wrapscan' option applies.

If the 's' flag is supplied, the ' mark is set, only if the cursor is moved. The 's' flag cannot be combined with the 'n' flag.

'ignorecase', 'smartcase' and 'magic' are used.

When the 'z' flag is not given, searching always starts in column zero and then matches before the cursor are skipped.
When the 'c' flag is present in 'cpo' the next search starts after the match. Without the 'c' flag the next search starts one column further.

When the {stopline} argument is given then the search stops after searching this line. This is useful to restrict the search to a range of lines. Examples:
```
let match = search('(', 'b', line("w0"))
let end = search('END', '', line("w$"))
```
When {stopline} is used and it is not zero this also implies that the search does not wrap around the end of the file.
A zero value is equal to not giving the argument.

When the {timeout} argument is given the search stops when

more than this many milliseconds have passed. Thus when
{timeout} is 500 the search stops after half a second.
The value must not be negative. A zero value is like not
giving the argument.
{only available when compiled with the |+reltime| feature}

search()-sub-match
With the 'p' flag the returned value is one more than the
first sub-match in \(\). One if none of them matched but the
whole pattern did match.
To get the column number too use searchpos() .

The cursor will be positioned at the match, unless the 'n'
flag is used.

Example (goes over all files in the argument list):
```
    :let n = 1
    :while n <= argc()      " loop over all files in arglist
    :  exe "argument " . n
    :  " start at the last char in the file and wrap for the
    :  " first search to find match at start of file
    :  normal G$
    :  let flags = "w"
    :  while search("foo", flags) > 0
    :    s/foo/bar/g
    :    let flags = "W"
    :  endwhile
    :  update               " write the file if modified
    :  let n = n + 1
    :endwhile
```

Example for using some flags:
```
    :echo search('\<if\|\(else\)\|\(endif\)', 'ncpe')
```
This will search for the keywords "if", "else", and "endif"
under or after the cursor. Because of the 'p' flag, it
returns 1, 2, or 3 depending on which keyword is found, or 0
if the search fails. With the cursor on the first word of the
line:
```
    if (foo == 0) | let foo = foo + 1 | endif
```
the function returns 1. Without the 'c' flag, the function
finds the "endif" and returns 3. The same thing happens
without the 'e' flag if the cursor is on the "f" of "if".
The 'n' flag tells the function not to move the cursor.

searchdecl({name} [, {global} [, {thisblock}]]) searchdecl()
Search for the declaration of {name}.

With a non-zero {global} argument it works like gD , find
first match in the file. Otherwise it works like gd , find
first match in the function.

With a non-zero {thisblock} argument matches in a {} block
that ends before the cursor position are ignored. Avoids

finding variable declarations only valid in another scope.

Moves the cursor to the found match.
Returns zero for success, non-zero for failure.
Example:
```
if searchdecl('myvar') == 0
   echo getline('.')
endif
```

searchpair()
searchpair({start}, {middle}, {end} [, {flags} [, {skip}
[, {stopline} [, {timeout}]]]])
Search for the match of a nested start-end pair. This can be used to find the "endif" that matches an "if", while other if/endif pairs in between are ignored.
The search starts at the cursor. The default is to search forward, include 'b' in {flags} to search backward.
If a match is found, the cursor is positioned at it and the line number is returned. If no match is found 0 or -1 is returned and the cursor doesn't move. No error message is given.

{start}, {middle} and {end} are patterns, see pattern . They must not contain \(\) pairs. Use of \%(\) is allowed. When {middle} is not empty, it is found when searching from either direction, but only when not in a nested start-end pair. A typical use is:
```
searchpair('\<if\>', '\<else\>', '\<endif\>')
```
By leaving {middle} empty the "else" is skipped.

{flags} 'b', 'c', 'n', 's', 'w' and 'W' are used like with search() . Additionally:
'r' Repeat until no more matches found; will find the outer pair. Implies the 'W' flag.
'm' Return number of matches instead of line number with the match; will be > 1 when 'r' is used.
Note: it's nearly always a good idea to use the 'W' flag, to avoid wrapping around the end of the file.

When a match for {start}, {middle} or {end} is found, the {skip} expression is evaluated with the cursor positioned on the start of the match. It should return non-zero if this match is to be skipped. E.g., because it is inside a comment or a string.
When {skip} is omitted or empty, every match is accepted.
When evaluating {skip} causes an error the search is aborted and -1 returned.
{skip} can be a string, a lambda, a funcref or a partial.
Anything else makes the function fail.

For {stopline} and {timeout} see search() .

The value of 'ignorecase' is used. 'magic' is ignored, the patterns are used like it's on.

The search starts exactly at the cursor. A match with {start}, {middle} or {end} at the next character, in the direction of searching, is the first one found. Example:

```
if 1
  if 2
  endif 2
endif 1
```

When starting at the "if 2", with the cursor on the "i", and searching forwards, the "endif 2" is found. When starting on the character just before the "if 2", the "endif 1" will be found. That's because the "if 2" will be found first, and then this is considered to be a nested if/endif from "if 2" to "endif 2".
When searching backwards and {end} is more than one character, it may be useful to put "\zs" at the end of the pattern, so that when the cursor is inside a match with the end it finds the matching start.

Example, to find the "endif" command in a Vim script:

```
:echo searchpair('\<if\>', '\<el\%[seif]\>', '\<en\%[dif]\>', 'W',
                \ 'getline(".") =~ "^\\s*\""')
```

The cursor must be at or after the "if" for which a match is to be found. Note that single-quote strings are used to avoid having to double the backslashes. The skip expression only catches comments at the start of a line, not after a command. Also, a word "en" or "if" halfway a line is considered a match.
Another example, to search for the matching "{" of a "}":

```
:echo searchpair('{', '', '}', 'bW')
```

This works when the cursor is at or before the "}" for which a match is to be found. To reject matches that syntax highlighting recognized as strings:

```
:echo searchpair('{', '', '}', 'bW',
    \ 'synIDattr(synID(line("."), col("."), 0), "name") =~? "string"')
```

searchpairpos()

```
searchpairpos({start}, {middle}, {end} [, {flags} [, {skip}
                              [, {stopline} [, {timeout}]]]])
```

Same as searchpair() , but returns a List with the line and column position of the match. The first element of the List is the line number and the second element is the byte index of the column position of the match. If no match is found, returns [0, 0].

```
:let [lnum,col] = searchpairpos('{', '', '}', 'n')
```

See match-parens for a bigger and more useful example.

searchpos({pattern} [, {flags} [, {stopline} [, {timeout}]]]) searchpos()
Same as search() , but returns a List with the line and column position of the match. The first element of the List is the line number and the second element is the byte index of the column position of the match. If no match is found, returns [0, 0].
Example:
```
:let [lnum, col] = searchpos('mypattern', 'n')
```

When the 'p' flag is given then there is an extra item with the sub-pattern match number search()-sub-match . Example:
```
:let [lnum, col, submatch] = searchpos('\(\l\)\|\(\u\)', 'np')
```
In this example "submatch" is 2 when a lowercase letter is found /\l , 3 when an uppercase letter is found /\u .

server2client({clientid}, {string}) server2client()
Send a reply string to {clientid}. The most recent {clientid} that sent a string can be retrieved with expand("<client>").
{only available when compiled with the |+clientserver| feature}
Note:
This id has to be stored before the next command can be received. I.e. before returning from the received command and before calling any commands that waits for input.
See also clientserver .
Example:
```
:echo server2client(expand("<client>"), "HELLO")
```

serverlist() serverlist()
Return a list of available server names, one per line.
When there are no servers or the information is not available an empty string is returned. See also clientserver .
{only available when compiled with the |+clientserver| feature}
Example:
```
:echo serverlist()
```

setbufline({expr}, {lnum}, {text}) setbufline()
Set line {lnum} to {text} in buffer {expr}. To insert lines use append() .

For the use of {expr}, see bufname() above.

{lnum} is used like with setline() .
This works like setline() for the specified buffer.
On success 0 is returned, on failure 1 is returned.

If {expr} is not a valid buffer or {lnum} is not valid, an error message is given.

setbufvar({expr}, {varname}, {val}) setbufvar()
Set option or local variable {varname} in buffer {expr} to {val}.
This also works for a global or local window option, but it doesn't work for a global or local window variable.
For a local window option the global value is unchanged.

For the use of {expr}, see bufname() above.
Note that the variable name without "b:" must be used.
Examples:
```
:call setbufvar(1, "&mod", 1)
:call setbufvar("todo", "myvar", "foobar")
```
This function is not available in the sandbox .

setcharsearch({dict}) setcharsearch()
Set the current character search information to {dict}, which contains one or more of the following entries:

char	character which will be used for a subsequent , or ; command; an empty string clears the character search
forward	direction of character search; 1 for forward, 0 for backward
until	type of character search; 1 for a t or T character search, 0 for an f or F character search

This can be useful to save/restore a user's character search from a script:
```
:let prevsearch = getcharsearch()
:" Perform a command which clobbers user's search
:call setcharsearch(prevsearch)
```
Also see getcharsearch() .

setcmdpos({pos}) setcmdpos()
Set the cursor position in the command line to byte position {pos}. The first position is 1.
Use getcmdpos() to obtain the current position.
Only works while editing the command line, thus you must use c_CTRL-_e , c_CTRL-R_= or c_CTRL-R_CTRL-R with '='. For c_CTRL-_e and c_CTRL-R_CTRL-R with '=' the position is set after the command line is set to the expression. For c_CTRL-R_= it is set after evaluating the expression but before inserting the resulting text.
When the number is too big the cursor is put at the end of the line. A number smaller than one has undefined results.
Returns 0 when successful, 1 when not editing the command line.

setfperm({fname}, {mode}) setfperm() chmod
Set the file permissions for {fname} to {mode}.
{mode} must be a string with 9 characters. It is of the form "rwxrwxrwx", where each group of "rwx" flags represent, in turn, the permissions of the owner of the file, the group the file belongs to, and other users. A '-' character means the permission is off, any other character means on. Multi-byte characters are not supported.

For example "rw-r-----" means read-write for the user, readable by the group, not accessible by others. "xx-x-----" would do the same thing.

Returns non-zero for success, zero for failure.

To read permissions see getfperm() .

setline({lnum}, {text}) setline()
Set line {lnum} of the current buffer to {text}. To insert lines use append() . To set lines in another buffer use setbufline() .

{lnum} is used like with getline() .
When {lnum} is just below the last line the {text} will be added as a new line.

If this succeeds, 0 is returned. If this fails (most likely because {lnum} is invalid) 1 is returned.

Example:
```
:call setline(5, strftime("%c"))
```

When {text} is a List then line {lnum} and following lines will be set to the items in the list. Example:
```
:call setline(5, ['aaa', 'bbb', 'ccc'])
```
This is equivalent to:
```
:for [n, l] in [[5, 'aaa'], [6, 'bbb'], [7, 'ccc']]
:  call setline(n, l)
:endfor
```

Note: The '[and '] marks are not set.

setloclist({nr}, {list} [, {action} [, {what}]]) setloclist()
Create or replace or add to the location list for window {nr}. {nr} can be the window number or the window-ID .
When {nr} is zero the current window is used.

For a location list window, the displayed location list is modified. For an invalid window number {nr}, -1 is returned. Otherwise, same as setqflist() .
Also see location-list .

If the optional {what} dictionary argument is supplied, then only the items listed in {what} are set. Refer to setqflist() for the list of supported keys in {what}.

setmatches({list}) setmatches()
Restores a list of matches saved by getmatches() . Returns 0 if successful, otherwise -1. All current matches are cleared before the list is restored. See example for getmatches() .

setpos({expr}, {list}) setpos()
Set the position for {expr}. Possible values:
. the cursor

'x	mark x

{list} must be a List with four or five numbers:
    [bufnum, lnum, col, off]
    [bufnum, lnum, col, off, curswant]

"bufnum" is the buffer number. Zero can be used for the current buffer. When setting an uppercase mark "bufnum" is used for the mark position. For other marks it specifies the buffer to set the mark in. You can use the bufnr() function to turn a file name into a buffer number.
For setting the cursor and the ' mark "bufnum" is ignored, since these are associated with a window, not a buffer.
Does not change the jumplist.

"lnum" and "col" are the position in the buffer. The first column is 1. Use a zero "lnum" to delete a mark. If "col" is smaller than 1 then 1 is used.

The "off" number is only used when 'virtualedit' is set. Then it is the offset in screen columns from the start of the character. E.g., a position within a <Tab> or after the last character.

The "curswant" number is only used when setting the cursor position. It sets the preferred column for when moving the cursor vertically. When the "curswant" number is missing the preferred column is not set. When it is present and setting a mark position it is not used.

Note that for '< and '> changing the line number may result in the marks to be effectively be swapped, so that '< is always before '>.

Returns 0 when the position could be set, -1 otherwise.
An error message is given if {expr} is invalid.

Also see getpos() and getcurpos() .

This does not restore the preferred column for moving vertically; if you set the cursor position with this, j and k motions will jump to previous columns! Use cursor() to also set the preferred column. Also see the "curswant" key in winrestview() .

setqflist({list} [, {action} [, {what}]])	setqflist()
Create or replace or add to the quickfix list.

When {what} is not present, use the items in {list}. Each item must be a dictionary. Non-dictionary items in {list} are ignored. Each dictionary item can contain the following entries:

    bufnr	buffer number; must be the number of a valid

```
                buffer
    filename    name of a file; only used when "bufnr" is not
                present or it is invalid.
    module      name of a module; if given it will be used in
                quickfix error window instead of the filename.
    lnum        line number in the file
    pattern     search pattern used to locate the error
    col         column number
    vcol        when non-zero: "col" is visual column
                when zero: "col" is byte index
    nr          error number
    text        description of the error
    type        single-character error type, 'E', 'W', etc.
    valid       recognized error message

The "col", "vcol", "nr", "type" and "text" entries are
optional.  Either "lnum" or "pattern" entry can be used to
locate a matching error line.
If the "filename" and "bufnr" entries are not present or
neither the "lnum" or "pattern" entries are present, then the
item will not be handled as an error line.
If both "pattern" and "lnum" are present then "pattern" will
be used.
If the "valid" entry is not supplied, then the valid flag is
set when "bufnr" is a valid buffer or "filename" exists.
If you supply an empty {list}, the quickfix list will be
cleared.
Note that the list is not exactly the same as what
 getqflist()  returns.

{action} values:                                        E927
'a'     The items from {list} are added to the existing
        quickfix list. If there is no existing list, then a
        new list is created.

'r'     The items from the current quickfix list are replaced
        with the items from {list}.  This can also be used to
        clear the list:
                :call setqflist([], 'r')

'f'     All the quickfix lists in the quickfix stack are
        freed.

If {action} is not present or is set to ' ', then a new list
is created. The new quickfix list is added after the current
quickfix list in the stack and all the following lists are
freed. To add a new quickfix list at the end of the stack,
set "nr" in {what} to "$".

If the optional {what} dictionary argument is supplied, then
only the items listed in {what} are set. The first {list}
argument is ignored.  The following items can be specified in
{what}:
    context     quickfix list context. See  quickfix-context
```

```
                efm         errorformat to use when parsing text from
                            "lines". If this is not present, then the
                            'errorformat' option value is used.
                id          quickfix list identifier  quickfix-ID
                items       list of quickfix entries. Same as the {list}
                            argument.
                lines       use 'errorformat' to parse a list of lines and
                            add the resulting entries to the quickfix list
                            {nr} or {id}.  Only a  List  value is supported.
                nr          list number in the quickfix stack; zero
                            means the current quickfix list and "$" means
                            the last quickfix list
                title       quickfix list title text
            Unsupported keys in {what} are ignored.
            If the "nr" item is not present, then the current quickfix list
            is modified. When creating a new quickfix list, "nr" can be
            set to a value one greater than the quickfix stack size.
            When modifying a quickfix list, to guarantee that the correct
            list is modified, "id" should be used instead of "nr" to
            specify the list.

            Examples (See also  setqflist-examples ):
               :call setqflist([], 'r', {'title': 'My search'})
               :call setqflist([], 'r', {'nr': 2, 'title': 'Errors'})
               :call setqflist([], 'a', {'id':qfid, 'lines':["F1:10:L10"]})

            Returns zero for success, -1 for failure.

            This function can be used to create a quickfix list
            independent of the 'errorformat' setting.  Use a command like
            `:cc 1` to jump to the first position.

                                                              setreg()
setreg({regname}, {value} [, {options}])
            Set the register {regname} to {value}.
            {value} may be any value returned by  getreg() , including
            a  List .
            If {options} contains "a" or {regname} is upper case,
            then the value is appended.
            {options} can also contain a register type specification:
                "c" or "v"          characterwise  mode
                "l" or "V"          linewise  mode
                "b" or "<CTRL-V>"  blockwise-visual  mode
            If a number immediately follows "b" or "<CTRL-V>" then this is
            used as the width of the selection - if it is not specified
            then the width of the block is set to the number of characters
            in the longest line (counting a <Tab> as 1 character).

            If {options} contains no register settings, then the default
            is to use character mode unless {value} ends in a <NL> for
            string {value} and linewise mode for list {value}. Blockwise
            mode is never selected automatically.
            Returns zero for success, non-zero for failure.
```

E883
Note: you may not use List containing more than one item to set search and expression registers. Lists containing no items act like empty strings.

Examples:
```
:call setreg(v:register, @*)
:call setreg('*', @%, 'ac')
:call setreg('a', "1\n2\n3", 'b5')
```

This example shows using the functions to save and restore a register:
```
:let var_a = getreg('a', 1, 1)
:let var_amode = getregtype('a')
    ....
:call setreg('a', var_a, var_amode)
```
Note: you may not reliably restore register value without using the third argument to getreg() as without it newlines are represented as newlines AND Nul bytes are represented as newlines as well, see NL-used-for-Nul .

You can also change the type of a register by appending nothing:
```
:call setreg('a', '', 'al')
```

settabvar({tabnr}, {varname}, {val}) settabvar()
Set tab-local variable {varname} to {val} in tab page {tabnr}. t:var
Note that the variable name without "t:" must be used.
Tabs are numbered starting with one.
This function is not available in the sandbox .

settabwinvar({tabnr}, {winnr}, {varname}, {val}) settabwinvar()
Set option or local variable {varname} in window {winnr} to {val}.
Tabs are numbered starting with one. For the current tabpage use setwinvar() .
{winnr} can be the window number or the window-ID .
When {winnr} is zero the current window is used.
This also works for a global or local buffer option, but it doesn't work for a global or local buffer variable.
For a local buffer option the global value is unchanged.
Note that the variable name without "w:" must be used.
Examples:
```
:call settabwinvar(1, 1, "&list", 0)
:call settabwinvar(3, 2, "myvar", "foobar")
```
This function is not available in the sandbox .

setwinvar({nr}, {varname}, {val}) setwinvar()
Like settabwinvar() for the current tab page.
Examples:
```
:call setwinvar(1, "&list", 0)
:call setwinvar(2, "myvar", "foobar")
```

sha256({string}) sha256()
Returns a String with 64 hex characters, which is the SHA256 checksum of {string}.
{only available when compiled with the |+cryptv| feature}

shellescape({string} [, {special}]) shellescape()
Escape {string} for use as a shell command argument.
On MS-Windows and MS-DOS, when 'shellslash' is not set, it will enclose {string} in double quotes and double all double quotes within {string}.
Otherwise it will enclose {string} in single quotes and replace all "'" with "'\''".

When the {special} argument is present and it's a non-zero Number or a non-empty String (non-zero-arg), then special items such as "!", "%", "#" and "<cword>" will be preceded by a backslash. This backslash will be removed again by the :! command.

The "!" character will be escaped (again with a non-zero-arg {special}) when 'shell' contains "csh" in the tail. That is because for csh and tcsh "!" is used for history replacement even when inside single quotes.

With a non-zero-arg {special} the <NL> character is also escaped. When 'shell' containing "csh" in the tail it's escaped a second time.

Example of use with a :! command:
    :exe '!dir ' . shellescape(expand('<cfile>'), 1)
This results in a directory listing for the file under the cursor. Example of use with system() :
    :call system("chmod +w -- " . shellescape(expand("%")))
See also ::S .

shiftwidth() shiftwidth()
Returns the effective value of 'shiftwidth'. This is the 'shiftwidth' value unless it is zero, in which case it is the 'tabstop' value. This function was introduced with patch 7.3.694 in 2012, everybody should have it by now.

simplify({filename}) simplify()
Simplify the file name as much as possible without changing the meaning. Shortcuts (on MS-Windows) or symbolic links (on Unix) are not resolved. If the first path component in {filename} designates the current directory, this will be valid for the result as well. A trailing path separator is not removed either.
Example:
        simplify("./dir/.././/file/") == "./file/"
Note: The combination "dir/.." is only removed if "dir" is

a searchable directory or does not exist. On Unix, it is also removed when "dir" is a symbolic link within the same directory. In order to resolve all the involved symbolic links before simplifying the path name, use resolve() .

sin({expr}) sin()
Return the sine of {expr}, measured in radians, as a Float . {expr} must evaluate to a Float or a Number .
Examples:
```
:echo sin(100)
-0.506366
:echo sin(-4.01)
0.763301
```
{only available when compiled with the |+float| feature}

sinh({expr}) sinh()
Return the hyperbolic sine of {expr} as a Float in the range [-inf, inf].
{expr} must evaluate to a Float or a Number .
Examples:
```
:echo sinh(0.5)
0.521095
:echo sinh(-0.9)
-1.026517
```
{only available when compiled with the |+float| feature}

sort({list} [, {func} [, {dict}]]) sort() E702
Sort the items in {list} in-place. Returns {list}.

If you want a list to remain unmodified make a copy first:
```
:let sortedlist = sort(copy(mylist))
```

When {func} is omitted, is empty or zero, then sort() uses the string representation of each item to sort on. Numbers sort after Strings, Lists after Numbers. For sorting text in the current buffer use :sort .

When {func} is given and it is '1' or 'i' then case is ignored.

When {func} is given and it is 'n' then all items will be sorted numerical (Implementation detail: This uses the strtod() function to parse numbers, Strings, Lists, Dicts and Funcrefs will be considered as being 0).

When {func} is given and it is 'N' then all items will be sorted numerical. This is like 'n' but a string containing digits will be used as the number they represent.

When {func} is given and it is 'f' then all items will be sorted numerical. All values must be a Number or a Float.

When {func} is a Funcref or a function name, this function is called to compare items. The function is invoked with two items as argument and must return zero if they are equal, 1 or bigger if the first one sorts after the second one, -1 or smaller if the first one sorts before the second one.

{dict} is for functions with the "dict" attribute. It will be used to set the local variable "self". Dictionary-function

The sort is stable, items which compare equal (as number or as string) will keep their relative position. E.g., when sorting on numbers, text strings will sort next to each other, in the same order as they were originally.

Also see uniq() .

Example:
```
func MyCompare(i1, i2)
   return a:i1 == a:i2 ? 0 : a:i1 > a:i2 ? 1 : -1
endfunc
let sortedlist = sort(mylist, "MyCompare")
```
A shorter compare version for this specific simple case, which ignores overflow:
```
func MyCompare(i1, i2)
   return a:i1 - a:i2
endfunc
```

soundfold()

soundfold({word})
Return the sound-folded equivalent of {word}. Uses the first language in 'spelllang' for the current window that supports soundfolding. 'spell' must be set. When no sound folding is possible the {word} is returned unmodified.
This can be used for making spelling suggestions. Note that the method can be quite slow.

spellbadword()

spellbadword([{sentence}])
Without argument: The result is the badly spelled word under or after the cursor. The cursor is moved to the start of the bad word. When no bad word is found in the cursor line the result is an empty string and the cursor doesn't move.

With argument: The result is the first word in {sentence} that is badly spelled. If there are no spelling mistakes the result is an empty string.

The return value is a list with two items:
- The badly spelled word or an empty string.
- The type of the spelling error:
```
"bad"           spelling mistake
"rare"          rare word
"local"         word only valid in another region
```

```
                "caps"          word should start with Capital
        Example:
                echo spellbadword("the quik brown fox")
               ['quik', 'bad']

        The spelling information for the current window is used.  The
        'spell' option must be set and the value of 'spelllang' is
        used.

                                                        spellsuggest()
spellsuggest({word} [, {max} [, {capital}]])
        Return a  List  with spelling suggestions to replace {word}.
        When {max} is given up to this number of suggestions are
        returned.  Otherwise up to 25 suggestions are returned.

        When the {capital} argument is given and it's non-zero only
        suggestions with a leading capital will be given.  Use this
        after a match with 'spellcapcheck'.

        {word} can be a badly spelled word followed by other text.
        This allows for joining two words that were split.  The
        suggestions also include the following text, thus you can
        replace a line.

        {word} may also be a good word.  Similar words will then be
        returned.  {word} itself is not included in the suggestions,
        although it may appear capitalized.

        The spelling information for the current window is used.  The
        'spell' option must be set and the values of 'spelllang' and
        'spellsuggest' are used.

split({expr} [, {pattern} [, {keepempty}]])                     split()
        Make a  List  out of {expr}.  When {pattern} is omitted or
        empty each white-separated sequence of characters becomes an
        item.
        Otherwise the string is split where {pattern} matches,
        removing the matched characters. 'ignorecase' is not used
        here, add \c to ignore case.  /\c
        When the first or last item is empty it is omitted, unless the
        {keepempty} argument is given and it's non-zero.
        Other empty items are kept when {pattern} matches at least one
        character or when {keepempty} is non-zero.
        Example:
                :let words = split(getline('.'), '\W\+')
       To split a string in individual characters:
                :for c in split(mystring, '\zs')
       If you want to keep the separator you can also use '\zs' at
        the end of the pattern:
                :echo split('abc:def:ghi', ':\zs')
               ['abc:', 'def:', 'ghi']
        Splitting a table where the first element can be empty:
                :let items = split(line, ':', 1)
```

The opposite function is join() .

sqrt({expr}) sqrt()
Return the non-negative square root of Float {expr} as a Float .
{expr} must evaluate to a Float or a Number . When {expr} is negative the result is NaN (Not a Number).
Examples:
```
:echo sqrt(100)
10.0
:echo sqrt(-4.01)
nan
```
"nan" may be different, it depends on system libraries.
{only available when compiled with the |+float| feature}

str2float({expr}) str2float()
Convert String {expr} to a Float. This mostly works the same as when using a floating point number in an expression, see floating-point-format . But it's a bit more permissive.
E.g., "1e40" is accepted, while in an expression you need to write "1.0e40".
Text after the number is silently ignored.
The decimal point is always '.', no matter what the locale is set to. A comma ends the number: "12,345.67" is converted to 12.0. You can strip out thousands separators with substitute() :
```
let f = str2float(substitute(text, ',', '', 'g'))
```
{only available when compiled with the |+float| feature}

str2nr({expr} [, {base}]) str2nr()
Convert string {expr} to a number.
{base} is the conversion base, it can be 2, 8, 10 or 16.
When {base} is omitted base 10 is used. This also means that a leading zero doesn't cause octal conversion to be used, as with the default String to Number conversion.
When {base} is 16 a leading "0x" or "0X" is ignored. With a different base the result will be zero. Similarly, when {base} is 8 a leading "0" is ignored, and when {base} is 2 a leading "0b" or "0B" is ignored.
Text after the number is silently ignored.

strchars({expr} [, {skipcc}]) strchars()
The result is a Number, which is the number of characters in String {expr}.
When {skipcc} is omitted or zero, composing characters are counted separately.
When {skipcc} set to 1, Composing characters are ignored.
Also see strlen() , strdisplaywidth() and strwidth() .

{skipcc} is only available after 7.4.755. For backward

compatibility, you can define a wrapper function:

```
if has("patch-7.4.755")
  function s:strchars(str, skipcc)
    return strchars(a:str, a:skipcc)
  endfunction
else
  function s:strchars(str, skipcc)
    if a:skipcc
      return strlen(substitute(a:str, ".", "x", "g"))
    else
      return strchars(a:str)
    endif
  endfunction
endif
```

strcharpart({src}, {start} [, {len}]) strcharpart()

Like strpart() but using character index and length instead of byte index and length.
When a character index is used where a character does not exist it is assumed to be one character. For example:

```
strcharpart('abc', -1, 2)
```

results in 'a'.

strdisplaywidth({expr} [, {col}]) strdisplaywidth()

The result is a Number, which is the number of display cells String {expr} occupies on the screen when it starts at {col}. When {col} is omitted zero is used. Otherwise it is the screen column where to start. This matters for Tab characters.
The option settings of the current window are used. This matters for anything that's displayed differently, such as 'tabstop' and 'display'.
When {expr} contains characters with East Asian Width Class Ambiguous, this function's return value depends on 'ambiwidth'.
Also see strlen(), strwidth() and strchars().

strftime({format} [, {time}]) strftime()

The result is a String, which is a formatted date and time, as specified by the {format} string. The given {time} is used, or the current time if no time is given. The accepted {format} depends on your system, thus this is not portable!
See the manual page of the C function strftime() for the format. The maximum length of the result is 80 characters.
See also localtime() and getftime().
The language can be changed with the :language command.
Examples:

```
:echo strftime("%c")            Sun Apr 27 11:49:23 1997
:echo strftime("%Y %b %d %X")   1997 Apr 27 11:53:25
:echo strftime("%y%m%d %T")     970427 11:53:55
:echo strftime("%H:%M")         11:55
:echo strftime("%c", getftime("file.c"))
                                Show mod time of file.c.
```

Not available on all systems. To check use:

```
:if exists("*strftime")
```

strgetchar({str}, {index})   strgetchar()
Get character {index} from {str}. This uses a character index, not a byte index. Composing characters are considered separate characters here.
Also see strcharpart() and strchars().

stridx({haystack}, {needle} [, {start}])   stridx()
The result is a Number, which gives the byte index in {haystack} of the first occurrence of the String {needle}.
If {start} is specified, the search starts at index {start}.
This can be used to find a second match:
```
:let colon1 = stridx(line, ":")
:let colon2 = stridx(line, ":", colon1 + 1)
```
The search is done case-sensitive.
For pattern searches use match().
-1 is returned if the {needle} does not occur in {haystack}.
See also strridx().
Examples:
```
:echo stridx("An Example", "Example")      3
:echo stridx("Starting point", "Start")    0
:echo stridx("Starting point", "start")   -1
```
strstr() strchr()
stridx() works similar to the C function strstr(). When used with a single character it works similar to strchr().

string()
string({expr}) Return {expr} converted to a String. If {expr} is a Number, Float, String or a composition of them, then the result can be parsed back with eval().

{expr} type	result
String	'string' (single quotes are doubled)
Number	123
Float	123.123456 or 1.123456e8
Funcref	function('name')
List	[item, item]
Dictionary	{key: value, key: value}

When a List or Dictionary has a recursive reference it is replaced by "[...]" or "{...}". Using eval() on the result will then fail.

Also see strtrans().

strlen()
strlen({expr}) The result is a Number, which is the length of the String {expr} in bytes.
If the argument is a Number it is first converted to a String.
For other types an error is given.
If you want to count the number of multi-byte characters use strchars().
Also see len(), strdisplaywidth() and strwidth().

strpart({src}, {start} [, {len}])   strpart()

The result is a String, which is part of {src}, starting from byte {start}, with the byte length {len}.
To count characters instead of bytes use strcharpart() .

When bytes are selected which do not exist, this doesn't result in an error, the bytes are simply omitted.
If {len} is missing, the copy continues from {start} till the end of the {src}.

```
strpart("abcdefg", 3, 2)    == "de"
strpart("abcdefg", -2, 4)   == "ab"
strpart("abcdefg", 5, 4)    == "fg"
strpart("abcdefg", 3)       == "defg"
```

Note: To get the first character, {start} must be 0. For example, to get three bytes under and after the cursor:

```
strpart(getline("."), col(".") - 1, 3)
```

strridx({haystack}, {needle} [, {start}]) strridx()

The result is a Number, which gives the byte index in {haystack} of the last occurrence of the String {needle}.
When {start} is specified, matches beyond this index are ignored. This can be used to find a match before a previous match:

```
:let lastcomma = strridx(line, ",")
:let comma2 = strridx(line, ",", lastcomma - 1)
```

The search is done case-sensitive.
For pattern searches use match() .
-1 is returned if the {needle} does not occur in {haystack}.
If the {needle} is empty the length of {haystack} is returned.
See also stridx() . Examples:

```
:echo strridx("an angry armadillo", "an")          3
```

strrchr()

When used with a single character it works similar to the C function strrchr().

strtrans({expr}) strtrans()

The result is a String, which is {expr} with all unprintable characters translated into printable characters 'isprint' .
Like they are shown in a window. Example:

```
echo strtrans(@a)
```

This displays a newline in register a as "^@" instead of starting a new line.

strwidth({expr}) strwidth()

The result is a Number, which is the number of display cells String {expr} occupies. A Tab character is counted as one cell, alternatively use strdisplaywidth() .
When {expr} contains characters with East Asian Width Class Ambiguous, this function's return value depends on 'ambiwidth'.
Also see strlen() , strdisplaywidth() and strchars() .

submatch({nr} [, {list}]) submatch() E935

Only for an expression in a :substitute command or substitute() function.

Returns the {nr}'th submatch of the matched text. When {nr}
is 0 the whole matched text is returned.
Note that a NL in the string can stand for a line break of a
multi-line match or a NUL character in the text.
Also see sub-replace-expression .

If {list} is present and non-zero then submatch() returns
a list of strings, similar to getline() with two arguments.
NL characters in the text represent NUL characters in the
text.
Only returns more than one item for :substitute , inside
substitute() this list will always contain one or zero
items, since there are no real line breaks.

When substitute() is used recursively only the submatches in
the current (deepest) call can be obtained.

Examples:
```
:s/\d\+/\=submatch(0) + 1/
:echo substitute(text, '\d\+', '\=submatch(0) + 1', '')
```
This finds the first number in the line and adds one to it.
A line break is included as a newline character.

substitute({expr}, {pat}, {sub}, {flags}) substitute()
The result is a String, which is a copy of {expr}, in which
the first match of {pat} is replaced with {sub}.
When {flags} is "g", all matches of {pat} in {expr} are
replaced. Otherwise {flags} should be "".

This works like the ":substitute" command (without any flags).
But the matching with {pat} is always done like the 'magic'
option is set and 'cpoptions' is empty (to make scripts
portable). 'ignorecase' is still relevant, use /\c or /\C
if you want to ignore or match case and ignore 'ignorecase'.
'smartcase' is not used. See string-match for how {pat} is
used.

A "~" in {sub} is not replaced with the previous {sub}.
Note that some codes in {sub} have a special meaning
sub-replace-special . For example, to replace something with
"\n" (two characters), use "\\\\n" or '\\n'.

When {pat} does not match in {expr}, {expr} is returned
unmodified.

Example:
```
:let &path = substitute(&path, ",\\=[^,]*$", "", "")
```
This removes the last component of the 'path' option.
```
:echo substitute("testing", ".*", "\\U\\0", "")
```
results in "TESTING".

When {sub} starts with "\=", the remainder is interpreted as
an expression. See sub-replace-expression . Example:
```
:echo substitute(s, '%\(\x\x\)',
```

```
                        \ '\=nr2char("0x" . submatch(1))', 'g')

              When {sub} is a Funcref that function is called, with one
               optional argument.  Example:
                  :echo substitute(s, '%\(\x\x\)', SubNr, 'g')
              The optional argument is a list which contains the whole
               matched string and up to nine submatches, like what
                submatch()  returns.  Example:
                  :echo substitute(s, '%\(\x\x\)', {m -> '0x' . m[1]}, 'g')

synID({lnum}, {col}, {trans})                                  synID()
              The result is a Number, which is the syntax ID at the position
              {lnum} and {col} in the current window.
              The syntax ID can be used with  synIDattr()  and
               synIDtrans()  to obtain syntax information about text.

              {col} is 1 for the leftmost column, {lnum} is 1 for the first
              line.  'synmaxcol' applies, in a longer line zero is returned.
              Note that when the position is after the last character,
              that's where the cursor can be in Insert mode, synID() returns
              zero.

              When {trans} is  TRUE , transparent items are reduced to the
              item that they reveal.  This is useful when wanting to know
              the effective color.  When {trans} is  FALSE , the transparent
              item is returned.  This is useful when wanting to know which
              syntax item is effective (e.g. inside parens).
              Warning: This function can be very slow.  Best speed is
              obtained by going through the file in forward direction.

              Example (echoes the name of the syntax item under the cursor):
                      :echo synIDattr(synID(line("."), col("."), 1), "name")

synIDattr({synID}, {what} [, {mode}])                          synIDattr()
              The result is a String, which is the {what} attribute of
              syntax ID {synID}.  This can be used to obtain information
              about a syntax item.
              {mode} can be "gui", "cterm" or "term", to get the attributes
              for that mode.  When {mode} is omitted, or an invalid value is
              used, the attributes for the currently active highlighting are
              used (GUI, cterm or term).
              Use synIDtrans() to follow linked highlight groups.
              {what}          result
              "name"          the name of the syntax item
              "fg"            foreground color (GUI: color name used to set
                              the color, cterm: color number as a string,
                              term: empty string)
              "bg"            background color (as with "fg")
              "font"          font name (only available in the GUI)
                               highlight-font
              "sp"            special color (as with "fg")  highlight-guisp
              "fg#"           like "fg", but for the GUI and the GUI is
                              running the name in "#RRGGBB" form
```

```
                "bg#"           like "fg#" for "bg"
                "sp#"           like "fg#" for "sp"
                "bold"          "1" if bold
                "italic"        "1" if italic
                "reverse"       "1" if reverse
                "inverse"       "1" if inverse (= reverse)
                "standout"      "1" if standout
                "underline"     "1" if underlined
                "undercurl"     "1" if undercurled
                "strike"        "1" if strikethrough

                Example (echoes the color of the syntax item under the
                cursor):
        :echo synIDattr(synIDtrans(synID(line("."), col("."), 1)), "fg")

synIDtrans({synID})                                     synIDtrans()
                The result is a Number, which is the translated syntax ID of
                {synID}.  This is the syntax group ID of what is being used to
                highlight the character.  Highlight links given with
                ":highlight link" are followed.

synconcealed({lnum}, {col})                             synconcealed()
                The result is a List with currently three items:
                1. The first item in the list is 0 if the character at the
                   position {lnum} and {col} is not part of a concealable
                   region, 1 if it is.
                2. The second item in the list is a string. If the first item
                   is 1, the second item contains the text which will be
                   displayed in place of the concealed text, depending on the
                   current setting of 'conceallevel' and 'listchars'.
                3. The third and final item in the list is a number
                   representing the specific syntax region matched in the
                   line. When the character is not concealed the value is
                   zero. This allows detection of the beginning of a new
                   concealable region if there are two consecutive regions
                   with the same replacement character.  For an example, if
                   the text is "123456" and both "23" and "45" are concealed
                   and replace by the character "X", then:
                        call                    returns
                        synconcealed(lnum, 1)   [0, '', 0]
                        synconcealed(lnum, 2)   [1, 'X', 1]
                        synconcealed(lnum, 3)   [1, 'X', 1]
                        synconcealed(lnum, 4)   [1, 'X', 2]
                        synconcealed(lnum, 5)   [1, 'X', 2]
                        synconcealed(lnum, 6)   [0, '', 0]

synstack({lnum}, {col})                                 synstack()
                Return a  List , which is the stack of syntax items at the
                position {lnum} and {col} in the current window.  Each item in
                the List is an ID like what  synID()  returns.
                The first item in the List is the outer region, following are
                items contained in that one.  The last one is what  synID()
                returns, unless not the whole item is highlighted or it is a
```

transparent item.
This function is useful for debugging a syntax file.
Example that shows the syntax stack under the cursor:

```
for id in synstack(line("."), col("."))
   echo synIDattr(id, "name")
endfor
```

When the position specified with {lnum} and {col} is invalid nothing is returned. The position just after the last character in a line and the first column in an empty line are valid positions.

system({expr} [, {input}]) system() E677

Get the output of the shell command {expr} as a string. See systemlist() to get the output as a List.

When {input} is given and is a string this string is written to a file and passed as stdin to the command. The string is written as-is, you need to take care of using the correct line separators yourself.
If {input} is given and is a List it is written to the file in a way writefile() does with {binary} set to "b" (i.e. with a newline between each list item with newlines inside list items converted to NULs).
When {input} is given and is a number that is a valid id for an existing buffer then the content of the buffer is written to the file line by line, each line terminated by a NL and NULs characters where the text has a NL.

Pipes are not used, the 'shelltemp' option is not used.

When prepended by :silent the terminal will not be set to cooked mode. This is meant to be used for commands that do not need the user to type. It avoids stray characters showing up on the screen which require CTRL-L to remove.

```
:silent let f = system('ls *.vim')
```

Note: Use shellescape() or ::S with expand() or fnamemodify() to escape special characters in a command argument. Newlines in {expr} may cause the command to fail.
The characters in 'shellquote' and 'shellxquote' may also cause trouble.
This is not to be used for interactive commands.

The result is a String. Example:

```
:let files = system("ls " .  shellescape(expand('%:h')))
:let files = system('ls ' . expand('%:h:S'))
```

To make the result more system-independent, the shell output is filtered to replace <CR> with <NL> for Macintosh, and <CR><NL> with <NL> for DOS-like systems.
To avoid the string being truncated at a NUL, all NUL characters are replaced with SOH (0x01).

The command executed is constructed using several options:

'shell' 'shellcmdflag' 'shellxquote' {expr} 'shellredir' {tmp} 'shellxquote'
({tmp} is an automatically generated file name).
For Unix and OS/2 braces are put around {expr} to allow for
concatenated commands.

The command will be executed in "cooked" mode, so that a
CTRL-C will interrupt the command (on Unix at least).

The resulting error code can be found in v:shell_error .
This function will fail in restricted-mode .

Note that any wrong value in the options mentioned above may
make the function fail. It has also been reported to fail
when using a security agent application.
Unlike ":!cmd" there is no automatic check for changed files.
Use :checktime to force a check.

systemlist({expr} [, {input}]) systemlist()
Same as system() , but returns a List with lines (parts of
output separated by NL) with NULs transformed into NLs. Output
is the same as readfile() will output with {binary} argument
set to "b". Note that on MS-Windows you may get trailing CR
characters.

Returns an empty string on error.

tabpagebuflist([{arg}]) tabpagebuflist()
The result is a List , where each item is the number of the
buffer associated with each window in the current tab page.
{arg} specifies the number of the tab page to be used. When
omitted the current tab page is used.
When {arg} is invalid the number zero is returned.
To get a list of all buffers in all tabs use this:

```
let buflist = []
for i in range(tabpagenr('$'))
   call extend(buflist, tabpagebuflist(i + 1))
endfor
```

Note that a buffer may appear in more than one window.

tabpagenr([{arg}]) tabpagenr()
The result is a Number, which is the number of the current
tab page. The first tab page has number 1.
When the optional argument is "$", the number of the last tab
page is returned (the tab page count).
The number can be used with the :tab command.

tabpagewinnr({tabarg} [, {arg}]) tabpagewinnr()
Like winnr() but for tab page {tabarg}.
{tabarg} specifies the number of tab page to be used.
{arg} is used like with winnr() :

- When omitted the current window number is returned. This is
  the window which will be used when going to this tab page.
- When "$" the number of windows is returned.
- When "#" the previous window nr is returned.
Useful examples:
```
    tabpagewinnr(1)         " current window of tab page 1
    tabpagewinnr(4, '$')    " number of windows in tab page 4
```
When {tabarg} is invalid zero is returned.

tagfiles()

tagfiles() Returns a List with the file names used to search for tags for the current buffer. This is the 'tags' option expanded.

taglist({expr} [, {filename}]) taglist()

Returns a list of tags matching the regular expression {expr}.

If {filename} is passed it is used to prioritize the results in the same way that :tselect does. See tag-priority . {filename} should be the full path of the file.

Each list item is a dictionary with at least the following entries:

name	Name of the tag.
filename	Name of the file where the tag is defined. It is either relative to the current directory or a full path.
cmd	Ex command used to locate the tag in the file.
kind	Type of the tag. The value for this entry depends on the language specific kind values. Only available when using a tags file generated by Exuberant ctags or hdrtag.
static	A file specific tag. Refer to static-tag for more information.

More entries may be present, depending on the content of the tags file: access, implementation, inherits and signature. Refer to the ctags documentation for information about these fields. For C code the fields "struct", "class" and "enum" may appear, they give the name of the entity the tag is contained in.

The ex-command "cmd" can be either an ex search pattern, a line number or a line number followed by a byte number.

If there are no matching tags, then an empty list is returned.

To get an exact tag match, the anchors '^' and '$' should be used in {expr}. This also make the function work faster. Refer to tag-regexp for more information about the tag search regular expression pattern.

Refer to 'tags' for information about how the tags file is

located by Vim. Refer to tags-file-format for the format of the tags file generated by the different ctags tools.

tan({expr}) tan()
Return the tangent of {expr}, measured in radians, as a Float in the range [-inf, inf].
{expr} must evaluate to a Float or a Number .
Examples:
```
:echo tan(10)
0.648361
:echo tan(-4.01)
-1.181502
```
{only available when compiled with the |+float| feature}

tanh({expr}) tanh()
Return the hyperbolic tangent of {expr} as a Float in the range [-1, 1].
{expr} must evaluate to a Float or a Number .
Examples:
```
:echo tanh(0.5)
0.462117
:echo tanh(-1)
-0.761594
```
{only available when compiled with the |+float| feature}

tempname() tempname() temp-file-name
The result is a String, which is the name of a file that doesn't exist. It can be used for a temporary file. The name is different for at least 26 consecutive calls. Example:
```
:let tmpfile = tempname()
:exe "redir > " . tmpfile
```
For Unix, the file will be in a private directory tempfile . For MS-Windows forward slashes are used when the 'shellslash' option is set or when 'shellcmdflag' starts with '-'.

term_dumpdiff() term_dumpdiff({filename}, {filename} [, {options}])
Open a new window displaying the difference between the two files. The files must have been created with term_dumpwrite() .
Returns the buffer number or zero when the diff fails.
Also see terminal-diff .
NOTE: this does not work with double-width characters yet.

The top part of the buffer contains the contents of the first file, the bottom part of the buffer contains the contents of the second file. The middle part shows the differences. The parts are separated by a line of dashes.

If the {options} argument is present, it must be a Dict with these possible members:
"term_name" name to use for the buffer name, instead

```
                                of the first file name.
                "term_rows"     vertical size to use for the terminal,
                                instead of using 'termwinsize'
                "term_cols"     horizontal size to use for the terminal,
                                instead of using 'termwinsize'
                "vertical"      split the window vertically
                "curwin"        use the current window, do not split the
                                window; fails if the current buffer
                                cannot be  abandon ed
                "norestore"     do not add the terminal window to a
                                session file

            Each character in the middle part indicates a difference. If
            there are multiple differences only the first in this list is
            used:
                    X       different character
                    w       different width
                    f       different foreground color
                    b       different background color
                    a       different attribute
                    +       missing position in first file
                    -       missing position in second file

            Using the "s" key the top and bottom parts are swapped.  This
            makes it easy to spot a difference.

                                                        term_dumpload()
term_dumpload({filename} [, {options}])
            Open a new window displaying the contents of {filename}
            The file must have been created with  term_dumpwrite() .
            Returns the buffer number or zero when it fails.
            Also see  terminal-diff .

            For {options} see  term_dumpdiff() .

                                                        term_dumpwrite()
term_dumpwrite({buf}, {filename} [, {options}])
            Dump the contents of the terminal screen of {buf} in the file
            {filename}.  This uses a format that can be used with
             term_dumpload()  and  term_dumpdiff() .
            If {filename} already exists an error is given.  E953
            Also see  terminal-diff .

            {options} is a dictionary with these optional entries:
                    "rows"          maximum number of rows to dump
                    "columns"       maximum number of columns to dump

term_getaltscreen({buf})                                term_getaltscreen()
            Returns 1 if the terminal of {buf} is using the alternate
            screen.
            {buf} is used as with  term_getsize() .
            {only available when compiled with the |+terminal| feature}

term_getansicolors({buf})                               term_getansicolors()
```

Get the ANSI color palette in use by terminal {buf}.
Returns a List of length 16 where each element is a String
representing a color in hexadecimal "#rrggbb" format.
Also see term_setansicolors() and g:terminal_ansi_colors .
If neither was used returns the default colors.

{buf} is used as with term_getsize() . If the buffer does not
exist or is not a terminal window, an empty list is returned.
{only available when compiled with the +terminal feature and
with GUI enabled and/or the +termguicolors feature}

term_getattr({attr}, {what}) term_getattr()
Given {attr}, a value returned by term_scrape() in the "attr"
item, return whether {what} is on. {what} can be one of:
bold
italic
underline
strike
reverse
{only available when compiled with the |+terminal| feature}

term_getcursor({buf}) term_getcursor()
Get the cursor position of terminal {buf}. Returns a list with
two numbers and a dictionary: [row, col, dict].

"row" and "col" are one based, the first screen cell is row
1, column 1. This is the cursor position of the terminal
itself, not of the Vim window.

"dict" can have these members:
"visible" one when the cursor is visible, zero when it
is hidden.
"blink" one when the cursor is visible, zero when it
is hidden.
"shape" 1 for a block cursor, 2 for underline and 3
for a vertical bar.

{buf} must be the buffer number of a terminal window. If the
buffer does not exist or is not a terminal window, an empty
list is returned.
{only available when compiled with the |+terminal| feature}

term_getjob({buf}) term_getjob()
Get the Job associated with terminal window {buf}.
{buf} is used as with term_getsize() .
Returns v:null when there is no job.
{only available when compiled with the |+terminal| feature}

term_getline({buf}, {row}) term_getline()
Get a line of text from the terminal window of {buf}.
{buf} is used as with term_getsize() .

The first line has {row} one. When {row} is "." the cursor
line is used. When {row} is invalid an empty string is

returned.

To get attributes of each character use term_scrape() .
{only available when compiled with the |+terminal| feature}

term_getscrolled({buf}) term_getscrolled()
Return the number of lines that scrolled to above the top of terminal {buf}. This is the offset between the row number used for term_getline() and getline() , so that:
```
term_getline(buf, N)
```
is equal to:
```
`getline(N + term_getscrolled(buf))
```
(if that line exists).

{buf} is used as with term_getsize() .
{only available when compiled with the |+terminal| feature}

term_getsize({buf}) term_getsize()
Get the size of terminal {buf}. Returns a list with two numbers: [rows, cols]. This is the size of the terminal, not the window containing the terminal.

{buf} must be the buffer number of a terminal window. Use an empty string for the current buffer. If the buffer does not exist or is not a terminal window, an empty list is returned.
{only available when compiled with the |+terminal| feature}

term_getstatus({buf}) term_getstatus()
Get the status of terminal {buf}. This returns a comma separated list of these items:
```
running         job is running
finished        job has finished
normal          in Terminal-Normal mode
```
One of "running" or "finished" is always present.

{buf} must be the buffer number of a terminal window. If the buffer does not exist or is not a terminal window, an empty string is returned.
{only available when compiled with the |+terminal| feature}

term_gettitle({buf}) term_gettitle()
Get the title of terminal {buf}. This is the title that the job in the terminal has set.

{buf} must be the buffer number of a terminal window. If the buffer does not exist or is not a terminal window, an empty string is returned.
{only available when compiled with the |+terminal| feature}

term_gettty({buf} [, {input}]) term_gettty()
Get the name of the controlling terminal associated with terminal window {buf}. {buf} is used as with term_getsize() .

When {input} is omitted or 0, return the name for writing

(stdout). When {input} is 1 return the name for reading
(stdin). On UNIX, both return same name.
{only available when compiled with the |+terminal| feature}

term_list() term_list()
Return a list with the buffer numbers of all buffers for
terminal windows.
{only available when compiled with the |+terminal| feature}

term_scrape({buf}, {row}) term_scrape()
Get the contents of {row} of terminal screen of {buf}.
For {buf} see term_getsize() .

The first line has {row} one. When {row} is "." the cursor
line is used. When {row} is invalid an empty string is
returned.

Return a List containing a Dict for each screen cell:
    "chars"   character(s) at the cell
    "fg"   foreground color as #rrggbb
    "bg"   background color as #rrggbb
    "attr"   attributes of the cell, use term_getattr()
                to get the individual flags
    "width"   cell width: 1 or 2
{only available when compiled with the |+terminal| feature}

term_sendkeys({buf}, {keys}) term_sendkeys()
Send keystrokes {keys} to terminal {buf}.
{buf} is used as with term_getsize() .

{keys} are translated as key sequences. For example, "\<c-x>"
means the character CTRL-X.
{only available when compiled with the |+terminal| feature}

term_setansicolors({buf}, {colors}) term_setansicolors()
Set the ANSI color palette used by terminal {buf}.
{colors} must be a List of 16 valid color names or hexadecimal
color codes, like those accepted by highlight-guifg .
Also see term_getansicolors() and g:terminal_ansi_colors .

The colors normally are:
        0   black
        1   dark red
        2   dark green
        3   brown
        4   dark blue
        5   dark magenta
        6   dark cyan
        7   light grey
        8   dark grey
        9   red
        10   green
        11   yellow
        12   blue

```
                13   magenta
                14   cyan
                15   white

            These colors are used in the GUI and in the terminal when
            'termguicolors' is set.  When not using GUI colors (GUI mode
            or 'termguicolors'), the terminal window always uses the 16
            ANSI colors of the underlying terminal.
            {only available when compiled with the  +terminal  feature and
            with GUI enabled and/or the  +termguicolors  feature}

term_setkill({buf}, {how})                                  term_setkill()
            When exiting Vim or trying to close the terminal window in
            another way, {how} defines whether the job in the terminal can
            be stopped.
            When {how} is empty (the default), the job will not be
            stopped, trying to exit will result in  E947 .
            Otherwise, {how} specifies what signal to send to the job.
            See  job_stop()  for the values.

            After sending the signal Vim will wait for up to a second to
            check that the job actually stopped.

term_setrestore({buf}, {command})                           term_setrestore()
            Set the command to write in a session file to restore the job
            in this terminal.  The line written in the session file is:
                    terminal ++curwin ++cols=%d ++rows=%d {command}
           Make sure to escape the command properly.

            Use an empty {command} to run 'shell'.
            Use "NONE" to not restore this window.
            {only available when compiled with the |+terminal| feature}

term_setsize({buf}, {rows}, {cols})              term_setsize()   E955
            Set the size of terminal {buf}. The size of the window
            containing the terminal will also be adjusted, if possible.
            If {rows} or {cols} is zero or negative, that dimension is not
            changed.

            {buf} must be the buffer number of a terminal window.  Use an
            empty string for the current buffer.  If the buffer does not
            exist or is not a terminal window, an error is given.
            {only available when compiled with the |+terminal| feature}

term_start({cmd}, {options})                                term_start()
            Open a terminal window and run {cmd} in it.

            {cmd} can be a string or a List, like with  job_start() . The
            string "NONE" can be used to open a terminal window without
            starting a job, the pty of the terminal can be used by a
            command like gdb.

            Returns the buffer number of the terminal window.  If {cmd}
            cannot be executed the window does open and shows an error
```

message.
If opening the window fails zero is returned.

{options} are similar to what is used for job_start() , see job-options . However, not all options can be used. These are supported:
   all timeout options
   "stoponexit"
   "callback", "out_cb", "err_cb"
   "exit_cb", "close_cb"
   "in_io", "in_top", "in_bot", "in_name", "in_buf"
   "out_io", "out_name", "out_buf", "out_modifiable", "out_msg"
   "err_io", "err_name", "err_buf", "err_modifiable", "err_msg"
However, at least one of stdin, stdout or stderr must be connected to the terminal. When I/O is connected to the terminal then the callback function for that part is not used.

There are extra options:

"term_name"	name to use for the buffer name, instead of the command name.
"term_rows"	vertical size to use for the terminal, instead of using 'termwinsize'
"term_cols"	horizontal size to use for the terminal, instead of using 'termwinsize'
"vertical"	split the window vertically; note that other window position can be defined with command modifiers, such as :belowright .
"curwin"	use the current window, do not split the window; fails if the current buffer cannot be abandon ed
"hidden"	do not open a window
"norestore"	do not add the terminal window to a session file
"term_kill"	what to do when trying to close the terminal window, see term_setkill()
"term_finish"	What to do when the job is finished: "close": close any windows "open": open window if needed Note that "open" can be interruptive. See term++close and term++open .
"term_opencmd"	command to use for opening the window when "open" is used for "term_finish"; must have "%d" where the buffer number goes, e.g. "10split|buffer %d"; when not specified "botright sbuf %d" is used
"eof_chars"	Text to send after all buffer lines were written to the terminal. When not set CTRL-D is used on MS-Windows. For Python use CTRL-Z or "exit()". For a shell use "exit". A CR is always added.
"ansi_colors"	A list of 16 color names or hex codes defining the ANSI palette used in GUI color modes. See g:terminal_ansi_colors .

{only available when compiled with the |+terminal| feature}

term_wait({buf} [, {time}]) term_wait()
Wait for pending updates of {buf} to be handled.
{buf} is used as with term_getsize() .
{time} is how long to wait for updates to arrive in msec. If not set then 10 msec will be used.
{only available when compiled with the |+terminal| feature}

test_alloc_fail({id}, {countdown}, {repeat}) test_alloc_fail()
This is for testing: If the memory allocation with {id} is called, then decrement {countdown}, and when it reaches zero let memory allocation fail {repeat} times. When {repeat} is smaller than one it fails one time.

test_autochdir() test_autochdir()
Set a flag to enable the effect of 'autochdir' before Vim startup has finished.

test_feedinput({string}) test_feedinput()
Characters in {string} are queued for processing as if they were typed by the user. This uses a low level input buffer. This function works only when with +unix or GUI is running.

test_garbagecollect_now() test_garbagecollect_now()
Like garbagecollect(), but executed right away. This must only be called directly to avoid any structure to exist internally, and v:testing must have been set before calling any function.

test_ignore_error({expr}) test_ignore_error()
Ignore any error containing {expr}. A normal message is given instead.
This is only meant to be used in tests, where catching the error with try/catch cannot be used (because it skips over following code).
{expr} is used literally, not as a pattern.
There is currently no way to revert this.

test_null_channel() test_null_channel()
Return a Channel that is null. Only useful for testing.
{only available when compiled with the +channel feature}

test_null_dict() test_null_dict()
Return a Dict that is null. Only useful for testing.

test_null_job() test_null_job()
Return a Job that is null. Only useful for testing.
{only available when compiled with the +job feature}

test_null_list() test_null_list()
Return a List that is null. Only useful for testing.

test_null_partial() test_null_partial()

Return a Partial that is null. Only useful for testing.

test_null_string() test_null_string()
Return a String that is null. Only useful for testing.

test_override({name}, {val}) test_override()
Overrides certain parts of Vims internal processing to be able
to run tests. Only to be used for testing Vim!
The override is enabled when {val} is non-zero and removed
when {val} is zero.
Current supported values for name are:

name	effect when {val} is non-zero
redraw	disable the redrawing() function
char_avail	disable the char_avail() function
starting	reset the "starting" variable, see below
nfa_fail	makes the NFA regexp engine fail to force a fallback to the old engine
ALL	clear all overrides ({val} is not used)

"starting" is to be used when a test should behave like
startup was done. Since the tests are run by sourcing a
script the "starting" variable is non-zero. This is usually a
good thing (tests run faster), but sometimes changes behavior
in a way that the test doesn't work properly.
When using:
```
call test_override('starting', 1)
```
The value of "starting" is saved. It is restored by:
```
call test_override('starting', 0)
```

test_settime({expr}) test_settime()
Set the time Vim uses internally. Currently only used for
timestamps in the history, as they are used in viminfo, and
for undo.
Using a value of 1 makes Vim not sleep after a warning or
error message.
{expr} must evaluate to a number. When the value is zero the
normal behavior is restored.

timer_info([{id}]) timer_info()
Return a list with information about timers.
When {id} is given only information about this timer is
returned. When timer {id} does not exist an empty list is
returned.
When {id} is omitted information about all timers is returned.

For each timer the information is stored in a Dictionary with
these items:

"id"	the timer ID
"time"	time the timer was started with
"remaining"	time until the timer fires
"repeat"	number of times the timer will still fire; -1 means forever

```
                "callback"      the callback
                "paused"        1 if the timer is paused, 0 otherwise

            {only available when compiled with the |+timers| feature}

timer_pause({timer}, {paused})                              timer_pause()
            Pause or unpause a timer.  A paused timer does not invoke its
            callback when its time expires.  Unpausing a timer may cause
            the callback to be invoked almost immediately if enough time
            has passed.

            Pausing a timer is useful to avoid the callback to be called
            for a short time.

            If {paused} evaluates to a non-zero Number or a non-empty
            String, then the timer is paused, otherwise it is unpaused.
            See  non-zero-arg .

            {only available when compiled with the |+timers| feature}

                                                 timer_start()   timer   timers
timer_start({time}, {callback} [, {options}])
            Create a timer and return the timer ID.

            {time} is the waiting time in milliseconds. This is the
            minimum time before invoking the callback.  When the system is
            busy or Vim is not waiting for input the time will be longer.

            {callback} is the function to call.  It can be the name of a
            function or a  Funcref .  It is called with one argument, which
            is the timer ID.  The callback is only invoked when Vim is
            waiting for input.

            {options} is a dictionary.  Supported entries:
               "repeat"     Number of times to repeat calling the
                            callback.  -1 means forever.  When not present
                            the callback will be called once.
                            If the timer causes an error three times in a
                            row the repeat is cancelled.  This avoids that
                            Vim becomes unusable because of all the error
                            messages.

            Example:
                    func MyHandler(timer)
                      echo 'Handler called'
                    endfunc
                    let timer = timer_start(500, 'MyHandler',
                            \ {'repeat': 3})
            This will invoke MyHandler() three times at 500 msec
            intervals.

            {only available when compiled with the |+timers| feature}

timer_stop({timer})                                         timer_stop()
```

Stop a timer. The timer callback will no longer be invoked.
{timer} is an ID returned by timer_start(), thus it must be a
Number. If {timer} does not exist there is no error.

{only available when compiled with the |+timers| feature}

timer_stopall() timer_stopall()
Stop all timers. The timer callbacks will no longer be
invoked. Useful if some timers is misbehaving. If there are
no timers there is no error.

{only available when compiled with the |+timers| feature}

tolower({expr}) tolower()
The result is a copy of the String given, with all uppercase
characters turned into lowercase (just like applying gu to
the string).

toupper({expr}) toupper()
The result is a copy of the String given, with all lowercase
characters turned into uppercase (just like applying gU to
the string).

tr({src}, {fromstr}, {tostr}) tr()
The result is a copy of the {src} string with all characters
which appear in {fromstr} replaced by the character in that
position in the {tostr} string. Thus the first character in
{fromstr} is translated into the first character in {tostr}
and so on. Exactly like the unix "tr" command.
This code also deals with multibyte characters properly.

Examples:
        echo tr("hello there", "ht", "HT")
returns "Hello THere"
        echo tr("<blob>", "<>", "{}")
returns "{blob}"

trim({text}[, {mask}]) trim()
Return {text} as a String where any character in {mask} is
removed from the beginning and end of {text}.
If {mask} is not given, {mask} is all characters up to 0x20,
which includes Tab, space, NL and CR, plus the non-breaking
space character 0xa0.
This code deals with multibyte characters properly.

Examples:
        echo trim("   some text ")
returns "some text"
        echo trim(" \r\t\t\r RESERVE \t\n\x0B\xA0") . "_TAIL"
returns "RESERVE_TAIL"
        echo trim("rm<Xrm<>X>rrm", "rm<>")
returns "Xrm<>X" (characters in the middle are not removed)

trunc({expr}) trunc()

Return the largest integral value with magnitude less than or
equal to {expr} as a Float (truncate towards zero).
{expr} must evaluate to a Float or a Number .
Examples:
```
 echo trunc(1.456)
1.0
 echo trunc(-5.456)
-5.0
 echo trunc(4.0)
4.0
```
{only available when compiled with the |+float| feature}

type({expr}) type()
The result is a Number representing the type of {expr}.
Instead of using the number directly, it is better to use the
v:t_ variable that has the value:

Number:	0	v:t_number
String:	1	v:t_string
Funcref:	2	v:t_func
List:	3	v:t_list
Dictionary:	4	v:t_dict
Float:	5	v:t_float
Boolean:	6	v:t_bool (v:false and v:true)
None	7	v:t_none (v:null and v:none)
Job	8	v:t_job
Channel	9	v:t_channel

For backward compatibility, this method can be used:
```
:if type(myvar) == type(0)
:if type(myvar) == type("")
:if type(myvar) == type(function("tr"))
:if type(myvar) == type([])
:if type(myvar) == type({})
:if type(myvar) == type(0.0)
:if type(myvar) == type(v:false)
:if type(myvar) == type(v:none)
```
To check if the v:t_ variables exist use this:
```
:if exists('v:t_number')
```

undofile({name}) undofile()
Return the name of the undo file that would be used for a file
with name {name} when writing. This uses the 'undodir'
option, finding directories that exist. It does not check if
the undo file exists.
{name} is always expanded to the full path, since that is what
is used internally.
If {name} is empty undofile() returns an empty string, since a
buffer without a file name will not write an undo file.
Useful in combination with :wundo and :rundo .
When compiled without the +persistent_undo option this always
returns an empty string.

undotree() undotree()
Return the current state of the undo tree in a dictionary with
the following items:

"seq_last" The highest undo sequence number used.
"seq_cur" The sequence number of the current position in the undo tree. This differs from "seq_last" when some changes were undone.
"time_cur" Time last used for :earlier and related commands. Use strftime() to convert to something readable.
"save_last" Number of the last file write. Zero when no write yet.
"save_cur" Number of the current position in the undo tree.
"synced" Non-zero when the last undo block was synced. This happens when waiting from input from the user. See undo-blocks .
"entries" A list of dictionaries with information about undo blocks.

The first item in the "entries" list is the oldest undo item. Each List item is a Dictionary with these items:
"seq" Undo sequence number. Same as what appears in :undolist .
"time" Timestamp when the change happened. Use strftime() to convert to something readable.
"newhead" Only appears in the item that is the last one that was added. This marks the last change and where further changes will be added.
"curhead" Only appears in the item that is the last one that was undone. This marks the current position in the undo tree, the block that will be used by a redo command. When nothing was undone after the last change this item will not appear anywhere.
"save" Only appears on the last block before a file write. The number is the write count. The first write has number 1, the last one the "save_last" mentioned above.
"alt" Alternate entry. This is again a List of undo blocks. Each item may again have an "alt" item.

uniq({list} [, {func} [, {dict}]]) uniq() E882
Remove second and succeeding copies of repeated adjacent {list} items in-place. Returns {list}. If you want a list to remain unmodified make a copy first:
:let newlist = uniq(copy(mylist))
The default compare function uses the string representation of each item. For the use of {func} and {dict} see sort() .

values({dict}) values()
Return a List with all the values of {dict}. The List is in arbitrary order.

virtcol({expr}) virtcol()

The result is a Number, which is the screen column of the file position given with {expr}. That is, the last screen position occupied by the character at that position, when the screen would be of unlimited width. When there is a <Tab> at the position, the returned Number will be the column at the end of the <Tab>. For example, for a <Tab> in column 1, with 'ts' set to 8, it returns 8. conceal is ignored.
For the byte position use col() .
For the use of {expr} see col() .
When 'virtualedit' is used {expr} can be [lnum, col, off], where "off" is the offset in screen columns from the start of the character. E.g., a position within a <Tab> or after the last character. When "off" is omitted zero is used.
When Virtual editing is active in the current mode, a position beyond the end of the line can be returned. 'virtualedit'
The accepted positions are:

.	the cursor position
$	the end of the cursor line (the result is the number of displayed characters in the cursor line plus one)
'x	position of mark x (if the mark is not set, 0 is returned)
v	In Visual mode: the start of the Visual area (the cursor is the end). When not in Visual mode returns the cursor position. Differs from '< in that it's updated right away.

Note that only marks in the current file can be used.
Examples:

```
virtcol(".")     with text "foo^Lbar", with cursor on the "^L", returns 5
virtcol("$")     with text "foo^Lbar", returns 9
virtcol("'t")    with text "    there", with 't at 'h', returns 6
```

The first column is 1. 0 is returned for an error.
A more advanced example that echoes the maximum length of all lines:

```
echo max(map(range(1, line('$')), "virtcol([v:val, '$'])"))
```

visualmode([expr]) visualmode()
The result is a String, which describes the last Visual mode used in the current buffer. Initially it returns an empty string, but once Visual mode has been used, it returns "v", "V", or "<CTRL-V>" (a single CTRL-V character) for character-wise, line-wise, or block-wise Visual mode respectively.
Example:

```
:exe "normal " . visualmode()
```

This enters the same Visual mode as before. It is also useful in scripts if you wish to act differently depending on the Visual mode that was used.
If Visual mode is active, use mode() to get the Visual mode (e.g., in a :vmap).
If [expr] is supplied and it evaluates to a non-zero Number or a non-empty String, then the Visual mode will be cleared and the old value is returned. See non-zero-arg .

wildmenumode()   wildmenumode()
		Returns TRUE when the wildmenu is active and FALSE
		otherwise. See 'wildmenu' and 'wildmode'.
		This can be used in mappings to handle the 'wildcharm' option
		gracefully. (Makes only sense with mapmode-c mappings).

		For example to make <c-j> work like <down> in wildmode, use:
	:cnoremap <expr> <C-j> wildmenumode() ? "\<Down>\<Tab>" : "\<c-j>"

		(Note, this needs the 'wildcharm' option set appropriately).

win_findbuf({bufnr})   win_findbuf()
		Returns a list with window-ID s for windows that contain
		buffer {bufnr}. When there is none the list is empty.

win_getid([{win} [, {tab}]])   win_getid()
		Get the window-ID for the specified window.
		When {win} is missing use the current window.
		With {win} this is the window number. The top window has
		number 1. Use `win_getid(winnr())` for the current window.
		Without {tab} use the current tab, otherwise the tab with
		number {tab}. The first tab has number one.
		Return zero if the window cannot be found.

win_gotoid({expr})   win_gotoid()
		Go to window with ID {expr}. This may also change the current
		tabpage.
		Return 1 if successful, 0 if the window cannot be found.

win_id2tabwin({expr})   win_id2tabwin()
		Return a list with the tab number and window number of window
		with ID {expr}: [tabnr, winnr].
		Return [0, 0] if the window cannot be found.

win_id2win({expr})   win_id2win()
		Return the window number of window with ID {expr}.
		Return 0 if the window cannot be found in the current tabpage.

win_screenpos({nr})   win_screenpos()
		Return the screen position of window {nr} as a list with two
		numbers: [row, col]. The first window always has position
		[1, 1], unless there is a tabline, then it is [2, 1].
		{nr} can be the window number or the window-ID .
		Return [0, 0] if the window cannot be found in the current
		tabpage.

                                                        winbufnr()
winbufnr({nr}) The result is a Number, which is the number of the buffer
		associated with window {nr}. {nr} can be the window number or
		the window-ID .
		When {nr} is zero, the number of the buffer in the current
		window is returned.

When window {nr} doesn't exist, -1 is returned.
Example:
```
:echo "The file in the current window is " . bufname(winbufnr(0))
```

wincol()

wincol()	The result is a Number, which is the virtual column of the cursor in the window. This is counting screen cells from the left side of the window. The leftmost column is one.

winheight({nr})

winheight()

The result is a Number, which is the height of window {nr}. {nr} can be the window number or the window-ID. When {nr} is zero, the height of the current window is returned. When window {nr} doesn't exist, -1 is returned. An existing window always has a height of zero or more. This excludes any window toolbar line.
Examples:
```
:echo "The current window has " . winheight(0) . " lines."
```

winline()

winline()	The result is a Number, which is the screen line of the cursor in the window. This is counting screen lines from the top of the window. The first line is one.
If the cursor was moved the view on the file will be updated first, this may cause a scroll.

winnr()

winnr([{arg}])	The result is a Number, which is the number of the current window. The top window has number 1.
When the optional argument is "$", the number of the last window is returned (the window count).
```
let window_count = winnr('$')
```
When the optional argument is "#", the number of the last accessed window is returned (where CTRL-W_p goes to).
If there is no previous window or it is in another tab page 0 is returned.
The number can be used with CTRL-W_w and ":wincmd w" :wincmd.
Also see tabpagewinnr() and win_getid().

winrestcmd()

winrestcmd()	Returns a sequence of :resize commands that should restore the current window sizes. Only works properly when no windows are opened or closed and the current window and tab page is unchanged.
Example:
```
:let cmd = winrestcmd()
:call MessWithWindowSizes()
:exe cmd
```

winrestview()

winrestview({dict})
Uses the Dictionary returned by winsaveview() to restore the view of the current window.

Note: The {dict} does not have to contain all values, that are returned by winsaveview() . If values are missing, those settings won't be restored. So you can use:

```
:call winrestview({'curswant': 4})
```

This will only set the curswant value (the column the cursor wants to move on vertical movements) of the cursor to column 5 (yes, that is 5), while all other settings will remain the same. This is useful, if you set the cursor position manually.

If you have changed the values the result is unpredictable. If the window size changed the result won't be the same.

winsaveview() winsaveview()

Returns a Dictionary that contains information to restore the view of the current window. Use winrestview() to restore the view.
This is useful if you have a mapping that jumps around in the buffer and you want to go back to the original view.
This does not save fold information. Use the 'foldenable' option to temporarily switch off folding, so that folds are not opened when moving around. This may have side effects.
The return value includes:

lnum	cursor line number
col	cursor column (Note: the first column zero, as opposed to what getpos() returns)
coladd	cursor column offset for 'virtualedit'
curswant	column for vertical movement
topline	first line in the window
topfill	filler lines, only in diff mode
leftcol	first column displayed
skipcol	columns skipped

Note that no option values are saved.

winwidth({nr}) winwidth()

The result is a Number, which is the width of window {nr}. {nr} can be the window number or the window-ID .
When {nr} is zero, the width of the current window is returned. When window {nr} doesn't exist, -1 is returned.
An existing window always has a width of zero or more.
Examples:

```
:echo "The current window has " . winwidth(0) . " columns."
:if winwidth(0) <= 50
:  50 wincmd |
:endif
```

For getting the terminal or screen size, see the 'columns' option.

wordcount() wordcount()

The result is a dictionary of byte/chars/word statistics for the current buffer. This is the same info as provided by

g_CTRL-G
The return value includes:

bytes	Number of bytes in the buffer
chars	Number of chars in the buffer
words	Number of words in the buffer
cursor_bytes	Number of bytes before cursor position (not in Visual mode)
cursor_chars	Number of chars before cursor position (not in Visual mode)
cursor_words	Number of words before cursor position (not in Visual mode)
visual_bytes	Number of bytes visually selected (only in Visual mode)
visual_chars	Number of chars visually selected (only in Visual mode)
visual_words	Number of words visually selected (only in Visual mode)

writefile()

writefile({list}, {fname} [, {flags}])
Write List {list} to file {fname}. Each list item is separated with a NL. Each list item must be a String or Number.
When {flags} contains "b" then binary mode is used: There will not be a NL after the last list item. An empty item at the end does cause the last line in the file to end in a NL.

When {flags} contains "a" then append mode is used, lines are appended to the file:
```
:call writefile(["foo"], "event.log", "a")
:call writefile(["bar"], "event.log", "a")
```

When {flags} contains "s" then fsync() is called after writing the file. This flushes the file to disk, if possible. This takes more time but avoids losing the file if the system crashes.
When {flags} does not contain "S" or "s" then fsync() is called if the 'fsync' option is set.
When {flags} contains "S" then fsync() is not called, even when 'fsync' is set.

All NL characters are replaced with a NUL character.
Inserting CR characters needs to be done before passing {list} to writefile().
An existing file is overwritten, if possible.
When the write fails -1 is returned, otherwise 0. There is an error message if the file can't be created or when writing fails.
Also see readfile() .
To copy a file byte for byte:
```
:let fl = readfile("foo", "b")
:call writefile(fl, "foocopy", "b")
```

xor({expr}, {expr})   xor()
                Bitwise XOR on the two arguments. The arguments are converted
                to a number. A List, Dict or Float argument causes an error.
                Example:
                        :let bits = xor(bits, 0x80)

                                                                 feature-list
There are four types of features:
1. Features that are only supported when they have been enabled when Vim
    was compiled +feature-list . Example:
        :if has("cindent")
2. Features that are only supported when certain conditions have been met.
    Example:
        :if has("gui_running")
                                                                 has-patch
3. Beyond a certain version or at a certain version and including a specific
    patch. The "patch-7.4.248" feature means that the Vim version is 7.5 or
    later, or it is version 7.4 and patch 248 was included. Example:
        :if has("patch-7.4.248")
    Note that it's possible for patch 248 to be omitted even though 249 is
    included. Only happens when cherry-picking patches.
    Note that this form only works for patch 7.4.237 and later, before that
    you need to check for the patch and the v:version. Example (checking
    version 6.2.148 or later):
        :if v:version > 602 || (v:version == 602 && has("patch148"))

Hint: To find out if Vim supports backslashes in a file name (MS-Windows),
use: `if exists('+shellslash')`

acl   Compiled with ACL support.
all_builtin_terms   Compiled with all builtin terminals enabled.
amiga   Amiga version of Vim.
arabic   Compiled with Arabic support Arabic .
arp   Compiled with ARP support (Amiga).
autocmd   Compiled with autocommand support. autocommand
autochdir   Compiled with support for 'autochdir'
autoservername   Automatically enable clientserver
balloon_eval   Compiled with balloon-eval support.
balloon_multiline   GUI supports multiline balloons.
beos   BeOS version of Vim.
browse   Compiled with :browse support, and browse() will
                        work.
browsefilter   Compiled with support for browsefilter .
builtin_terms   Compiled with some builtin terminals.
byte_offset   Compiled with support for 'o' in 'statusline'
cindent   Compiled with 'cindent' support.
clientserver   Compiled with remote invocation support clientserver .
clipboard   Compiled with 'clipboard' support.
cmdline_compl   Compiled with cmdline-completion support.
cmdline_hist   Compiled with cmdline-history support.

```
cmdline_info            Compiled with 'showcmd' and 'ruler' support.
comments                Compiled with  'comments'  support.
compatible              Compiled to be very Vi compatible.
cryptv                  Compiled with encryption support  encryption .
cscope                  Compiled with  cscope  support.
debug                   Compiled with "DEBUG" defined.
dialog_con              Compiled with console dialog support.
dialog_gui              Compiled with GUI dialog support.
diff                    Compiled with  vimdiff  and 'diff' support.
digraphs                Compiled with support for digraphs.
directx                 Compiled with support for DirectX and 'renderoptions'.
dnd                     Compiled with support for the "~ register  quote_~ .
ebcdic                  Compiled on a machine with ebcdic character set.
emacs_tags              Compiled with support for Emacs tags.
eval                    Compiled with expression evaluation support.  Always
                        true, of course!
ex_extra                +ex_extra , always true now
extra_search            Compiled with support for  'incsearch'  and
                        'hlsearch'
farsi                   Compiled with Farsi support  farsi .
file_in_path            Compiled with support for  gf  and  <cfile>
filterpipe              When 'shelltemp' is off pipes are used for shell
                        read/write/filter commands
find_in_path            Compiled with support for include file searches
                        +find_in_path .
float                   Compiled with support for  Float .
fname_case              Case in file names matters (for Amiga, MS-DOS, and
                        Windows this is not present).
folding                 Compiled with  folding  support.
footer                  Compiled with GUI footer support.  gui-footer
fork                    Compiled to use fork()/exec() instead of system().
gettext                 Compiled with message translation  multi-lang
gui                     Compiled with GUI enabled.
gui_athena              Compiled with Athena GUI.
gui_gnome               Compiled with Gnome support (gui_gtk is also defined).
gui_gtk                 Compiled with GTK+ GUI (any version).
gui_gtk2                Compiled with GTK+ 2 GUI (gui_gtk is also defined).
gui_gtk3                Compiled with GTK+ 3 GUI (gui_gtk is also defined).
gui_mac                 Compiled with Macintosh GUI.
gui_motif               Compiled with Motif GUI.
gui_photon              Compiled with Photon GUI.
gui_running             Vim is running in the GUI, or it will start soon.
gui_win32               Compiled with MS Windows Win32 GUI.
gui_win32s              idem, and Win32s system being used (Windows 3.1)
hangul_input            Compiled with Hangul input support.  hangul
iconv                   Can use iconv() for conversion.
insert_expand           Compiled with support for CTRL-X expansion commands in
                        Insert mode.
jumplist                Compiled with  jumplist  support.
keymap                  Compiled with 'keymap' support.
lambda                  Compiled with  lambda  support.
langmap                 Compiled with 'langmap' support.
libcall                 Compiled with  libcall()  support.
linebreak               Compiled with 'linebreak', 'breakat', 'showbreak' and
```

```
                        'breakindent' support.
lispindent              Compiled with support for lisp indenting.
listcmds                Compiled with commands for the buffer list  :files
                        and the argument list  arglist .
localmap                Compiled with local mappings and abbr.  :map-local
lua                     Compiled with Lua interface  Lua .
mac                     Any Macintosh version of Vim  cf. osx
macunix                 Synonym for osxdarwin
menu                    Compiled with support for  :menu .
mksession               Compiled with support for  :mksession .
modify_fname            Compiled with file name modifiers.  filename-modifiers
mouse                   Compiled with support mouse.
mouse_dec               Compiled with support for Dec terminal mouse.
mouse_gpm               Compiled with support for gpm (Linux console mouse)
mouse_netterm           Compiled with support for netterm mouse.
mouse_pterm             Compiled with support for qnx pterm mouse.
mouse_sysmouse          Compiled with support for sysmouse (*BSD console mouse)
mouse_sgr               Compiled with support for sgr mouse.
mouse_urxvt             Compiled with support for urxvt mouse.
mouse_xterm             Compiled with support for xterm mouse.
mouseshape              Compiled with support for 'mouseshape'.
multi_byte              Compiled with support for 'encoding'
multi_byte_encoding     'encoding' is set to a multi-byte encoding.
multi_byte_ime          Compiled with support for IME input method.
multi_lang              Compiled with support for multiple languages.
mzscheme                Compiled with MzScheme interface  mzscheme .
netbeans_enabled        Compiled with support for  netbeans  and connected.
netbeans_intg           Compiled with support for  netbeans .
num64                   Compiled with 64-bit  Number  support.
ole                     Compiled with OLE automation support for Win32.
osx                     Compiled for macOS  cf. mac
osxdarwin               Compiled for macOS, with  mac-darwin-feature
packages                Compiled with  packages  support.
path_extra              Compiled with up/downwards search in 'path' and 'tags'
perl                    Compiled with Perl interface.
persistent_undo         Compiled with support for persistent undo history.
postscript              Compiled with PostScript file printing.
printer                 Compiled with  :hardcopy  support.
profile                 Compiled with  :profile  support.
python                  Python 2.x interface available.  has-python
python_compiled         Compiled with Python 2.x interface.  has-python
python_dynamic          Python 2.x interface is dynamically loaded.  has-python
python3                 Python 3.x interface available.  has-python
python3_compiled        Compiled with Python 3.x interface.  has-python
python3_dynamic         Python 3.x interface is dynamically loaded.  has-python
pythonx                 Compiled with  python_x  interface.  has-pythonx
qnx                     QNX version of Vim.
quickfix                Compiled with  quickfix  support.
reltime                 Compiled with  reltime()  support.
rightleft               Compiled with 'rightleft' support.
ruby                    Compiled with Ruby interface  ruby .
scrollbind              Compiled with 'scrollbind' support.
showcmd                 Compiled with 'showcmd' support.
signs                   Compiled with  :sign  support.
```

```
smartindent             Compiled with 'smartindent' support.
spell                   Compiled with spell checking support  spell .
startuptime             Compiled with  --startuptime  support.
statusline              Compiled with support for 'statusline', 'rulerformat'
                        and special formats of 'titlestring' and 'iconstring'.
sun_workshop            Compiled with support for Sun  workshop .
syntax                  Compiled with syntax highlighting support  syntax .
syntax_items            There are active syntax highlighting items for the
                        current buffer.
system                  Compiled to use system() instead of fork()/exec().
tag_binary              Compiled with binary searching in tags files
                         tag-binary-search .
tag_old_static          Compiled with support for old static tags
                         tag-old-static .
tag_any_white           Compiled with support for any white characters in tags
                        files  tag-any-white .
tcl                     Compiled with Tcl interface.
termguicolors           Compiled with true color in terminal support.
terminal                Compiled with  terminal  support.
terminfo                Compiled with terminfo instead of termcap.
termresponse            Compiled with support for  t_RV  and  v:termresponse .
textobjects             Compiled with support for  text-objects .
tgetent                 Compiled with tgetent support, able to use a termcap
                        or terminfo file.
timers                  Compiled with  timer_start()  support.
title                   Compiled with window title support  'title' .
toolbar                 Compiled with support for  gui-toolbar .
ttyin                   input is a terminal (tty)
ttyout                  output is a terminal (tty)
unix                    Unix version of Vim.  +unix
unnamedplus             Compiled with support for "unnamedplus" in 'clipboard'
user_commands           User-defined commands.
vcon                    Win32: Virtual console support is working, can use
                        'termguicolors'. Also see  +vtp .
vertsplit               Compiled with vertically split windows  :vsplit .
vim_starting            True while initial source'ing takes place.  startup
                         vim_starting
viminfo                 Compiled with viminfo support.
virtualedit             Compiled with 'virtualedit' option.
visual                  Compiled with Visual mode.
visualextra             Compiled with extra Visual mode commands.
                         blockwise-operators .
vms                     VMS version of Vim.
vreplace                Compiled with  gR  and  gr  commands.
vtp                     Compiled for vcon support  +vtp  (check vcon to find
                        out if it works in the current console).
wildignore              Compiled with 'wildignore' option.
wildmenu                Compiled with 'wildmenu' option.
win16                   old version for MS-Windows 3.1 (always False)
win32                   Win32 version of Vim (MS-Windows 95 and later, 32 or
                        64 bits)
win32unix               Win32 version of Vim, using Unix files (Cygwin)
win64                   Win64 version of Vim (MS-Windows 64 bit).
win95                   Win32 version for MS-Windows 95/98/ME (always False)
```

```
winaltkeys              Compiled with 'winaltkeys' option.
windows                 Compiled with support for more than one window.
writebackup             Compiled with 'writebackup' default on.
xfontset                Compiled with X fontset support  xfontset .
xim                     Compiled with X input method support  xim .
xpm                     Compiled with pixmap support.
xpm_w32                 Compiled with pixmap support for Win32. (Only for
                        backward compatibility. Use "xpm" instead.)
xsmp                    Compiled with X session management support.
xsmp_interact           Compiled with interactive X session management support.
xterm_clipboard         Compiled with support for xterm clipboard.

```

string-match

Matching a pattern in a String

A regexp pattern as explained at pattern is normally used to find a match in the buffer lines. When a pattern is used to find a match in a String, almost everything works in the same way. The difference is that a String is handled like it is one line. When it contains a "\n" character, this is not seen as a line break for the pattern. It can be matched with a "\n" in the pattern, or with ".". Example:

```
:let a = "aaaa\nxxxx"
:echo matchstr(a, "..\n..")
aa
xx
:echo matchstr(a, "a.x")
a
x
```

Don't forget that "^" will only match at the first character of the String and "$" at the last character of the string. They don't match after or before a "\n".

==

5. Defining functions   user-functions

New functions can be defined. These can be called just like builtin functions. The function executes a sequence of Ex commands. Normal mode commands can be executed with the :normal command.

The function name must start with an uppercase letter, to avoid confusion with builtin functions. To prevent from using the same name in different scripts avoid obvious, short names. A good habit is to start the function name with the name of the script, e.g., "HTMLcolor()".

It's also possible to use curly braces, see curly-braces-names . And the autoload facility is useful to define a function only when it's called.

local-function

A function local to a script must start with "s:". A local script function can only be called from within the script and from functions, user commands

and autocommands defined in the script. It is also possible to call the function from a mapping defined in the script, but then <SID> must be used instead of "s:" when the mapping is expanded outside of the script.
There are only script-local functions, no buffer-local or window-local functions.

:fu :function E128 E129 E123
:fu[nction] List all functions and their arguments.

:fu[nction] {name} List function {name}.
{name} can also be a Dictionary entry that is a Funcref :
:function dict.init

:fu[nction] /{pattern} List functions with a name matching {pattern}.
Example that lists all functions ending with "File":
:function /File$

:function-verbose
When 'verbose' is non-zero, listing a function will also display where it was last defined. Example:

```
:verbose function SetFileTypeSH
    function SetFileTypeSH(name)
        Last set from /usr/share/vim/vim-7.0/filetype.vim
```

See :verbose-cmd for more information.

E124 E125 E853 E884
:fu[nction][!] {name}([arguments]) [range] [abort] [dict] [closure]
Define a new function by the name {name}. The body of the function follows in the next lines, until the matching :endfunction .

The name must be made of alphanumeric characters and '_', and must start with a capital or "s:" (see above). Note that using "b:" or "g:" is not allowed. (since patch 7.4.260 E884 is given if the function name has a colon in the name, e.g. for "foo:bar()". Before that patch no error was given).

{name} can also be a Dictionary entry that is a Funcref :
:function dict.init(arg)
"dict" must be an existing dictionary. The entry "init" is added if it didn't exist yet. Otherwise [!] is required to overwrite an existing function. The result is a Funcref to a numbered function. The function can only be used with a Funcref and will be deleted if there are no more references to it.
E127 E122
When a function by this name already exists and [!] is not used an error message is given. When [!] is used, an existing function is silently replaced. Unless it

is currently being executed, that is an error.
NOTE: Use ! wisely. If used without care it can cause an existing function to be replaced unexpectedly, which is hard to debug.

For the {arguments} see function-argument .

:func-range a:firstline a:lastline
When the [range] argument is added, the function is expected to take care of a range itself. The range is passed as "a:firstline" and "a:lastline". If [range] is excluded, ":{range}call" will call the function for each line in the range, with the cursor on the start of each line. See function-range-example .
The cursor is still moved to the first line of the range, as is the case with all Ex commands.

:func-abort
When the [abort] argument is added, the function will abort as soon as an error is detected.

:func-dict
When the [dict] argument is added, the function must be invoked through an entry in a Dictionary . The local variable "self" will then be set to the dictionary. See Dictionary-function .

:func-closure E932
When the [closure] argument is added, the function can access variables and arguments from the outer scope. This is usually called a closure. In this example Bar() uses "x" from the scope of Foo(). It remains referenced even after Foo() returns:

```
:function! Foo()
:  let x = 0
:  function! Bar() closure
:    let x += 1
:    return x
:  endfunction
:  return funcref('Bar')
:endfunction

:let F = Foo()
:echo F()
1
:echo F()
2
:echo F()
3
```

function-search-undo
The last used search pattern and the redo command "." will not be changed by the function. This also implies that the effect of :nohlsearch is undone when the function returns.

:endf :endfunction E126 E193 W22

:endf[unction] [argument]
The end of a function definition. Best is to put it on a line by its own, without [argument].

[argument] can be:

| command	command to execute next
\n command	command to execute next
" comment	always ignored
anything else	ignored, warning given when 'verbose' is non-zero

The support for a following command was added in Vim 8.0.0654, before that any argument was silently ignored.

To be able to define a function inside an `:execute` command, use line breaks instead of :bar :

```
:exe "func Foo()\necho 'foo'\nendfunc"
```

:delf :delfunction E130 E131 E933

:delf[unction][!] {name}
Delete function {name}.
{name} can also be a Dictionary entry that is a Funcref :

```
:delfunc dict.init
```

This will remove the "init" entry from "dict". The function is deleted if there are no more references to it.
With the ! there is no error if the function does not exist.

:retu :return E133

:retu[rn] [expr] Return from a function. When "[expr]" is given, it is evaluated and returned as the result of the function. If "[expr]" is not given, the number 0 is returned. When a function ends without an explicit ":return", the number 0 is returned.
Note that there is no check for unreachable lines, thus there is no warning if commands follow ":return".

If the ":return" is used after a :try but before the matching :finally (if present), the commands following the ":finally" up to the matching :endtry are executed first. This process applies to all nested ":try"s inside the function. The function returns at the outermost ":endtry".

function-argument a:var

An argument can be defined by giving its name. In the function this can then be used as "a:name" ("a:" for argument).

a:0 a:1 a:000 E740 ...

Up to 20 arguments can be given, separated by commas. After the named arguments an argument "..." can be specified, which means that more arguments may optionally be following. In the function the extra arguments can be used as "a:1", "a:2", etc. "a:0" is set to the number of extra arguments (which can be 0). "a:000" is set to a List that contains these arguments. Note

that "a:1" is the same as "a:000[0]".
E742

The a: scope and the variables in it cannot be changed, they are fixed. However, if a composite type is used, such as List or Dictionary , you can change their contents. Thus you can pass a List to a function and have the function add an item to it. If you want to make sure the function cannot change a List or Dictionary use :lockvar .

When not using "...", the number of arguments in a function call must be equal to the number of named arguments. When using "...", the number of arguments may be larger.

It is also possible to define a function without any arguments. You must still supply the () then.

It is allowed to define another function inside a function body.

local-variables

Inside a function local variables can be used. These will disappear when the function returns. Global variables need to be accessed with "g:".

Example:
```
:function Table(title, ...)
:  echohl Title
:  echo a:title
:  echohl None
:  echo a:0 . " items:"
:  for s in a:000
:    echon ' ' . s
:  endfor
:endfunction
```

This function can then be called with:
```
call Table("Table", "line1", "line2")
call Table("Empty Table")
```

To return more than one value, return a List :
```
:function Compute(n1, n2)
:  if a:n2 == 0
:    return ["fail", 0]
:  endif
:  return ["ok", a:n1 / a:n2]
:endfunction
```

This function can then be called with:
```
:let [success, div] = Compute(102, 6)
:if success == "ok"
:  echo div
:endif
```

:cal :call E107 E117

:[range]cal[l] {name}([arguments])
Call a function. The name of the function and its arguments are as specified with :function . Up to 20 arguments can be

used. The returned value is discarded.
Without a range and for functions that accept a range, the function is called once. When a range is given the cursor is positioned at the start of the first line before executing the function.
When a range is given and the function doesn't handle it itself, the function is executed for each line in the range, with the cursor in the first column of that line. The cursor is left at the last line (possibly moved by the last function call). The arguments are re-evaluated for each line. Thus this works:
function-range-example

```
:function Mynumber(arg)
:  echo line(".") . " " . a:arg
:endfunction
:1,5call Mynumber(getline("."))
```

The "a:firstline" and "a:lastline" are defined anyway, they can be used to do something different at the start or end of the range.

Example of a function that handles the range itself:

```
:function Cont() range
:  execute (a:firstline + 1) . "," . a:lastline . 's/^/\t\\ '
:endfunction
:4,8call Cont()
```

This function inserts the continuation character "\" in front of all the lines in the range, except the first one.

When the function returns a composite value it can be further dereferenced, but the range will not be used then. Example:

```
:4,8call GetDict().method()
```

Here GetDict() gets the range but method() does not.

E132

The recursiveness of user functions is restricted with the 'maxfuncdepth' option.

AUTOMATICALLY LOADING FUNCTIONS

autoload-functions

When using many or large functions, it's possible to automatically define them only when they are used. There are two methods: with an autocommand and with the "autoload" directory in 'runtimepath'.

Using an autocommand

This is introduced in the user manual, section 41.14 .

The autocommand is useful if you have a plugin that is a long Vim script file. You can define the autocommand and quickly quit the script with :finish .

That makes Vim startup faster. The autocommand should then load the same file again, setting a variable to skip the :finish command.

Use the FuncUndefined autocommand event with a pattern that matches the function(s) to be defined. Example:

```
:au FuncUndefined BufNet* source ~/vim/bufnetfuncs.vim
```

The file "~/vim/bufnetfuncs.vim" should then define functions that start with "BufNet". Also see FuncUndefined .

Using an autoload script

autoload E746

This is introduced in the user manual, section 41.15 .

Using a script in the "autoload" directory is simpler, but requires using exactly the right file name. A function that can be autoloaded has a name like this:

```
:call filename#funcname()
```

When such a function is called, and it is not defined yet, Vim will search the "autoload" directories in 'runtimepath' for a script file called "filename.vim". For example "~/.vim/autoload/filename.vim". That file should then define the function like this:

```
function filename#funcname()
   echo "Done!"
endfunction
```

The file name and the name used before the # in the function must match exactly, and the defined function must have the name exactly as it will be called.

It is possible to use subdirectories. Every # in the function name works like a path separator. Thus when calling a function:

```
:call foo#bar#func()
```

Vim will look for the file "autoload/foo/bar.vim" in 'runtimepath'.

This also works when reading a variable that has not been set yet:

```
:let l = foo#bar#lvar
```

However, when the autoload script was already loaded it won't be loaded again for an unknown variable.

When assigning a value to such a variable nothing special happens. This can be used to pass settings to the autoload script before it's loaded:

```
:let foo#bar#toggle = 1
:call foo#bar#func()
```

Note that when you make a mistake and call a function that is supposed to be defined in an autoload script, but the script doesn't actually define the function, the script will be sourced every time you try to call the function. And you will get an error message every time.

Also note that if you have two script files, and one calls a function in the other and vice versa, before the used function is defined, it won't work. Avoid using the autoload functionality at the toplevel.

Hint: If you distribute a bunch of scripts you can pack them together with the vimball utility. Also read the user manual distribute-script .

==
6. Curly braces names curly-braces-names

In most places where you can use a variable, you can use a "curly braces name" variable. This is a regular variable name with one or more expressions wrapped in braces {} like this:

```
my_{adjective}_variable
```

When Vim encounters this, it evaluates the expression inside the braces, puts that in place of the expression, and re-interprets the whole as a variable name. So in the above example, if the variable "adjective" was set to "noisy", then the reference would be to "my_noisy_variable", whereas if "adjective" was set to "quiet", then it would be to "my_quiet_variable".

One application for this is to create a set of variables governed by an option value. For example, the statement

```
echo my_{&background}_message
```

would output the contents of "my_dark_message" or "my_light_message" depending on the current value of 'background'.

You can use multiple brace pairs:

```
echo my_{adverb}_{adjective}_message
```

..or even nest them:

```
echo my_{ad{end_of_word}}_message
```

where "end_of_word" is either "verb" or "jective".

However, the expression inside the braces must evaluate to a valid single variable name, e.g. this is invalid:

```
:let foo='a + b'
:echo c{foo}d
```

.. since the result of expansion is "ca + bd", which is not a variable name.

curly-braces-function-names

You can call and define functions by an evaluated name in a similar way. Example:

```
:let func_end='whizz'
:call my_func_{func_end}(parameter)
```

This would call the function "my_func_whizz(parameter)".

This does NOT work:
```
  :let i = 3
  :let @{i} = ''  " error
  :echo @{i}      " error
```

==========

7. Commands expression-commands

:let {var-name} = {expr1} :let E18
Set internal variable {var-name} to the result of the expression {expr1}. The variable will get the type from the {expr}. If {var-name} didn't exist yet, it is created.

:let {var-name}[{idx}] = {expr1} E689
Set a list item to the result of the expression {expr1}. {var-name} must refer to a list and {idx} must be a valid index in that list. For nested list the index can be repeated.
This cannot be used to add an item to a List .
This cannot be used to set a byte in a String. You can do that like this:
```
:let var = var[0:2] . 'X' . var[4:]
```

E711 E719
:let {var-name}[{idx1}:{idx2}] = {expr1} E708 E709 E710
Set a sequence of items in a List to the result of the expression {expr1}, which must be a list with the correct number of items.
{idx1} can be omitted, zero is used instead.
{idx2} can be omitted, meaning the end of the list.
When the selected range of items is partly past the end of the list, items will be added.

:let+= :let-= :let.= E734
:let {var} += {expr1} Like ":let {var} = {var} + {expr1}".
:let {var} -= {expr1} Like ":let {var} = {var} - {expr1}".
:let {var} .= {expr1} Like ":let {var} = {var} . {expr1}".
These fail if {var} was not set yet and when the type of {var} and {expr1} don't fit the operator.

:let ${env-name} = {expr1} :let-environment :let-$
Set environment variable {env-name} to the result of the expression {expr1}. The type is always String.
:let ${env-name} .= {expr1}
Append {expr1} to the environment variable {env-name}. If the environment variable didn't exist yet this works like "=".

:let @{reg-name} = {expr1} :let-register :let-@
Write the result of the expression {expr1} in register {reg-name}. {reg-name} must be a single letter, and must be the name of a writable register (see

registers). "@@" can be used for the unnamed register, "@/" for the search pattern. If the result of {expr1} ends in a <CR> or <NL>, the register will be linewise, otherwise it will be set to characterwise. This can be used to clear the last search pattern:

```
:let @/ = ""
```

This is different from searching for an empty string, that would match everywhere.

:let @{reg-name} .= {expr1}
Append {expr1} to register {reg-name}. If the register was empty it's like setting it to {expr1}.

:let &{option-name} = {expr1} :let-option :let-&
Set option {option-name} to the result of the expression {expr1}. A String or Number value is always converted to the type of the option. For an option local to a window or buffer the effect is just like using the :set command: both the local value and the global value are changed. Example:

```
:let &path = &path . ',/usr/local/include'
```

This also works for terminal codes in the form t_xx. But only for alphanumerical names. Example:

```
:let &t_k1 = "\<Esc>[234;"
```

When the code does not exist yet it will be created as a terminal key code, there is no error.

:let &{option-name} .= {expr1}
For a string option: Append {expr1} to the value. Does not insert a comma like :set+= .

:let &{option-name} += {expr1}
:let &{option-name} -= {expr1}
For a number or boolean option: Add or subtract {expr1}.

:let &l:{option-name} = {expr1}
:let &l:{option-name} .= {expr1}
:let &l:{option-name} += {expr1}
:let &l:{option-name} -= {expr1}
Like above, but only set the local value of an option (if there is one). Works like :setlocal .

:let &g:{option-name} = {expr1}
:let &g:{option-name} .= {expr1}
:let &g:{option-name} += {expr1}
:let &g:{option-name} -= {expr1}
Like above, but only set the global value of an option (if there is one). Works like :setglobal .

:let [{name1}, {name2}, ...] = {expr1} :let-unpack E687 E688
{expr1} must evaluate to a List . The first item in

the list is assigned to {name1}, the second item to
{name2}, etc.
The number of names must match the number of items in
the List .
Each name can be one of the items of the ":let"
command as mentioned above.
Example:
:let [s, item] = GetItem(s)
Detail: {expr1} is evaluated first, then the
assignments are done in sequence. This matters if
{name2} depends on {name1}. Example:
:let x = [0, 1]
:let i = 0
:let [i, x[i]] = [1, 2]
:echo x
The result is [0, 2].

:let [{name1}, {name2}, ...] .= {expr1}
:let [{name1}, {name2}, ...] += {expr1}
:let [{name1}, {name2}, ...] -= {expr1}
Like above, but append/add/subtract the value for each
List item.

:let [{name}, ..., ; {lastname}] = {expr1}
Like :let-unpack above, but the List may have more
items than there are names. A list of the remaining
items is assigned to {lastname}. If there are no
remaining items {lastname} is set to an empty list.
Example:
:let [a, b; rest] = ["aval", "bval", 3, 4]

:let [{name}, ..., ; {lastname}] .= {expr1}
:let [{name}, ..., ; {lastname}] += {expr1}
:let [{name}, ..., ; {lastname}] -= {expr1}
Like above, but append/add/subtract the value for each
List item.

E121
:let {var-name} .. List the value of variable {var-name}. Multiple
variable names may be given. Special names recognized
here: E738
g: global variables
b: local buffer variables
w: local window variables
t: local tab page variables
s: script-local variables
l: local function variables
v: Vim variables.

:let List the values of all variables. The type of the
variable is indicated before the value:
<nothing> String
Number
* Funcref

```
:unl[et][!] {name} ...                                  :unlet   :unl   E108   E795
                        Remove the internal variable {name}.  Several variable
                        names can be given, they are all removed.  The name
                        may also be a  List  or  Dictionary  item.
                        With [!] no error message is given for non-existing
                        variables.
                        One or more items from a  List  can be removed:
                                :unlet list[3]    " remove fourth item
                                :unlet list[3:]   " remove fourth item to last
                       One item from a  Dictionary  can be removed at a time:
                                :unlet dict['two']
                                :unlet dict.two
                       This is especially useful to clean up used global
                        variables and script-local variables (these are not
                        deleted when the script ends).  Function-local
                        variables are automatically deleted when the function
                        ends.

:unl[et] ${env-name} ...                                :unlet-environment   :unlet-$
                        Remove environment variable {env-name}.
                        Can mix {name} and ${env-name} in one :unlet command.
                        No error message is given for a non-existing
                        variable, also without !.
                        If the system does not support deleting an environment
                        variable, it is made emtpy.

:lockv[ar][!] [depth] {name} ...                         :lockvar   :lockv
                        Lock the internal variable {name}.  Locking means that
                        it can no longer be changed (until it is unlocked).
                        A locked variable can be deleted:
                                :lockvar v
                                :let v = 'asdf'         " fails!
                                :unlet v
                                                        E741   E940
                        If you try to change a locked variable you get an
                        error message: "E741: Value is locked: {name}".
                        If you try to lock or unlock a built-in variable you
                        get an error message: "E940: Cannot lock or unlock
                        variable {name}".

                        [depth] is relevant when locking a  List  or
                         Dictionary .  It specifies how deep the locking goes:
                                1       Lock the  List  or  Dictionary  itself,
                                        cannot add or remove items, but can
                                        still change their values.
                                2       Also lock the values, cannot change
                                        the items.  If an item is a  List  or
                                         Dictionary , cannot add or remove
                                        items, but can still change the
                                        values.
                                3       Like 2 but for the  List  /
                                         Dictionary  in the  List  /
```

Dictionary , one level deeper.
The default [depth] is 2, thus when {name} is a List or Dictionary the values cannot be changed.
E743
For unlimited depth use [!] and omit [depth].
However, there is a maximum depth of 100 to catch loops.

Note that when two variables refer to the same List and you lock one of them, the List will also be locked when used through the other variable.
Example:
```
:let l = [0, 1, 2, 3]
:let cl = l
:lockvar l
:let cl[1] = 99         " won't work!
```
You may want to make a copy of a list to avoid this.
See deepcopy() .

:unlo[ckvar][!] [depth] {name} ... :unlockvar :unlo
Unlock the internal variable {name}. Does the opposite of :lockvar .

:if {expr1} :if :endif :en E171 E579 E580
:en[dif]
Execute the commands until the next matching ":else" or ":endif" if {expr1} evaluates to non-zero.

From Vim version 4.5 until 5.0, every Ex command in between the ":if" and ":endif" is ignored. These two commands were just to allow for future expansions in a backward compatible way. Nesting was allowed. Note that any ":else" or ":elseif" was ignored, the "else" part was not executed either.

You can use this to remain compatible with older versions:
```
:if version >= 500
:  version-5-specific-commands
:endif
```
The commands still need to be parsed to find the "endif". Sometimes an older Vim has a problem with a new command. For example, ":silent" is recognized as a ":substitute" command. In that case ":execute" can avoid problems:
```
:if version >= 600
:  execute "silent 1,$delete"
:endif
```

NOTE: The ":append" and ":insert" commands don't work properly in between ":if" and ":endif".

:else :el E581 E583

:el[se] Execute the commands until the next matching ":else" or ":endif" if they previously were not being executed.

:elseif :elsei E582 E584

:elsei[f] {expr1} Short for ":else" ":if", with the addition that there is no extra ":endif".

:wh[ile] {expr1} :while :endwhile :wh :endw E170 E585 E588 E733

:endw[hile] Repeat the commands between ":while" and ":endwhile", as long as {expr1} evaluates to non-zero.
When an error is detected from a command inside the loop, execution continues after the "endwhile".
Example:

```
:let lnum = 1
:while lnum <= line("$")
   :call FixLine(lnum)
   :let lnum = lnum + 1
:endwhile
```

NOTE: The ":append" and ":insert" commands don't work properly inside a ":while" and ":for" loop.

:for {var} in {list} :for E690 E732

:endfo[r] :endfo :endfor

Repeat the commands between ":for" and ":endfor" for each item in {list}. Variable {var} is set to the value of each item.
When an error is detected for a command inside the loop, execution continues after the "endfor".
Changing {list} inside the loop affects what items are used. Make a copy if this is unwanted:

```
:for item in copy(mylist)
```

When not making a copy, Vim stores a reference to the next item in the list, before executing the commands with the current item. Thus the current item can be removed without effect. Removing any later item means it will not be found. Thus the following example works (an inefficient way to make a list empty):

```
for item in mylist
   call remove(mylist, 0)
endfor
```

Note that reordering the list (e.g., with sort() or reverse()) may have unexpected effects.

:for [{var1}, {var2}, ...] in {listlist}

:endfo[r]

Like ":for" above, but each item in {listlist} must be a list, of which each item is assigned to {var1}, {var2}, etc. Example:

```
:for [lnum, col] in [[1, 3], [2, 5], [3, 8]]
   :echo getline(lnum)[col]
:endfor
```

:continue :con E586

:con[tinue] When used inside a ":while" or ":for" loop, jumps back to the start of the loop.
If it is used after a :try inside the loop but before the matching :finally (if present), the commands following the ":finally" up to the matching :endtry are executed first. This process applies to all nested ":try"s inside the loop. The outermost ":endtry" then jumps back to the start of the loop.

:break :brea E587

:brea[k] When used inside a ":while" or ":for" loop, skips to the command after the matching ":endwhile" or ":endfor".
If it is used after a :try inside the loop but before the matching :finally (if present), the commands following the ":finally" up to the matching :endtry are executed first. This process applies to all nested ":try"s inside the loop. The outermost ":endtry" then jumps to the command after the loop.

:try :try :endt :endtry E600 E601 E602

:endt[ry] Change the error handling for the commands between ":try" and ":endtry" including everything being executed across ":source" commands, function calls, or autocommand invocations.

When an error or interrupt is detected and there is a :finally command following, execution continues after the ":finally". Otherwise, or when the ":endtry" is reached thereafter, the next (dynamically) surrounding ":try" is checked for a corresponding ":finally" etc. Then the script processing is terminated. (Whether a function definition has an "abort" argument does not matter.) Example:

```
:try | edit too much | finally | echo "cleanup" | endtry
:echo "impossible"      " not reached, script terminated above
```

Moreover, an error or interrupt (dynamically) inside ":try" and ":endtry" is converted to an exception. It can be caught as if it were thrown by a :throw command (see :catch). In this case, the script processing is not terminated.

The value "Vim:Interrupt" is used for an interrupt exception. An error in a Vim command is converted to a value of the form "Vim({command}):{errmsg}", other errors are converted to a value of the form "Vim:{errmsg}". {command} is the full command name, and {errmsg} is the message that is displayed if the error exception is not caught, always beginning with the error number.

Examples:

```
:try | sleep 100 | catch /^Vim:Interrupt$/ | endtry
:try | edit | catch /^Vim(edit):E\d\+/ | echo "error" | endtry
```

:cat :catch E603 E604 E605

:cat[ch] /{pattern}/ The following commands until the next :catch , :finally , or :endtry that belongs to the same :try as the ":catch" are executed when an exception matching {pattern} is being thrown and has not yet been caught by a previous ":catch". Otherwise, these commands are skipped.
When {pattern} is omitted all errors are caught.
Examples:

```
:catch /^Vim:Interrupt$/        " catch interrupts (CTRL-C)
:catch /^Vim\%((\a\+)\)\=:E/    " catch all Vim errors
:catch /^Vim\%((\a\+)\)\=:/     " catch errors and interrupts
:catch /^Vim(write):/           " catch all errors in :write
:catch /^Vim\%((\a\+)\)\=:E123/ " catch error E123
:catch /my-exception/           " catch user exception
:catch /.*/                     " catch everything
:catch                          " same as /.*/
```

Another character can be used instead of / around the {pattern}, so long as it does not have a special meaning (e.g., '|' or '"') and doesn't occur inside {pattern}.
Information about the exception is available in v:exception . Also see throw-variables .
NOTE: It is not reliable to ":catch" the TEXT of an error message because it may vary in different locales.

:fina :finally E606 E607

:fina[lly] The following commands until the matching :endtry are executed whenever the part between the matching :try and the ":finally" is left: either by falling through to the ":finally" or by a :continue , :break , :finish , or :return , or by an error or interrupt or exception (see :throw).

:th :throw E608

:th[row] {expr1} The {expr1} is evaluated and thrown as an exception. If the ":throw" is used after a :try but before the first corresponding :catch , commands are skipped until the first ":catch" matching {expr1} is reached. If there is no such ":catch" or if the ":throw" is used after a ":catch" but before the :finally , the commands following the ":finally" (if present) up to the matching :endtry are executed. If the ":throw" is after the ":finally", commands up to the ":endtry" are skipped. At the ":endtry", this process applies again for the next dynamically surrounding ":try" (which may be found in a calling function or sourcing script), until a matching ":catch" has been found.

If the exception is not caught, the command processing is terminated.
Example:

```
:try | throw "oops" | catch /^oo/ | echo "caught" | endtry
```

Note that "catch" may need to be on a separate line for when an error causes the parsing to skip the whole line and not see the "|" that separates the commands.

:ec :echo

:ec[ho] {expr1} .. Echoes each {expr1}, with a space in between. The first {expr1} starts on a new line.
Also see :comment .
Use "\n" to start a new line. Use "\r" to move the cursor to the first column.
Uses the highlighting set by the :echohl command.
Cannot be followed by a comment.
Example:

```
:echo "the value of 'shell' is" &shell
```

:echo-redraw

A later redraw may make the message disappear again. And since Vim mostly postpones redrawing until it's finished with a sequence of commands this happens quite often. To avoid that a command from before the ":echo" causes a redraw afterwards (redraws are often postponed until you type something), force a redraw with the :redraw command. Example:

```
:new | redraw | echo "there is a new window"
```

:echon

:echon {expr1} .. Echoes each {expr1}, without anything added. Also see :comment .
Uses the highlighting set by the :echohl command.
Cannot be followed by a comment.
Example:

```
:echon "the value of 'shell' is " &shell
```

Note the difference between using ":echo", which is a Vim command, and ":!echo", which is an external shell command:

```
:!echo %                --> filename
```

The arguments of ":!" are expanded, see :_% .

```
:!echo "%"              --> filename or "filename"
```

Like the previous example. Whether you see the double quotes or not depends on your 'shell'.

```
:echo %                 --> nothing
```

The '%' is an illegal character in an expression.

```
:echo "%"               --> %
```

This just echoes the '%' character.

```
:echo expand("%")       --> filename
```

This calls the expand() function to expand the '%'.

:echoh :echohl

:echoh[l] {name} Use the highlight group {name} for the following :echo , :echon and :echomsg commands. Also used

for the input() prompt. Example:
:echohl WarningMsg | echo "Don't panic!" | echohl None
Don't forget to set the group back to "None",
otherwise all following echo's will be highlighted.

:echom :echomsg
:echom[sg] {expr1} .. Echo the expression(s) as a true message, saving the
message in the message-history .
Spaces are placed between the arguments as with the
:echo command. But unprintable characters are
displayed, not interpreted.
The parsing works slightly different from :echo ,
more like :execute . All the expressions are first
evaluated and concatenated before echoing anything.
The expressions must evaluate to a Number or String, a
Dictionary or List causes an error.
Uses the highlighting set by the :echohl command.
Example:
:echomsg "It's a Zizzer Zazzer Zuzz, as you can plainly see."
See :echo-redraw to avoid the message disappearing
when the screen is redrawn.

:echoe :echoerr
:echoe[rr] {expr1} .. Echo the expression(s) as an error message, saving the
message in the message-history . When used in a
script or function the line number will be added.
Spaces are placed between the arguments as with the
:echo command. When used inside a try conditional,
the message is raised as an error exception instead
(see try-echoerr).
Example:
:echoerr "This script just failed!"
If you just want a highlighted message use :echohl .
And to get a beep:
:exe "normal \<Esc>"

:exe :execute
:exe[cute] {expr1} .. Executes the string that results from the evaluation
of {expr1} as an Ex command.
Multiple arguments are concatenated, with a space in
between. To avoid the extra space use the "."
operator to concatenate strings into one argument.
{expr1} is used as the processed command, command line
editing keys are not recognized.
Cannot be followed by a comment.
Examples:
:execute "buffer" nextbuf
:execute "normal" count . "w"

":execute" can be used to append a command to commands
that don't accept a '|'. Example:
:execute '!ls' | echo "theend"

":execute" is also a nice way to avoid having to type
control characters in a Vim script for a ":normal"

command:
```
:execute "normal ixxx\<Esc>"
```
This has an <Esc> character, see expr-string .

Be careful to correctly escape special characters in file names. The fnameescape() function can be used for Vim commands, shellescape() for :! commands. Examples:
```
:execute "e " . fnameescape(filename)
:execute "!ls " . shellescape(filename, 1)
```

Note: The executed string may be any command-line, but starting or ending "if", "while" and "for" does not always work, because when commands are skipped the ":execute" is not evaluated and Vim loses track of where blocks start and end. Also "break" and "continue" should not be inside ":execute". This example does not work, because the ":execute" is not evaluated and Vim does not see the "while", and gives an error for finding an ":endwhile":
```
:if 0
: execute 'while i > 5'
:  echo "test"
: endwhile
:endif
```

It is allowed to have a "while" or "if" command completely in the executed string:
```
:execute 'while i < 5 | echo i | let i = i + 1 | endwhile'
```

:exe-comment

":execute", ":echo" and ":echon" cannot be followed by a comment directly, because they see the '"' as the start of a string. But, you can use '|' followed by a comment. Example:
```
:echo "foo" | "this is a comment
```

==========

8. Exception handling exception-handling

The Vim script language comprises an exception handling feature. This section explains how it can be used in a Vim script.

Exceptions may be raised by Vim on an error or on interrupt, see catch-errors and catch-interrupt . You can also explicitly throw an exception by using the ":throw" command, see throw-catch .

TRY CONDITIONALS try-conditionals

Exceptions can be caught or can cause cleanup code to be executed. You can use a try conditional to specify catch clauses (that catch exceptions) and/or a finally clause (to be executed for cleanup).

A try conditional begins with a :try command and ends at the matching :endtry command. In between, you can use a :catch command to start a catch clause, or a :finally command to start a finally clause. There may be none or multiple catch clauses, but there is at most one finally clause, which must not be followed by any catch clauses. The lines before the catch clauses and the finally clause is called a try block.

```
:try
:  ...
:  ...                              TRY BLOCK
:  ...
:catch /{pattern}/
:  ...
:  ...                              CATCH CLAUSE
:  ...
:catch /{pattern}/
:  ...
:  ...                              CATCH CLAUSE
:  ...
:finally
:  ...
:  ...                              FINALLY CLAUSE
:  ...
:endtry
```

The try conditional allows to watch code for exceptions and to take the appropriate actions. Exceptions from the try block may be caught. Exceptions from the try block and also the catch clauses may cause cleanup actions.

When no exception is thrown during execution of the try block, the control is transferred to the finally clause, if present. After its execution, the script continues with the line following the ":endtry".

When an exception occurs during execution of the try block, the remaining lines in the try block are skipped. The exception is matched against the patterns specified as arguments to the ":catch" commands. The catch clause after the first matching ":catch" is taken, other catch clauses are not executed. The catch clause ends when the next ":catch", ":finally", or ":endtry" command is reached - whatever is first. Then, the finally clause (if present) is executed. When the ":endtry" is reached, the script execution continues in the following line as usual.

When an exception that does not match any of the patterns specified by the ":catch" commands is thrown in the try block, the exception is not caught by that try conditional and none of the catch clauses is executed. Only the finally clause, if present, is taken. The exception pends during execution of the finally clause. It is resumed at the ":endtry", so that commands after the ":endtry" are not executed and the exception might be caught elsewhere, see try-nesting .

When during execution of a catch clause another exception is thrown, the remaining lines in that catch clause are not executed. The new exception is not matched against the patterns in any of the ":catch" commands of the same try conditional and none of its catch clauses is taken. If there is, however, a finally clause, it is executed, and the exception pends during its execution. The commands following the ":endtry" are not executed. The new exception might, however, be caught elsewhere, see try-nesting .

When during execution of the finally clause (if present) an exception is

thrown, the remaining lines in the finally clause are skipped. If the finally clause has been taken because of an exception from the try block or one of the catch clauses, the original (pending) exception is discarded. The commands following the ":endtry" are not executed, and the exception from the finally clause is propagated and can be caught elsewhere, see try-nesting .

The finally clause is also executed, when a ":break" or ":continue" for a ":while" loop enclosing the complete try conditional is executed from the try block or a catch clause. Or when a ":return" or ":finish" is executed from the try block or a catch clause of a try conditional in a function or sourced script, respectively. The ":break", ":continue", ":return", or ":finish" pends during execution of the finally clause and is resumed when the ":endtry" is reached. It is, however, discarded when an exception is thrown from the finally clause.

When a ":break" or ":continue" for a ":while" loop enclosing the complete try conditional or when a ":return" or ":finish" is encountered in the finally clause, the rest of the finally clause is skipped, and the ":break", ":continue", ":return" or ":finish" is executed as usual. If the finally clause has been taken because of an exception or an earlier ":break", ":continue", ":return", or ":finish" from the try block or a catch clause, this pending exception or command is discarded.

For examples see throw-catch and try-finally .

NESTING OF TRY CONDITIONALS try-nesting

Try conditionals can be nested arbitrarily. That is, a complete try conditional can be put into the try block, a catch clause, or the finally clause of another try conditional. If the inner try conditional does not catch an exception thrown in its try block or throws a new exception from one of its catch clauses or its finally clause, the outer try conditional is checked according to the rules above. If the inner try conditional is in the try block of the outer try conditional, its catch clauses are checked, but otherwise only the finally clause is executed. It does not matter for nesting, whether the inner try conditional is directly contained in the outer one, or whether the outer one sources a script or calls a function containing the inner try conditional.

When none of the active try conditionals catches an exception, just their finally clauses are executed. Thereafter, the script processing terminates. An error message is displayed in case of an uncaught exception explicitly thrown by a ":throw" command. For uncaught error and interrupt exceptions implicitly raised by Vim, the error message(s) or interrupt message are shown as usual.

For examples see throw-catch .

EXAMINING EXCEPTION HANDLING CODE except-examine

Exception handling code can get tricky. If you are in doubt what happens, set 'verbose' to 13 or use the ":13verbose" command modifier when sourcing your script file. Then you see when an exception is thrown, discarded, caught, or

finished. When using a verbosity level of at least 14, things pending in a finally clause are also shown. This information is also given in debug mode (see debug-scripts).

THROWING AND CATCHING EXCEPTIONS throw-catch

You can throw any number or string as an exception. Use the :throw command and pass the value to be thrown as argument:

```
:throw 4711
:throw "string"
```

throw-expression

You can also specify an expression argument. The expression is then evaluated first, and the result is thrown:

```
:throw 4705 + strlen("string")
:throw strpart("strings", 0, 6)
```

An exception might be thrown during evaluation of the argument of the ":throw" command. Unless it is caught there, the expression evaluation is abandoned. The ":throw" command then does not throw a new exception.
Example:

```
:function! Foo(arg)
:  try
:    throw a:arg
:  catch /foo/
:  endtry
:  return 1
:endfunction
:
:function! Bar()
:  echo "in Bar"
:  return 4710
:endfunction
:
:throw Foo("arrgh") + Bar()
```

This throws "arrgh", and "in Bar" is not displayed since Bar() is not executed.

```
:throw Foo("foo") + Bar()
```

however displays "in Bar" and throws 4711.

Any other command that takes an expression as argument might also be abandoned by an (uncaught) exception during the expression evaluation. The exception is then propagated to the caller of the command.
Example:

```
:if Foo("arrgh")
:  echo "then"
:else
:  echo "else"
:endif
```

Here neither of "then" or "else" is displayed.

catch-order

Exceptions can be caught by a try conditional with one or more :catch commands, see try-conditionals . The values to be caught by each ":catch" command can be specified as a pattern argument. The subsequent catch clause gets executed when a matching exception is caught.
Example:

```
:function! Foo(value)
:  try
:    throw a:value
:  catch /^\d\+$/
:    echo "Number thrown"
:  catch /.*/
:    echo "String thrown"
:  endtry
:endfunction
:
:call Foo(0x1267)
:call Foo('string')
```

The first call to Foo() displays "Number thrown", the second "String thrown". An exception is matched against the ":catch" commands in the order they are specified. Only the first match counts. So you should place the more specific ":catch" first. The following order does not make sense:

```
:  catch /.*/
:    echo "String thrown"
:  catch /^\d\+$/
:    echo "Number thrown"
```

The first ":catch" here matches always, so that the second catch clause is never taken.

throw-variables

If you catch an exception by a general pattern, you may access the exact value in the variable v:exception :

```
:  catch /^\d\+$/
:    echo "Number thrown.  Value is" v:exception
```

You may also be interested where an exception was thrown. This is stored in v:throwpoint . Note that "v:exception" and "v:throwpoint" are valid for the exception most recently caught as long it is not finished.
Example:

```
:function! Caught()
:  if v:exception != ""
:    echo 'Caught "' . v:exception . '" in ' . v:throwpoint
:  else
:    echo 'Nothing caught'
:  endif
:endfunction
:
```

```
:function! Foo()
:  try
:    try
:      try
:        throw 4711
:      finally
:        call Caught()
:      endtry
:    catch /.*/
:      call Caught()
:      throw "oops"
:    endtry
:  catch /.*/
:    call Caught()
:  finally
:    call Caught()
:  endtry
:endfunction
:
:call Foo()
```

This displays

```
Nothing caught
Caught "4711" in function Foo, line 4
Caught "oops" in function Foo, line 10
Nothing caught
```

A practical example: The following command ":LineNumber" displays the line number in the script or function where it has been used:

```
:function! LineNumber()
:    return substitute(v:throwpoint, '.*\D\(\d\+\).*', '\1', "")
:endfunction
:command! LineNumber try | throw "" | catch | echo LineNumber() | endtry
```

try-nested

An exception that is not caught by a try conditional can be caught by a surrounding try conditional:

```
:try
:  try
:    throw "foo"
:  catch /foobar/
:    echo "foobar"
:  finally
:    echo "inner finally"
:  endtry
:catch /foo/
:  echo "foo"
:endtry
```

The inner try conditional does not catch the exception, just its finally clause is executed. The exception is then caught by the outer try

conditional. The example displays "inner finally" and then "foo".

throw-from-catch

You can catch an exception and throw a new one to be caught elsewhere from the catch clause:

```
:function! Foo()
:  throw "foo"
:endfunction
:
:function! Bar()
:  try
:    call Foo()
:  catch /foo/
:    echo "Caught foo, throw bar"
:    throw "bar"
:  endtry
:endfunction
:
:try
:  call Bar()
:catch /.*/
:  echo "Caught" v:exception
:endtry
```

This displays "Caught foo, throw bar" and then "Caught bar".

rethrow

There is no real rethrow in the Vim script language, but you may throw "v:exception" instead:

```
:function! Bar()
:  try
:    call Foo()
:  catch /.*/
:    echo "Rethrow" v:exception
:    throw v:exception
:  endtry
:endfunction
```

try-echoerr

Note that this method cannot be used to "rethrow" Vim error or interrupt exceptions, because it is not possible to fake Vim internal exceptions. Trying so causes an error exception. You should throw your own exception denoting the situation. If you want to cause a Vim error exception containing the original error exception value, you can use the :echoerr command:

```
:try
:  try
:    asdf
:  catch /.*/
:    echoerr v:exception
:  endtry
:catch /.*/
:  echo v:exception
```

```
:endtry
```

This code displays

```
Vim(echoerr):Vim:E492: Not an editor command:   asdf
```

CLEANUP CODE try-finally

Scripts often change global settings and restore them at their end. If the user however interrupts the script by pressing CTRL-C, the settings remain in an inconsistent state. The same may happen to you in the development phase of a script when an error occurs or you explicitly throw an exception without catching it. You can solve these problems by using a try conditional with a finally clause for restoring the settings. Its execution is guaranteed on normal control flow, on error, on an explicit ":throw", and on interrupt. (Note that errors and interrupts from inside the try conditional are converted to exceptions. When not caught, they terminate the script after the finally clause has been executed.)
Example:

```
:try
:  let s:saved_ts = &ts
:  set ts=17
:
:  " Do the hard work here.
:
:finally
:  let &ts = s:saved_ts
:  unlet s:saved_ts
:endtry
```

This method should be used locally whenever a function or part of a script changes global settings which need to be restored on failure or normal exit of that function or script part.

break-finally

Cleanup code works also when the try block or a catch clause is left by a ":continue", ":break", ":return", or ":finish".
Example:

```
:let first = 1
:while 1
:  try
:    if first
:      echo "first"
:      let first = 0
:      continue
:    else
:      throw "second"
:    endif
:  catch /.*/
:    echo v:exception
:    break
```

```
:  finally
:    echo "cleanup"
:  endtry
:  echo "still in while"
:endwhile
:echo "end"
```

This displays "first", "cleanup", "second", "cleanup", and "end".

```
:function! Foo()
:  try
:    return 4711
:  finally
:    echo "cleanup\n"
:  endtry
:  echo "Foo still active"
:endfunction
:
:echo Foo() "returned by Foo"
```

This displays "cleanup" and "4711 returned by Foo". You don't need to add an extra ":return" in the finally clause. (Above all, this would override the return value.)

except-from-finally

Using either of ":continue", ":break", ":return", ":finish", or ":throw" in a finally clause is possible, but not recommended since it abandons the cleanup actions for the try conditional. But, of course, interrupt and error exceptions might get raised from a finally clause.

Example where an error in the finally clause stops an interrupt from working correctly:

```
:try
:  try
:    echo "Press CTRL-C for interrupt"
:    while 1
:    endwhile
:  finally
:    unlet novar
:  endtry
:catch /novar/
:endtry
:echo "Script still running"
:sleep 1
```

If you need to put commands that could fail into a finally clause, you should think about catching or ignoring the errors in these commands, see catch-errors and ignore-errors .

CATCHING ERRORS

catch-errors

If you want to catch specific errors, you just have to put the code to be watched in a try block and add a catch clause for the error message. The

presence of the try conditional causes all errors to be converted to an exception. No message is displayed and v:errmsg is not set then. To find the right pattern for the ":catch" command, you have to know how the format of the error exception is.
   Error exceptions have the following format:

        Vim({cmdname}):{errmsg}
or
        Vim:{errmsg}

{cmdname} is the name of the command that failed; the second form is used when the command name is not known. {errmsg} is the error message usually produced when the error occurs outside try conditionals. It always begins with a capital "E", followed by a two or three-digit error number, a colon, and a space.

Examples:

The command
        :unlet novar
normally produces the error message
        E108: No such variable: "novar"
which is converted inside try conditionals to an exception
        Vim(unlet):E108: No such variable: "novar"

The command
        :dwim
normally produces the error message
        E492: Not an editor command: dwim
which is converted inside try conditionals to an exception
        Vim:E492: Not an editor command: dwim

You can catch all ":unlet" errors by a
        :catch /^Vim(unlet):/
or all errors for misspelled command names by a
        :catch /^Vim:E492:/

Some error messages may be produced by different commands:
        :function nofunc
and
        :delfunction nofunc
both produce the error message
        E128: Function name must start with a capital: nofunc
which is converted inside try conditionals to an exception
        Vim(function):E128: Function name must start with a capital: nofunc
or
        Vim(delfunction):E128: Function name must start with a capital: nofunc
respectively. You can catch the error by its number independently on the command that caused it if you use the following pattern:
        :catch /^Vim(\a\+):E128:/

Some commands like
        :let x = novar
produce multiple error messages, here:

```
        E121: Undefined variable: novar
        E15: Invalid expression:  novar
```
Only the first is used for the exception value, since it is the most specific one (see except-several-errors). So you can catch it by
```
        :catch /^Vim(\a\+):E121:/
```

You can catch all errors related to the name "nofunc" by
```
        :catch /\<nofunc\>/
```

You can catch all Vim errors in the ":write" and ":read" commands by
```
        :catch /^Vim(\(write\|read\)):E\d\+:/
```

You can catch all Vim errors by the pattern
```
        :catch /^Vim\((\a\+)\)\=:E\d\+:/
```

catch-text

NOTE: You should never catch the error message text itself:
```
        :catch /No such variable/
```
only works in the English locale, but not when the user has selected a different language by the :language command. It is however helpful to cite the message text in a comment:
```
        :catch /^Vim(\a\+):E108:/   " No such variable
```

IGNORING ERRORS

ignore-errors

You can ignore errors in a specific Vim command by catching them locally:

```
        :try
        :  write
        :catch
        :endtry
```

But you are strongly recommended NOT to use this simple form, since it could catch more than you want. With the ":write" command, some autocommands could be executed and cause errors not related to writing, for instance:

```
        :au BufWritePre * unlet novar
```

There could even be such errors you are not responsible for as a script writer: a user of your script might have defined such autocommands. You would then hide the error from the user.
   It is much better to use

```
        :try
        :  write
        :catch /^Vim(write):/
        :endtry
```

which only catches real write errors. So catch only what you'd like to ignore intentionally.

For a single command that does not cause execution of autocommands, you could even suppress the conversion of errors to exceptions by the ":silent!"

command:

```
:silent! nunmap k
```

This works also when a try conditional is active.

CATCHING INTERRUPTS catch-interrupt

When there are active try conditionals, an interrupt (CTRL-C) is converted to the exception "Vim:Interrupt". You can catch it like every exception. The script is not terminated, then.

Example:

```
:function! TASK1()
:  sleep 10
:endfunction

:function! TASK2()
:  sleep 20
:endfunction

:while 1
:  let command = input("Type a command: ")
:  try
:    if command == ""
:      continue
:    elseif command == "END"
:      break
:    elseif command == "TASK1"
:      call TASK1()
:    elseif command == "TASK2"
:      call TASK2()
:    else
:      echo "\nIllegal command:" command
:      continue
:    endif
:  catch /^Vim:Interrupt$/
:    echo "\nCommand interrupted"
:    " Caught the interrupt.  Continue with next prompt.
:  endtry
:endwhile
```

You can interrupt a task here by pressing CTRL-C; the script then asks for a new command. If you press CTRL-C at the prompt, the script is terminated.

For testing what happens when CTRL-C would be pressed on a specific line in your script, use the debug mode and execute the >quit or >interrupt command on that line. See debug-scripts .

CATCHING ALL catch-all

The commands

```
:catch /.*/
```

```
:catch //
:catch
```

catch everything, error exceptions, interrupt exceptions and exceptions explicitly thrown by the :throw command. This is useful at the top level of a script in order to catch unexpected things.
Example:

```
:try
:
:  " do the hard work here
:
:catch /MyException/
:
:  " handle known problem
:
:catch /^Vim:Interrupt$/
:    echo "Script interrupted"
:catch /.*/
:  echo "Internal error (" . v:exception . ")"
:  echo " - occurred at " . v:throwpoint
:endtry
:" end of script
```

Note: Catching all might catch more things than you want. Thus, you are strongly encouraged to catch only for problems that you can really handle by specifying a pattern argument to the ":catch".
Example: Catching all could make it nearly impossible to interrupt a script by pressing CTRL-C:

```
:while 1
:  try
:    sleep 1
:  catch
:  endtry
:endwhile
```

EXCEPTIONS AND AUTOCOMMANDS except-autocmd

Exceptions may be used during execution of autocommands. Example:

```
:autocmd User x try
:autocmd User x   throw "Oops!"
:autocmd User x catch
:autocmd User x   echo v:exception
:autocmd User x endtry
:autocmd User x throw "Arrgh!"
:autocmd User x echo "Should not be displayed"
:
:try
:  doautocmd User x
:catch
:  echo v:exception
```

```
        :endtry
```

This displays "Oops!" and "Arrgh!".

except-autocmd-Pre

For some commands, autocommands get executed before the main action of the command takes place. If an exception is thrown and not caught in the sequence of autocommands, the sequence and the command that caused its execution are abandoned and the exception is propagated to the caller of the command.
Example:

```
        :autocmd BufWritePre * throw "FAIL"
        :autocmd BufWritePre * echo "Should not be displayed"
        :
        :try
        :  write
        :catch
        :  echo "Caught:" v:exception "from" v:throwpoint
        :endtry
```

Here, the ":write" command does not write the file currently being edited (as you can see by checking 'modified'), since the exception from the BufWritePre autocommand abandons the ":write". The exception is then caught and the script displays:

```
        Caught: FAIL from BufWrite Auto commands for "*"
```

except-autocmd-Post

For some commands, autocommands get executed after the main action of the command has taken place. If this main action fails and the command is inside an active try conditional, the autocommands are skipped and an error exception is thrown that can be caught by the caller of the command.
Example:

```
        :autocmd BufWritePost * echo "File successfully written!"
        :
        :try
        :  write /i/m/p/o/s/s/i/b/l/e
        :catch
        :  echo v:exception
        :endtry
```

This just displays:

```
        Vim(write):E212: Can't open file for writing (/i/m/p/o/s/s/i/b/l/e)
```

If you really need to execute the autocommands even when the main action fails, trigger the event from the catch clause.
Example:

```
        :autocmd BufWritePre  * set noreadonly
        :autocmd BufWritePost * set readonly
        :
        :try
```

```
:  write /i/m/p/o/s/s/i/b/l/e
:catch
:  doautocmd BufWritePost /i/m/p/o/s/s/i/b/l/e
:endtry
```

You can also use ":silent!":

```
:let x = "ok"
:let v:errmsg = ""
:autocmd BufWritePost * if v:errmsg != ""
:autocmd BufWritePost *   let x = "after fail"
:autocmd BufWritePost * endif
:try
:  silent! write /i/m/p/o/s/s/i/b/l/e
:catch
:endtry
:echo x
```

This displays "after fail".

If the main action of the command does not fail, exceptions from the autocommands will be catchable by the caller of the command:

```
:autocmd BufWritePost * throw ":-("
:autocmd BufWritePost * echo "Should not be displayed"
:
:try
:  write
:catch
:  echo v:exception
:endtry
```

except-autocmd-Cmd

For some commands, the normal action can be replaced by a sequence of autocommands. Exceptions from that sequence will be catchable by the caller of the command.

Example: For the ":write" command, the caller cannot know whether the file had actually been written when the exception occurred. You need to tell it in some way.

```
:if !exists("cnt")
:  let cnt = 0
:
:  autocmd BufWriteCmd * if &modified
:  autocmd BufWriteCmd *   let cnt = cnt + 1
:  autocmd BufWriteCmd *   if cnt % 3 == 2
:  autocmd BufWriteCmd *     throw "BufWriteCmdError"
:  autocmd BufWriteCmd *   endif
:  autocmd BufWriteCmd *   write | set nomodified
:  autocmd BufWriteCmd *   if cnt % 3 == 0
:  autocmd BufWriteCmd *     throw "BufWriteCmdError"
:  autocmd BufWriteCmd *   endif
:  autocmd BufWriteCmd *   echo "File successfully written!"
:  autocmd BufWriteCmd * endif
```

```
:endif
:
:try
:       write
:catch /^BufWriteCmdError$/
:  if &modified
:    echo "Error on writing (file contents not changed)"
:  else
:    echo "Error after writing"
:  endif
:catch /^Vim(write):/
:    echo "Error on writing"
:endtry
```

When this script is sourced several times after making changes, it displays first

```
File successfully written!
```

then

```
Error on writing (file contents not changed)
```

then

```
Error after writing
```

etc.

except-autocmd-ill

You cannot spread a try conditional over autocommands for different events. The following code is ill-formed:

```
:autocmd BufWritePre  * try
:
:autocmd BufWritePost * catch
:autocmd BufWritePost *   echo v:exception
:autocmd BufWritePost * endtry
:
:write
```

EXCEPTION HIERARCHIES AND PARAMETERIZED EXCEPTIONS except-hier-param

Some programming languages allow to use hierarchies of exception classes or to pass additional information with the object of an exception class. You can do similar things in Vim.

In order to throw an exception from a hierarchy, just throw the complete class name with the components separated by a colon, for instance throw the string "EXCEPT:MATHERR:OVERFLOW" for an overflow in a mathematical library.

When you want to pass additional information with your exception class, add it in parentheses, for instance throw the string "EXCEPT:IO:WRITEERR(myfile)" for an error when writing "myfile".

With the appropriate patterns in the ":catch" command, you can catch for base classes or derived classes of your hierarchy. Additional information in parentheses can be cut out from v:exception with the ":substitute" command.

Example:

```
:function! CheckRange(a, func)
:  if a:a < 0
```

```
:    throw "EXCEPT:MATHERR:RANGE(" . a:func . ")"
:  endif
:endfunction
:
:function! Add(a, b)
:  call CheckRange(a:a, "Add")
:  call CheckRange(a:b, "Add")
:  let c = a:a + a:b
:  if c < 0
:    throw "EXCEPT:MATHERR:OVERFLOW"
:  endif
:  return c
:endfunction
:
:function! Div(a, b)
:  call CheckRange(a:a, "Div")
:  call CheckRange(a:b, "Div")
:  if (a:b == 0)
:    throw "EXCEPT:MATHERR:ZERODIV"
:  endif
:  return a:a / a:b
:endfunction
:
:function! Write(file)
:  try
:    execute "write" fnameescape(a:file)
:  catch /^Vim(write):/
:    throw "EXCEPT:IO(" . getcwd() . ", " . a:file . "):WRITEERR"
:  endtry
:endfunction
:
:try
:
:  " something with arithmetics and I/O
:
:catch /^EXCEPT:MATHERR:RANGE/
:  let function = substitute(v:exception, '.*(\(\a\+\)).*', '\1', "")
:  echo "Range error in" function
:
:catch /^EXCEPT:MATHERR/        " catches OVERFLOW and ZERODIV
:  echo "Math error"
:
:catch /^EXCEPT:IO/
:  let dir = substitute(v:exception, '.*(\(.\+\),\s*.\+).*', '\1', "")
:  let file = substitute(v:exception, '.*(.\+,\s*\(.\+\)).*', '\1', "")
:  if file !~ '^/'
:    let file = dir . "/" . file
:  endif
:  echo 'I/O error for "' . file . '"'
:
:catch /^EXCEPT/
:  echo "Unspecified error"
:
:endtry
```

The exceptions raised by Vim itself (on error or when pressing CTRL-C) use a flat hierarchy: they are all in the "Vim" class. You cannot throw yourself exceptions with the "Vim" prefix; they are reserved for Vim.

Vim error exceptions are parameterized with the name of the command that failed, if known. See catch-errors .

PECULIARITIES

except-compat

The exception handling concept requires that the command sequence causing the exception is aborted immediately and control is transferred to finally clauses and/or a catch clause.

In the Vim script language there are cases where scripts and functions continue after an error: in functions without the "abort" flag or in a command after ":silent!", control flow goes to the following line, and outside functions, control flow goes to the line following the outermost ":endwhile" or ":endif". On the other hand, errors should be catchable as exceptions (thus, requiring the immediate abortion).

This problem has been solved by converting errors to exceptions and using immediate abortion (if not suppressed by ":silent!") only when a try conditional is active. This is no restriction since an (error) exception can be caught only from an active try conditional. If you want an immediate termination without catching the error, just use a try conditional without catch clause. (You can cause cleanup code being executed before termination by specifying a finally clause.)

When no try conditional is active, the usual abortion and continuation behavior is used instead of immediate abortion. This ensures compatibility of scripts written for Vim 6.1 and earlier.

However, when sourcing an existing script that does not use exception handling commands (or when calling one of its functions) from inside an active try conditional of a new script, you might change the control flow of the existing script on error. You get the immediate abortion on error and can catch the error in the new script. If however the sourced script suppresses error messages by using the ":silent!" command (checking for errors by testing v:errmsg if appropriate), its execution path is not changed. The error is not converted to an exception. (See :silent .) So the only remaining cause where this happens is for scripts that don't care about errors and produce error messages. You probably won't want to use such code from your new scripts.

except-syntax-err

Syntax errors in the exception handling commands are never caught by any of the ":catch" commands of the try conditional they belong to. Its finally clauses, however, is executed.

Example:

```
:try
:  try
:    throw 4711
```

```
        :  catch /\(/
        :    echo "in catch with syntax error"
        :  catch
        :    echo "inner catch-all"
        :  finally
        :    echo "inner finally"
        :  endtry
        :catch
        :  echo 'outer catch-all caught "' . v:exception . '"'
        :  finally
        :    echo "outer finally"
        :endtry
```

This displays:

```
    inner finally
    outer catch-all caught "Vim(catch):E54: Unmatched \("
    outer finally
```

The original exception is discarded and an error exception is raised, instead.

except-single-line

The ":try", ":catch", ":finally", and ":endtry" commands can be put on a single line, but then syntax errors may make it difficult to recognize the "catch" line, thus you better avoid this.

Example:

```
        :try | unlet! foo # | catch | endtry
```

raises an error exception for the trailing characters after the ":unlet!" argument, but does not see the ":catch" and ":endtry" commands, so that the error exception is discarded and the "E488: Trailing characters" message gets displayed.

except-several-errors

When several errors appear in a single command, the first error message is usually the most specific one and therefor converted to the error exception.

Example:

```
        echo novar
```

causes

```
        E121: Undefined variable: novar
        E15: Invalid expression: novar
```

The value of the error exception inside try conditionals is:

```
        Vim(echo):E121: Undefined variable: novar
```

except-syntax-error

But when a syntax error is detected after a normal error in the same command, the syntax error is used for the exception being thrown.

Example:

```
        unlet novar #
```

causes

```
        E108: No such variable: "novar"
        E488: Trailing characters
```

The value of the error exception inside try conditionals is:

```
        Vim(unlet):E488: Trailing characters
```

This is done because the syntax error might change the execution path in a way not intended by the user. Example:

```
        try
            try | unlet novar # | catch | echo v:exception | endtry
```

```
        catch /.*/
            echo "outer catch:" v:exception
        endtry
```
This displays "outer catch: Vim(unlet):E488: Trailing characters", and then
a "E600: Missing :endtry" error message is given, see except-single-line .

==
9. Examples eval-examples

Printing in Binary

```
  :" The function Nr2Bin() returns the binary string representation of a number.
  :func Nr2Bin(nr)
  :  let n = a:nr
  :  let r = ""
  :  while n
  :    let r = '01'[n % 2] . r
  :    let n = n / 2
  :  endwhile
  :  return r
  :endfunc

  :" The function String2Bin() converts each character in a string to a
  :" binary string, separated with dashes.
  :func String2Bin(str)
  :  let out = ''
  :  for ix in range(strlen(a:str))
  :    let out = out . '-' . Nr2Bin(char2nr(a:str[ix]))
  :  endfor
  :  return out[1:]
  :endfunc
```

Example of its use:
```
  :echo Nr2Bin(32)
result: "100000"
  :echo String2Bin("32")
result: "110011-110010"
```

Sorting lines

This example sorts lines with a specific compare function.

```
  :func SortBuffer()
  :  let lines = getline(1, '$')
  :  call sort(lines, function("Strcmp"))
  :  call setline(1, lines)
  :endfunction
```

As a one-liner:
```
  :call setline(1, sort(getline(1, '$'), function("Strcmp")))
```

scanf() replacement

sscanf

There is no sscanf() function in Vim. If you need to extract parts from a line, you can use matchstr() and substitute() to do it. This example shows how to get the file name, line number and column number out of a line like "foobar.txt, 123, 45".

```
:" Set up the match bit
:let mx='\(\f\+\),\s*\(\d\+\),\s*\(\d\+\)'
:"get the part matching the whole expression
:let l = matchstr(line, mx)
:"get each item out of the match
:let file = substitute(l, mx, '\1', '')
:let lnum = substitute(l, mx, '\2', '')
:let col = substitute(l, mx, '\3', '')
```

The input is in the variable "line", the results in the variables "file", "lnum" and "col". (idea from Michael Geddes)

getting the scriptnames in a Dictionary

scriptnames-dictionary

The :scriptnames command can be used to get a list of all script files that have been sourced. There is no equivalent function or variable for this (because it's rarely needed). In case you need to manipulate the list this code can be used:

```
" Get the output of ":scriptnames" in the scriptnames_output variable.
let scriptnames_output = ''
redir => scriptnames_output
silent scriptnames
redir END

" Split the output into lines and parse each line.  Add an entry to the
" "scripts" dictionary.
let scripts = {}
for line in split(scriptnames_output, "\n")
  " Only do non-blank lines.
  if line =~ '\S'
    " Get the first number in the line.
    let nr = matchstr(line, '\d\+')
    " Get the file name, remove the script number " 123: ".
    let name = substitute(line, '.\+:\s*', '', '')
    " Add an item to the Dictionary
    let scripts[nr] = name
  endif
endfor
unlet scriptnames_output
```

==

10. No +eval feature

no-eval-feature

When the +eval feature was disabled at compile time, none of the expression evaluation commands are available. To prevent this from causing Vim scripts to generate all kinds of errors, the ":if" and ":endif" commands are still recognized, though the argument of the ":if" and everything between the ":if" and the matching ":endif" is ignored. Nesting of ":if" blocks is allowed, but

only if the commands are at the start of the line. The ":else" command is not recognized.

Example of how to avoid executing commands when the +eval feature is missing:

```
:if 1
:  echo "Expression evaluation is compiled in"
:else
:  echo "You will _never_ see this message"
:endif
```

To execute a command only when the +eval feature is disabled requires a trick, as this example shows:

```
silent! while 0
  set history=111
silent! endwhile
```

When the +eval feature is available the command is skipped because of the "while 0". Without the +eval feature the "while 0" is an error, which is silently ignored, and the command is executed.

==
11. The sandbox   eval-sandbox sandbox E48

The 'foldexpr', 'formatexpr', 'includeexpr', 'indentexpr', 'statusline' and 'foldtext' options may be evaluated in a sandbox. This means that you are protected from these expressions having nasty side effects. This gives some safety for when these options are set from a modeline. It is also used when the command from a tags file is executed and for CTRL-R = in the command line. The sandbox is also used for the :sandbox command.

These items are not allowed in the sandbox:
- changing the buffer text
- defining or changing mapping, autocommands, user commands
- setting certain options (see option-summary)
- setting certain v: variables (see v:var) E794
- executing a shell command
- reading or writing a file
- jumping to another buffer or editing a file
- executing Python, Perl, etc. commands

This is not guaranteed 100% secure, but it should block most attacks.

                                                    :san :sandbox
:san[dbox] {cmd}   Execute {cmd} in the sandbox. Useful to evaluate an
                        option that may have been set from a modeline, e.g.
                        'foldexpr'.

                                                    sandbox-option
A few options contain an expression. When this expression is evaluated it may have to be done in the sandbox to avoid a security risk. But the sandbox is restrictive, thus this only happens when the option was set from an insecure location. Insecure in this context are:

- sourcing a .vimrc or .exrc in the current directory
- while executing in the sandbox
- value coming from a modeline
- executing a function that was defined in the sandbox

Note that when in the sandbox and saving an option value and restoring it, the option will still be marked as it was set in the sandbox.

==
12. Textlock   textlock

In a few situations it is not allowed to change the text in the buffer, jump to another window and some other things that might confuse or break what Vim is currently doing. This mostly applies to things that happen when Vim is actually doing something else. For example, evaluating the 'balloonexpr' may happen any moment the mouse cursor is resting at some position.

This is not allowed when the textlock is active:
        - changing the buffer text
        - jumping to another buffer or window
        - editing another file
        - closing a window or quitting Vim
        - etc.

==
13. Testing   testing

Vim can be tested after building it, usually with "make test".
The tests are located in the directory "src/testdir".

There are several types of tests added over time:
        test33.in   oldest, don't add any more
        test_something.in   old style tests
        test_something.vim   new style tests

                                                        new-style-testing
New tests should be added as new style tests. These use functions such as assert_equal() to keep the test commands and the expected result in one place.
                                                        old-style-testing
In some cases an old style test needs to be used. E.g. when testing Vim without the +eval feature.

Find more information in the file src/testdir/README.txt.

fold.txt For Vim version 8.1. Last change: 2017 Mar 18

VIM REFERENCE MANUAL by Bram Moolenaar

Folding Folding folding folds

You can find an introduction on folding in chapter 28 of the user manual.
usr_28.txt

{Vi has no Folding}
{not available when compiled without the |+folding| feature}

==========
1. Fold methods fold-methods

The folding method can be set with the 'foldmethod' option.

When setting 'foldmethod' to a value other than "manual", all folds are deleted and new ones created. Switching to the "manual" method doesn't remove the existing folds. This can be used to first define the folds automatically and then change them manually.

There are six methods to select folds:

manual	manually define folds
indent	more indent means a higher fold level
expr	specify an expression to define folds
syntax	folds defined by syntax highlighting
diff	folds for unchanged text
marker	folds defined by markers in the text

MANUAL fold-manual

Use commands to manually define the fold regions. This can also be used by a script that parses text to find folds.

The level of a fold is only defined by its nesting. To increase the fold level of a fold for a range of lines, define a fold inside it that has the same lines.

The manual folds are lost when you abandon the file. To save the folds use the :mkview command. The view can be restored later with :loadview .

INDENT fold-indent

The folds are automatically defined by the indent of the lines.

The foldlevel is computed from the indent of the line, divided by the 'shiftwidth' (rounded down). A sequence of lines with the same or higher fold level form a fold, with the lines with a higher level forming a nested fold.

The nesting of folds is limited with 'foldnestmax'.

Some lines are ignored and get the fold level of the line above or below it, whichever is lower. These are empty or white lines and lines starting with a character in 'foldignore'. White space is skipped before checking for characters in 'foldignore'. For C use "#" to ignore preprocessor lines.

When you want to ignore lines in another way, use the "expr" method. The indent() function can be used in 'foldexpr' to get the indent of a line.

EXPR fold-expr

The folds are automatically defined by their foldlevel, like with the "indent" method. The value of the 'foldexpr' option is evaluated to get the foldlevel of a line. Examples:
This will create a fold for all consecutive lines that start with a tab:

```
:set foldexpr=getline(v:lnum)[0]==\"\\t\"
```

This will call a function to compute the fold level:

```
:set foldexpr=MyFoldLevel(v:lnum)
```

This will make a fold out of paragraphs separated by blank lines:

```
:set foldexpr=getline(v:lnum)=~'^\\s*$'&&getline(v:lnum+1)=~'\\S'?'<1':1
```

This does the same:

```
:set foldexpr=getline(v:lnum-1)=~'^\\s*$'&&getline(v:lnum)=~'\\S'?'>1':1
```

Note that backslashes must be used to escape characters that ":set" handles differently (space, backslash, double quote, etc., see option-backslash).

These are the conditions with which the expression is evaluated:
- The current buffer and window are set for the line.
- The variable "v:lnum" is set to the line number.
- The result is used for the fold level in this way:

value	meaning
0	the line is not in a fold
1, 2, ..	the line is in a fold with this level
-1	the fold level is undefined, use the fold level of a line before or after this line, whichever is the lowest.
"="	use fold level from the previous line
"a1", "a2", ..	add one, two, .. to the fold level of the previous line, use the result for the current line
"s1", "s2", ..	subtract one, two, .. from the fold level of the previous line, use the result for the next line
"<1", "<2", ..	a fold with this level ends at this line
">1", ">2", ..	a fold with this level starts at this line

It is not required to mark the start (end) of a fold with ">1" ("<1"), a fold will also start (end) when the fold level is higher (lower) than the fold level of the previous line.

There must be no side effects from the expression. The text in the buffer,
cursor position, the search patterns, options etc. must not be changed.
You can change and restore them if you are careful.

If there is some error in the expression, or the resulting value isn't
recognized, there is no error message and the fold level will be zero.
For debugging the 'debug' option can be set to "msg", the error messages will
be visible then.

Note: Since the expression has to be evaluated for every line, this fold
method can be very slow!

Try to avoid the "=", "a" and "s" return values, since Vim often has to search
backwards for a line for which the fold level is defined. This can be slow.

An example of using "a1" and "s1": For a multi-line C comment, a line
containing "/*" would return "a1" to start a fold, and a line containing "*/"
would return "s1" to end the fold after that line:
```
  if match(thisline, '/\*') >= 0
    return 'a1'
  elseif match(thisline, '\*/') >= 0
    return 's1'
  else
    return '='
  endif
```
However, this won't work for single line comments, strings, etc.

 foldlevel() can be useful to compute a fold level relative to a previous
fold level. But note that foldlevel() may return -1 if the level is not known
yet. And it returns the level at the start of the line, while a fold might
end in that line.

It may happen that folds are not updated properly. You can use zx or zX
to force updating folds.

SYNTAX fold-syntax

A fold is defined by syntax items that have the "fold" argument. :syn-fold

The fold level is defined by nesting folds. The nesting of folds is limited
with 'foldnestmax'.

Be careful to specify proper syntax syncing. If this is not done right, folds
may differ from the displayed highlighting. This is especially relevant when
using patterns that match more than one line. In case of doubt, try using
brute-force syncing:
```
        :syn sync fromstart
```

DIFF fold-diff

The folds are automatically defined for text that is not part of a change or

close to a change.

This method only works properly when the 'diff' option is set for the current window and changes are being displayed. Otherwise the whole buffer will be one big fold.

The 'diffopt' option can be used to specify the context. That is, the number of lines between the fold and a change that are not included in the fold. For example, to use a context of 8 lines:

```
:set diffopt=filler,context:8
```

The default context is six lines.

When 'scrollbind' is also set, Vim will attempt to keep the same folds open in other diff windows, so that the same text is visible.

MARKER fold-marker

Markers in the text tell where folds start and end. This allows you to precisely specify the folds. This will allow deleting and putting a fold, without the risk of including the wrong lines. The 'foldtext' option is normally set such that the text before the marker shows up in the folded line. This makes it possible to give a name to the fold.

Markers can have a level included, or can use matching pairs. Including a level is easier, you don't have to add end markers and avoid problems with non-matching marker pairs. Example:

```
/* global variables {{{1 */
int varA, varB;

/* functions {{{1 */
/* funcA() {{{2 */
void funcA() {}

/* funcB() {{{2 */
void funcB() {}
```

A fold starts at a "{{{" marker. The following number specifies the fold level. What happens depends on the difference between the current fold level and the level given by the marker:

1. If a marker with the same fold level is encountered, the previous fold ends and another fold with the same level starts.
2. If a marker with a higher fold level is found, a nested fold is started.
3. If a marker with a lower fold level is found, all folds up to and including this level end and a fold with the specified level starts.

The number indicates the fold level. A zero cannot be used (a marker with level zero is ignored). You can use "}}}" with a digit to indicate the level of the fold that ends. The fold level of the following line will be one less than the indicated level. Note that Vim doesn't look back to the level of the matching marker (that would take too much time). Example:

```
{{{1
fold level here is 1
```

```
{{{3
fold level here is 3
}}}3
fold level here is 2
```

You can also use matching pairs of "{{{" and "}}}" markers to define folds.
Each "{{{" increases the fold level by one, each "}}}" decreases the fold
level by one. Be careful to keep the markers matching! Example:

```
{{{
fold level here is 1
{{{
fold level here is 2
}}}
fold level here is 1
```

You can mix using markers with a number and without a number. A useful way of
doing this is to use numbered markers for large folds, and unnumbered markers
locally in a function. For example use level one folds for the sections of
your file like "structure definitions", "local variables" and "functions".
Use level 2 markers for each definition and function, Use unnumbered markers
inside functions. When you make changes in a function to split up folds, you
don't have to renumber the markers.

The markers can be set with the 'foldmarker' option. It is recommended to
keep this at the default value of "{{{,}}}", so that files can be exchanged
between Vim users. Only change it when it is required for the file (e.g., it
contains markers from another folding editor, or the default markers cause
trouble for the language of the file).

fold-create-marker

"zf" can be used to create a fold defined by markers. Vim will insert the
markers for you. Vim will append the start and end marker, as specified with
'foldmarker'. The markers are appended to the end of the line.
'commentstring' is used if it isn't empty.
This does not work properly when:
- The line already contains a marker with a level number. Vim then doesn't
  know what to do.
- Folds nearby use a level number in their marker which gets in the way.
- The line is inside a comment, 'commentstring' isn't empty and nested
  comments don't work. For example with C: adding /* {{{ */ inside a comment
  will truncate the existing comment. Either put the marker before or after
  the comment, or add the marker manually.
Generally it's not a good idea to let Vim create markers when you already have
markers with a level number.

fold-delete-marker

"zd" can be used to delete a fold defined by markers. Vim will delete the
markers for you. Vim will search for the start and end markers, as specified
with 'foldmarker', at the start and end of the fold. When the text around the
marker matches with 'commentstring', that text is deleted as well.
This does not work properly when:
- A line contains more than one marker and one of them specifies a level.
  Only the first one is removed, without checking if this will have the

  desired effect of deleting the fold.
- The marker contains a level number and is used to start or end several folds
  at the same time.

==
2. Fold commands   fold-commands   E490

All folding commands start with "z". Hint: the "z" looks like a folded piece
of paper, if you look at it from the side.

CREATING AND DELETING FOLDS

                                                                    zf   E350
zf{motion} or
{Visual}zf   Operator to create a fold.
                This only works when 'foldmethod' is "manual" or "marker".
                The new fold will be closed for the "manual" method.
                'foldenable' will be set.
                Also see fold-create-marker .

                                                                    zF
zF   Create a fold for [count] lines. Works like "zf".

:{range}fo[ld]   :fold   :fo
                Create a fold for the lines in {range}. Works like "zf".

                                                                    zd   E351
zd   Delete one fold at the cursor. When the cursor is on a folded
                line, that fold is deleted. Nested folds are moved one level
                up. In Visual mode one level of all folds (partially) in the
                selected area are deleted.
                Careful: This easily deletes more folds than you expect and
                there is no undo for manual folding.
                This only works when 'foldmethod' is "manual" or "marker".
                Also see fold-delete-marker .

                                                                    zD
zD   Delete folds recursively at the cursor. In Visual mode all
                folds (partially) in the selected area and all nested folds in
                them are deleted.
                This only works when 'foldmethod' is "manual" or "marker".
                Also see fold-delete-marker .

                                                                    zE   E352
zE   Eliminate all folds in the window.
                This only works when 'foldmethod' is "manual" or "marker".
                Also see fold-delete-marker .

OPENING AND CLOSING FOLDS

A fold smaller than 'foldminlines' will always be displayed like it was open.
Therefore the commands below may work differently on small folds.

zo

zo Open one fold under the cursor. When a count is given, that many folds deep will be opened. In Visual mode one level of folds is opened for all lines in the selected area.

zO

zO Open all folds under the cursor recursively. Folds that don't contain the cursor line are unchanged.
In Visual mode it opens all folds that are in the selected area, also those that are only partly selected.

zc

zc Close one fold under the cursor. When a count is given, that many folds deep are closed. In Visual mode one level of folds is closed for all lines in the selected area.
'foldenable' will be set.

zC

zC Close all folds under the cursor recursively. Folds that don't contain the cursor line are unchanged.
In Visual mode it closes all folds that are in the selected area, also those that are only partly selected.
'foldenable' will be set.

za

za When on a closed fold: open it. When folds are nested, you may have to use "za" several times. When a count is given, that many closed folds are opened.
When on an open fold: close it and set 'foldenable'. This will only close one level, since using "za" again will open the fold. When a count is given that many folds will be closed (that's not the same as repeating "za" that many times).

zA

zA When on a closed fold: open it recursively.
When on an open fold: close it recursively and set 'foldenable'.

zv

zv View cursor line: Open just enough folds to make the line in which the cursor is located not folded.

zx

zx Update folds: Undo manually opened and closed folds: re-apply 'foldlevel', then do "zv": View cursor line.
Also forces recomputing folds. This is useful when using 'foldexpr' and the buffer is changed in a way that results in folds not to be updated properly.

zX

zX Undo manually opened and closed folds: re-apply 'foldlevel'.
Also forces recomputing folds, like zx .

zm

zm Fold more: Subtract v:count1 from 'foldlevel'. If 'foldlevel' was already zero nothing happens.
'foldenable' will be set.

zM

zM Close all folds: set 'foldlevel' to 0.
'foldenable' will be set.

zr

zr Reduce folding: Add v:count1 to 'foldlevel'.

zR

zR Open all folds. This sets 'foldlevel' to highest fold level.

:foldo :foldopen

:{range}foldo[pen][!]
Open folds in {range}. When [!] is added all folds are opened. Useful to see all the text in {range}. Without [!] one level of folds is opened.

:foldc :foldclose

:{range}foldc[lose][!]
Close folds in {range}. When [!] is added all folds are closed. Useful to hide all the text in {range}. Without [!] one level of folds is closed.

zn

zn Fold none: reset 'foldenable'. All folds will be open.

zN

zN Fold normal: set 'foldenable'. All folds will be as they were before.

zi

zi Invert 'foldenable'.

MOVING OVER FOLDS

[z

[z Move to the start of the current open fold. If already at the start, move to the start of the fold that contains it. If there is no containing fold, the command fails.
When a count is used, repeats the command [count] times.

]z

]z Move to the end of the current open fold. If already at the end, move to the end of the fold that contains it. If there is no containing fold, the command fails.
When a count is used, repeats the command [count] times.

zj

zj Move downwards to the start of the next fold. A closed fold is counted as one fold.

When a count is used, repeats the command [count] times.
This command can be used after an operator .

zk
zk Move upwards to the end of the previous fold. A closed fold is counted as one fold.
When a count is used, repeats the command [count] times.
This command can be used after an operator .

EXECUTING COMMANDS ON FOLDS

:[range]foldd[oopen] {cmd} :foldd :folddoopen
Execute {cmd} on all lines that are not in a closed fold.
When [range] is given, only these lines are used.
Each time {cmd} is executed the cursor is positioned on the line it is executed for.
This works like the ":global" command: First all lines that are not in a closed fold are marked. Then the {cmd} is executed for all marked lines. Thus when {cmd} changes the folds, this has no influence on where it is executed (except when lines are deleted, of course).
Example:

```
:folddoopen s/end/loop_end/ge
```

Note the use of the "e" flag to avoid getting an error message where "end" doesn't match.

:[range]folddoc[losed] {cmd} :folddoc :folddoclosed
Execute {cmd} on all lines that are in a closed fold.
Otherwise like ":folddoopen".

---

3. Fold options fold-options

COLORS fold-colors

The colors of a closed fold are set with the Folded group hl-Folded . The colors of the fold column are set with the FoldColumn group hl-FoldColumn .
Example to set the colors:

```
:highlight Folded guibg=grey guifg=blue
:highlight FoldColumn guibg=darkgrey guifg=white
```

FOLDLEVEL fold-foldlevel

'foldlevel' is a number option: The higher the more folded regions are open.
When 'foldlevel' is 0, all folds are closed.
When 'foldlevel' is positive, some folds are closed.
When 'foldlevel' is very high, all folds are open.
'foldlevel' is applied when it is changed. After that manually folds can be opened and closed.
When increased, folds above the new level are opened. No manually opened folds will be closed.

When decreased, folds above the new level are closed. No manually closed
folds will be opened.

FOLDTEXT fold-foldtext

'foldtext' is a string option that specifies an expression. This expression
is evaluated to obtain the text displayed for a closed fold. Example:

```
    :set foldtext=v:folddashes.substitute(getline(v:foldstart),'/\\*\\|\\*/\\|{{{\\d\\='
```

This shows the first line of the fold, with "/*", "*/" and "{{{" removed.
Note the use of backslashes to avoid some characters to be interpreted by the
":set" command. It's simpler to define a function and call that:

```
    :set foldtext=MyFoldText()
    :function MyFoldText()
    :  let line = getline(v:foldstart)
    :  let sub = substitute(line, '/\*\|\*/\|{{{\d\=', '', 'g')
    :  return v:folddashes . sub
    :endfunction
```

Evaluating 'foldtext' is done in the sandbox . The current window is set to
the window that displays the line. Errors are ignored.

The default value is foldtext() . This returns a reasonable text for most
types of folding. If you don't like it, you can specify your own 'foldtext'
expression. It can use these special Vim variables:

v:foldstart	line number of first line in the fold
v:foldend	line number of last line in the fold
v:folddashes	a string that contains dashes to represent the foldlevel.
v:foldlevel	the foldlevel of the fold

In the result a TAB is replaced with a space and unprintable characters are
made into printable characters.

The resulting line is truncated to fit in the window, it never wraps.
When there is room after the text, it is filled with the character specified
by 'fillchars'.

Note that backslashes need to be used for characters that the ":set" command
handles differently: Space, backslash and double-quote. option-backslash

FOLDCOLUMN fold-foldcolumn

'foldcolumn' is a number, which sets the width for a column on the side of the
window to indicate folds. When it is zero, there is no foldcolumn. A normal
value is 4 or 5. The minimal useful value is 2, although 1 still provides
some information. The maximum is 12.

An open fold is indicated with a column that has a '-' at the top and '|'
characters below it. This column stops where the open fold stops. When folds

nest, the nested fold is one character right of the fold it's contained in.

A closed fold is indicated with a '+'.

Where the fold column is too narrow to display all nested folds, digits are shown to indicate the nesting level.

The mouse can also be used to open and close folds by clicking in the fold column:
- Click on a '+' to open the closed fold at this row.
- Click on any other non-blank character to close the open fold at this row.

OTHER OPTIONS

'foldenable'	'fen':	Open all folds while not set.
'foldexpr'	'fde':	Expression used for "expr" folding.
'foldignore'	'fdi':	Characters used for "indent" folding.
'foldmarker'	'fmr':	Defined markers used for "marker" folding.
'foldmethod'	'fdm':	Name of the current folding method.
'foldminlines'	'fml':	Minimum number of screen lines for a fold to be displayed closed.
'foldnestmax'	'fdn':	Maximum nesting for "indent" and "syntax" folding.
'foldopen'	'fdo':	Which kinds of commands open closed folds.
'foldclose'	'fcl':	When the folds not under the cursor are closed.

==========
4. Behavior of folds fold-behavior

When moving the cursor upwards or downwards and when scrolling, the cursor will move to the first line of a sequence of folded lines. When the cursor is already on a folded line, it moves to the next unfolded line or the next closed fold.

While the cursor is on folded lines, the cursor is always displayed in the first column. The ruler does show the actual cursor position, but since the line is folded, it cannot be displayed there.

Many movement commands handle a sequence of folded lines like an empty line. For example, the "w" command stops once in the first column.

When in Insert mode, the cursor line is never folded. That allows you to see what you type!

When using an operator, a closed fold is included as a whole. Thus "dl" deletes the whole closed fold under the cursor.

For Ex commands that work on buffer lines the range is adjusted to always start at the first line of a closed fold and end at the last line of a closed fold. Thus this command:

```
:s/foo/bar/g
```

when used with the cursor on a closed fold, will replace "foo" with "bar" in all lines of the fold.
This does not happen for :folddoopen and :folddoclosed .

When editing a buffer that has been edited before, the last used folding
settings are used again. For manual folding the defined folds are restored.
For all folding methods the manually opened and closed folds are restored.
If this buffer has been edited in this window, the values from back then are
used. Otherwise the values from the window where the buffer was edited last
are used.

print.txt For Vim version 8.1. Last change: 2010 Jul 20

VIM REFERENCE MANUAL by Bram Moolenaar

Printing printing

{Vi has None of this}
{only available when compiled with the |+printer| feature}

==========

1. Introduction print-intro

On MS-Windows Vim can print your text on any installed printer. On other systems a PostScript file is produced. This can be directly sent to a PostScript printer. For other printers a program like ghostscript needs to be used.

Note: If you have problems printing with :hardcopy , an alternative is to use :TOhtml and print the resulting html file from a browser.

:ha :hardcopy E237 E238 E324

:[range]ha[rdcopy][!] [arguments]
Send [range] lines (default whole file) to the printer.

On MS-Windows a dialog is displayed to allow selection of printer, paper size etc. To skip the dialog, use the [!]. In this case the printer defined by 'printdevice' is used, or, if 'printdevice' is empty, the system default printer.

For systems other than MS-Windows, PostScript is written in a temp file and 'printexpr' is used to actually print it. Then [arguments] can be used by 'printexpr' through v:cmdarg . Otherwise [arguments] is ignored. 'printoptions' can be used to specify paper size, duplex, etc.

:[range]ha[rdcopy][!] >{filename}
As above, but write the resulting PostScript in file {filename}.
Things like "%" are expanded cmdline-special
Careful: An existing file is silently overwritten.

{only available when compiled with the +postscript feature}
On MS-Windows use the "print to file" feature of the printer driver.

Progress is displayed during printing as a page number and a percentage. To abort printing use the interrupt key (CTRL-C or, on MS-systems, CTRL-Break).

Printer output is controlled by the 'printfont' and 'printoptions' options. 'printheader' specifies the format of a page header.

The printed file is always limited to the selected margins, irrespective of the current window's 'wrap' or 'linebreak' settings. The "wrap" item in 'printoptions' can be used to switch wrapping off.
The current highlighting colors are used in the printout, with the following considerations:
1) The normal background is always rendered as white (i.e. blank paper).
2) White text or the default foreground is rendered as black, so that it shows up!
3) If 'background' is "dark", then the colours are darkened to compensate for the fact that otherwise they would be too bright to show up clearly on white paper.

==
2. Print options print-options

Here are the details for the options that change the way printing is done.
For generic info about setting options see options.txt .

pdev-option
'printdevice' 'pdev' string (default empty)
global
This defines the name of the printer to be used when the :hardcopy command is issued with a bang (!) to skip the printer selection dialog. On Win32, it should be the printer name exactly as it appears in the standard printer dialog.
If the option is empty, then vim will use the system default printer for ":hardcopy!"

penc-option E620
'printencoding' 'penc' String (default empty, except for:
Windows, OS/2: cp1252,
Macintosh: mac-roman,
VMS: dec-mcs,
HPUX: hp-roman8,
EBCDIC: ebcdic-uk)
global
Sets the character encoding used when printing. This option tells Vim which print character encoding file from the "print" directory in 'runtimepath' to use.

This option will accept any value from encoding-names . Any recognized names are converted to Vim standard names - see 'encoding' for more details. Names not recognized by Vim will just be converted to lower case and underscores

replaced with '-' signs.

If 'printencoding' is empty or Vim cannot find the file then it will use 'encoding' (if Vim is compiled with +multi_byte and it is set an 8-bit encoding) to find the print character encoding file. If Vim is unable to find a character encoding file then it will use the "latin1" print character encoding file.

When 'encoding' is set to a multi-byte encoding, Vim will try to convert characters to the printing encoding for printing (if 'printencoding' is empty then the conversion will be to latin1). Conversion to a printing encoding other than latin1 will require Vim to be compiled with the +iconv feature. If no conversion is possible then printing will fail. Any characters that cannot be converted will be replaced with upside down question marks.

Four print character encoding files are provided to support default Mac, VMS, HPUX, and EBCDIC character encodings and are used by default on these platforms. Code page 1252 print character encoding is used by default on Windows and OS/2 platforms.

pexpr-option

'printexpr' 'pexpr' String (default: see below)
global
Expression that is evaluated to print the PostScript produced with :hardcopy .
The file name to be printed is in v:fname_in .
The arguments to the ":hardcopy" command are in v:cmdarg .
The expression must take care of deleting the file after printing it.
When there is an error, the expression must return a non-zero number.
If there is no error, return zero or an empty string.
The default for non MS-Windows or VMS systems is to simply use "lpr" to print the file:

```
system('lpr' . (&printdevice == '' ? '' : ' -P' . &printdevice)
    . ' ' . v:fname_in) . delete(v:fname_in) + v:shell_error
```

On MS-Dos, MS-Windows and OS/2 machines the default is to copy the file to the currently specified printdevice:

```
system('copy' . ' ' . v:fname_in . (&printdevice == ''
            ? ' LPT1:' : (' \"' . &printdevice . '\"')))
            . delete(v:fname_in)
```

On VMS machines the default is to send the file to either the default or currently specified printdevice:

```
system('print' . (&printdevice == '' ? '' : ' /queue=' .
            &printdevice) . ' ' . v:fname_in) . delete(v:fname_in)
```

If you change this option, using a function is an easy way to avoid having to escape all the spaces. Example:

```
:set printexpr=PrintFile(v:fname_in)
:function PrintFile(fname)
```

```
        :  call system("ghostview " . a:fname)
        :  call delete(a:fname)
        :  return v:shell_error
        :endfunc
```

Be aware that some print programs return control before they have read the file. If you delete the file too soon it will not be printed. These programs usually offer an option to have them remove the file when printing is done.
E365
If evaluating the expression fails or it results in a non-zero number, you get an error message. In that case Vim will delete the file. In the default value for non-MS-Windows a trick is used: Adding "v:shell_error" will result in a non-zero number when the system() call fails.

This option cannot be set from a modeline or in the sandbox, for security reasons.

pfn-option E613
'printfont' 'pfn' string (default "courier")
global
This is the name of the font that will be used for the :hardcopy command's output. It has the same format as the 'guifont' option, except that only one font may be named, and the special "guifont=*" syntax is not available.

In the Win32 GUI version this specifies a font name with its extra attributes, as with the 'guifont' option.

For other systems, only ":h11" is recognized, where "11" is the point size of the font. When omitted, the point size is 10.

pheader-option
'printheader' 'pheader' string (default "%<%f%h%m%=Page %N")
global
This defines the format of the header produced in :hardcopy output. The option is defined in the same way as the 'statusline' option. If Vim has not been compiled with the +statusline feature, this option has no effect and a simple default header is used, which shows the page number. The same simple header is used when this option is empty.

pmbcs-option
'printmbcharset' 'pmbcs' string (default "")
global
Sets the CJK character set to be used when generating CJK output from :hardcopy. The following predefined values are currently recognised by Vim:

	Value	Description
Chinese (Simplified)	GB_2312-80	
	GBT_12345-90	
	MAC	Apple Mac Simplified Chinese
	GBT-90_MAC	GB/T 12345-90 Apple Mac Simplified Chinese
	GBK	GBK (GB 13000.1-93)
	ISO10646	ISO 10646-1:1993

```
  Chinese       CNS_1993        CNS 11643-1993, Planes 1 & 2
  (Traditional) BIG5
                ETEN            Big5 with ETen extensions
                ISO10646        ISO 10646-1:1993

  Japanese      JIS_C_1978
                JIS_X_1983
                JIS_X_1990
                MSWINDOWS       Win3.1/95J (JIS X 1997 + NEC +
                                  IBM extensions)
                KANJITALK6      Apple Mac KanjiTalk V6.x
                KANJITALK7      Apple Mac KanjiTalk V7.x

  Korean        KS_X_1992
                MAC             Apple Macintosh Korean
                MSWINDOWS       KS X 1992 with MS extensions
                ISO10646        ISO 10646-1:1993
```

Only certain combinations of the above values and 'printencoding' are possible. The following tables show the valid combinations:

```
                              euc-cn   gbk    ucs-2   utf-8
  Chinese       GB_2312-80        x
  (Simplified)  GBT_12345-90      x
                MAC               x
                GBT-90_MAC        x
                GBK                       x
                ISO10646                        x       x

                              euc-tw   big5   ucs-2   utf-8
  Chinese       CNS_1993          x
  (Traditional) BIG5                      x
                ETEN                      x
                ISO10646                        x       x

                              euc-jp   sjis   ucs-2   utf-8
  Japanese      JIS_C_1978        x       x
                JIS_X_1983        x       x
                JIS_X_1990        x               x       x
                MSWINDOWS         x
                KANJITALK6        x
                KANJITALK7        x

                              euc-kr   cp949  ucs-2   utf-8
  Korean        KS_X_1992         x
                MAC               x
                MSWINDOWS                 x
                ISO10646                        x       x
```

To set up the correct encoding and character set for printing some Japanese text you would do the following;

```
        :set printencoding=euc-jp
        :set printmbcharset=JIS_X_1983
```

If 'printmbcharset' is not one of the above values then it is assumed to specify a custom multi-byte character set and no check will be made that it is compatible with the value for 'printencoding'. Vim will look for a file defining the character set in the "print" directory in 'runtimepath'.

pmbfn-option

'printmbfont' 'pmbfn' string (default "")
global

This is a comma-separated list of fields for font names to be used when generating CJK output from :hardcopy . Each font name has to be preceded with a letter indicating the style the font is to be used for as follows:

```
r:{font-name}          font to use for normal characters
b:{font-name}          font to use for bold characters
i:{font-name}          font to use for italic characters
o:{font-name}          font to use for bold-italic characters
```

A field with the r: prefix must be specified when doing CJK printing. The other fontname specifiers are optional. If a specifier is missing then another font will be used as follows:

```
if b: is missing, then use r:
if i: is missing, then use r:
if o: is missing, then use b:
```

Some CJK fonts do not contain characters for codes in the ASCII code range. Also, some characters in the CJK ASCII code ranges differ in a few code points from traditional ASCII characters. There are two additional fields to control printing of characters in the ASCII code range.

```
c:yes                  Use Courier font for characters in the ASCII
c:no (default)         code range.

a:yes                  Use ASCII character set for codes in the ASCII
a:no (default)         code range.
```

The following is an example of specifying two multi-byte fonts, one for normal and italic printing and one for bold and bold-italic printing, and using Courier to print codes in the ASCII code range but using the national character set:

```
:set printmbfont=r:WadaMin-Regular,b:WadaMin-Bold,c:yes
```

popt-option

'printoptions' 'popt' string (default "")
global

This is a comma-separated list of items that control the format of the output of :hardcopy :

```
left:{spec}            left margin (default: 10pc)
right:{spec}           right margin (default: 5pc)
top:{spec}             top margin (default: 5pc)
bottom:{spec}          bottom margin (default: 5pc)
                       {spec} is a number followed by "in" for inches, "pt"
                       for points (1 point is 1/72 of an inch), "mm" for
```

millimeters or "pc" for a percentage of the media size.
Weird example:
    left:2in,top:30pt,right:16mm,bottom:3pc
If the unit is not recognized there is no error and the default value is used.

header:{nr} Number of lines to reserve for the header. Only the first line is actually filled, thus when {nr} is 2 there is one empty line. The header is formatted according to 'printheader'.
header:0 Do not print a header.
header:2 (default) Use two lines for the header

syntax:n Do not use syntax highlighting. This is faster and thus useful when printing large files.
syntax:y Do syntax highlighting.
syntax:a (default) Use syntax highlighting if the printer appears to be able to print color or grey.

number:y Include line numbers in the printed output.
number:n (default) No line numbers.

wrap:y (default) Wrap long lines.
wrap:n Truncate long lines.

duplex:off Print on one side.
duplex:long (default) Print on both sides (when possible), bind on long side.
duplex:short Print on both sides (when possible), bind on short side.

collate:y (default) Collating: 1 2 3, 1 2 3, 1 2 3
collate:n No collating: 1 1 1, 2 2 2, 3 3 3

jobsplit:n (default) Do all copies in one print job
jobsplit:y Do each copy as a separate print job. Useful when doing N-up postprocessing.

portrait:y (default) Orientation is portrait.
portrait:n Orientation is landscape.

a4 letter

paper:A4 (default) Paper size: A4
paper:{name} Paper size from this table:

{name}	size in cm	size in inch
10x14	25.4 x 35.57	10 x 14
A3	29.7 x 42	11.69 x 16.54
A4	21 x 29.7	8.27 x 11.69
A5	14.8 x 21	5.83 x 8.27
B4	25 x 35.3	10.12 x 14.33
B5	17.6 x 25	7.17 x 10.12
executive	18.42 x 26.67	7.25 x 10.5
folio	21 x 33	8.27 x 13
ledger	43.13 x 27.96	17 x 11

```
                        legal       21.59 x 35.57     8.5  x 14
                        letter      21.59 x 27.96     8.5  x 11
                        quarto      21.59 x 27.5      8.5  x 10.83
                        statement   13.97 x 21.59     5.5  x  8.5
                        tabloid     27.96 x 43.13    11    x 17

  formfeed:n (default)  Treat form feed characters (0x0c) as a normal print
                        character.
  formfeed:y            When a form feed character is encountered, continue
                        printing of the current line at the beginning of the
                        first line on a new page.

The item indicated with (default) is used when the item is not present.  The
values are not always used, especially when using a dialog to select the
printer and options.
Example:
        :set printoptions=paper:letter,duplex:off

==============================================================================
3. PostScript Printing                                  postscript-printing
                                                  E455   E456   E457   E624

Provided you have enough disk space there should be no problems generating a
PostScript file.  You need to have the runtime files correctly installed (if
you can find the help files, they probably are).

There are currently a number of limitations with PostScript printing:

- 'printfont' - The font name is ignored (the Courier family is always used -
  it should be available on all PostScript printers) but the font size is
  used.

- 'printoptions' - The duplex setting is used when generating PostScript
  output, but it is up to the printer to take notice of the setting.  If the
  printer does not support duplex printing then it should be silently ignored.
  Some printers, however, don't print at all.

- 8-bit support - While a number of 8-bit print character encodings are
  supported it is possible that some characters will not print.  Whether a
  character will print depends on the font in the printer knowing the
  character.  Missing characters will be replaced with an upside down question
  mark, or a space if that character is also not known by the font.  It may be
  possible to get all the characters in an encoding to print by installing a
  new version of the Courier font family.

- Multi-byte support - Currently Vim will try to convert multi-byte characters
  to the 8-bit encoding specified by 'printencoding' (or latin1 if it is
  empty).  Any characters that are not successfully converted are shown as
  unknown characters.  Printing will fail if Vim cannot convert the multi-byte
  to the 8-bit encoding.

==============================================================================
4. Custom 8-bit Print Character Encodings       postscript-print-encoding
                                                          E618   E619

To use your own print character encoding when printing 8-bit character data
```

you need to define your own PostScript font encoding vector. Details on how to define a font encoding vector is beyond the scope of this help file, but you can find details in the PostScript Language Reference Manual, 3rd Edition, published by Addison-Wesley and available in PDF form at http://www.adobe.com/. The following describes what you need to do for Vim to locate and use your print character encoding.

i. Decide on a unique name for your encoding vector, one that does not clash with any of the recognized or standard encoding names that Vim uses (see encoding-names for a list), and that no one else is likely to use.
ii. Copy $VIMRUNTIME/print/latin1.ps to the print subdirectory in your 'runtimepath' and rename it with your unique name.
iii. Edit your renamed copy of latin1.ps, replacing all occurrences of latin1 with your unique name (don't forget the line starting %%Title:), and modify the array of glyph names to define your new encoding vector. The array must have exactly 256 entries or you will not be able to print!
iv. Within Vim, set 'printencoding' to your unique encoding name and then print your file. Vim will now use your custom print character encoding.

Vim will report an error with the resource file if you change the order or content of the first 3 lines, other than the name of the encoding on the line starting %%Title: or the version number on the line starting %%Version:.

[Technical explanation for those that know PostScript - Vim looks for a file with the same name as the encoding it will use when printing. The file defines a new PostScript Encoding resource called /VIM-name, where name is the print character encoding Vim will use.]

==
5. PostScript CJK Printing postscript-cjk-printing

E673 E674 E675

Vim supports printing of Chinese, Japanese, and Korean files. Setting up Vim to correctly print CJK files requires setting up a few more options.

Each of these countries has many standard character sets and encodings which require that both be specified when printing. In addition, CJK fonts normally do not have the concept of italic glyphs and use different weight or stroke style to achieve emphasis when printing. This in turn requires a different approach to specifying fonts to use when printing.

The encoding and character set are specified with the 'printencoding' and 'printmbcharset' options. If 'printencoding' is not specified then 'encoding' is used as normal. If 'printencoding' is specified then characters will be translated to this encoding for printing. You should ensure that the encoding is compatible with the character set needed for the file contents or some characters may not appear when printed.

The fonts to use for CJK printing are specified with 'printmbfont'. This option allows you to specify different fonts to use when printing characters which are syntax highlighted with the font styles normal, italic, bold and bold-italic.

No CJK fonts are supplied with Vim. There are some free Korean, Japanese, and

Traditional Chinese fonts available at:

  http://examples.oreilly.com/cjkvinfo/adobe/samples/

You can find descriptions of the various fonts in the read me file at

  http://examples.oreilly.de/english_examples/cjkvinfo/adobe/00README

Please read your printer documentation on how to install new fonts.

CJK fonts can be large containing several thousand glyphs, and it is not
uncommon to find that they only contain a subset of a national standard. It
is not unusual to find the fonts to not include characters for codes in the
ASCII code range. If you find half-width Roman characters are not appearing
in your printout then you should configure Vim to use the Courier font the
half-width ASCII characters with 'printmbfont'. If your font does not include
other characters then you will need to find another font that does.

Another issue with ASCII characters, is that the various national character
sets specify a couple of different glyphs in the ASCII code range. If you
print ASCII text using the national character set you may see some unexpected
characters. If you want true ASCII code printing then you need to configure
Vim to output ASCII characters for the ASCII code range with 'printmbfont'.

It is possible to define your own multi-byte character set although this
should not be attempted lightly. A discussion on the process if beyond the
scope of these help files. You can find details on CMap (character map) files
in the document 'Adobe CMap and CIDFont Files Specification, Version 1.0',
available from http://www.adobe.com as a PDF file.

==
6. PostScript Printing Troubleshooting   postscript-print-trouble
                                                                        E621
Usually the only sign of a problem when printing with PostScript is that your
printout does not appear. If you are lucky you may get a printed page that
tells you the PostScript operator that generated the error that prevented the
print job completing.

There are a number of possible causes as to why the printing may have failed:

- Wrong version of the prolog resource file. The prolog resource file
  contains some PostScript that Vim needs to be able to print. Each version
  of Vim needs one particular version. Make sure you have correctly installed
  the runtime files, and don't have any old versions of a file called prolog
  in the print directory in your 'runtimepath' directory.

- Paper size. Some PostScript printers will abort printing a file if they do
  not support the requested paper size. By default Vim uses A4 paper. Find
  out what size paper your printer normally uses and set the appropriate paper
  size with 'printoptions'. If you cannot find the name of the paper used,
  measure a sheet and compare it with the table of supported paper sizes listed
  for 'printoptions', using the paper that is closest in both width AND height.
  Note: The dimensions of actual paper may vary slightly from the ones listed.
  If there is no paper listed close enough, then you may want to try psresize

from PSUtils, discussed below.

- Two-sided printing (duplex). Normally a PostScript printer that does not support two-sided printing will ignore any request to do it. However, some printers may abort the job altogether. Try printing with duplex turned off. Note: Duplex prints can be achieved manually using PS utils - see below.

- Collated printing. As with Duplex printing, most PostScript printers that do not support collating printouts will ignore a request to do so. Some may not. Try printing with collation turned off.

- Syntax highlighting. Some print management code may prevent the generated PostScript file from being printed on a black and white printer when syntax highlighting is turned on, even if solid black is the only color used. Try printing with syntax highlighting turned off.

A safe printoptions setting to try is:

```
:set printoptions=paper:A4,duplex:off,collate:n,syntax:n
```

Replace "A4" with the paper size that best matches your printer paper.

==
7. PostScript Utilities postscript-print-util

7.1 Ghostscript

Ghostscript is a PostScript and PDF interpreter that can be used to display and print on non-PostScript printers PostScript and PDF files. It can also generate PDF files from PostScript.

Ghostscript will run on a wide variety of platforms.

There are three available versions:

- AFPL Ghostscript (formerly Aladdin Ghostscript) which is free for non-commercial use. It can be obtained from:

  http://www.cs.wisc.edu/~ghost/

- GNU Ghostscript which is available under the GNU General Public License. It can be obtained from:

  ftp://mirror.cs.wisc.edu/pub/mirrors/ghost/gnu/

- A commercial version for inclusion in commercial products.

Additional information on Ghostscript can also be found at:

http://www.ghostscript.com/

Support for a number of non PostScript printers is provided in the distribution as standard, but if you cannot find support for your printer check the Ghostscript site for other printers not included by default.

7.2 Ghostscript Previewers.

The interface to Ghostscript is very primitive so a number of graphical front ends have been created. These allow easier PostScript file selection, previewing at different zoom levels, and printing. Check supplied documentation for full details.

X11

- Ghostview. Obtainable from:

    http://www.cs.wisc.edu/~ghost/gv/

- gv. Derived from Ghostview. Obtainable from:

    http://wwwthep.physik.uni-mainz.de/~plass/gv/

  Copies (possibly not the most recent) can be found at:

    http://www.cs.wisc.edu/~ghost/gv/

OpenVMS

- Is apparently supported in the main code now (untested). See:

    http://wwwthep.physik.uni-mainz.de/~plass/gv/

Windows and OS/2

- GSview. Obtainable from:

    http://www.cs.wisc.edu/~ghost/gsview/

DOS

- ps_view. Obtainable from:

    ftp://ftp.pg.gda.pl/pub/TeX/support/ps_view/
    ftp://ftp.dante.de/tex-archive/support/ps_view/

Linux

- GSview. Linux version of the popular Windows and OS/2 previewer.
  Obtainable from:

    http://www.cs.wisc.edu/~ghost/gsview/

- BMV. Different from Ghostview and gv in that it doesn't use X but svgalib.
  Obtainable from:

    ftp://sunsite.unc.edu/pub/Linux/apps/graphics/viewers/svga/bmv-1.2.tgz

7.3 PSUtils

PSUtils is a collection of utility programs for manipulating PostScript documents. Binary distributions are available for many platforms, as well as the full source. PSUtils can be found at:

  http://knackered.org/angus/psutils

The utilities of interest include:

- psnup. Convert PS files for N-up printing.
- psselect. Select page range and order of printing.
- psresize. Change the page size.
- psbook. Reorder and lay out pages ready for making a book.

The output of one program can be used as the input to the next, allowing for complex print document creation.

N-UP PRINTING

The psnup utility takes an existing PostScript file generated from Vim and convert it to an n-up version. The simplest way to create a 2-up printout is to first create a PostScript file with:

```
:hardcopy > test.ps
```

Then on your command line execute:

```
psnup -n 2 test.ps final.ps
```

Note: You may get warnings from some Ghostscript previewers for files produced by psnup - these may safely be ignored.

Finally print the file final.ps to your PostScript printer with your platform's print command. (You will need to delete the two PostScript files afterwards yourself.) 'printexpr' could be modified to perform this extra step before printing.

ALTERNATE DUPLEX PRINTING

It is possible to achieve a poor man's version of duplex printing using the PS utility psselect. This utility has options -e and -o for printing just the even or odd pages of a PS file respectively.

First generate a PS file with the 'hardcopy' command, then generate new files with all the odd and even numbered pages with:

```
psselect -o test.ps odd.ps
psselect -e test.ps even.ps
```

Next print odd.ps with your platform's normal print command. Then take the

print output, turn it over and place it back in the paper feeder. Now print even.ps with your platform's print command. All the even pages should now appear on the back of the odd pages.

There are a couple of points to bear in mind:

1. Position of the first page. If the first page is on top of the printout when printing the odd pages then you need to reverse the order that the odd pages are printed. This can be done with the -r option to psselect. This will ensure page 2 is printed on the back of page 1.
   Note: it is better to reverse the odd numbered pages rather than the even numbered in case there are an odd number of pages in the original PS file.

2. Paper flipping. When turning over the paper with the odd pages printed on them you may have to either flip them horizontally (along the long edge) or vertically (along the short edge), as well as possibly rotating them 180 degrees. All this depends on the printer - it will be more obvious for desktop ink jets than for small office laser printers where the paper path is hidden from view.

==
8. Formfeed Characters   printing-formfeed

By default Vim does not do any special processing of formfeed control characters. Setting the 'printoptions' formfeed item will make Vim recognize formfeed characters and continue printing the current line at the beginning of the first line on a new page. The use of formfeed characters provides rudimentary print control but there are certain things to be aware of.

Vim will always start printing a line (including a line number if enabled) containing a formfeed character, even if it is the first character on the line. This means if a line starting with a formfeed character is the first line of a page then Vim will print a blank page.

Since the line number is printed at the start of printing the line containing the formfeed character, the remainder of the line printed on the new page will not have a line number printed for it (in the same way as the wrapped lines of a long line when wrap in 'printoptions' is enabled).

If the formfeed character is the last character on a line, then printing will continue on the second line of the new page, not the first. This is due to Vim processing the end of the line after the formfeed character and moving down a line to continue printing.

Due to the points made above it is recommended that when formfeed character processing is enabled, printing of line numbers is disabled, and that form feed characters are not the last character on a line. Even then you may need to adjust the number of lines before a formfeed character to prevent accidental blank pages.

remote.txt For Vim version 8.1. Last change: 2017 Nov 12

VIM REFERENCE MANUAL by Bram Moolenaar

Vim client-server communication client-server

{Vi does not have any of these commands}

==========

1. Common functionality clientserver

When compiled with the +clientserver option, Vim can act as a command server. It accepts messages from a client and executes them. At the same time, Vim can function as a client and send commands to a Vim server.

The following command line arguments are available:

argument	meaning
--remote [+{cmd}] {file} ...	--remote Open the file list in a remote Vim. When there is no Vim server, execute locally. There is one optional init command: +{cmd}. This must be an Ex command that can be followed by "|". The rest of the command line is taken as the file list. Thus any non-file arguments must come before this. You cannot edit stdin this way -- . The remote Vim is raised. If you don't want this use vim --remote-send "<C-\><C-N>:n filename<CR>"
--remote-silent [+{cmd}] {file} ...	--remote-silent As above, but don't complain if there is no server and the file is edited locally.
--remote-wait [+{cmd}] {file} ...	--remote-wait As --remote, but wait for files to complete (unload) in remote Vim.
--remote-wait-silent [+{cmd}] {file} ...	--remote-wait-silent As --remote-wait, but don't complain if there is no server.
--remote-tab	--remote-tab Like --remote but open each file in a new tabpage.
--remote-tab-silent	--remote-tab-silent Like --remote-silent but open each file in a new tabpage.

--remote-tab-wait

--remote-tab-wait — Like --remote-wait but open each file in a new tabpage.

--remote-tab-wait-silent

--remote-tab-wait-silent — Like --remote-wait-silent but open each file in a new tabpage.

--servername

--servername {name} — Become the server {name}. When used together with one of the --remote commands: connect to server {name} instead of the default (see below). The name used will be uppercase.

--remote-send

--remote-send {keys} — Send {keys} to server and exit. The {keys} are not mapped. Special key names are recognized, e.g., "<CR>" results in a CR character.

--remote-expr

--remote-expr {expr} — Evaluate {expr} in server and print the result on stdout.

--serverlist

--serverlist — Output a list of server names.

Examples

Edit "file.txt" in an already running GVIM server:

```
gvim --remote file.txt
```

Edit "file.txt" in an already running server called FOOBAR:

```
gvim --servername FOOBAR --remote file.txt
```

Edit "file.txt" in server "FILES" if it exists, become server "FILES" otherwise:

```
gvim --servername FILES --remote-silent file.txt
```

This doesn't work, all arguments after --remote will be used as file names:

```
gvim --remote --servername FOOBAR file.txt
```

Edit file "+foo" in a remote server (note the use of "./" to avoid the special meaning of the leading plus):

```
vim --remote ./+foo
```

Tell the remote server "BLA" to write all files and exit:

```
vim --servername BLA --remote-send '<C-\><C-N>:wqa<CR>'
```

SERVER NAME

client-server-name

By default Vim will try to register the name under which it was invoked (gvim, egvim ...). This can be overridden with the --servername argument. If the specified name is not available, a postfix is applied until a free name is encountered, i.e. "gvim1" for the second invocation of gvim on a particular X-server. The resulting name is available in the servername builtin variable

v:servername . The case of the server name is ignored, thus "gvim" and "GVIM" are considered equal.

When Vim is invoked with --remote, --remote-wait or --remote-send it will try to locate the server name determined by the invocation name and --servername argument as described above. If an exact match is not available, the first server with the number postfix will be used. If a name with the number postfix is specified with the --servername argument, it must match exactly.

If no server can be located and --remote or --remote-wait was used, Vim will start up according to the rest of the command line and do the editing by itself. This way it is not necessary to know whether gvim is already started when sending command to it.

The --serverlist argument will cause Vim to print a list of registered command servers on the standard output (stdout) and exit.

Win32 Note: Making the Vim server go to the foreground doesn't always work, because MS-Windows doesn't allow it. The client will move the server to the foreground when using the --remote or --remote-wait argument and the server name starts with "g".

REMOTE EDITING

The --remote argument will cause a :drop command to be constructed from the rest of the command line and sent as described above.
The --remote-wait argument does the same thing and additionally sets up to wait for each of the files to have been edited. This uses the BufUnload event, thus as soon as a file has been unloaded, Vim assumes you are done editing it.
Note that the --remote and --remote-wait arguments will consume the rest of the command line. I.e. all remaining arguments will be regarded as filenames. You can not put options there!

FUNCTIONS

E240 E573

There are a number of Vim functions for scripting the command server. See the description in eval.txt or use CTRL-] on the function name to jump to the full explanation.

synopsis	explanation
remote_startserver(name)	run a server
remote_expr(server, string, idvar)	send expression
remote_send(server, string, idvar)	send key sequence
serverlist()	get a list of available servers
remote_peek(serverid, retvar)	check for reply string
remote_read(serverid)	read reply string
server2client(serverid, string)	send reply string
remote_foreground(server)	bring server to the front

See also the explanation of CTRL-_CTRL-N . Very useful as a leading key sequence.

The {serverid} for server2client() can be obtained with expand("<client>")

==
2. X11 specific items   x11-clientserver
                                        E247 E248 E251 E258 E277

The communication between client and server goes through the X server. The
display of the Vim server must be specified. The usual protection of the X
server is used, you must be able to open a window on the X server for the
communication to work. It is possible to communicate between different
systems.

By default, a GUI Vim will register a name on the X-server by which it can be
addressed for subsequent execution of injected strings. Vim can also act as
a client and send strings to other instances of Vim on the same X11 display.

When an X11 GUI Vim (gvim) is started, it will try to register a send-server
name on the 'VimRegistry' property on the root window.

A non GUI Vim with access to the X11 display (xterm-clipboard enabled), can
also act as a command server if a server name is explicitly given with the
--servername argument, or when Vim was build with the +autoservername
feature.

An empty --servername argument will cause the command server to be disabled.

To send commands to a Vim server from another application, read the source
file src/if_xcmdsrv.c, it contains some hints about the protocol used.

==
3. Win32 specific items   w32-clientserver

Every Win32 Vim can work as a server, also in the console. You do not need a
version compiled with OLE. Windows messages are used, this works on any
version of MS-Windows. But only communication within one system is possible.

Since MS-Windows messages are used, any other application should be able to
communicate with a Vim server. An alternative is using the OLE functionality
ole-interface .

When using gvim, the --remote-wait only works properly this way:

```
start /w gvim --remote-wait file.txt
```

vim:tw=78:sw=4:ts=8:noet:ft=help:norl:

term.txt For Vim version 8.1. Last change: 2017 Oct 14

VIM REFERENCE MANUAL by Bram Moolenaar

Terminal information terminal-info

Vim uses information about the terminal you are using to fill the screen and recognize what keys you hit. If this information is not correct, the screen may be messed up or keys may not be recognized. The actions which have to be performed on the screen are accomplished by outputting a string of characters. Special keys produce a string of characters. These strings are stored in the terminal options, see terminal-options .

NOTE: Most of this is not used when running the GUI .

==========

1. Startup startup-terminal

When Vim is started a default terminal type is assumed. For the Amiga this is a standard CLI window, for MS-DOS the pc terminal, for Unix an ansi terminal. A few other terminal types are always available, see below builtin-terms .

You can give the terminal name with the '-T' Vim argument. If it is not given Vim will try to get the name from the TERM environment variable.

termcap terminfo E557 E558 E559

On Unix the terminfo database or termcap file is used. This is referred to as "termcap" in all the documentation. At compile time, when running configure, the choice whether to use terminfo or termcap is done automatically. When running Vim the output of ":version" will show +terminfo if terminfo is used. Also see xterm-screens .

On non-Unix systems a termcap is only available if Vim was compiled with TERMCAP defined.

builtin-terms builtin_terms

Which builtin terminals are available depends on a few defines in feature.h, which need to be set at compile time:

define	output of ":version"	terminals builtin
NO_BUILTIN_TCAPS	-builtin_terms	none
SOME_BUILTIN_TCAPS	+builtin_terms	most common ones (default)
ALL_BUILTIN_TCAPS	++builtin_terms	all available

You can see a list of available builtin terminals with ":set term=xxx" (when not running the GUI). Also see +builtin_terms .

If the termcap code is included Vim will try to get the strings for the terminal you are using from the termcap file and the builtin termcaps. Both are always used, if an entry for the terminal you are using is present. Which one is used first depends on the 'ttybuiltin' option:

'ttybuiltin' on 1: builtin termcap 2: external termcap
'ttybuiltin' off 1: external termcap 2: builtin termcap

If an option is missing in one of them, it will be obtained from the other one. If an option is present in both, the one first encountered is used.

Which external termcap file is used varies from system to system and may depend on the environment variables "TERMCAP" and "TERMPATH". See "man tgetent".

Settings depending on terminal term-dependent-settings

If you want to set options or mappings, depending on the terminal name, you can do this best in your .vimrc. Example:

```
if &term == "xterm"
  ... xterm maps and settings ...
elseif &term =~ "vt10."
  ... vt100, vt102 maps and settings ...
endif
```

raw-terminal-mode

For normal editing the terminal will be put into "raw" mode. The strings defined with 't_ti' and 't_ks' will be sent to the terminal. Normally this puts the terminal in a state where the termcap codes are valid and activates the cursor and function keys. When Vim exits the terminal will be put back into the mode it was before Vim started. The strings defined with 't_te' and 't_ke' will be sent to the terminal. On the Amiga, with commands that execute an external command (e.g., "!!"), the terminal will be put into Normal mode for a moment. This means that you can stop the output to the screen by hitting a printing key. Output resumes when you hit <BS>.

xterm-bracketed-paste

When the 't_BE' option is set then 't_BE' will be sent to the terminal when entering "raw" mode and 't_BD' when leaving "raw" mode. The terminal is then expected to put 't_PS' before pasted text and 't_PE' after pasted text. This way Vim can separate text that is pasted from characters that are typed. The pasted text is handled like when the middle mouse button is used, it is inserted literally and not interpreted as commands.

When the cursor is in the first column, the pasted text will be inserted before it. Otherwise the pasted text is appended after the cursor position. This means one cannot paste after the first column. Unfortunately Vim does not have a way to tell where the mouse pointer was.

Note that in some situations Vim will not recognize the bracketed paste and you will get the raw text. In other situations Vim will only get the first pasted character and drop the rest, e.g. when using the "r" command. If you have a problem with this, disable bracketed paste by putting this in your

.vimrc:
```
	set t_BE=
```
If this is done while Vim is running the 't_BD' will be sent to the terminal
to disable bracketed paste.

If your terminal supports bracketed paste, but the options are not set
automatically, you can try using something like this:

```
	if &term =~ "screen"
	  let &t_BE = "\e[?2004h"
	  let &t_BD = "\e[?2004l"
	  exec "set t_PS=\e[200~"
	  exec "set t_PE=\e[201~"
	endif
```

cs7-problem

Note: If the terminal settings are changed after running Vim, you might have
an illegal combination of settings. This has been reported on Solaris 2.5
with "stty cs8 parenb", which is restored as "stty cs7 parenb". Use
"stty cs8 -parenb -istrip" instead, this is restored correctly.

Some termcap entries are wrong in the sense that after sending 't_ks' the
cursor keys send codes different from the codes defined in the termcap. To
avoid this you can set 't_ks' (and 't_ke') to empty strings. This must be
done during initialization (see initialization), otherwise it's too late.

Some termcap entries assume that the highest bit is always reset. For
example: The cursor-up entry for the Amiga could be ":ku=\E[A:". But the
Amiga really sends "\233A". This works fine if the highest bit is reset,
e.g., when using an Amiga over a serial line. If the cursor keys don't work,
try the entry ":ku=\233A:".

Some termcap entries have the entry ":ku=\E[A:". But the Amiga really sends
"\233A". On output "\E[" and "\233" are often equivalent, on input they
aren't. You will have to change the termcap entry, or change the key code with
the :set command to fix this.

Many cursor key codes start with an <Esc>. Vim must find out if this is a
single hit of the <Esc> key or the start of a cursor key sequence. It waits
for a next character to arrive. If it does not arrive within one second a
single <Esc> is assumed. On very slow systems this may fail, causing cursor
keys not to work sometimes. If you discover this problem reset the 'timeout'
option. Vim will wait for the next character to arrive after an <Esc>. If
you want to enter a single <Esc> you must type it twice. Resetting the
'esckeys' option avoids this problem in Insert mode, but you lose the
possibility to use cursor and function keys in Insert mode.

On the Amiga the recognition of window resizing is activated only when the
terminal name is "amiga" or "builtin_amiga".

Some terminals have confusing codes for the cursor keys. The televideo 925 is
such a terminal. It sends a CTRL-H for cursor-left. This would make it
impossible to distinguish a backspace and cursor-left. To avoid this problem
CTRL-H is never recognized as cursor-left.

vt100-cursor-keys xterm-cursor-keys
Other terminals (e.g., vt100 and xterm) have cursor keys that send <Esc>OA, <Esc>OB, etc. Unfortunately these are valid commands in insert mode: Stop insert, Open a new line above the new one, start inserting 'A', 'B', etc. Instead of performing these commands Vim will erroneously recognize this typed key sequence as a cursor key movement. To avoid this and make Vim do what you want in either case you could use these settings:

```
:set notimeout          " don't timeout on mappings
:set ttimeout           " do timeout on terminal key codes
:set timeoutlen=100     " timeout after 100 msec
```

This requires the key-codes to be sent within 100 msec in order to recognize them as a cursor key. When you type you normally are not that fast, so they are recognized as individual typed commands, even though Vim receives the same sequence of bytes.

vt100-function-keys xterm-function-keys
An xterm can send function keys F1 to F4 in two modes: vt100 compatible or not. Because Vim may not know what the xterm is sending, both types of keys are recognized. The same happens for the <Home> and <End> keys.

		normal		vt100	
<F1>	t_k1	<Esc>[11~	<xF1>	<Esc>OP	<xF1>-xterm
<F2>	t_k2	<Esc>[12~	<xF2>	<Esc>OQ	<xF2>-xterm
<F3>	t_k3	<Esc>[13~	<xF3>	<Esc>OR	<xF3>-xterm
<F4>	t_k4	<Esc>[14~	<xF4>	<Esc>OS	<xF4>-xterm
<Home>	t_kh	<Esc>[7~	<xHome>	<Esc>OH	<xHome>-xterm
<End>	t_@7	<Esc>[4~	<xEnd>	<Esc>OF	<xEnd>-xterm

When Vim starts, <xF1> is mapped to <F1>, <xF2> to <F2> etc. This means that by default both codes do the same thing. If you make a mapping for <xF2>, because your terminal does have two keys, the default mapping is overwritten, thus you can use the <F2> and <xF2> keys for something different.

xterm-shifted-keys
Newer versions of xterm support shifted function keys and special keys. Vim recognizes most of them. Use ":set termcap" to check which are supported and what the codes are. Mostly these are not in a termcap, they are only supported by the builtin_xterm termcap.

xterm-modifier-keys
Newer versions of xterm support Alt and Ctrl for most function keys. To avoid having to add all combinations of Alt, Ctrl and Shift for every key a special sequence is recognized at the end of a termcap entry: ";*X". The "X" can be any character, often '~' is used. The ";*" stands for an optional modifier argument. ";2" is Shift, ";3" is Alt, ";5" is Ctrl and ";9" is Meta (when it's different from Alt). They can be combined. Examples:

```
:set <F8>=^[[19;*~
:set <Home>=^[[1;*H
```

Another speciality about these codes is that they are not overwritten by another code. That is to avoid that the codes obtained from xterm directly t_RV overwrite them.

xterm-scroll-region
The default termcap entry for xterm on Sun and other platforms does not contain the entry for scroll regions. Add ":cs=\E[%i%d;%dr:" to the xterm

entry in /etc/termcap and everything should work.

xterm-end-home-keys
On some systems (at least on FreeBSD with XFree86 3.1.2) the codes that the <End> and <Home> keys send contain a <Nul> character. To make these keys send the proper key code, add these lines to your ~/.Xdefaults file:

```
*VT100.Translations:            #override \n\
                <Key>Home: string("0x1b") string("[7~") \n\
                <Key>End: string("0x1b") string("[8~")
```

xterm-8bit xterm-8-bit
Xterm can be run in a mode where it uses 8-bit escape sequences. The CSI code is used instead of <Esc>[. The advantage is that an <Esc> can quickly be recognized in Insert mode, because it can't be confused with the start of a special key.
For the builtin termcap entries, Vim checks if the 'term' option contains "8bit" anywhere. It then uses 8-bit characters for the termcap entries, the mouse and a few other things. You would normally set $TERM in your shell to "xterm-8bit" and Vim picks this up and adjusts to the 8-bit setting automatically.
When Vim receives a response to the t_RV (request version) sequence and it starts with CSI, it assumes that the terminal is in 8-bit mode and will convert all key sequences to their 8-bit variants.

==
2. Terminal options terminal-options termcap-options E436

The terminal options can be set just like normal options. But they are not shown with the ":set all" command. Instead use ":set termcap".

It is always possible to change individual strings by setting the appropriate option. For example:

```
:set t_ce=^V^[[K        (CTRL-V, <Esc>, [, K)
```

{Vi: no terminal options. You have to exit Vi, edit the termcap entry and try again}

The options are listed below. The associated termcap code is always equal to the last two characters of the option name. Only one termcap code is required: Cursor motion, 't_cm'.

The options 't_da', 't_db', 't_ms', 't_xs', 't_xn' represent flags in the termcap. When the termcap flag is present, the option will be set to "y". But any non-empty string means that the flag is set. An empty string means that the flag is not set. 't_CS' works like this too, but it isn't a termcap flag.

OUTPUT CODES terminal-output-codes

option	meaning	
t_AB	set background color (ANSI)	t_AB 't_AB'
t_AF	set foreground color (ANSI)	t_AF 't_AF'
t_AL	add number of blank lines	t_AL 't_AL'

```
        t_al    add new blank line                                  t_al   't_al'
        t_bc    backspace character                                 t_bc   't_bc'
        t_cd    clear to end of screen                              t_cd   't_cd'
        t_ce    clear to end of line                                t_ce   't_ce'
        t_cl    clear screen                                        t_cl   't_cl'
        t_cm    cursor motion (required!)                 E437      t_cm   't_cm'
        t_Co    number of colors                                    t_Co   't_Co'
        t_CS    if non-empty, cursor relative to scroll region      t_CS   't_CS'
        t_cs    define scrolling region                             t_cs   't_cs'
        t_CV    define vertical scrolling region                    t_CV   't_CV'
        t_da    if non-empty, lines from above scroll down          t_da   't_da'
        t_db    if non-empty, lines from below scroll up            t_db   't_db'
        t_DL    delete number of lines                              t_DL   't_DL'
        t_dl    delete line                                         t_dl   't_dl'
        t_fs    set window title end (from status line)             t_fs   't_fs'
        t_ke    exit "keypad transmit" mode                         t_ke   't_ke'
        t_ks    start "keypad transmit" mode                        t_ks   't_ks'
        t_le    move cursor one char left                           t_le   't_le'
        t_mb    blinking mode                                       t_mb   't_mb'
        t_md    bold mode                                           t_md   't_md'
        t_me    Normal mode (undoes t_mr, t_mb, t_md and color)     t_me   't_me'
        t_mr    reverse (invert) mode                               t_mr   't_mr'
                                                                    t_ms   't_ms'
        t_ms    if non-empty, cursor can be moved in standout/inverse mode
        t_nd    non destructive space character                     t_nd   't_nd'
        t_op    reset to original color pair                        t_op   't_op'
        t_RI    cursor number of chars right                        t_RI   't_RI'
        t_Sb    set background color                                t_Sb   't_Sb'
        t_Sf    set foreground color                                t_Sf   't_Sf'
        t_se    standout end                                        t_se   't_se'
        t_so    standout mode                                       t_so   't_so'
        t_sr    scroll reverse (backward)                           t_sr   't_sr'
        t_te    out of "termcap" mode                               t_te   't_te'
        t_ti    put terminal in "termcap" mode                      t_ti   't_ti'
        t_ts    set window title start (to status line)             t_ts   't_ts'
        t_ue    underline end                                       t_ue   't_ue'
        t_us    underline mode                                      t_us   't_us'
        t_ut    clearing uses the current background color          t_ut   't_ut'
        t_vb    visual bell                                         t_vb   't_vb'
        t_ve    cursor visible                                      t_ve   't_ve'
        t_vi    cursor invisible                                    t_vi   't_vi'
        t_vs    cursor very visible (blink)                         t_vs   't_vs'
                                                                    t_xs   't_xs'
        t_xs    if non-empty, standout not erased by overwriting (hpterm)
                                                                    t_xn   't_xn'
        t_xn    if non-empty, writing a character at the last screen cell
                does not cause scrolling
        t_ZH    italics mode                                        t_ZH   't_ZH'
        t_ZR    italics end                                         t_ZR   't_ZR'

Added by Vim (there are no standard codes for these):
        t_Ce    undercurl end                                       t_Ce   't_Ce'
        t_Cs    undercurl mode                                      t_Cs   't_Cs'
        t_Te    strikethrough end                                   t_Te   't_Te'
```

```
        t_Ts    strikethrough mode                                  t_Ts   't_Ts'
        t_IS    set icon text start                                 t_IS   't_IS'
        t_IE    set icon text end                                   t_IE   't_IE'
        t_WP    set window position (Y, X) in pixels                t_WP   't_WP'
        t_GP    get window position (Y, X) in pixels                t_GP   't_GP'
        t_WS    set window size (height, width in cells)            t_WS   't_WS'
        t_VS    cursor normally visible (no blink)                  t_VS   't_VS'
        t_SI    start insert mode (bar cursor shape)                t_SI   't_SI'
        t_SR    start replace mode (underline cursor shape)         t_SR   't_SR'
        t_EI    end insert or replace mode (block cursor shape)     t_EI   't_EI'
                 termcap-cursor-shape
        t_RV    request terminal version string (for xterm)         t_RV   't_RV'
                 xterm-8bit   v:termresponse   'ttymouse'   xterm-codes
        t_u7    request cursor position (for xterm)                 t_u7   't_u7'
                see  'ambiwidth'
        t_RF    request terminal foreground color                   t_RF   't_RF'
        t_RB    request terminal background color                   t_RB   't_RB'
        t_8f    set foreground color (R, G, B)                      t_8f   't_8f'
                 xterm-true-color
        t_8b    set background color (R, G, B)                      t_8b   't_8b'
                 xterm-true-color
        t_BE    enable bracketed paste mode                         t_BE   't_BE'
                 xterm-bracketed-paste
        t_BD    disable bracketed paste mode                        t_BD   't_BD'
                 xterm-bracketed-paste
        t_SC    set cursor color start                              t_SC   't_SC'
        t_EC    set cursor color end                                t_EC   't_EC'
        t_SH    set cursor shape                                    t_SH   't_SH'
        t_RC    request terminal cursor blinking                    t_RC   't_RC'
        t_RS    request terminal cursor style                       t_RS   't_RS'
        t_ST    save window title to stack                          t_ST   't_ST'
        t_RT    restore window title from stack                     t_RT   't_RT'
        t_Si    save icon text to stack                             t_Si   't_Si'
        t_Ri    restore icon text from stack                        t_Ri   't_Ri'

Some codes have a start, middle and end part.  The start and end are defined
by the termcap option, the middle part is text.
        set title text:     t_ts {title text} t_fs
        set icon text:      t_IS {icon text} t_IE
        set cursor color:   t_SC  {color name}  t_EC

t_SH must take one argument:
        0, 1 or none    blinking block cursor
        2               block cursor
        3               blinking underline cursor
        4               underline cursor
        5               blinking vertical bar cursor
        6               vertical bar cursor

t_RS is sent only if the response to t_RV has been received.  It is not used
on Mac OS when Terminal.app could be recognized from the termresponse.

t_PS    start of bracketed paste  xterm-bracketed-paste
t_PE    end of bracketed paste  xterm-bracketed-paste    t_PE    't_PE'
```

Note about t_so and t_mr: When the termcap entry "so" is not present the entry for "mr" is used. And vice versa. The same is done for "se" and "me". If your terminal supports both inversion and standout mode, you can see two different modes. If your terminal supports only one of the modes, both will look the same.

keypad-comma

The keypad keys, when they are not mapped, behave like the equivalent normal key. There is one exception: if you have a comma on the keypad instead of a decimal point, Vim will use a dot anyway. Use these mappings to fix that:

```
:noremap <kPoint> ,
:noremap! <kPoint> ,
```

xterm-codes

There is a special trick to obtain the key codes which currently only works

for xterm. When t_RV is defined and a response is received which indicates an xterm with patchlevel 141 or higher, Vim uses special escape sequences to request the key codes directly from the xterm. The responses are used to adjust the various t_ codes. This avoids the problem that the xterm can produce different codes, depending on the mode it is in (8-bit, VT102, VT220, etc.). The result is that codes like <xF1> are no longer needed.
Note: This is only done on startup. If the xterm options are changed after Vim has started, the escape sequences may not be recognized anymore.

xterm-true-color
Vim supports using true colors in the terminal (taken from highlight-guifg and highlight-guibg), given that the terminal supports this. To make this work the 'termguicolors' option needs to be set.
See https://gist.github.com/XVilka/8346728 for a list of terminals that support true colors.

Sometimes setting 'termguicolors' is not enough and one has to set the t_8f and t_8b options explicitly. Default values of these options are "^[[38;2;%lu;%lu;%lum" and "^[[48;2;%lu;%lu;%lum" respectively, but it is only set when `$TERM` is `xterm`. Some terminals accept the same sequences, but with all semicolons replaced by colons (this is actually more compatible, but less widely supported):

```
let &t_8f = "\<Esc>[38:2:%lu:%lu:%lum"
let &t_8b = "\<Esc>[48:2:%lu:%lu:%lum"
```

These options contain printf strings, with printf() (actually, its C equivalent hence `l` modifier) invoked with the t_ option value and three unsigned long integers that may have any value between 0 and 255 (inclusive) representing red, green and blue colors respectively.

xterm-resize
Window resizing with xterm only works if the allowWindowOps resource is enabled. On some systems and versions of xterm it's disabled by default because someone thought it would be a security issue. It's not clear if this is actually the case.

To overrule the default, put this line in your ~/.Xdefaults or ~/.Xresources:

```
XTerm*allowWindowOps:           true
```

And run "xrdb -merge .Xresources" to make it effective. You can check the value with the context menu (right mouse button while CTRL key is pressed), there should be a tick at allow-window-ops.

termcap-colors
Note about colors: The 't_Co' option tells Vim the number of colors available. When it is non-zero, the 't_AB' and 't_AF' options are used to set the color. If one of these is not available, 't_Sb' and 't_Sf' are used. 't_me' is used to reset to the default colors.

termcap-cursor-shape termcap-cursor-color
When Vim enters Insert mode the 't_SI' escape sequence is sent. When Vim enters Replace mode the 't_SR' escape sequence is sent if it is set, otherwise

't_SI' is sent. When leaving Insert mode or Replace mode 't_EI' is used. This can be used to change the shape or color of the cursor in Insert or Replace mode. These are not standard termcap/terminfo entries, you need to set them yourself.
Example for an xterm, this changes the color of the cursor:

```
    if &term =~ "xterm"
        let &t_SI = "\<Esc>]12;purple\x7"
        let &t_SR = "\<Esc>]12;red\x7"
        let &t_EI = "\<Esc>]12;blue\x7"
    endif
```

NOTE: When Vim exits the shape for Normal mode will remain. The shape from before Vim started will not be restored.
{not available when compiled without the |+cursorshape| feature}

termcap-title

The 't_ts' and 't_fs' options are used to set the window title if the terminal allows title setting via sending strings. They are sent before and after the title string, respectively. Similar 't_IS' and 't_IE' are used to set the icon text. These are Vim-internal extensions of the Unix termcap, so they cannot be obtained from an external termcap. However, the builtin termcap contains suitable entries for xterm and iris-ansi, so you don't need to set them here.

hpterm

If inversion or other highlighting does not work correctly, try setting the 't_xs' option to a non-empty string. This makes the 't_ce' code be used to remove highlighting from a line. This is required for "hpterm". Setting the 'weirdinvert' option has the same effect as making 't_xs' non-empty, and vice versa.

scroll-region

Some termcaps do not include an entry for 'cs' (scroll region), although the terminal does support it. For example: xterm on a Sun. You can use the builtin_xterm or define t_cs yourself. For example:

```
        :set t_cs=^V^[[%i%d;%dr
```

Where ^V is CTRL-V and ^[is <Esc>.

The vertical scroll region t_CV is not a standard termcap code. Vim uses it internally in the GUI. But it can also be defined for a terminal, if you can find one that supports it. The two arguments are the left and right column of the region which to restrict the scrolling to. Just like t_cs defines the top and bottom lines. Defining t_CV will make scrolling in vertically split windows a lot faster. Don't set t_CV when t_da or t_db is set (text isn't cleared when scrolling).

Unfortunately it is not possible to deduce from the termcap how cursor positioning should be done when using a scrolling region: Relative to the beginning of the screen or relative to the beginning of the scrolling region. Most terminals use the first method. A known exception is the MS-DOS console (pcterm). The 't_CS' option should be set to any string when cursor positioning is relative to the start of the scrolling region. It should be set to an empty string otherwise. It defaults to "yes" when 'term' is "pcterm".

Note for xterm users: The shifted cursor keys normally don't work. You can

make them work with the xmodmap command and some mappings in Vim.

Give these commands in the xterm:
```
xmodmap -e "keysym Up = Up F13"
xmodmap -e "keysym Down = Down F16"
xmodmap -e "keysym Left = Left F18"
xmodmap -e "keysym Right = Right F19"
```

And use these mappings in Vim:
```
:map <t_F3> <S-Up>
:map! <t_F3> <S-Up>
:map <t_F6> <S-Down>
:map! <t_F6> <S-Down>
:map <t_F8> <S-Left>
:map! <t_F8> <S-Left>
:map <t_F9> <S-Right>
:map! <t_F9> <S-Right>
```

Instead of, say, <S-Up> you can use any other command that you want to use the shift-cursor-up key for. (Note: To help people that have a Sun keyboard with left side keys F14 is not used because it is confused with the undo key; F15 is not used, because it does a window-to-front; F17 is not used, because it closes the window. On other systems you can probably use them.)

==
3. Window size window-size

[This is about the size of the whole window Vim is using, not a window that is created with the ":split" command.]

If you are running Vim on an Amiga and the terminal name is "amiga" or "builtin_amiga", the amiga-specific window resizing will be enabled. On Unix systems three methods are tried to get the window size:

- an ioctl call (TIOCGSIZE or TIOCGWINSZ, depends on your system)
- the environment variables "LINES" and "COLUMNS"
- from the termcap entries "li" and "co"

If everything fails a default size of 24 lines and 80 columns is assumed. If a window-resize signal is received the size will be set again. If the window size is wrong you can use the 'lines' and 'columns' options to set the correct values.

One command can be used to set the screen size:

:mod :mode E359

:mod[e] [mode]

Without argument this only detects the screen size and redraws the screen. With MS-DOS it is possible to switch screen mode. [mode] can be one of these values:

"bw40"	40 columns black&white
"c40"	40 columns color
"bw80"	80 columns black&white

```
        "c80"           80 columns color (most people use this)
        "mono"          80 columns monochrome
        "c4350"         43 or 50 lines EGA/VGA mode
        number          mode number to use, depends on your video card
```

==
4. Slow and fast terminals   slow-fast-terminal
                                                        slow-terminal

If you have a fast terminal you may like to set the 'ruler' option. The
cursor position is shown in the status line. If you are using horizontal
scrolling ('wrap' option off) consider setting 'sidescroll' to a small
number.

If you have a slow terminal you may want to reset the 'showcmd' option.
The command characters will not be shown in the status line. If the terminal
scrolls very slowly, set the 'scrolljump' to 5 or so. If the cursor is moved
off the screen (e.g., with "j") Vim will scroll 5 lines at a time. Another
possibility is to reduce the number of lines that Vim uses with the command
"z{height}<CR>".

If the characters from the terminal are arriving with more than 1 second
between them you might want to set the 'timeout' and/or 'ttimeout' option.
See the "Options" chapter options .

If your terminal does not support a scrolling region, but it does support
insert/delete line commands, scrolling with multiple windows may make the
lines jump up and down. If you don't want this set the 'ttyfast' option.
This will redraw the window instead of scroll it.

If your terminal scrolls very slowly, but redrawing is not slow, set the
'ttyscroll' option to a small number, e.g., 3. This will make Vim redraw the
screen instead of scrolling, when there are more than 3 lines to be scrolled.

If you are using a color terminal that is slow, use this command:
```
        hi NonText cterm=NONE ctermfg=NONE
```
This avoids that spaces are sent when they have different attributes. On most
terminals you can't see this anyway.

If you are using Vim over a slow serial line, you might want to try running
Vim inside the "screen" program. Screen will optimize the terminal I/O quite
a bit.

If you are testing termcap options, but you cannot see what is happening,
you might want to set the 'writedelay' option. When non-zero, one character
is sent to the terminal at a time (does not work for MS-DOS). This makes the
screen updating a lot slower, making it possible to see what is happening.

==
5. Using the mouse   mouse-using

This section is about using the mouse on a terminal or a terminal window. How
to use the mouse in a GUI window is explained in gui-mouse . For scrolling
with a mouse wheel see scroll-mouse-wheel .

Don't forget to enable the mouse with this command:
	:set mouse=a
Otherwise Vim won't recognize the mouse in all modes (See 'mouse').

Currently the mouse is supported for Unix in an xterm window, in a *BSD
console with sysmouse , in a Linux console (with GPM gpm-mouse), for
MS-DOS and in a Windows console.
Mouse clicks can be used to position the cursor, select an area and paste.

These characters in the 'mouse' option tell in which situations the mouse will
be used by Vim:

n	Normal mode
v	Visual mode
i	Insert mode
c	Command-line mode
h	all previous modes when in a help file
a	all previous modes
r	for hit-enter prompt

The default for 'mouse' is empty, the mouse is not used. Normally you would
do:
	:set mouse=a
to start using the mouse (this is equivalent to setting 'mouse' to "nvich").
If you only want to use the mouse in a few modes or also want to use it for
the two questions you will have to concatenate the letters for those modes.
For example:
	:set mouse=nv
Will make the mouse work in Normal mode and Visual mode.
	:set mouse=h
Will make the mouse work in help files only (so you can use "g<LeftMouse>" to
jump to tags).

Whether the selection that is started with the mouse is in Visual mode or
Select mode depends on whether "mouse" is included in the 'selectmode'
option.

In an xterm, with the currently active mode included in the 'mouse' option,
normal mouse clicks are used by Vim, mouse clicks with the shift or ctrl key
pressed go to the xterm. With the currently active mode not included in
'mouse' all mouse clicks go to the xterm.

xterm-clipboard
In the Athena and Motif GUI versions, when running in a terminal and there is
access to the X-server (DISPLAY is set), the copy and paste will behave like
in the GUI. If not, the middle mouse button will insert the unnamed register.
In that case, here is how you copy and paste a piece of text:

Copy/paste with the mouse and Visual mode ('mouse' option must be set, see
above):
1. Press left mouse button on first letter of text, move mouse pointer to last
   letter of the text and release the button. This will start Visual mode and
   highlight the selected area.
2. Press "y" to yank the Visual text in the unnamed register.

3. Click the left mouse button at the insert position.
4. Click the middle mouse button.

Shortcut: If the insert position is on the screen at the same time as the Visual text, you can do 2, 3 and 4 all in one: Click the middle mouse button at the insert position.

Note: When the -X command line argument is used, Vim will not connect to the X server and copy/paste to the X clipboard (selection) will not work. Use the shift key with the mouse buttons to let the xterm do the selection.

xterm-command-server
When the X-server clipboard is available, the command server described in x11-clientserver can be enabled with the --servername command line argument.

xterm-copy-paste
NOTE: In some (older) xterms, it's not possible to move the cursor past column 95 or 223. This is an xterm problem, not Vim's. Get a newer xterm color-xterm . Also see 'ttymouse' .

Copy/paste in xterm with (current mode NOT included in 'mouse'):
1. Press left mouse button on first letter of text, move mouse pointer to last letter of the text and release the button.
2. Use normal Vim commands to put the cursor at the insert position.
3. Press "a" to start Insert mode.
4. Click the middle mouse button.
5. Press ESC to end Insert mode.
(The same can be done with anything in 'mouse' if you keep the shift key pressed while using the mouse.)

Note: if you lose the 8th bit when pasting (special characters are translated into other characters), you may have to do "stty cs8 -istrip -parenb" in your shell before starting Vim.

Thus in an xterm the shift and ctrl keys cannot be used with the mouse. Mouse commands requiring the CTRL modifier can be simulated by typing the "g" key before using the mouse:

```
        "g<LeftMouse>"  is "<C-LeftMouse>       (jump to tag under mouse click)
        "g<RightMouse>" is "<C-RightMouse>      ("CTRL-T")
```

mouse-mode-table mouse-overview
A short overview of what the mouse buttons do, when 'mousemodel' is "extend":

Normal Mode:

event	position cursor	selection	change window	action	
<LeftMouse>	yes	end	yes		
<C-LeftMouse>	yes	end	yes	"CTRL-]" (2)	
<S-LeftMouse>	yes	no change	yes	"*" (2)	<S-LeftMouse>
<LeftDrag>	yes	start or extend (1)	no		<LeftDrag>
<LeftRelease>	yes	start or extend (1)	no		
<MiddleMouse>	yes	if not active	no	put	
<MiddleMouse>	yes	if active	no	yank and put	
<RightMouse>	yes	start or extend	yes		

```
<A-RightMouse>  yes start or extend blockw. yes                <A-RightMouse>
<S-RightMouse>  yes        no change        yes    "#" (2)     <S-RightMouse>
<C-RightMouse>  no         no change        no     "CTRL-T"
<RightDrag>     yes         extend          no                 <RightDrag>
<RightRelease>  yes         extend          no                 <RightRelease>

Insert or Replace Mode:
event         position     selection      change  action
               cursor                     window
<LeftMouse>     yes     (cannot be active)  yes
<C-LeftMouse>   yes     (cannot be active)  yes    "CTRL-O^]" (2)
<S-LeftMouse>   yes     (cannot be active)  yes    "CTRL-O*" (2)
<LeftDrag>      yes     start or extend (1) no     like CTRL-O (1)
<LeftRelease>   yes     start or extend (1) no     like CTRL-O (1)
<MiddleMouse>   no      (cannot be active)  no     put register
<RightMouse>    yes     start or extend     yes    like CTRL-O
<A-RightMouse>  yes start or extend blockw. yes
<S-RightMouse>  yes     (cannot be active)  yes    "CTRL-O#" (2)
<C-RightMouse>  no      (cannot be active)  no     "CTRL-O CTRL-T"

In a help window:
event         position     selection      change  action
               cursor                     window
<2-LeftMouse>   yes     (cannot be active)  no     "^]" (jump to help tag)

When 'mousemodel' is "popup", these are different:

Normal Mode:
event         position     selection      change  action
               cursor                     window
<S-LeftMouse>   yes     start or extend (1) no
<A-LeftMouse>   yes start or extend blockw. no                 <A-LeftMouse>
<RightMouse>    no      popup menu          no

Insert or Replace Mode:
event         position     selection      change  action
               cursor                     window
<S-LeftMouse>   yes     start or extend (1) no     like CTRL-O (1)
<A-LeftMouse>   yes start or extend blockw. no
<RightMouse>    no      popup menu          no

(1) only if mouse pointer moved since press
(2) only if click is in same buffer

Clicking the left mouse button causes the cursor to be positioned.  If the
click is in another window that window is made the active window.  When
editing the command-line the cursor can only be positioned on the
command-line.  When in Insert mode Vim remains in Insert mode.  If 'scrolloff'
is set, and the cursor is positioned within 'scrolloff' lines from the window
border, the text is scrolled.

A selection can be started by pressing the left mouse button on the first
character, moving the mouse to the last character, then releasing the mouse
button.  You will not always see the selection until you release the button,
```

only in some versions (GUI, MS-DOS, WIN32) will the dragging be shown immediately. Note that you can make the text scroll by moving the mouse at least one character in the first/last line in the window when 'scrolloff' is non-zero.

In Normal, Visual and Select mode clicking the right mouse button causes the Visual area to be extended. When 'mousemodel' is "popup", the left button has to be used while keeping the shift key pressed. When clicking in a window which is editing another buffer, the Visual or Select mode is stopped.

In Normal, Visual and Select mode clicking the right mouse button with the alt key pressed causes the Visual area to become blockwise. When 'mousemodel' is "popup" the left button has to be used with the alt key. Note that this won't work on systems where the window manager consumes the mouse events when the alt key is pressed (it may move the window).

double-click

Double, triple and quadruple clicks are supported when the GUI is active, for MS-DOS and Win32, and for an xterm (if the gettimeofday() function is available). For selecting text, extra clicks extend the selection:

click	select	
double	word or % match	<2-LeftMouse>
triple	line	<3-LeftMouse>
quadruple	rectangular block	<4-LeftMouse>

Exception: In a Help window a double click jumps to help for the word that is clicked on.
A double click on a word selects that word. 'iskeyword' is used to specify which characters are included in a word. A double click on a character that has a match selects until that match (like using "v%"). If the match is an #if/#else/#endif block, the selection becomes linewise.
For MS-DOS and xterm the time for double clicking can be set with the 'mousetime' option. For the other systems this time is defined outside of Vim.
An example, for using a double click to jump to the tag under the cursor:

```
:map <2-LeftMouse> :exe "tag ". expand("<cword>")<CR>
```

Dragging the mouse with a double click (button-down, button-up, button-down and then drag) will result in whole words to be selected. This continues until the button is released, at which point the selection is per character again.

gpm-mouse

The GPM mouse is only supported when the +mouse_gpm feature was enabled at compile time. The GPM mouse driver (Linux console) does not support quadruple clicks.

In Insert mode, when a selection is started, Vim goes into Normal mode temporarily. When Visual or Select mode ends, it returns to Insert mode. This is like using CTRL-O in Insert mode. Select mode is used when the 'selectmode' option contains "mouse".

sysmouse

The sysmouse is only supported when the +mouse_sysmouse feature was enabled at compile time. The sysmouse driver (*BSD console) does not support keyboard modifiers.

drag-status-line
When working with several windows, the size of the windows can be changed by dragging the status line with the mouse. Point the mouse at a status line, press the left button, move the mouse to the new position of the status line, release the button. Just clicking the mouse in a status line makes that window the current window, without moving the cursor. If by selecting a window it will change position or size, the dragging of the status line will look confusing, but it will work (just try it).

<MiddleRelease> <MiddleDrag>
Mouse clicks can be mapped. The codes for mouse clicks are:

code	mouse button	normal action	
<LeftMouse>	left pressed	set cursor position	
<LeftDrag>	left moved while pressed	extend selection	
<LeftRelease>	left released	set selection end	
<MiddleMouse>	middle pressed	paste text at cursor position	
<MiddleDrag>	middle moved while pressed	-	
<MiddleRelease>	middle released	-	
<RightMouse>	right pressed	extend selection	
<RightDrag>	right moved while pressed	extend selection	
<RightRelease>	right released	set selection end	
<X1Mouse>	X1 button pressed	-	X1Mouse
<X1Drag>	X1 moved while pressed	-	X1Drag
<X1Release>	X1 button release	-	X1Release
<X2Mouse>	X2 button pressed	-	X2Mouse
<X2Drag>	X2 moved while pressed	-	X2Drag
<X2Release>	X2 button release	-	X2Release

The X1 and X2 buttons refer to the extra buttons found on some mice. The 'Microsoft Explorer' mouse has these buttons available to the right thumb. Currently X1 and X2 only work on Win32 and X11 environments.

Examples:

```
:noremap <MiddleMouse> <LeftMouse><MiddleMouse>
```

Paste at the position of the middle mouse button click (otherwise the paste would be done at the cursor position).

```
:noremap <LeftRelease> <LeftRelease>y
```

Immediately yank the selection, when using Visual mode.

Note the use of ":noremap" instead of "map" to avoid a recursive mapping.

```
:map <X1Mouse> <C-O>
:map <X2Mouse> <C-I>
```

Map the X1 and X2 buttons to go forwards and backwards in the jump list, see CTRL-O and CTRL-I .

mouse-swap-buttons
To swap the meaning of the left and right mouse buttons:

```
:noremap  <LeftMouse>   <RightMouse>
:noremap  <LeftDrag>    <RightDrag>
:noremap  <LeftRelease> <RightRelease>
:noremap  <RightMouse>  <LeftMouse>
```

```
:noremap        <RightDrag>     <LeftDrag>
:noremap        <RightRelease>  <LeftRelease>
:noremap        g<LeftMouse>    <C-RightMouse>
:noremap        g<RightMouse>   <C-LeftMouse>
:noremap!       <LeftMouse>     <RightMouse>
:noremap!       <LeftDrag>      <RightDrag>
:noremap!       <LeftRelease>   <RightRelease>
:noremap!       <RightMouse>    <LeftMouse>
:noremap!       <RightDrag>     <LeftDrag>
:noremap!       <RightRelease>  <LeftRelease>
```

vim:tw=78:ts=8:noet:ft=help:norl:

digraph.txt For Vim version 8.1. Last change: 2016 Nov 04

VIM REFERENCE MANUAL by Bram Moolenaar

Digraphs digraph digraphs Digraphs

Digraphs are used to enter characters that normally cannot be entered by an ordinary keyboard. These are mostly printable non-ASCII characters. The digraphs are easier to remember than the decimal number that can be entered with CTRL-V (see i_CTRL-V).

There is a brief introduction on digraphs in the user manual: 24.9
An alternative is using the 'keymap' option.

{Vi does not have any of these commands}

==========
1. Defining digraphs digraphs-define

:dig :digraphs
:dig[raphs] show currently defined digraphs.
E104 E39
:dig[raphs] {char1}{char2} {number} ...
Add digraph {char1}{char2} to the list. {number} is the decimal representation of the character. Normally it is the Unicode character, see digraph-encoding . Example:
:digr e: 235 a: 228
Avoid defining a digraph with '_' (underscore) as the first character, it has a special meaning in the future.

Vim is normally compiled with the +digraphs feature. If the feature is disabled, the ":digraph" command will display an error message.

Example of the output of ":digraphs":
TH Þ 222 ss ß 223 a! à 224 a' á 225 a> â 226 a? ã 227 a: ä 228

The first two characters in each column are the characters you have to type to enter the digraph.

In the middle of each column is the resulting character. This may be mangled if you look at it on a system that does not support digraphs or if you print this file.

digraph-encoding
The decimal number normally is the Unicode number of the character. Note that the meaning doesn't change when 'encoding' changes. The character will be

converted from Unicode to 'encoding' when needed. This does require the conversion to be available, it might fail. For the NUL character you will see "10". That's because NUL characters are internally represented with a NL character. When you write the file it will become a NUL character.

When Vim was compiled without the +multi_byte feature, you need to specify the character in the encoding given with 'encoding'. You might want to use something like this:

```
if has("multi_byte")
        digraph oe 339
elseif &encoding == "iso-8859-15"
        digraph oe 189
endif
```

This defines the "oe" digraph for a character that is number 339 in Unicode and 189 in latin9 (iso-8859-15).

==
2. Using digraphs digraphs-use

There are two methods to enter digraphs: i_digraph
        CTRL-K {char1} {char2} or
        {char1} <BS> {char2}
The first is always available; the second only when the 'digraph' option is set.

If a digraph with {char1}{char2} does not exist, Vim searches for a digraph {char2}{char1}. This helps when you don't remember which character comes first.

Note that when you enter CTRL-K {char1}, where {char1} is a special key, Vim enters the code for that special key. This is not a digraph.

Once you have entered the digraph, Vim treats the character like a normal character that occupies only one character in the file and on the screen. Example:

```
'B' <BS> 'B'    will enter the broken '|' character (166)
'a' <BS> '>'    will enter an 'a' with a circumflex (226)
CTRL-K '-' '-'  will enter a soft hyphen (173)
```

The current digraphs are listed with the ":digraphs" command. Some of the default ones are listed below digraph-table .

For CTRL-K, there is one general digraph: CTRL-K <Space> {char} will enter {char} with the highest bit set. You can use this to enter meta-characters.

The <Esc> character cannot be part of a digraph. When hitting <Esc>, Vim stops digraph entry and ends Insert mode or Command-line mode, just like hitting an <Esc> out of digraph context. Use CTRL-V 155 to enter meta-ESC (CSI).

If you accidentally typed an 'a' that should be an 'e', you will type 'a' <BS> 'e'. But that is a digraph, so you will not get what you want. To correct

this, you will have to type <BS> e again. To avoid this don't set the 'digraph' option and use CTRL-K to enter digraphs.

You may have problems using Vim with characters which have a value above 128. For example: You insert ue (u-umlaut) and the editor echoes \334 in Insert mode. After leaving the Insert mode everything is fine. Note that fmt removes all characters with a value above 128 from the text being formatted. On some Unix systems this means you have to define the environment-variable LC_CTYPE. If you are using csh, then put the following line in your .cshrc:

```
setenv LC_CTYPE iso_8859_1
```

==

3. Default digraphs digraphs-default

Vim comes with a set of default digraphs. Check the output of ":digraphs" to see them.

On most systems Vim uses the same digraphs. They work for the Unicode and ISO-8859-1 character sets. These default digraphs are taken from the RFC1345 mnemonics. To make it easy to remember the mnemonic, the second character has a standard meaning:

char name	char	meaning
Exclamation mark	!	Grave
Apostrophe	'	Acute accent
Greater-Than sign	>	Circumflex accent
Question mark	?	Tilde
Hyphen-Minus	-	Macron
Left parenthesis	(	Breve
Full stop	.	Dot above
Colon	:	Diaeresis
Comma	,	Cedilla
Underline	_	Underline
Solidus	/	Stroke
Quotation mark	"	Double acute accent
Semicolon	;	Ogonek
Less-Than sign	<	Caron
Zero	0	Ring above
Two	2	Hook
Nine	9	Horn
Equals	=	Cyrillic (= used as second char)
Asterisk	*	Greek
Percent sign	%	Greek/Cyrillic special
Plus	+	smalls: Arabic, capitals: Hebrew
Three	3	some Latin/Greek/Cyrillic letters
Four	4	Bopomofo
Five	5	Hiragana
Six	6	Katakana

Example: a: is ä and o: is ö

These are the RFC1345 digraphs for the one-byte characters. See the output of ":digraphs" for the others. The characters above 255 are only available when

Vim was compiled with the +multi_byte feature.

EURO

Exception: RFC1345 doesn't specify the euro sign. In Vim the digraph =e was added for this. Note the difference between latin1, where the digraph Cu is used for the currency sign, and latin9 (iso-8859-15), where the digraph =e is used for the euro sign, while both of them are the character 164, 0xa4. For compatibility with zsh Eu can also be used for the euro sign.

ROUBLE

The rouble sign was added in 2014 as 0x20bd. Vim supports the digraphs =R and =P for this. Note that R= and P= are other characters.

mbyte.txt For Vim version 8.1. Last change: 2018 Jan 21

VIM REFERENCE MANUAL by Bram Moolenaar et al.

Multi-byte support multibyte multi-byte
Chinese Japanese Korean

This is about editing text in languages which have many characters that can not be represented using one byte (one octet). Examples are Chinese, Japanese and Korean. Unicode is also covered here.

For an introduction to the most common features, see usr_45.txt in the user manual.
For changing the language of messages and menus see mlang.txt .

{not available when compiled without the |+multi_byte| feature}

NOTE: This file contains UTF-8 characters. These may show up as strange characters or boxes when using another encoding.

==========

1. Getting started mbyte-first

This is a summary of the multibyte features in Vim. If you are lucky it works as described and you can start using Vim without much trouble. If something doesn't work you will have to read the rest. Don't be surprised if it takes quite a bit of work and experimenting to make Vim use all the multi-byte features. Unfortunately, every system has its own way to deal with multibyte languages and it is quite complicated.

COMPILING

If you already have a compiled Vim program, check if the +multi_byte feature is included. The :version command can be used for this.

If +multi_byte is not included, you should compile Vim with "normal", "big" or "huge" features. You can further tune what features are included. See the INSTALL files in the source directory.

LOCALE

First of all, you must make sure your current locale is set correctly. If your system has been installed to use the language, it probably works right away. If not, you can often make it work by setting the $LANG environment variable in your shell:

```
setenv LANG ja_JP.EUC
```

Unfortunately, the name of the locale depends on your system. Japanese might also be called "ja_JP.EUCjp" or just "ja". To see what is currently used:

```
:language
```

To change the locale inside Vim use:

```
:language ja_JP.EUC
```

Vim will give an error message if this doesn't work. This is a good way to experiment and find the locale name you want to use. But it's always better to set the locale in the shell, so that it is used right from the start.

See mbyte-locale for details.

ENCODING

If your locale works properly, Vim will try to set the 'encoding' option accordingly. If this doesn't work you can overrule its value:

```
:set encoding=utf-8
```

See encoding-values for a list of acceptable values.

The result is that all the text that is used inside Vim will be in this encoding. Not only the text in the buffers, but also in registers, variables, etc. This also means that changing the value of 'encoding' makes the existing text invalid! The text doesn't change, but it will be displayed wrong.

You can edit files in another encoding than what 'encoding' is set to. Vim will convert the file when you read it and convert it back when you write it. See 'fileencoding', 'fileencodings' and ++enc .

DISPLAY AND FONTS

If you are working in a terminal (emulator) you must make sure it accepts the same encoding as which Vim is working with. If this is not the case, you can use the 'termencoding' option to make Vim convert text automatically.

For the GUI you must select fonts that work with the current 'encoding'. This is the difficult part. It depends on the system you are using, the locale and

a few other things. See the chapters on fonts: mbyte-fonts-X11 for
X-Windows and mbyte-fonts-MSwin for MS-Windows.

For GTK+ 2, you can skip most of this section. The option 'guifontset' does
no longer exist. You only need to set 'guifont' and everything should "just
work". If your system comes with Xft2 and fontconfig and the current font
does not contain a certain glyph, a different font will be used automatically
if available. The 'guifontwide' option is still supported but usually you do
not need to set it. It is only necessary if the automatic font selection does
not suit your needs.

For X11 you can set the 'guifontset' option to a list of fonts that together
cover the characters that are used. Example for Korean:

```
:set guifontset=k12,r12
```

Alternatively, you can set 'guifont' and 'guifontwide'. 'guifont' is used for
the single-width characters, 'guifontwide' for the double-width characters.
Thus the 'guifontwide' font must be exactly twice as wide as 'guifont'.
Example for UTF-8:

```
:set guifont=-misc-fixed-medium-r-normal-*-18-120-100-100-c-90-iso10646-1
:set guifontwide=-misc-fixed-medium-r-normal-*-18-120-100-100-c-180-iso10646-1
```

You can also set 'guifont' alone, Vim will try to find a matching
'guifontwide' for you.

INPUT

There are several ways to enter multi-byte characters:
- For X11 XIM can be used. See XIM .
- For MS-Windows IME can be used. See IME .
- For all systems keymaps can be used. See mbyte-keymap .

The options 'iminsert', 'imsearch' and 'imcmdline' can be used to chose
the different input methods or disable them temporarily.

==
2. Locale   mbyte-locale

The easiest setup is when your whole system uses the locale you want to work
in. But it's also possible to set the locale for one shell you are working
in, or just use a certain locale inside Vim.

WHAT IS A LOCALE?   locale

There are many of languages in the world. And there are different cultures
and environments at least as much as the number of languages. A linguistic
environment corresponding to an area is called "locale". This includes
information about the used language, the charset, collating order for sorting,
date format, currency format and so on. For Vim only the language and charset
really matter.

You can only use a locale if your system has support for it. Some systems have only a few locales, especially in the USA. The language which you want to use may not be on your system. In that case you might be able to install it as an extra package. Check your system documentation for how to do that.

The location in which the locales are installed varies from system to system. For example, "/usr/share/locale" or "/usr/lib/locale". See your system's setlocale() man page.

Looking in these directories will show you the exact name of each locale. Mostly upper/lowercase matters, thus "ja_JP.EUC" and "ja_jp.euc" are different. Some systems have a locale.alias file, which allows translation from a short name like "nl" to the full name "nl_NL.ISO_8859-1".

Note that X-windows has its own locale stuff. And unfortunately uses locale names different from what is used elsewhere. This is confusing! For Vim it matters what the setlocale() function uses, which is generally NOT the X-windows stuff. You might have to do some experiments to find out what really works.

locale-name

The (simplified) format of locale name is:

```
        language
or      language_territory
or      language_territory.codeset
```

Territory means the country (or part of it), codeset means the charset . For example, the locale name "ja_JP.eucJP" means:

```
        ja      the language is Japanese
        JP      the country is Japan
        eucJP   the codeset is EUC-JP
```

But it also could be "ja", "ja_JP.EUC", "ja_JP.ujis", etc. And unfortunately, the locale name for a specific language, territory and codeset is not unified and depends on your system.

Examples of locale name:

charset	language	locale name
GB2312	Chinese (simplified)	zh_CN.EUC, zh_CN.GB2312
Big5	Chinese (traditional)	zh_TW.BIG5, zh_TW.Big5
CNS-11643	Chinese (traditional)	zh_TW
EUC-JP	Japanese	ja, ja_JP.EUC, ja_JP.ujis, ja_JP.eucJP
Shift_JIS	Japanese	ja_JP.SJIS, ja_JP.Shift_JIS
EUC-KR	Korean	ko, ko_KR.EUC

USING A LOCALE

To start using a locale for the whole system, see the documentation of your system. Mostly you need to set it in a configuration file in "/etc".

To use a locale in a shell, set the $LANG environment value. When you want to use Korean and the locale name is "ko", do this:

```
    sh:    export LANG=ko
    csh:   setenv LANG ko

You can put this in your ~/.profile or ~/.cshrc file to always use it.

To use a locale in Vim only, use the  :language  command:

        :language ko

Put this in your ~/.vimrc file to use it always.

Or specify $LANG when starting Vim:

   sh:    LANG=ko vim {vim-arguments}
   csh:   env LANG=ko vim {vim-arguments}

You could make a small shell script for this.

==============================================================================
3.  Encoding                                    mbyte-encoding

Vim uses the 'encoding' option to specify how characters are identified and
encoded when they are used inside Vim.  This applies to all the places where
text is used, including buffers (files loaded into memory), registers and
variables.

                                                        charset   codeset
Charset is another name for encoding.  There are subtle differences, but these
don't matter when using Vim.  "codeset" is another similar name.

Each character is encoded as one or more bytes.  When all characters are
encoded with one byte, we call this a single-byte encoding.  The most often
used one is called "latin1".  This limits the number of characters to 256.
Some of these are control characters, thus even fewer can be used for text.

When some characters use two or more bytes, we call this a multi-byte
encoding.  This allows using much more than 256 characters, which is required
for most East Asian languages.

Most multi-byte encodings use one byte for the first 127 characters.  These
are equal to ASCII, which makes it easy to exchange plain-ASCII text, no
matter what language is used.  Thus you might see the right text even when the
encoding was set wrong.

                                                        encoding-names
Vim can use many different character encodings.  There are three major groups:

1   8bit        Single-byte encodings, 256 different characters.  Mostly used
                in USA and Europe.  Example: ISO-8859-1 (Latin1).  All
                characters occupy one screen cell only.

2   2byte       Double-byte encodings, over 10000 different characters.
                Mostly used in Asian countries.  Example: euc-kr (Korean)
```

```
                The number of screen cells is equal to the number of bytes
                (except for euc-jp when the first byte is 0x8e).

u   Unicode     Universal encoding, can replace all others.  ISO 10646.
                Millions of different characters.  Example: UTF-8.  The
                relation between bytes and screen cells is complex.

Other encodings cannot be used by Vim internally.  But files in other
encodings can be edited by using conversion, see 'fileencoding'.
Note that all encodings must use ASCII for the characters up to 128 (except
when compiled for EBCDIC).

Supported 'encoding' values are:                          encoding-values
1   latin1      8-bit characters (ISO 8859-1, also used for cp1252)
1   iso-8859-n  ISO_8859 variant (n = 2 to 15)
1   koi8-r      Russian
1   koi8-u      Ukrainian
1   macroman    MacRoman (Macintosh encoding)
1   8bit-{name} any 8-bit encoding (Vim specific name)
1   cp437       similar to iso-8859-1
1   cp737       similar to iso-8859-7
1   cp775       Baltic
1   cp850       similar to iso-8859-4
1   cp852       similar to iso-8859-1
1   cp855       similar to iso-8859-2
1   cp857       similar to iso-8859-5
1   cp860       similar to iso-8859-9
1   cp861       similar to iso-8859-1
1   cp862       similar to iso-8859-1
1   cp863       similar to iso-8859-8
1   cp865       similar to iso-8859-1
1   cp866       similar to iso-8859-5
1   cp869       similar to iso-8859-7
1   cp874       Thai
1   cp1250      Czech, Polish, etc.
1   cp1251      Cyrillic
1   cp1253      Greek
1   cp1254      Turkish
1   cp1255      Hebrew
1   cp1256      Arabic
1   cp1257      Baltic
1   cp1258      Vietnamese
1   cp{number}  MS-Windows: any installed single-byte codepage
2   cp932       Japanese (Windows only)
2   euc-jp      Japanese (Unix only)
2   sjis        Japanese (Unix only)
2   cp949       Korean (Unix and Windows)
2   euc-kr      Korean (Unix only)
2   cp936       simplified Chinese (Windows only)
2   euc-cn      simplified Chinese (Unix only)
2   cp950       traditional Chinese (on Unix alias for big5)
2   big5        traditional Chinese (on Windows alias for cp950)
2   euc-tw      traditional Chinese (Unix only)
2   2byte-{name} Unix: any double-byte encoding (Vim specific name)
```

```
2   cp{number}  MS-Windows: any installed double-byte codepage
u   utf-8       32 bit UTF-8 encoded Unicode (ISO/IEC 10646-1)
u   ucs-2       16 bit UCS-2 encoded Unicode (ISO/IEC 10646-1)
u   ucs-2le     like ucs-2, little endian
u   utf-16      ucs-2 extended with double-words for more characters
u   utf-16le    like utf-16, little endian
u   ucs-4       32 bit UCS-4 encoded Unicode (ISO/IEC 10646-1)
u   ucs-4le     like ucs-4, little endian
```

The {name} can be any encoding name that your system supports. It is passed to iconv() to convert between the encoding of the file and the current locale. For MS-Windows "cp{number}" means using codepage {number}.
Examples:

```
:set encoding=8bit-cp1252
:set encoding=2byte-cp932
```

The MS-Windows codepage 1252 is very similar to latin1. For practical reasons the same encoding is used and it's called latin1. 'isprint' can be used to display the characters 0x80 - 0xA0 or not.

Several aliases can be used, they are translated to one of the names above. An incomplete list:

```
1   ansi        same as latin1 (obsolete, for backward compatibility)
2   japan       Japanese: on Unix "euc-jp", on MS-Windows cp932
2   korea       Korean: on Unix "euc-kr", on MS-Windows cp949
2   prc         simplified Chinese: on Unix "euc-cn", on MS-Windows cp936
2   chinese     same as "prc"
2   taiwan      traditional Chinese: on Unix "euc-tw", on MS-Windows cp950
u   utf8        same as utf-8
u   unicode     same as ucs-2
u   ucs2be      same as ucs-2 (big endian)
u   ucs-2be     same as ucs-2 (big endian)
u   ucs-4be     same as ucs-4 (big endian)
u   utf-32      same as ucs-4
u   utf-32le    same as ucs-4le
    default     stands for the default value of 'encoding', depends on the
                environment
```

For the UCS codes the byte order matters. This is tricky, use UTF-8 whenever you can. The default is to use big-endian (most significant byte comes first):

```
            name        bytes           char
            ucs-2             11 22         1122
            ucs-2le           22 11         1122
            ucs-4       11 22 33 44     11223344
            ucs-4le     44 33 22 11     11223344
```

On MS-Windows systems you often want to use "ucs-2le", because it uses little endian UCS-2.

There are a few encodings which are similar, but not exactly the same. Vim treats them as if they were different encodings, so that conversion will be done when needed. You might want to use the similar name to avoid conversion

or when conversion is not possible:

```
        cp932, shift-jis, sjis
        cp936, euc-cn
```

encoding-table

Normally 'encoding' is equal to your current locale and 'termencoding' is empty. This means that your keyboard and display work with characters encoded in your current locale, and Vim uses the same characters internally.

You can make Vim use characters in a different encoding by setting the 'encoding' option to a different value. Since the keyboard and display still use the current locale, conversion needs to be done. The 'termencoding' then takes over the value of the current locale, so Vim converts between 'encoding' and 'termencoding'. Example:

```
        :let &termencoding = &encoding
        :set encoding=utf-8
```

However, not all combinations of values are possible. The table below tells you how each of the nine combinations works. This is further restricted by not all conversions being possible, iconv() being present, etc. Since this depends on the system used, no detailed list can be given.

('tenc' is the short name for 'termencoding' and 'enc' short for 'encoding')

'tenc'	'enc'	remark
8bit	8bit	Works. When 'termencoding' is different from 'encoding' typing and displaying may be wrong for some characters, Vim does NOT perform conversion (set 'encoding' to "utf-8" to get this).
8bit	2byte	MS-Windows: works for all codepages installed on your system; you can only type 8bit characters; Other systems: does NOT work.
8bit	Unicode	Works, but only 8bit characters can be typed directly (others through digraphs, keymaps, etc.); in a terminal you can only see 8bit characters; the GUI can show all characters that the 'guifont' supports.
2byte	8bit	Works, but typing non-ASCII characters might be a problem.
2byte	2byte	MS-Windows: works for all codepages installed on your system; typing characters might be a problem when locale is different from 'encoding'. Other systems: Only works when 'termencoding' is equal to 'encoding', you might as well leave it empty.
2byte	Unicode	works, Vim will translate typed characters.
Unicode	8bit	works (unusual)
Unicode	2byte	does NOT work
Unicode	Unicode	works very well (leaving 'termencoding' empty works the same way, because all Unicode is handled internally as UTF-8)

CONVERSION charset-conversion

Vim will automatically convert from one to another encoding in several places:
- When reading a file and 'fileencoding' is different from 'encoding'
- When writing a file and 'fileencoding' is different from 'encoding'
- When displaying characters and 'termencoding' is different from 'encoding'
- When reading input and 'termencoding' is different from 'encoding'
- When displaying messages and the encoding used for LC_MESSAGES differs from 'encoding' (requires a gettext version that supports this).
- When reading a Vim script where :scriptencoding is different from 'encoding'.
- When reading or writing a viminfo file.

Most of these require the +iconv feature. Conversion for reading and writing files may also be specified with the 'charconvert' option.

Useful utilities for converting the charset:

All: iconv

GNU iconv can convert most encodings. Unicode is used as the intermediate encoding, which allows conversion from and to all other encodings. See http://www.gnu.org/directory/libiconv.html.

Japanese: nkf

Nkf is "Network Kanji code conversion Filter". One of the most unique facility of nkf is the guess of the input Kanji code. So, you don't need to know what the inputting file's charset is. When convert to EUC-JP from ISO-2022-JP or Shift_JIS, simply do the following command in Vim:

```
:%!nkf -e
```

Nkf can be found at:
http://www.sfc.wide.ad.jp/~max/FreeBSD/ports/distfiles/nkf-1.62.tar.gz

Chinese: hc

Hc is "Hanzi Converter". Hc convert a GB file to a Big5 file, or Big5 file to GB file. Hc can be found at:
ftp://ftp.cuhk.hk/pub/chinese/ifcss/software/unix/convert/hc-30.tar.gz

Korean: hmconv

Hmconv is Korean code conversion utility especially for E-mail. It can convert between EUC-KR and ISO-2022-KR. Hmconv can be found at:
ftp://ftp.kaist.ac.kr/pub/hangul/code/hmconv/

Multilingual: lv

Lv is a Powerful Multilingual File Viewer. And it can be worked as charset converter. Supported charset : ISO-2022-CN, ISO-2022-JP, ISO-2022-KR, EUC-CN, EUC-JP, EUC-KR, EUC-TW, UTF-7, UTF-8, ISO-8859 series, Shift_JIS, Big5 and HZ. Lv can be found at:
http://www.ff.iij4u.or.jp/~nrt/lv/index.html

mbyte-conversion

When reading and writing files in an encoding different from 'encoding', conversion needs to be done. These conversions are supported:
- All conversions between Latin-1 (ISO-8859-1), UTF-8, UCS-2 and UCS-4 are handled internally.

- For MS-Windows, when 'encoding' is a Unicode encoding, conversion from and
  to any codepage should work.
- Conversion specified with 'charconvert'
- Conversion with the iconv library, if it is available.
	Old versions of GNU iconv() may cause the conversion to fail (they
	request a very large buffer, more than Vim is willing to provide).
	Try getting another iconv() implementation.

iconv-dynamic
On MS-Windows Vim can be compiled with the +iconv/dyn feature. This means Vim will search for the "iconv.dll" and "libiconv.dll" libraries. When neither of them can be found Vim will still work but some conversions won't be possible.

==
4. Using a terminal mbyte-terminal

The GUI fully supports multi-byte characters. It is also possible in a terminal, if the terminal supports the same encoding that Vim uses. Thus this is less flexible.

For example, you can run Vim in a xterm with added multi-byte support and/or XIM. Examples are kterm (Kanji term) and hanterm (for Korean), Eterm (Enlightened terminal) and rxvt.

If your terminal does not support the right encoding, you can set the 'termencoding' option. Vim will then convert the typed characters from 'termencoding' to 'encoding'. And displayed text will be converted from 'encoding' to 'termencoding'. If the encoding supported by the terminal doesn't include all the characters that Vim uses, this leads to lost characters. This may mess up the display. If you use a terminal that supports Unicode, such as the xterm mentioned below, it should work just fine, since nearly every character set can be converted to Unicode without loss of information.

UTF-8 IN XFREE86 XTERM UTF8-xterm

This is a short explanation of how to use UTF-8 character encoding in the xterm that comes with XFree86 by Thomas Dickey (text by Markus Kuhn).

Get the latest xterm version which has now UTF-8 support:

	http://invisible-island.net/xterm/xterm.html

Compile it with "./configure --enable-wide-chars ; make"

Also get the ISO 10646-1 version of various fonts, which is available on

	http://www.cl.cam.ac.uk/~mgk25/download/ucs-fonts.tar.gz

and install the font as described in the README file.

Now start xterm with

```
  xterm -u8 -fn -misc-fixed-medium-r-semicondensed--13-120-75-75-c-60-iso10646-1
or, for bigger character:
  xterm -u8 -fn -misc-fixed-medium-r-normal--15-140-75-75-c-90-iso10646-1

and you will have a working UTF-8 terminal emulator.  Try both

   cat utf-8-demo.txt
   vim utf-8-demo.txt

with the demo text that comes with ucs-fonts.tar.gz in order to see
whether there are any problems with UTF-8 in your xterm.

For Vim you may need to set 'encoding' to "utf-8".

==============================================================================
5.  Fonts on X11                                            mbyte-fonts-X11

Unfortunately, using fonts in X11 is complicated.  The name of a single-byte
font is a long string.  For multi-byte fonts we need several of these...

Note: Most of this is no longer relevant for GTK+ 2.  Selecting a font via
its XLFD is not supported; see 'guifont' for an example of how to
set the font.  Do yourself a favor and ignore the  XLFD  and  xfontset
sections below.

First of all, Vim only accepts fixed-width fonts for displaying text.  You
cannot use proportionally spaced fonts.  This excludes many of the available
(and nicer looking) fonts.  However, for menus and tooltips any font can be
used.

Note that Display and Input are independent.  It is possible to see your
language even though you have no input method for it.

You should get a default font for menus and tooltips that works, but it might
be ugly.  Read the following to find out how to select a better font.

X LOGICAL FONT DESCRIPTION (XLFD)
                                                                  XLFD
XLFD is the X font name and contains the information about the font size,
charset, etc.  The name is in this format:

FOUNDRY-FAMILY-WEIGHT-SLANT-WIDTH-STYLE-PIXEL-POINT-X-Y-SPACE-AVE-CR-CE

Each field means:

- FOUNDRY:  FOUNDRY field.  The company that created the font.
- FAMILY:   FAMILY_NAME field.  Basic font family name.  (helvetica, gothic,
            times, etc)
- WEIGHT:   WEIGHT_NAME field.  How thick the letters are.  (light, medium,
            bold, etc)
- SLANT:    SLANT field.
                r:  Roman (no slant)
```

```
                i:  Italic
                o:  Oblique
                ri: Reverse Italic
                ro: Reverse Oblique
                ot: Other
                number: Scaled font
- WIDTH:    SETWIDTH_NAME field.  Width of characters.  (normal, condensed,
            narrow, double wide)
- STYLE:    ADD_STYLE_NAME field.  Extra info to describe font.  (Serif, Sans
            Serif, Informal, Decorated, etc)
- PIXEL:    PIXEL_SIZE field.  Height, in pixels, of characters.
- POINT:    POINT_SIZE field.  Ten times height of characters in points.
- X:        RESOLUTION_X field.  X resolution (dots per inch).
- Y:        RESOLUTION_Y field.  Y resolution (dots per inch).
- SPACE:    SPACING field.
                p:  Proportional
                m:  Monospaced
                c:  CharCell
- AVE:      AVERAGE_WIDTH field.  Ten times average width in pixels.
- CR:       CHARSET_REGISTRY field.  The name of the charset group.
- CE:       CHARSET_ENCODING field.  The rest of the charset name.  For some
            charsets, such as JIS X 0208, if this field is 0, code points has
            the same value as GL, and GR if 1.

For example, in case of a 16 dots font corresponding to JIS X 0208, it is
written like:
    -misc-fixed-medium-r-normal--16-110-100-100-c-160-jisx0208.1990-0

X FONTSET                                                   fontset   xfontset

A single-byte charset is typically associated with one font.  For multi-byte
charsets a combination of fonts is often used.  This means that one group of
characters are used from one font and another group from another font (which
might be double wide).  This collection of fonts is called a fontset.

Which fonts are required in a fontset depends on the current locale.  X
windows maintains a table of which groups of characters are required for a
locale.  You have to specify all the fonts that a locale requires in the
'guifontset' option.

NOTE: The fontset always uses the current locale, even though 'encoding' may
be set to use a different charset.  In that situation you might want to use
'guifont' and 'guifontwide' instead of 'guifontset'.

Example:
    |charset| language              "groups of characters"
    GB2312    Chinese (simplified)  ISO-8859-1 and GB 2312
    Big5      Chinese (traditional) ISO-8859-1 and Big5
    CNS-11643 Chinese (traditional) ISO-8859-1, CNS 11643-1 and CNS 11643-2
    EUC-JP    Japanese              JIS X 0201 and JIS X 0208
    EUC-KR    Korean                ISO-8859-1 and KS C 5601 (KS X 1001)

You can search for fonts using the xlsfonts command.  For example, when you're
```

searching for a font for KS C 5601:
    xlsfonts | grep ksc5601

This is complicated and confusing. You might want to consult the X-Windows
documentation if there is something you don't understand.

                                                    base_font_name_list
When you have found the names of the fonts you want to use, you need to set
the 'guifontset' option. You specify the list by concatenating the font names
and putting a comma in between them.

For example, when you use the ja_JP.eucJP locale, this requires JIS X 0201
and JIS X 0208. You could supply a list of fonts that explicitly specifies
the charsets, like:

 :set guifontset=-misc-fixed-medium-r-normal--14-130-75-75-c-140-jisx0208.1983-0,
       \-misc-fixed-medium-r-normal--14-130-75-75-c-70-jisx0201.1976-0

Alternatively, you can supply a base font name list that omits the charset
name, letting X-Windows select font characters required for the locale. For
example:

 :set guifontset=-misc-fixed-medium-r-normal--14-130-75-75-c-140,
       \-misc-fixed-medium-r-normal--14-130-75-75-c-70

Alternatively, you can supply a single base font name that allows X-Windows to
select from all available fonts. For example:

 :set guifontset=-misc-fixed-medium-r-normal--14-*

Alternatively, you can specify alias names. See the fonts.alias file in the
fonts directory (e.g., /usr/X11R6/lib/X11/fonts/). For example:

 :set guifontset=k14,r14

                                                              E253
Note that in East Asian fonts, the standard character cell is square. When
mixing a Latin font and an East Asian font, the East Asian font width should
be twice the Latin font width.

If 'guifontset' is not empty, the "font" argument of the :highlight command
is also interpreted as a fontset. For example, you should use for
highlighting:
        :hi Comment font=english_font,your_font
If you use a wrong "font" argument you will get an error message.
Also make sure that you set 'guifontset' before setting fonts for highlight
groups.

USING RESOURCE FILES

Instead of specifying 'guifontset', you can set X11 resources and Vim will
pick them up. This is only for people who know how X resource files work.

For Motif and Athena insert these three lines in your $HOME/.Xdefaults file:

```
Vim.font:  base_font_name_list
Vim*fontSet:  base_font_name_list
Vim*fontList: your_language_font
```

Note: Vim.font is for text area.
Vim*fontSet is for menu.
Vim*fontList is for menu (for Motif GUI)

For example, when you are using Japanese and a 14 dots font,

```
Vim.font: -misc-fixed-medium-r-normal--14-*
Vim*fontSet: -misc-fixed-medium-r-normal--14-*
Vim*fontList: -misc-fixed-medium-r-normal--14-*
```

or:

```
Vim*font: k14,r14
Vim*fontSet: k14,r14
Vim*fontList: k14,r14
```

To have them take effect immediately you will have to do

```
xrdb -merge ~/.Xdefaults
```

Otherwise you will have to stop and restart the X server before the changes take effect.

The GTK+ version of GUI Vim does not use .Xdefaults, use ~/.gtkrc instead. The default mostly works OK. But for the menus you might have to change it. Example:

```
style "default"
{
        fontset="-*-*-medium-r-normal--14-*-*-*-c-*-*-*"
}
widget_class "*" style "default"
```

==========

6. Fonts on MS-Windows mbyte-fonts-MSwin

The simplest is to use the font dialog to select fonts and try them out. You can find this at the "Edit/Select Font..." menu. Once you find a font name that works well you can use this command to see its name:

```
:set guifont
```

Then add a command to your gvimrc file to set 'guifont':

```
:set guifont=courier_new:h12
```

==========

7. Input on X11 mbyte-XIM

X INPUT METHOD (XIM) BACKGROUND XIM xim x-input-method

XIM is an international input module for X. There are two kinds of structures, Xlib unit type and IM-server (Input-Method server) type. IM-server type is suitable for complex input, such as CJK.

- IM-server

  IM-server

  In IM-server type input structures, the input event is handled by either of the two ways: FrontEnd system and BackEnd system. In the FrontEnd system, input events are snatched by the IM-server first, then IM-server give the application the result of input. On the other hand, the BackEnd system works reverse order. MS Windows adopt BackEnd system. In X, most of IM-server s adopt FrontEnd system. The demerit of BackEnd system is the large overhead in communication, but it provides safe synchronization with no restrictions on applications.

  For example, there are xwnmo and kinput2 Japanese IM-server , both are FrontEnd system. Xwnmo is distributed with Wnn (see below), kinput2 can be found at: ftp://ftp.sra.co.jp/pub/x11/kinput2/

  For Chinese, there's a great XIM server named "xcin", you can input both Traditional and Simplified Chinese characters. And it can accept other locale if you make a correct input table. Xcin can be found at:
  http://cle.linux.org.tw/xcin/
  Others are scim: http://scim.freedesktop.org/ and fcitx:
  http://www.fcitx.org/

- Conversion Server

  conversion-server

  Some system needs additional server: conversion server. Most of Japanese IM-server s need it, Kana-Kanji conversion server. For Chinese inputting, it depends on the method of inputting, in some methods, PinYin or ZhuYin to HanZi conversion server is needed. For Korean inputting, if you want to input Hanja, Hangul-Hanja conversion server is needed.

  For example, the Japanese inputting process is divided into 2 steps. First we pre-input Hira-gana, second Kana-Kanji conversion. There are so many Kanji characters (6349 Kanji characters are defined in JIS X 0208) and the number of Hira-gana characters are 76. So, first, we pre-input text as pronounced in Hira-gana, second, we convert Hira-gana to Kanji or Kata-Kana, if needed. There are some Kana-Kanji conversion server: jserver (distributed with Wnn, see below) and canna. Canna can be found at:
  http://canna.sourceforge.jp/

There is a good input system: Wnn4.2. Wnn 4.2 contains,
    xwnmo (IM-server)
    jserver (Japanese Kana-Kanji conversion server)
    cserver (Chinese PinYin or ZhuYin to simplified HanZi conversion server)
    tserver (Chinese PinYin or ZhuYin to traditional HanZi conversion server)
    kserver (Hangul-Hanja conversion server)
Wnn 4.2 for several systems can be found at various places on the internet.

Use the RPM or port for your system.

- Input Style
                                                        xim-input-style

  When inputting CJK, there are four areas:
      1. The area to display of the input while it is being composed
      2. The area to display the currently active input mode.
      3. The area to display the next candidate for the selection.
      4. The area to display other tools.

  The third area is needed when converting. For example, in Japanese inputting, multiple Kanji characters could have the same pronunciation, so a sequence of Hira-gana characters could map to a distinct sequence of Kanji characters.

  The first and second areas are defined in international input of X with the names of "Preedit Area", "Status Area" respectively. The third and fourth areas are not defined and are left to be managed by the IM-server . In the international input, four input styles have been defined using combinations of Preedit Area and Status Area: OnTheSpot , OffTheSpot , OverTheSpot and Root .

  Currently, GUI Vim supports three styles, OverTheSpot , OffTheSpot and Root .
  When compiled with +GUI_GTK feature, GUI Vim supports two styles, OnTheSpot and OverTheSpot . You can select the style with the 'imstyle' option.

*. on-the-spot   OnTheSpot
    Preedit Area and Status Area are performed by the client application in the area of application. The client application is directed by the IM-server to display all pre-edit data at the location of text insertion. The client registers callbacks invoked by the input method during pre-editing.
*. over-the-spot   OverTheSpot
    Status Area is created in a fixed position within the area of application, in case of Vim, the position is the additional status line. Preedit Area is made at present input position of application. The input method displays pre-edit data in a window which it brings up directly over the text insertion position.
*. off-the-spot   OffTheSpot
    Preedit Area and Status Area are performed in the area of application, in case of Vim, the area is additional status line. The client application provides display windows for the pre-edit data to the input method which displays into them directly.
*. root-window   Root
    Preedit Area and Status Area are outside of the application. The input method displays all pre-edit data in a separate area of the screen in a window specific to the input method.

USING XIM   multibyte-input E284 E286 E287 E288
                                E285 E289

Note that Display and Input are independent. It is possible to see your language even though you have no input method for it. But when your Display method doesn't match your Input method, the text will be displayed wrong.

```
        Note: You can not use IM unless you specify 'guifontset'.
              Therefore, Latin users, you have to also use 'guifontset'
              if you use IM.
```

To input your language you should run the IM-server which supports your language and conversion-server if needed.

The next 3 lines should be put in your ~/.Xdefaults file. They are common for all X applications which uses XIM . If you already use XIM , you can skip this.

```
        *international: True
        *.inputMethod: your_input_server_name
        *.preeditType: your_input_style
```

input_server_name	is your IM-server name (check your IM-server manual).
your_input_style	is one of OverTheSpot , OffTheSpot , Root . See also xim-input-style .

*international may not necessary if you use X11R6.
*.inputMethod and *.preeditType are optional if you use X11R6.

For example, when you are using kinput2 as IM-server ,

```
        *international: True
        *.inputMethod: kinput2
        *.preeditType: OverTheSpot
```

When using OverTheSpot , GUI Vim always connects to the IM Server even in Normal mode, so you can input your language with commands like "f" and "r". But when using one of the other two methods, GUI Vim connects to the IM Server only if it is not in Normal mode.

If your IM Server does not support OverTheSpot , and if you want to use your language with some Normal mode command like "f" or "r", then you should use a localized xterm or an xterm which supports XIM

If needed, you can set the XMODIFIERS environment variable:

```
        sh:  export XMODIFIERS="@im=input_server_name"
        csh: setenv XMODIFIERS "@im=input_server_name"
```

For example, when you are using kinput2 as IM-server and sh,

```
        export XMODIFIERS="@im=kinput2"
```

FULLY CONTROLLED XIM

You can fully control XIM, like with IME of MS-Windows (see multibyte-ime).
This is currently only available for the GTK GUI.

Before using fully controlled XIM, one setting is required. Set the
'imactivatekey' option to the key that is used for the activation of the input
method. For example, when you are using kinput2 + canna as IM Server, the
activation key is probably Shift+Space:

```
:set imactivatekey=S-space
```

See 'imactivatekey' for the format.

==
8. Input on MS-Windows mbyte-IME

(Windows IME support) multibyte-ime IME

{only works Windows GUI and compiled with the |+multi_byte_ime| feature}

To input multibyte characters on Windows, you can use an Input Method Editor
(IME). In process of your editing text, you must switch status (on/off) of
IME many many many times. Because IME with status on is hooking all of your
key inputs, you cannot input 'j', 'k', or almost all of keys to Vim directly.

This +multi_byte_ime feature help this. It reduce times of switch status of
IME manually. In normal mode, there are almost no need working IME, even
editing multibyte text. So exiting insert mode with ESC, Vim memorize last
status of IME and force turn off IME. When re-enter insert mode, Vim revert
IME status to that memorized automatically.

This works on not only insert-normal mode, but also search-command input and
replace mode.
The options 'iminsert', 'imsearch' and 'imcmdline' can be used to chose
the different input methods or disable them temporarily.

WHAT IS IME
    IME is a part of East asian version Windows. That helps you to input
    multibyte character. English and other language version Windows does not
    have any IME. (Also there is no need usually.) But there is one that
    called Microsoft Global IME. Global IME is a part of Internet Explorer
    4.0 or above. You can get more information about Global IME, at below
    URL.

WHAT IS GLOBAL IME global-ime
    Global IME makes capability to input Chinese, Japanese, and Korean text
    into Vim buffer on any language version of Windows 98, Windows 95, and
    Windows NT 4.0.
    On Windows 2000 and XP it should work as well (without downloading). On
    Windows 2000 Professional, Global IME is built in, and the Input Locales
    can be added through Control Panel/Regional Options/Input Locales.
    Please see below URL for detail of Global IME. You can also find various
    language version of Global IME at same place.

- Global IME detailed information.
  http://search.microsoft.com/results.aspx?q=global+ime

- Active Input Method Manager (Global IME)
  http://msdn.microsoft.com/en-us/library/aa741221(v=VS.85).aspx

Support for Global IME is an experimental feature.

NOTE: For IME to work you must make sure the input locales of your language
are added to your system. The exact location of this depends on the version
of Windows you use. For example, on my Windows 2000 box:
1. Control Panel
2. Regional Options
3. Input Locales Tab
4. Add Installed input locales -> Chinese(PRC)
   The default is still English (United Stated)

Cursor color when IME or XIM is on CursorIM

There is a little cute feature for IME. Cursor can indicate status of IME by changing its color. Usually status of IME was indicated by little icon at a corner of desktop (or taskbar). It is not easy to verify status of IME. But this feature help this.
This works in the same way when using XIM.

You can select cursor color when status is on by using highlight group CursorIM. For example, add these lines to your gvimrc :

```
if has('multi_byte_ime')
    highlight Cursor guifg=NONE guibg=Green
    highlight CursorIM guifg=NONE guibg=Purple
endif
```

Cursor color with off IME is green. And purple cursor indicates that status is on.

==
9. Input with a keymap mbyte-keymap

When the keyboard doesn't produce the characters you want to enter in your text, you can use the 'keymap' option. This will translate one or more (English) characters to another (non-English) character. This only happens when typing text, not when typing Vim commands. This avoids having to switch between two keyboard settings.
{only available when compiled with the |+keymap| feature}

The value of the 'keymap' option specifies a keymap file to use. The name of this file is one of these two:

```
keymap/{keymap}_{encoding}.vim
keymap/{keymap}.vim
```

Here {keymap} is the value of the 'keymap' option and {encoding} of the 'encoding' option. The file name with the {encoding} included is tried first.

'runtimepath' is used to find these files. To see an overview of all
available keymap files, use this:
	:echo globpath(&rtp, "keymap/*.vim")

In Insert and Command-line mode you can use CTRL-^ to toggle between using the
keyboard map or not. i_CTRL-^ c_CTRL-^
This flag is remembered for Insert mode with the 'iminsert' option. When
leaving and entering Insert mode the previous value is used. The same value
is also used for commands that take a single character argument, like f and
 r .
For Command-line mode the flag is NOT remembered. You are expected to type an
Ex command first, which is ASCII.
For typing search patterns the 'imsearch' option is used. It can be set to
use the same value as for 'iminsert'.
lCursor
It is possible to give the GUI cursor another color when the language mappings
are being used. This is disabled by default, to avoid that the cursor becomes
invisible when you use a non-standard background color. Here is an example to
use a brightly colored cursor:
	:highlight Cursor guifg=NONE guibg=Green
	:highlight lCursor guifg=NONE guibg=Cyan

keymap-file-format :loadk :loadkeymap E105 E791
The keymap file looks something like this:

```
	" Maintainer:	name <email@address>
	" Last Changed: 2001 Jan 1

	let b:keymap_name = "short"

	loadkeymap
	a	A
	b	B	comment
```

The lines starting with a " are comments and will be ignored. Blank lines are
also ignored. The lines with the mappings may have a comment after the useful
text.

The "b:keymap_name" can be set to a short name, which will be shown in the
status line. The idea is that this takes less room than the value of
'keymap', which might be long to distinguish between different languages,
keyboards and encodings.

The actual mappings are in the lines below "loadkeymap". In the example "a"
is mapped to "A" and "b" to "B". Thus the first item is mapped to the second
item. This is done for each line, until the end of the file.
These items are exactly the same as what can be used in a :lnoremap command,
using "<buffer>" to make the mappings local to the buffer.
You can check the result with this command:
	:lmap
The two items must be separated by white space. You cannot include white
space inside an item, use the special names "<Tab>" and "<Space>" instead.
The length of the two items together must not exceed 200 bytes.

It's possible to have more than one character in the first column. This works
like a dead key. Example:

```
        'a      á
```

Since Vim doesn't know if the next character after a quote is really an "a",
it will wait for the next character. To be able to insert a single quote,
also add this line:

```
        ''      '
```

Since the mapping is defined with :lnoremap the resulting quote will not be
used for the start of another character.
The "accents" keymap uses this.   keymap-accents

The first column can also be in <> form:

```
        <C-c>           Ctrl-C
        <A-c>           Alt-c
        <A-C>           Alt-C
```

Note that the Alt mappings may not work, depending on your keyboard and
terminal.

Although it's possible to have more than one character in the second column,
this is unusual. But you can use various ways to specify the character:

```
        A       a               literal character
        A       <char-97>       decimal value
        A       <char-0x61>     hexadecimal value
        A       <char-0141>     octal value
        x       <Space>         special key name
```

The characters are assumed to be encoded for the current value of 'encoding'.
It's possible to use ":scriptencoding" when all characters are given
literally. That doesn't work when using the <char-> construct, because the
conversion is done on the keymap file, not on the resulting character.

The lines after "loadkeymap" are interpreted with 'cpoptions' set to "C".
This means that continuation lines are not used and a backslash has a special
meaning in the mappings. Examples:

```
        " a comment line
        \"      x       maps " to x
        \\      y       maps \ to y
```

If you write a keymap file that will be useful for others, consider submitting
it to the Vim maintainer for inclusion in the distribution:
<maintainer@vim.org>

HEBREW KEYMAP   keymap-hebrew

This file explains what characters are available in UTF-8 and CP1255 encodings,
and what the keymaps are to get those characters:

```
glyph   encoding          keymap
Char   utf-8 cp1255  hebrew  hebrewp  name
□    0x5d0  0xe0     t        a     'alef
```

==========

10. Input with imactivatefunc() mbyte-func

Vim has the 'imactivatefunc' and 'imstatusfunc' options. These are useful to activate/deactivate the input method from Vim in any way, also with an external command. For example, fcitx provide fcitx-remote command:

```
set iminsert=2
set imsearch=2
set imcmdline

set imactivatefunc=ImActivate
```

```
        function! ImActivate(active)
          if a:active
            call system('fcitx-remote -o')
          else
            call system('fcitx-remote -c')
          endif
        endfunction

        set imstatusfunc=ImStatus
        function! ImStatus()
          return system('fcitx-remote')[0] is# '2'
        endfunction
```

Using this script, you can activate/deactivate XIM via Vim even when it is not compiled with +xim .

==

11. Using UTF-8 mbyte-utf8 UTF-8 utf-8 utf8 Unicode unicode

The Unicode character set was designed to include all characters from other character sets. Therefore it is possible to write text in any language using Unicode (with a few rarely used languages excluded). And it's mostly possible to mix these languages in one file, which is impossible with other encodings.

Unicode can be encoded in several ways. The most popular one is UTF-8, which uses one or more bytes for each character and is backwards compatible with ASCII. On MS-Windows UTF-16 is also used (previously UCS-2), which uses 16-bit words. Vim can support all of these encodings, but always uses UTF-8 internally.

Vim has comprehensive UTF-8 support. It works well in:
- xterm with utf-8 support enabled
- Athena, Motif and GTK GUI
- MS-Windows GUI
- several other platforms

Double-width characters are supported. This works best with 'guifontwide' or 'guifontset'. When using only 'guifont' the wide characters are drawn in the normal width and a space to fill the gap. Note that the 'guifontset' option is no longer relevant in the GTK+ 2 GUI.

bom-bytes

When reading a file a BOM (Byte Order Mark) can be used to recognize the Unicode encoding:

```
        EF BB BF     utf-8
        FE FF        utf-16 big endian
        FF FE        utf-16 little endian
        00 00 FE FF  utf-32 big endian
        FF FE 00 00  utf-32 little endian
```

Utf-8 is the recommended encoding. Note that it's difficult to tell utf-16 and utf-32 apart. Utf-16 is often used on MS-Windows, utf-32 is not widespread as file format.

mbyte-combining mbyte-composing

A composing or combining character is used to change the meaning of the character before it. The combining characters are drawn on top of the preceding character.
Up to two combining characters can be used by default. This can be changed with the 'maxcombine' option.
When editing text a composing character is mostly considered part of the preceding character. For example "x" will delete a character and its following composing characters by default.
If the 'delcombine' option is on, then pressing 'x' will delete the combining characters, one at a time, then the base character. But when inserting, you type the first character and the following composing characters separately, after which they will be joined. The "r" command will not allow you to type a combining character, because it doesn't know one is coming. Use "R" instead.

Bytes which are not part of a valid UTF-8 byte sequence are handled like a single character and displayed as <xx>, where "xx" is the hex value of the byte.

Overlong sequences are not handled specially and displayed like a valid character. However, search patterns may not match on an overlong sequence. (an overlong sequence is where more bytes are used than required for the character.) An exception is NUL (zero) which is displayed as "<00>".

In the file and buffer the full range of Unicode characters can be used (31 bits). However, displaying only works for the characters present in the selected font.

Useful commands:
- "ga" shows the decimal, hexadecimal and octal value of the character under the cursor. If there are composing characters these are shown too. (If the message is truncated, use ":messages").
- "g8" shows the bytes used in a UTF-8 character, also the composing characters, as hex numbers.
- ":set encoding=utf-8 fileencodings=" forces using UTF-8 for all files. The default is to use the current locale for 'encoding' and set 'fileencodings' to automatically detect the encoding of a file.

STARTING VIM

If your current locale is in an utf-8 encoding, Vim will automatically start in utf-8 mode.

If you are using another locale:

```
set encoding=utf-8
```

You might also want to select the font used for the menus. Unfortunately this doesn't always work. See the system specific remarks below, and 'langmenu'.

USING UTF-8 IN X-Windows utf-8-in-xwindows

Note: This section does not apply to the GTK+ 2 GUI.

You need to specify a font to be used. For double-wide characters another font is required, which is exactly twice as wide. There are three ways to do this:

1. Set 'guifont' and let Vim find a matching 'guifontwide'
2. Set 'guifont' and 'guifontwide'
3. Set 'guifontset'

See the documentation for each option for details. Example:

```
:set guifont=-misc-fixed-medium-r-normal--15-140-75-75-c-90-iso10646-1
```

You might also want to set the font used for the menus. This only works for Motif. Use the ":hi Menu font={fontname}" command for this. :highlight

TYPING UTF-8 utf-8-typing

If you are using X-Windows, you should find an input method that supports utf-8.

If your system does not provide support for typing utf-8, you can use the 'keymap' feature. This allows writing a keymap file, which defines a utf-8 character as a sequence of ASCII characters. See mbyte-keymap .

Another method is to set the current locale to the language you want to use and for which you have a XIM available. Then set 'termencoding' to that language and Vim will convert the typed characters to 'encoding' for you.

If everything else fails, you can type any character as four hex bytes:

```
CTRL-V u 1234
```

"1234" is interpreted as a hex number. You must type four characters, prepend a zero if necessary.

COMMAND ARGUMENTS utf-8-char-arg

Commands like f , F , t and r take an argument of one character. For UTF-8 this argument may include one or two composing characters. These need to be produced together with the base character, Vim doesn't wait for the next character to be typed to find out if it is a composing character or not. Using 'keymap' or :lmap is a nice way to type these characters.

The commands that search for a character in a line handle composing characters as follows. When searching for a character without a composing character, this will find matches in the text with or without composing characters. When searching for a character with a composing character, this will only find matches with that composing character. It was implemented this way, because not everybody is able to type a composing character.

==
12. Overview of options   mbyte-options

These options are relevant for editing multi-byte files. Check the help in
options.txt for detailed information.

'encoding'   Encoding used for the keyboard and display. It is also the
                default encoding for files.

'fileencoding' Encoding of a file. When it's different from 'encoding'
                conversion is done when reading or writing the file.

'fileencodings' List of possible encodings of a file. When opening a file
                these will be tried and the first one that doesn't cause an
                error is used for 'fileencoding'.

'charconvert'   Expression used to convert files from one encoding to another.

'formatoptions' The 'm' flag can be included to have formatting break a line
                at a multibyte character of 256 or higher. Thus is useful for
                languages where a sequence of characters can be broken
                anywhere.

'guifontset'   The list of font names used for a multi-byte encoding. When
                this option is not empty, it replaces 'guifont'.

'keymap'   Specify the name of a keyboard mapping.

VIM REFERENCE MANUAL by Bram Moolenaar

Multi-language features multilang multi-lang

This is about using messages and menus in various languages. For editing multi-byte text see multibyte .

The basics are explained in the user manual: usr_45.txt .

Also see help-translated for multi-language help.

{Vi does not have any of these features}
{not available when compiled without the |+multi_lang| feature}

---

1. Messages multilang-messages

Vim picks up the locale from the environment. In most cases this means Vim will use the language that you prefer, unless it's not available.

To see a list of supported locale names on your system, look in one of these directories (for Unix):

```
/usr/lib/locale
/usr/share/locale
```

Unfortunately, upper/lowercase differences matter. Also watch out for the use of "-" and "_".

:lan :lang :language E197

:lan[guage]
:lan[guage] mes[sages]
:lan[guage] cty[pe]
:lan[guage] tim[e]

Print the current language (aka locale).
With the "messages" argument the language used for messages is printed. Technical: LC_MESSAGES.
With the "ctype" argument the language used for character encoding is printed. Technical: LC_CTYPE.
With the "time" argument the language used for strftime() is printed. Technical: LC_TIME.
Without argument all parts of the locale are printed (this is system dependent).
The current language can also be obtained with the v:lang , v:ctype and v:lc_time variables.

:lan[guage] {name}
:lan[guage] mes[sages] {name}

:lan[guage] cty[pe] {name}
:lan[guage] tim[e] {name}
Set the current language (aka locale) to {name}.
The locale {name} must be a valid locale on your
system. Some systems accept aliases like "en" or
"en_US", but some only accept the full specification
like "en_US.ISO_8859-1". On Unix systems you can use
this command to see what locales are supported:

```
:!locale -a
```

With the "messages" argument the language used for
messages is set. This can be different when you want,
for example, English messages while editing Japanese
text. This sets $LC_MESSAGES.
With the "ctype" argument the language used for
character encoding is set. This affects the libraries
that Vim was linked with. It's unusual to set this to
a different value from 'encoding' or "C". This sets
$LC_CTYPE.
With the "time" argument the language used for time
and date messages is set. This affects strftime().
This sets $LC_TIME.
Without an argument both are set, and additionally
$LANG is set.
When compiled with the +float feature the LC_NUMERIC
value will always be set to "C", so that floating
point numbers use '.' as the decimal point.
This will make a difference for items that depend on
the language (some messages, time and date format).
Not fully supported on all systems
If this fails there will be an error message. If it
succeeds there is no message. Example:

```
:language
Current language: C
:language de_DE.ISO_8859-1
:language mes
Current messages language: de_DE.ISO_8859-1
:lang mes en
```

MS-WINDOWS MESSAGE TRANSLATIONS win32-gettext

If you used the self-installing .exe file, message translations should work
already. Otherwise get the libintl.dll file if you don't have it yet:

http://sourceforge.net/projects/gettext
Or:
https://mlocati.github.io/gettext-iconv-windows/

This also contains tools xgettext, msgformat and others.

libintl.dll should be placed in same directory with (g)vim.exe, or some
place where PATH environment value describe. Vim also finds libintl-8.dll.
Message files (vim.mo) have to be placed in "$VIMRUNTIME/lang/xx/LC_MESSAGES",
where "xx" is the abbreviation of the language (mostly two letters).

If you write your own translations you need to generate the .po file and convert it to a .mo file. You need to get the source distribution and read the file "src/po/README.txt".

To overrule the automatic choice of the language, set the $LANG variable to the language of your choice. use "en" to disable translations.

```
:let $LANG = 'ja'
```

(text for Windows by Muraoka Taro)

==
2. Menus multilang-menus

See 45.2 for the basics, esp. using 'langmenu'.

Note that if changes have been made to the menus after the translation was done, some of the menus may be shown in English. Please try contacting the maintainer of the translation and ask him to update it. You can find the name and e-mail address of the translator in "$VIMRUNTIME/lang/menu_<lang>.vim".

To set the font (or fontset) to use for the menus, use the :highlight command. Example:

```
:highlight Menu font=k12,r12
```

ALIAS LOCALE NAMES

Unfortunately, the locale names are different on various systems, even though they are for the same language and encoding. If you do not get the menu translations you expected, check the output of this command:

```
echo v:lang
```

Now check the "$VIMRUNTIME/lang" directory for menu translation files that use a similar language. A difference in a "-" being a "_" already causes a file not to be found! Another common difference to watch out for is "iso8859-1" versus "iso_8859-1". Fortunately Vim makes all names lowercase, thus you don't have to worry about case differences. Spaces are changed to underscores, to avoid having to escape them.

If you find a menu translation file for your language with a different name, create a file in your own runtime directory to load that one. The name of that file could be:

```
~/.vim/lang/menu_<v:lang>.vim
```

Check the 'runtimepath' option for directories which are searched. In that file put a command to load the menu file with the other name:

```
runtime lang/menu_<other_lang>.vim
```

TRANSLATING MENUS

If you want to do your own translations, you can use the :menutrans command, explained below. It is recommended to put the translations for one language in a Vim script. For a language that has no translation yet, please consider becoming the maintainer and make your translations available to all Vim users. Send an e-mail to the Vim maintainer <maintainer@vim.org>.

:menut :menutrans :menutranslate

:menut[ranslate] clear
Clear all menu translations.

:menut[ranslate] {english} {mylang}
Translate menu name {english} to {mylang}. All special characters like "&" and "<Tab>" need to be included. Spaces and dots need to be escaped with a backslash, just like in other :menu commands. Case in {english} is ignored.

See the $VIMRUNTIME/lang directory for examples.

To try out your translations you first have to remove all menus. This is how you can do it without restarting Vim:

```
:source $VIMRUNTIME/delmenu.vim
:source <your-new-menu-file>
:source $VIMRUNTIME/menu.vim
```

Each part of a menu path is translated separately. The result is that when "Help" is translated to "Hilfe" and "Overview" to "Überblick" then "Help.Overview" will be translated to "Hilfe.Überblick".

==
3. Scripts multilang-scripts

In Vim scripts you can use the v:lang variable to get the current language (locale). The default value is "C" or comes from the $LANG environment variable.

The following example shows how this variable is used in a simple way, to make a message adapt to language preferences of the user,

```
:if v:lang =~ "de_DE"
:  echo "Guten Morgen"
:else
:  echo "Good morning"
:endif
```

arabic.txt For Vim version 8.1. Last change: 2010 Nov 13

VIM REFERENCE MANUAL by Nadim Shaikli

Arabic Language support (options & mappings) for Vim Arabic

{Vi does not have any of these commands}

E800

In order to use right-to-left and Arabic mapping support, it is necessary to compile Vim with the +arabic feature.

These functions have been created by Nadim Shaikli <nadim-at-arabeyes.org>

It is best to view this file with these settings within Vim's GUI:

```
:set encoding=utf-8
:set arabicshape
```

Introduction

Arabic is a rather demanding language in which a number of special features are required. Characters are right-to-left oriented and ought to appear as such on the screen (i.e. from right to left). Arabic also requires shaping of its characters, meaning the same character has a different visual form based on its relative location within a word (initial, medial, final or stand-alone). Arabic also requires two different forms of combining and the ability, in certain instances, to either superimpose up to two characters on top of another (composing) or the actual substitution of two characters into one (combining). Lastly, to display Arabic properly one will require not only ISO-8859-6 (U+0600-U+06FF) fonts, but will also require Presentation Form-B (U+FE70-U+FEFF) fonts both of which are subsets within a so-called ISO-10646-1 font.

The commands, prompts and help files are not in Arabic, therefore the user interface remains the standard Vi interface.

Highlights

- Editing left-to-right files as in the original Vim hasn't changed.
- Viewing and editing files in right-to-left windows. File orientation is per window, so it is possible to view the same file in right-to-left and left-to-right modes, simultaneously.
- No special terminal with right-to-left capabilities is required. The right-to-left changes are completely hardware independent. Only Arabic fonts are necessary.

o Compatible with the original Vim. Almost all features work in
   right-to-left mode (there are liable to be bugs).

o Changing keyboard mapping and reverse insert modes using a single
   command.

o Toggling complete Arabic support via a single command.

o While in Arabic mode, numbers are entered from left to right. Upon
   entering a none number character, that character will be inserted
   just into the left of the last number.

o Arabic keymapping on the command line in reverse insert mode.

o Proper Bidirectional functionality is possible given Vim is
   started within a Bidi capable terminal emulator.

Arabic Fonts arabicfonts

Vim requires monospaced fonts of which there are many out there.
Arabic requires ISO-8859-6 as well as Presentation Form-B fonts
(without Form-B, Arabic will _NOT_ be usable). It is highly
recommended that users search for so-called 'ISO-10646-1' fonts.
Do an Internet search or check www.arabeyes.org for further
info on where to attain the necessary Arabic fonts.

Font Installation

o Installation of fonts for X Window systems (Unix/Linux)

   Depending on your system, copy your_ARABIC_FONT file into a
   directory of your choice. Change to the directory containing
   the Arabic fonts and execute the following commands:

     % mkfontdir
     % xset +fp path_name_of_arabic_fonts_directory

Usage

Prior to the actual usage of Arabic within Vim, a number of settings
need to be accounted for and invoked.

o Setting the Arabic fonts

   + For Vim GUI set the 'guifont' to your_ARABIC_FONT. This is done
      by entering the following command in the Vim window.

                :set guifont=your_ARABIC_FONT

NOTE: the string 'your_ARABIC_FONT' is used to denote a complete
font name akin to that used in Linux/Unix systems.
(e.g. -misc-fixed-medium-r-normal--20-200-75-75-c-100-iso10646-1)

You can append the 'guifont' set command to your .vimrc file
in order to get the same above noted results. In other words,
you can include ':set guifont=your_ARABIC_FONT' to your .vimrc
file.

+ Under the X Window environment, you can also start Vim with
'-fn your_ARABIC_FONT' option.

o Setting the appropriate character Encoding
To enable the correct Arabic encoding the following command needs
to be appended,

:set encoding=utf-8

to your .vimrc file (entering the command manually into you Vim
window is highly discouraged). In short, include ':set
encoding=utf-8' to your .vimrc file.

Attempts to use Arabic without UTF-8 will result the following
warning message,

W17
Arabic requires UTF-8, do ':set encoding=utf-8'

o Enable Arabic settings [short-cut]

In order to simplify and streamline things, you can either invoke
Vim with the command-line option,

% vim -A my_utf8_arabic_file ...

or enable 'arabic' via the following command within Vim

:set arabic

The two above noted possible invocations are the preferred manner
in which users are instructed to proceed. Barring an enabled 'termbidi'
setting, both command options:

1. set the appropriate keymap
2. enable the deletion of a single combined pair character
3. enable rightleft mode
4. enable rightleftcmd mode (affecting the command-line)
5. enable arabicshape mode (do visual character alterations)

You may also append the command to your .vimrc file and simply
include ':set arabic' to it.

You are also capable of disabling Arabic support via

```
            :set noarabic

which resets everything that the command had enabled without touching
the global settings as they could affect other possible open buffers.
In short the 'noarabic' command,

  1. resets to the alternate keymap
  2. disables the deletion of a single combined pair character
  3. disables rightleft mode

NOTE: the 'arabic' command takes into consideration 'termbidi' for
      possible external bi-directional (bidi) support from the
      terminal ("mlterm" for instance offers such support).
      'termbidi', if available, is superior to rightleft support
      and its support is preferred due to its level of offerings.
      'arabic' when 'termbidi' is enabled only sets the keymap.

If, on the other hand, you'd like to be verbose and explicit and
are opting not to use the 'arabic' short-cut command, here's what
is needed (i.e. if you use ':set arabic' you can skip this section) -

+  Arabic Keymapping Activation

   To activate the Arabic keymap (i.e. to remap your English/Latin
   keyboard to look-n-feel like a standard Arabic one), set the
   'keymap' command to "arabic".  This is done by entering

            :set keymap=arabic

   in your Vim window.  You can also append the 'keymap' set command to
   your .vimrc file.  In other words, you can include ':set keymap=arabic'
   to your .vimrc file.

   To turn toggle (or switch) your keymapping between Arabic and the
   default mapping (English), it is advised that users use the 'CTRL-^'
   key press while in insert (or add/replace) mode.  The command-line
   will display your current mapping by displaying an "Arabic" string
   next to your insertion mode (e.g. -- INSERT Arabic --) indicating
   your current keymap.

+  Arabic deletion of a combined pair character

   By default Vim has the 'delcombine' option disabled.  This option
   allows the deletion of ALEF in a LAM_ALEF (LAA) combined character
   and still retain the LAM (i.e. it reverts to treating the combined
   character as its natural two characters form -- this also pertains
   to harakat and their combined forms).  You can enable this option
   by entering

            :set delcombine

   in our Vim window.  You can also append the 'delcombine' set command
   to your .vimrc file.  In other words, you can include ':set delcombine'
   to your .vimrc file.
```

+ Arabic right-to-left Mode

  By default Vim starts in Left-to-right mode. 'rightleft' is the
  command that allows one to alter a window's orientation - that can
  be accomplished via,

  - Toggling between left-to-right and right-to-left modes is
    accomplished through ':set rightleft' and ':set norightleft'.

  - While in Left-to-right mode, enter ':set rl' in the command line
    ('rl' is the abbreviation for rightleft).

  - Put the ':set rl' line in your '.vimrc' file to start Vim in
    right-to-left mode permanently.

+ Arabic right-to-left command-line Mode

  For certain commands the editing can be done in right-to-left mode.
  Currently this is only applicable to search commands.

  This is controlled with the 'rightleftcmd' option. The default is
  "search", which means that windows in which 'rightleft' is set will
  edit search commands in right-left mode. To disable this behavior,

          :set rightleftcmd=

  To enable right-left editing of search commands again,

          :set rightleftcmd&

+ Arabic Shaping Mode

  To activate the required visual characters alterations (shaping,
  composing, combining) which the Arabic language requires, enable
  the 'arabicshape' command. This is done by entering

          :set arabicshape

  in our Vim window. You can also append the 'arabicshape' set
  command to your .vimrc file. In other words, you can include
  ':set arabicshape' to your .vimrc file.

Keymap/Keyboard   arabickeymap

The character/letter encoding used in Vim is the standard UTF-8.
It is widely discouraged that any other encoding be used or even
attempted.

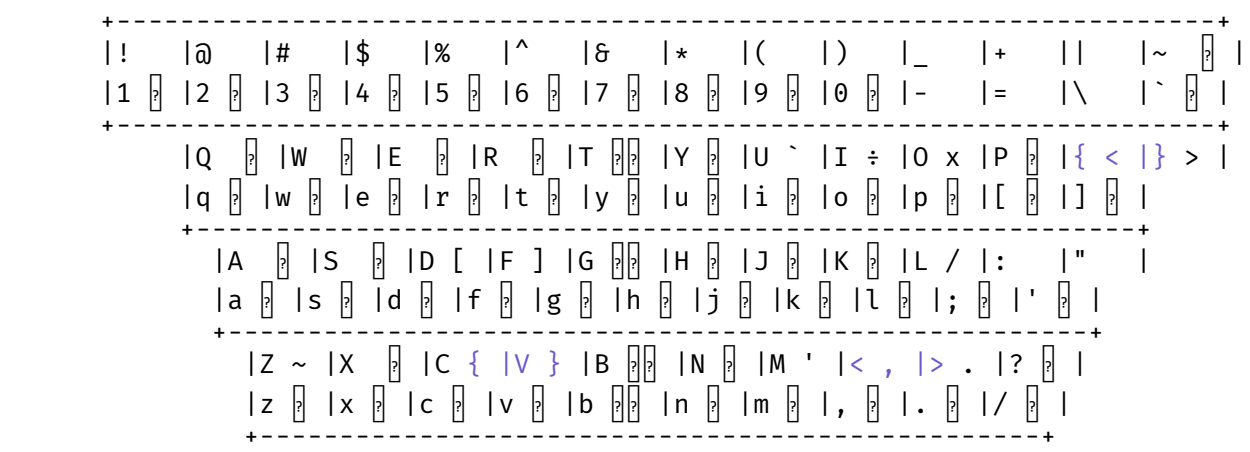
Note: UTF-8 is an all encompassing encoding and as such is
      the only supported (and encouraged) encoding with
      regard to Arabic (all other proprietary encodings

should be discouraged and frowned upon).

o Keyboard

   + CTRL-^ in insert/replace mode toggles between Arabic/Latin mode

   + Keyboard mapping is based on the Microsoft's Arabic keymap (the
      de facto standard in the Arab world):



Restrictions
----

o Vim in its GUI form does not currently support Bi-directionality
   (i.e. the ability to see both Arabic and Latin intermixed within
   the same line).

Known Bugs

There is one known minor bug,

 1. If you insert a haraka (e.g. Fatha (U+064E)) after a LAM (U+0644)
    and then insert an ALEF (U+0627), the appropriate combining will
    not happen due to the sandwiched haraka resulting in something
    that will NOT be displayed correctly.

    WORK-AROUND: Don't include harakats between LAM and ALEF combos.
                 In general, don't anticipate to see correct visual
                 representation with regard to harakats and LAM+ALEF
                 combined characters (even those entered after both
                 characters). The problem noted is strictly a visual
                 one, meaning saving such a file will contain all the
                 appropriate info/encodings - nothing is lost.

No other bugs are known to exist.

farsi.txt For Vim version 8.1. Last change: 2015 Aug 29

VIM REFERENCE MANUAL by Mortaza Ghassab Shiran

Right to Left and Farsi Mapping for Vim farsi Farsi

{Vi does not have any of these commands}

E27
In order to use right-to-left and Farsi mapping support, it is necessary to compile Vim with the +farsi feature.

These functions have been made by Mortaza G. Shiran <shiran@jps.net>

Introduction

In right-to-left oriented files the characters appear on the screen from right to left. This kind of file is most useful when writing Farsi documents, composing faxes or writing Farsi memos.

The commands, prompts and help files are not in Farsi, therefore the user interface remains the standard Vi interface.

Highlights

- Editing left-to-right files as in the original Vim, no change.
- Viewing and editing files in right-to-left windows. File orientation is per window, so it is possible to view the same file in right-to-left and left-to-right modes, simultaneously.
- Compatibility to the original Vim. Almost all features work in right-to-left mode (see bugs below).
- Changing keyboard mapping and reverse insert modes using a single command.
- Backing from reverse insert mode to the correct place in the file (if possible).
- While in Farsi mode, numbers are entered from left to right. Upon entering a none number character, that character will be inserted just into the left of the last number.
- No special terminal with right-to-left capabilities is required. The right-to-left changes are completely hardware independent. Only Farsi font is necessary.
- Farsi keymapping on the command line in reverse insert mode.

o Toggling between left-to-right and right-to-left via F8 function key.

o Toggling between Farsi ISIR-3342 standard encoding and Vim Farsi via F9
   function key. Since this makes sense only for the text written in
   right-to-left mode, this function is also supported only in right-to-left
   mode.

Farsi Fonts farsi-fonts

The following files are found in the subdirectories of the '$VIM/farsi/fonts'
directory:

   + far-a01.pcf   X Windows fonts for Unix including Linux systems
   + far-a01.bf   X Windows fonts for SunOS
   + far-a01.f16   a screen fonts for Unix including Linux systems
   + far-a01.fon   a monospaced fonts for Windows NT/95/98
   + far-a01.com   a screen fonts for DOS

Font Installation

o Installation of fonts for MS Window systems (NT/95/98)

   From 'Control Panel' folder, start the 'Fonts' program. Then from 'file'
   menu item select 'Install New Fonts ...'. Browse and select the
   'far-a01.fon', then follow the installation guide.
   NOTE: several people have reported that this does not work. The solution
   is unknown.

o Installation of fonts for X Window systems (Unix/Linux)

   Depending on your system, copy far-a01.pcf.Z or far-a01.pcf.gz into a
   directory of your choice. Change to the directory containing the Farsi
   fonts and execute the following commands:

   > mkfontdir
   > xset +fp path_name_of_farsi_fonts_directory

o Installation of fonts for X Window systems (SunOS)

   Copy far-a01.bf font into a directory of your choice.
   Change to the directory containing the far-a01.fb fonts and
   execute the following commands:

   > fldfamily
   > xset +fp path_name_of_fonts_directory

o Installation of ASCII screen fonts (Unix/Linux)

   For Linux system, copy the far-a01.f16 fonts into /usr/lib/kbd/consolefonts
   directory and execute the setfont program as "setfont far-a01.f16". For
   other systems (e.g. SCO Unix), please refer to the fonts installation

section of your system administration manuals.

o Installation of ASCII screen fonts (DOS)

   After system power on, prior to the first use of Vim, upload the Farsi
   fonts by executing the far-a01.com font uploading program.

Usage

Prior to starting Vim, the environment in which Vim can run in Farsi mode,
must be set. In addition to installation of Farsi fonts, following points
refer to some of the system environments, which you may need to set:
Key code mapping, loading graphic card in ASCII screen mode, setting the IO
driver in 8 bit clean mode ... .

o Setting the Farsi fonts

   + For Vim GUI set the 'guifont' to far-a01. This is done by entering
      ':set guifont=far-a01' in the Vim window.

      You can have 'guifont' set to far-a01 by Vim during the Vim startup
      by appending the ':set guifont=far-a01' into your .vimrc file
      (in case of NT/95/98 platforms _vimrc).

      Under the X Window environment, you can also start Vim with the
      '-fn far-a01' option.

   + For Vim within a xterm, start a xterm with the Farsi fonts (e.g.
      kterm -fn far-a01). Then start Vim inside the kterm.

   + For Vim under DOS, prior to the first usage of Vim, upload the Farsi
      fonts by executing the far-a01.com fonts uploading program.

o Farsi Keymapping Activation

   To activate the Farsi keymapping, set either 'altkeymap' or 'fkmap'.
   This is done by entering ':set akm' or ':set fk' in the Vim window.
   You can have 'altkeymap' or 'fkmap' set as default by appending ':set akm'
   or ':set fk' in your .vimrc file or _vimrc in case of NT/95/98 platforms.

   To turn off the Farsi keymapping as a default second language keymapping,
   reset the 'altkeymap' by entering ':set noakm'.

o right-to-left Farsi Mode

   By default Vim starts in Left-to-right mode. Following are ways to change
   the window orientation:

   + Start Vim with the -F option (e.g. vim -F ...).

   + Use the F8 function key to toggle between left-to-right and right-to-left.

   + While in Left-to-right mode, enter 'set rl' in the command line ('rl' is

the abbreviation for rightleft).

+ Put the 'set rl' line in your '.vimrc' file to start Vim in right-to-left mode permanently.

Encoding

The letter encoding used is the Vim extended ISIR-3342 standard with a built in function to convert between Vim extended ISIR-3342 and ISIR-3342 standard.

For document portability reasons, the letter encoding is kept the same across different platforms (i.e. UNIX's, NT/95/98, MS DOS, ...).

o Keyboard

+ CTRL-_ in insert/replace modes toggles between Farsi(akm)/Latin mode as follows:

+ CTRL-_ moves the cursor to the end of the typed text in edit mode.

+ CTRL-_ in command mode only toggles keyboard mapping between Farsi(akm)/ Latin. The Farsi text is then entered in reverse insert mode.

+ F8 - Toggles between left-to-right and right-to-left.

+ F9 - Toggles the encoding between ISIR-3342 standard and Vim extended ISIR-3342 (supported only in right-to-left mode).

+ Keyboard mapping is based on the Iranian ISIRI-2901 standard. Following table shows the keyboard mapping while Farsi(akm) mode set:

`	1	2	3	4	5	6	7	8	9	0	-	=
¢	±	²	³	´	µ	¶	·	¸	¹	º		½
~	!	@	#	$	%	^	&	*	(	)	_	+
~	£	§	®	¤	¥	ª	¬	è	¨	©	é	«
q	w	e	r	t	z	u	i	o	p	[	]	
Ó	Ò	Æ	Ù	Ø	Õ	Ö	à	Ê	É	Ç	?	
Q	W	E	R	T	Z	U	I	O	P	{	}	
÷	õ	ô	ó	ò	ý	ð	ö	[	]	{	}	
a	s	d	f	g	h	j	k	l	;	'	\	
Ñ	Ð	á	Ã	Ü	Á	Å	Þ	Ý	Ú	Û	ë	
A	S	D	F	G	H	J	K	L	:	"	|	
ù	û	þ	ú	ø	À	ü	æ	ç	º	»	ê	
<	y	x	c	v	b	n	m	,	.	/		
¾	×	Ô	Î	Í	Ì	Ë	Ä	ß	¦	¯		

```
        ------------------------------------
        >  Y  X  C  V  B  N  M  <  >  ?
        ¼  ñ  Ô  Ï  Í  ¡  Ë  Â  ¾  ¼  ¿
        ------------------------------------
```

Note:

```
        ¡  stands for Farsi PSP (break without space)

        ¿  stands for Farsi PCN (for HAMZE attribute)
```

Restrictions
----

o In insert/replace mode and fkmap (Farsi mode) set, CTRL-B is not supported.

o If you change the character mapping between Latin/Farsi, the redo buffer will be reset (emptied). That is, redo is valid and will function (using '.') only within the mode you are in.

o While numbers are entered in Farsi mode, the redo buffer will be reset (emptied). That is, you cannot redo the last changes (using '.') after entering numbers.

o While in left-to-right mode and Farsi mode set, CTRL-R is not supported.

o While in right-to-left mode, the search on 'Latin' pattern does not work, except if you enter the Latin search pattern in reverse.

o In command mode there is no support for entering numbers from left to right and also for the sake of flexibility the keymapping logic is restricted.

o Under the X Window environment, if you want to run Vim within a xterm terminal emulator and Farsi mode set, you need to have an ANSI compatible xterm terminal emulator. This is because the letter codes above 128 decimal have certain meanings in the standard xterm terminal emulator.

  Note: Under X Window environment, Vim GUI works fine in Farsi mode. This eliminates the need of any xterm terminal emulator.

Bugs

While in insert/replace and Farsi mode set, if you repeatedly change the cursor position (via cursor movement) and enter new text and then try to undo the last change, the undo will lag one change behind. But as you continue to undo, you will reach the original line of text. You can also use U to undo all changes made in the current line.

For more information about the bugs refer to rileft.txt.

vim:tw=78:ts=8:noet:ft=help:norl:

hebrew.txt For Vim version 8.1. Last change: 2007 Jun 14

VIM REFERENCE MANUAL by Ron Aaron (and Avner Lottem)

Hebrew Language support (options & mapping) for Vim hebrew

The supporting 'rightleft' functionality was originally created by Avner Lottem. <alottem at gmail dot com> Ron Aaron <ron at ronware dot org> is currently helping support these features.

{Vi does not have any of these commands}

All this is only available when the +rightleft feature was enabled at compile time.

Introduction

Hebrew-specific options are 'hkmap', 'hkmapp' 'keymap'=hebrew and 'aleph'. Hebrew-useful options are 'delcombine', 'allowrevins', 'revins', 'rightleft' and 'rightleftcmd'.

The 'rightleft' mode reverses the display order, so characters are displayed from right to left instead of the usual left to right. This is useful primarily when editing Hebrew or other Middle-Eastern languages.
See rileft.txt for further details.

Details

+ Options:
  + 'rightleft' ('rl') sets window orientation to right-to-left. This means that the logical text 'ABC' will be displayed as 'CBA', and will start drawing at the right edge of the window, not the left edge.
  + 'hkmap' ('hk') sets keyboard mapping to Hebrew, in insert/replace modes.
  + 'aleph' ('al'), numeric, holds the decimal code of Aleph, for keyboard mapping.
  + 'hkmapp' ('hkp') sets keyboard mapping to 'phonetic hebrew'

  NOTE: these three ('hkmap', 'hkmapp' and 'aleph') are obsolete. You should use ":set keymap=hebrewp" instead.

  + 'delcombine' ('deco'), boolean, if editing UTF-8 encoded Hebrew, allows one to remove the niqud or te`amim by pressing 'x' on a character (with associated niqud).

  + 'rightleftcmd' ('rlc') makes the command-prompt for searches show up on the right side. It only takes effect if the window is 'rightleft'.

+ Encoding:
  + Under Unix, ISO 8859-8 encoding (Hebrew letters codes: 224-250).
  + Under MS DOS, PC encoding (Hebrew letters codes: 128-154).
  These are defaults, that can be overridden using the 'aleph' option.

- You should prefer using UTF8, as it supports the combining-characters ('deco' does nothing if UTF8 encoding is not active).

- Vim arguments:
  - 'vim -H file' starts editing a Hebrew file, i.e. 'rightleft' and 'hkmap' are set.

- Keyboard:
  - The 'allowrevins' option enables the CTRL-_ command in Insert mode and in Command-line mode.

  - CTRL-_ in insert/replace modes toggles 'revins' and 'hkmap' as follows:

    When in rightleft window, 'revins' and 'nohkmap' are toggled, since English will likely be inserted in this case.

    When in norightleft window, 'revins' 'hkmap' are toggled, since Hebrew will likely be inserted in this case.

    CTRL-_ moves the cursor to the end of the typed text.

  - CTRL-_ in command mode only toggles keyboard mapping (see Bugs below). This setting is independent of 'hkmap' option, which only applies to insert/replace mode.

    Note: On some keyboards, CTRL-_ is mapped to CTRL-?.

  - Keyboard mapping while 'hkmap' is set (standard Israeli keyboard):

    
    This is also the keymap when 'keymap=hebrew' is set. The advantage of 'keymap' is that it works properly when using UTF8, e.g. it inserts the correct characters; 'hkmap' does not. The 'keymap' keyboard can also insert niqud and te`amim. To see what those mappings are, look at the keymap file 'hebrew.vim' etc.

Typing backwards

If the 'revins' (reverse insert) option is set, inserting happens backwards. This can be used to type Hebrew. When inserting characters the cursor is not moved and the text moves rightwards. A <BS> deletes the character under the cursor. CTRL-W and CTRL-U also work in the opposite direction. <BS>, CTRL-W and CTRL-U do not stop at the start of insert or end of line, no matter how the 'backspace' option is set.

There is no reverse replace mode (yet).

If the 'showmode' option is set, "-- REVERSE INSERT --" will be shown in the status line when reverse Insert mode is active.

When the 'allowrevins' option is set, reverse Insert mode can be also entered via CTRL-_, which has some extra functionality: First, keyboard mapping is changed according to the window orientation -- if in a left-to-right window, 'revins' is used to enter Hebrew text, so the keyboard changes to Hebrew ('hkmap' is set); if in a right-to-left window, 'revins' is used to enter English text, so the keyboard changes to English ('hkmap' is reset). Second, when exiting 'revins' via CTRL-_, the cursor moves to the end of the typed text (if possible).

Pasting when in a rightleft window

When cutting text with the mouse and pasting it in a rightleft window the text will be reversed, because the characters come from the cut buffer from the left to the right, while inserted in the file from the right to the left. In order to avoid it, toggle 'revins' (by typing CTRL-? or CTRL-_) before pasting.

Hebrew characters and the 'isprint' variable

Sometimes Hebrew character codes are in the non-printable range defined by the 'isprint' variable. For example in the Linux console, the Hebrew font encoding starts from 128, while the default 'isprint' variable is @,161-255. The result is that all Hebrew characters are displayed as ~x. To solve this problem, set isprint=@,128-255.

vim:tw=78:ts=8:noet:ft=help:norl:

russian.txt For Vim version 8.1. Last change: 2006 Apr 24

VIM REFERENCE MANUAL by Vassily Ragosin

Russian language localization and support in Vim russian Russian

==========
1. Introduction russian-intro

Russian language is supported perfectly well in Vim. You can type and view
Russian text just as any other, without the need to tweak the settings.

==========
2. Russian keymaps russian-keymap

To switch between languages you can use your system native keyboard switcher,
or use one of the Russian keymaps, included in the Vim distribution. For
example,

```
:set keymap=russian-jcukenwin
```

In the latter case, you can switch between languages even if you do not have
system Russian keyboard or independently from a system-wide keyboard settings.
See 'keymap'. You can also map a key to switch between keyboards, if you
choose the latter option. See :map .

For your convenience, to avoid switching between keyboards, when you need to
enter Normal mode command, you can also set 'langmap' option:

```
:set langmap=ФИСВУАПРШОЛДЬТЩЗЙКЫЕГМЦЧНЯ;ABCDEFGHIJKLMNOPQRSTUVWXYZ,
фисвуапршолдьтщзйкыегмцчня;abcdefghijklmnopqrstuvwxyz
```

This is in utf-8, you cannot read this if your 'encoding' is not utf-8.
You have to type this command in one line, it is wrapped for the sake of
readability.

==========
3. Localization russian-l18n

If you wish to use messages, help files, menus and other items translated to
Russian, you will need to install the RuVim Language Pack, available in
different codepages from

http://www.sourceforge.net/projects/ruvim/

Make sure that your Vim is at least 6.2.506 and use ruvim 0.5 or later for
automatic installs. Vim also needs to be compiled with +gettext feature for

user interface items translations to work.

After downloading an archive from RuVim project, unpack it into your
$VIMRUNTIME directory. We recommend using UTF-8 archive, if your version of
Vim is compiled with +multi_byte feature enabled.

In order to use the Russian documentation, make sure you have set the
'helplang' option to "ru".

==
4. Known issues   russian-issues

-- If you are using Russian message translations in Win32 console, then
   you may see the output produced by "vim --help", "vim --version" commands
   and Win32 console window title appearing in a wrong codepage. This problem
   is related to a bug in GNU gettext library and may be fixed in the future
   releases of gettext.

ft_ada.txt For Vim version 8.1. Last change: 2010 Jul 20

ADA FILE TYPE PLUG-INS REFERENCE MANUAL

ADA ada.vim

==

1. Syntax Highlighting

ft-ada-syntax

This mode is designed for the 2005 edition of Ada ("Ada 2005"), which includes support for objected-programming, protected types, and so on. It handles code written for the original Ada language ("Ada83", "Ada87", "Ada95") as well, though code which uses Ada 2005-only keywords will be wrongly colored (such code should be fixed anyway). For more information about Ada, see http://www.adapower.com.

The Ada mode handles a number of situations cleanly.

For example, it knows that the "-" in "-5" is a number, but the same character in "A-5" is an operator. Normally, a "with" or "use" clause referencing another compilation unit is coloured the same way as C's "#include" is coloured. If you have "Conditional" or "Repeat" groups coloured differently, then "end if" and "end loop" will be coloured as part of those respective groups.

You can set these to different colours using vim's "highlight" command (e.g., to change how loops are displayed, enter the command ":hi Repeat" followed by the colour specification; on simple terminals the colour specification ctermfg=White often shows well).

There are several options you can select in this Ada mode. See ft-ada-options for a complete list.

To enable them, assign a value to the option. For example, to turn one on:

```
> let g:ada_standard_types = 1
```

To disable them use ":unlet". Example:

```
> unlet g:ada_standard_types
```

You can just use ":" and type these into the command line to set these temporarily before loading an Ada file. You can make these option settings permanent by adding the "let" command(s), without a colon, to your "~/.vimrc" file.

Even on a slow (90Mhz) PC this mode works quickly, but if you find the performance unacceptable, turn on g:ada_withuse_ordinary .

Syntax folding instructions (fold-syntax) are added when g:ada_folding is set.

2. File type Plug-in

ft-ada-indent ft-ada-plugin

The Ada plug-in provides support for:

- auto indenting   (indent.txt)
- insert completion   (i_CTRL-N)
- user completion   (i_CTRL-X_CTRL-U)
- tag searches   (tagsrch.txt)
- Quick Fix   (quickfix.txt)
- backspace handling   ('backspace')
- comment handling   ('comments' , 'commentstring')

The plug-in only activates the features of the Ada mode whenever an Ada file is opened and adds Ada related entries to the main and pop-up menu.

3. Omni Completion

ft-ada-omni

The Ada omni-completions (i_CTRL-X_CTRL-O) uses tags database created either by "gnat xref -v" or the "exuberant Ctags (http://ctags.sourceforge.net). The complete function will automatically detect which tool was used to create the tags file.

3.1 Omni Completion with "gnat xref"

gnat-xref

GNAT XREF uses the compiler internal information (ali-files) to produce the tags file. This has the advantage to be 100% correct and the option of deep nested analysis. However the code must compile, the generator is quite slow and the created tags file contains only the basic Ctags information for each entry - not enough for some of the more advanced Vim code browser plug-ins.

NOTE: "gnat xref -v" is very tricky to use as it has almost no diagnostic
      output - If nothing is printed then usually the parameters are wrong.

Here some important tips:

1) You need to compile your code first and use the "-aO" option to point to your .ali files.
2) "gnat xref -v ../Include/adacl.ads" won't work - use the "gnat xref -v -aI../Include adacl.ads" instead.
3) "gnat xref -v -aI../Include *.ad?" won't work - use "cd ../Include" and then "gnat xref -v *.ad?"
4) Project manager support is completely broken - don't even try "gnat xref -Padacl.gpr".
5) Vim is faster when the tags file is sorted - use "sort --unique --ignore-case --output=tags tags" .
6) Remember to insert "!_TAG_FILE_SORTED 2 %sort ui" as first line to mark the file assorted.

3.2 Omni Completion with "ctags"

ada-ctags

Exuberant Ctags uses its own multi-language code parser. The parser is quite fast, produces a lot of extra information (hence the name "Exuberant Ctags") and can run on files which currently do not compile.

There are also lots of other Vim-tools which use exuberant Ctags.

You will need to install a version of the Exuberant Ctags which has Ada support patched in. Such a version is available from the GNU Ada Project (http://gnuada.sourceforge.net).

The Ada parser for Exuberant Ctags is fairly new - don't expect complete support yet.

==========

4. Compiler Support

ada-compiler

The Ada mode supports more than one Ada compiler and will automatically load the compiler set in g:ada_default_compiler whenever an Ada source is opened. The provided compiler plug-ins are split into the actual compiler plug-in and a collection of support functions and variables. This allows the easy development of specialized compiler plug-ins fine tuned to your development environment.

4.1 GNAT

compiler-gnat

GNAT is the only free (beer and speech) Ada compiler available. There are several versions available which differ in the licence terms used.

The GNAT compiler plug-in will perform a compile on pressing <F7> and then immediately shows the result. You can set the project file to be used by setting:

```
 > call g:gnat.Set_Project_File ('my_project.gpr')
```

Setting a project file will also create a Vim session (views-sessions) so - like with the GPS - opened files, window positions etc. will be remembered separately for all projects.

gnat_members

GNAT OBJECT

g:gnat.Make()

g:gnat.Make()
Calls g:gnat.Make_Command and displays the result inside a quickfix window.

g:gnat.Pretty()

g:gnat.Pretty()
Calls g:gnat.Pretty_Program

g:gnat.Find()

g:gnat.Find()
Calls g:gnat.Find_Program

g:gnat.Tags()

g:gnat.Tags()
Calls g:gnat.Tags_Command

g:gnat.Set_Project_File()

g:gnat.Set_Project_File([{file}])
Set gnat project file and load associated session. An open project will be closed and the session written. If called without file name the file selector opens for selection of a project file. If called with an empty string then the project and associated session are closed.

g:gnat.Project_File

g:gnat.Project_File string
Current project file.

g:gnat.Make_Command

g:gnat.Make_Command string
External command used for g:gnat.Make() ('makeprg').

g:gnat.Pretty_Program

g:gnat.Pretty_Program string
External command used for g:gnat.Pretty()

g:gnat.Find_Program

g:gnat.Find_Program string
External command used for g:gnat.Find()

g:gnat.Tags_Command

g:gnat.Tags_Command string
External command used for g:gnat.Tags()

g:gnat.Error_Format

g:gnat.Error_Format   string
                Error format ('errorformat')

4.2 Dec Ada

compiler-hpada compiler-decada
compiler-vaxada compiler-compaqada

Dec Ada (also known by - in chronological order - VAX Ada, Dec Ada, Compaq Ada and HP Ada) is a fairly dated Ada 83 compiler. Support is basic: <F7> will compile the current unit.

The Dec Ada compiler expects the package name and not the file name to be passed as a parameter. The compiler plug-in supports the usual file name convention to convert the file into a unit name. Both '-' and '__' are allowed as separators.

decada_members

DEC ADA OBJECT

g:decada.Make()

g:decada.Make()   function
                Calls g:decada.Make_Command and displays the result inside a quickfix window.

g:decada.Unit_Name()

g:decada.Unit_Name()   function
                Get the Unit name for the current file.

g:decada.Make_Command

g:decada.Make_Command   string
                External command used for g:decada.Make() ('makeprg').

g:decada.Error_Format

g:decada.Error_Format   string
                Error format ('errorformat').

==========

5. References

ada-reference

5.1 Options

ft-ada-options

g:ada_standard_types

g:ada_standard_types   bool (true when exists)
                Highlight types in package Standard (e.g., "Float").

g:ada_space_errors
g:ada_no_trail_space_error
g:ada_no_tab_space_error
g:ada_all_tab_usage

```
g:ada_space_errors       bool (true when exists)
                Highlight extraneous errors in spaces ...
                g:ada_no_trail_space_error
                    - but ignore trailing spaces at the end of a line
                g:ada_no_tab_space_error
                    - but ignore tabs after spaces
                g:ada_all_tab_usage
                    - highlight all tab use

                                                        g:ada_line_errors
g:ada_line_errors        bool (true when exists)
                Highlight lines which are too long. Note: This highlighting
                option is quite CPU intensive.

                                                      g:ada_rainbow_color
g:ada_rainbow_color      bool (true when exists)
                Use rainbow colours for '(' and ')'. You need the
                rainbow_parenthesis for this to work.

                                                          g:ada_folding
g:ada_folding            set ('sigpft')
                Use folding for Ada sources.
                    's':    activate syntax folding on load
                        'p':    fold packages
                        'f':    fold functions and procedures
                        't':    fold types
                        'c':    fold conditionals
                    'g':    activate gnat pretty print folding on load
                        'i':    lone 'is' folded with line above
                        'b':    lone 'begin' folded with line above
                        'p':    lone 'private' folded with line above
                        'x':    lone 'exception' folded with line above
                    'i':    activate indent folding on load

                Note: Syntax folding is in an early (unusable) stage and
                      indent or gnat pretty folding is suggested.

                For gnat pretty folding to work the following settings are
                suggested: -cl3 -M79 -c2 -c3 -c4 -A1 -A2 -A3 -A4 -A5

                For indent folding to work the following settings are
                suggested: shiftwidth=3 softtabstop=3

                                                           g:ada_abbrev
g:ada_abbrev             bool (true when exists)
                Add some abbreviations. This feature is more or less superseded
                by the various completion methods.

                                                    g:ada_withuse_ordinary
g:ada_withuse_ordinary   bool (true when exists)
                Show "with" and "use" as ordinary keywords (when used to
                reference other compilation units they're normally highlighted
                specially).
```

g:ada_begin_preproc

g:ada_begin_preproc bool (true when exists)
Show all begin-like keywords using the colouring of C preprocessor commands.

g:ada_omni_with_keywords

g:ada_omni_with_keywords
Add Keywords, Pragmas, Attributes to omni-completions (compl-omni). Note: You can always complete then with user completion (i_CTRL-X_CTRL-U).

g:ada_extended_tagging

g:ada_extended_tagging enum ('jump', 'list')
use extended tagging, two options are available
'jump': use tjump to jump.
'list': add tags quick fix list.
Normal tagging does not support function or operator overloading as these features are not available in C and tagging was originally developed for C.

g:ada_extended_completion

g:ada_extended_completion
Uses extended completion for <C-N> and <C-R> completions (i_CTRL-N). In this mode the '.' is used as part of the identifier so that 'Object.Method' or 'Package.Procedure' are completed together.

g:ada_gnat_extensions

g:ada_gnat_extensions bool (true when exists)
Support GNAT extensions.

g:ada_with_gnat_project_files

g:ada_with_gnat_project_files bool (true when exists)
Add gnat project file keywords and Attributes.

g:ada_default_compiler

g:ada_default_compiler string
set default compiler. Currently supported are 'gnat' and 'decada'.

An "exists" type is a boolean considered true when the variable is defined and false when the variable is undefined. The value to which the variable is set makes no difference.

5.2 Commands

ft-ada-commands

:AdaRainbow :AdaRainbow
Toggles rainbow colour (g:ada_rainbow_color) mode for '(' and ')'.

:AdaLines :AdaLines
Toggles line error (g:ada_line_errors) display.

:AdaSpaces :AdaSpaces
Toggles space error (g:ada_space_errors) display.

:AdaTagDir :AdaTagDir
Creates tags file for the directory of the current file.

:AdaTagFile :AdaTagFile
Creates tags file for the current file.

:AdaTypes :AdaTypes
Toggles standard types (g:ada_standard_types) colour.

:GnatFind :GnatFind
Calls g:gnat.Find()

:GnatPretty :GnatPretty
Calls g:gnat.Pretty()

:GnatTags :GnatTags
Calls g:gnat.Tags()

5.3 Variables

ft-ada-variables

g:gnat

g:gnat object
Control object which manages GNAT compiles. The object is created when the first Ada source code is loaded provided that g:ada_default_compiler is set to 'gnat'. See gnat_members for details.

g:decada

g:decada object
Control object which manages Dec Ada compiles. The object is created when the first Ada source code is loaded provided that g:ada_default_compiler is set to 'decada'. See decada_members for details.

5.4 Constants

ft-ada-constants

All constants are locked. See :lockvar for details.

g:ada#WordRegex

g:ada#WordRegex string
Regular expression to search for Ada words.

g:ada#DotWordRegex

g:ada#DotWordRegex string
Regular expression to search for Ada words separated by dots.

g:ada#Comment

g:ada#Comment string
Regular expression to search for Ada comments.

g:ada#Keywords

g:ada#Keywords list of dictionaries
List of keywords, attributes etc. pp. in the format used by omni completion. See complete-items for details.

g:ada#Ctags_Kinds

g:ada#Ctags_Kinds dictionary of lists
Dictionary of the various kinds of items which the Ada support for Ctags generates.

5.5 Functions

ft-ada-functions

ada#Word([{line}, {col}]) ada#Word()
Return full name of Ada entity under the cursor (or at given line/column), stripping white space/newlines as necessary.

ada#List_Tag([{line}, {col}]) ada#Listtags()
List all occurrences of the Ada entity under the cursor (or at given line/column) inside the quick-fix window.

ada#Jump_Tag ({ident}, {mode}) ada#Jump_Tag()
List all occurrences of the Ada entity under the cursor (or at given line/column) in the tag jump list. Mode can either be 'tjump' or 'stjump'.

ada#Create_Tags ({option}) ada#Create_Tags()
Creates tag file using Ctags. The option can either be 'file' for the current file, 'dir' for the directory of the current file or a file name.

gnat#Insert_Tags_Header() gnat#Insert_Tags_Header()
Adds the tag file header (!_TAG_) information to the current file which are missing from the GNAT XREF output.

ada#Switch_Syntax_Option ({option}) ada#Switch_Syntax_Option()
Toggles highlighting options on or off. Used for the Ada menu.

gnat#New()

gnat#New ()
Create a new gnat object. See g:gnat for details.

==========

6. Extra Plugins

ada-extra-plugins

You can optionally install the following extra plug-ins. They work well with Ada and enhance the ability of the Ada mode:

backup.vim
	http://www.vim.org/scripts/script.php?script_id=1537
	Keeps as many backups as you like so you don't have to.

rainbow_parenthsis.vim
	http://www.vim.org/scripts/script.php?script_id=1561
	Very helpful since Ada uses only '(' and ')'.

nerd_comments.vim
	http://www.vim.org/scripts/script.php?script_id=1218
	Excellent commenting and uncommenting support for almost any
	programming language.

matchit.vim
	http://www.vim.org/scripts/script.php?script_id=39
	'%' jumping for any language. The normal '%' jump only works for '{}'
	style languages. The Ada mode will set the needed search patterns.

taglist.vim
	http://www.vim.org/scripts/script.php?script_id=273
	Source code explorer sidebar. There is a patch for Ada available.

The GNU Ada Project distribution (http://gnuada.sourceforge.net) of Vim
contains all of the above.

==
vim: textwidth=78 nowrap tabstop=8 shiftwidth=4 softtabstop=4 noexpandtab
vim: filetype=help

ft_sql.txt For Vim version 8.1. Last change: 2013 May 15

by David Fishburn

This is a filetype plugin to work with SQL files.

The Structured Query Language (SQL) is a standard which specifies statements
that allow a user to interact with a relational database. Vim includes
features for navigation, indentation and syntax highlighting.

==
1. Navigation sql-navigation

The SQL ftplugin provides a number of options to assist with file
navigation.

1.1 Matchit sql-matchit

The matchit plugin (http://www.vim.org/scripts/script.php?script_id=39)
provides many additional features and can be customized for different
languages. The matchit plugin is configured by defining a local
buffer variable, b:match_words. Pressing the % key while on various
keywords will move the cursor to its match. For example, if the cursor
is on an "if", pressing % will cycle between the "else", "elseif" and
"end if" keywords.

The following keywords are supported:

```
if
elseif | elsif
else [if]
end if
```

```
    [while condition] loop
        leave
        break
        continue
        exit
    end loop

    for
        leave
        break
        continue
        exit
    end loop

    do
        statements
    doend

    case
    when
    when
    default
    end case

    merge
    when not matched
    when matched

    create[ or replace] procedure|function|event
    returns
```

1.2 Text Object Motions sql-object-motions

Vim has a number of predefined keys for working with text object-motions . This filetype plugin attempts to translate these keys to maps which make sense for the SQL language.

The following Normal mode and Visual mode maps exist (when you edit a SQL file):

```
    ]]              move forward to the next 'begin'
    [[              move backwards to the previous 'begin'
    ][              move forward to the next 'end'
    []              move backwards to the previous 'end'
```

1.3 Predefined Object Motions sql-predefined-objects

Most relational databases support various standard features, tables, indices, triggers and stored procedures. Each vendor also has a variety of proprietary objects. The next set of maps have been created to help move between these objects. Depends on which database vendor you are using, the list of objects must be configurable. The filetype plugin attempts to define many of the

standard objects, plus many additional ones. In order to make this as flexible as possible, you can override the list of objects from within your vimrc with the following:

```
let g:ftplugin_sql_objects = 'function,procedure,event,table,trigger' .
            \ ',schema,service,publication,database,datatype,domain' .
            \ ',index,subscription,synchronization,view,variable'
```

The following Normal mode and Visual mode maps have been created which use the above list:

```
]}              move forward to the next 'create <object name>'
[{              move backward to the previous 'create <object name>'
```

Repeatedly pressing]} will cycle through each of these create statements:

```
create table t1 (
    ...
);

create procedure p1
begin
    ...
end;

create index i1 on t1 (c1);
```

The default setting for g:ftplugin_sql_objects is:

```
let g:ftplugin_sql_objects = 'function,procedure,event,' .
            \ '\\(existing\\\\|global\\s\\+temporary\\s\\+\\)\\\{,1}' .
            \ 'table,trigger' .
            \ ',schema,service,publication,database,datatype,domain' .
            \ ',index,subscription,synchronization,view,variable'
```

The above will also handle these cases:

```
create table t1 (
    ...
);
create existing table t2 (
    ...
);
create global temporary table t3 (
    ...
);
```

By default, the ftplugin only searches for CREATE statements. You can also override this via your vimrc with the following:

```
let g:ftplugin_sql_statements = 'create,alter'
```

The filetype plugin defines three types of comments:

```
1.  --
2.  //
3.  /*
     *
     */
```

The following Normal mode and Visual mode maps have been created to work

with comments:
    ]"   move forward to the beginning of a comment
    ["   move forward to the end of a comment

1.4 Macros   sql-macros

Vim's feature to find macro definitions, 'define', is supported using this regular expression:

```
\c\<\(VARIABLE\|DECLARE\|IN\|OUT\|INOUT\)\>
```

This addresses the following code:

```
CREATE VARIABLE myVar1 INTEGER;

CREATE PROCEDURE sp_test(
    IN myVar2 INTEGER,
    OUT myVar3 CHAR(30),
    INOUT myVar4 NUMERIC(20,0)
)
BEGIN
    DECLARE myVar5 INTEGER;

    SELECT c1, c2, c3
      INTO myVar2, myVar3, myVar4
      FROM T1
     WHERE c4 = myVar1;
END;
```

Place your cursor on "myVar1" on this line:

```
     WHERE c4 = myVar1;
                ^
```

Press any of the following keys:

    [d
    [D
    [CTRL-D

==

2. SQL Dialects   sql-dialects sql-types
                                                  sybase TSQL Transact-SQL
                                                  sqlanywhere
                                                  oracle plsql sqlj
                                                  sqlserver
                                                  mysql postgresql psql
                                                  informix

All relational databases support SQL. There is a portion of SQL that is portable across vendors (ex. CREATE TABLE, CREATE INDEX), but there is a great deal of vendor specific extensions to SQL. Oracle supports the "CREATE OR REPLACE" syntax, column defaults specified in the CREATE TABLE statement and the procedural language (for stored procedures and triggers).

The default Vim distribution ships with syntax highlighting based on Oracle's PL/SQL. The default SQL indent script works for Oracle and SQL Anywhere. The default filetype plugin works for all vendors and should remain vendor neutral, but extendable.

Vim currently has support for a variety of different vendors, currently this is via syntax scripts. Unfortunately, to flip between different syntax rules you must either create:

1. New filetypes
2. Custom autocmds
3. Manual steps / commands

The majority of people work with only one vendor's database product, it would be nice to specify a default in your vimrc .

2.1 SQLSetType sqlsettype SQLSetType

For the people that work with many different databases, it is nice to be able to flip between the various vendors rules (indent, syntax) on a per buffer basis, at any time. The ftplugin/sql.vim file defines this function:

```
SQLSetType
```

Executing this function without any parameters will set the indent and syntax scripts back to their defaults, see sql-type-default . If you have turned off Vi's compatibility mode, 'compatible' , you can use the <Tab> key to complete the optional parameter.

After typing the function name and a space, you can use the completion to supply a parameter. The function takes the name of the Vim script you want to source. Using the cmdline-completion feature, the SQLSetType function will search the 'runtimepath' for all Vim scripts with a name containing 'sql'. This takes the guess work out of the spelling of the names. The following are examples:

```
:SQLSetType
:SQLSetType sqloracle
:SQLSetType sqlanywhere
:SQLSetType sqlinformix
:SQLSetType mysql
```

The easiest approach is to the use <Tab> character which will first complete the command name (SQLSetType), after a space and another <Tab>, display a list of available Vim script names:

```
:SQL<Tab><space><Tab>
```

2.2 SQLGetType sqlgettype SQLGetType

At anytime you can determine which SQL dialect you are using by calling the SQLGetType command. The ftplugin/sql.vim file defines this function:

```
SQLGetType
```

This will echo:

```
Current SQL dialect in use:sqlanywhere
```

2.3 SQL Dialect Default sql-type-default

As mentioned earlier, the default syntax rules for Vim is based on Oracle (PL/SQL). You can override this default by placing one of the following in your vimrc :

```
let g:sql_type_default = 'sqlanywhere'
let g:sql_type_default = 'sqlinformix'
let g:sql_type_default = 'mysql'
```

If you added the following to your vimrc :

```
let g:sql_type_default = 'sqlinformix'
```

The next time edit a SQL file the following scripts will be automatically loaded by Vim:

```
ftplugin/sql.vim
syntax/sqlinformix.vim
indent/sql.vim
```

Notice indent/sqlinformix.sql was not loaded. There is no indent file for Informix, Vim loads the default files if the specified files does not exist.

3. Adding new SQL Dialects sql-adding-dialects

If you begin working with a SQL dialect which does not have any customizations available with the default Vim distribution you can check http://www.vim.org to see if any customization currently exist. If not, you can begin by cloning an existing script. Read filetype-plugins for more details.

To help identify these scripts, try to create the files with a "sql" prefix. If you decide you wish to create customizations for the SQLite database, you can create any of the following:

```
Unix
    ~/.vim/syntax/sqlite.vim
    ~/.vim/indent/sqlite.vim
Windows
    $VIM/vimfiles/syntax/sqlite.vim
    $VIM/vimfiles/indent/sqlite.vim
```

No changes are necessary to the SQLSetType function. It will automatically pickup the new SQL files and load them when you issue the SQLSetType command.

4. OMNI SQL Completion sql-completion omni-sql-completion

Vim 7 includes a code completion interface and functions which allows plugin developers to build in code completion for any language. Vim 7 includes code completion for the SQL language.

There are two modes to the SQL completion plugin, static and dynamic. The static mode populates the popups with the data generated from current syntax highlight rules. The dynamic mode populates the popups with data retrieved directly from a database. This includes, table lists, column lists, procedures names and more.

4.1 Static Mode sql-completion-static

The static popups created contain items defined by the active syntax rules while editing a file with a filetype of SQL. The plugin defines (by default) various maps to help the user refine the list of items to be displayed. The defaults static maps are:

```
imap <buffer> <C-C>a <C-\><C-O>:call sqlcomplete#Map('syntax')<CR><C-X><C-O>
imap <buffer> <C-C>k <C-\><C-O>:call sqlcomplete#Map('sqlKeyword')<CR><C-X><C-O>
imap <buffer> <C-C>f <C-\><C-O>:call sqlcomplete#Map('sqlFunction')<CR><C-X><C-O>
imap <buffer> <C-C>o <C-\><C-O>:call sqlcomplete#Map('sqlOption')<CR><C-X><C-O>
imap <buffer> <C-C>T <C-\><C-O>:call sqlcomplete#Map('sqlType')<CR><C-X><C-O>
imap <buffer> <C-C>s <C-\><C-O>:call sqlcomplete#Map('sqlStatement')<CR><C-X><C-O>
```

The use of "<C-C>" can be user chosen by using the following in your .vimrc as it may not work properly on all platforms:

```
let g:ftplugin_sql_omni_key = '<C-C>'
```

The static maps (which are based on the syntax highlight groups) follow this format:

```
imap <buffer> <C-C>k <C-\><C-O>:call sqlcomplete#Map('sqlKeyword')<CR><C-X><C-O>
imap <buffer> <C-C>k <C-\><C-O>:call sqlcomplete#Map('sqlKeyword\w*')<CR><C-X><C-O>
```

This command breaks down as:

```
imap                    - Create an insert map
<buffer>                - Only for this buffer
<C-C>k                  - Your choice of key map
<C-\><C-O>              - Execute one command, return to Insert mode
:call sqlcomplete#Map(  - Allows the SQL completion plugin to perform some
                          housekeeping functions to allow it to be used in
                          conjunction with other completion plugins.
                          Indicate which item you want the SQL completion
                          plugin to complete.
                          In this case we are asking the plugin to display
                          items from the syntax highlight group
                          'sqlKeyword'.
                          You can view a list of highlight group names to
                          choose from by executing the
                              :syntax list
                          command while editing a SQL file.
'sqlKeyword'            - Display the items for the sqlKeyword highlight
                          group
'sqlKeyword\w*'         - A second option available with Vim 7.4 which
                          uses a regular expression to determine which
                          syntax groups to use
)<CR>                   - Execute the :let command
<C-X><C-O>              - Trigger the standard omni completion key stroke.
                          Passing in 'sqlKeyword' instructs the SQL
```

completion plugin to populate the popup with
items from the sqlKeyword highlight group. The
plugin will also cache this result until Vim is
restarted. The syntax list is retrieved using
the syntaxcomplete plugin.

Using the 'syntax' keyword is a special case. This instructs the
syntaxcomplete plugin to retrieve all syntax items. So this will effectively
work for any of Vim's SQL syntax files. At the time of writing this includes
10 different syntax files for the different dialects of SQL (see section 3
above, sql-dialects).

Here are some examples of the entries which are pulled from the syntax files:

All
    - Contains the contents of all syntax highlight groups
Statements
    - Select, Insert, Update, Delete, Create, Alter, ...
Functions
    - Min, Max, Trim, Round, Date, ...
Keywords
    - Index, Database, Having, Group, With
Options
    - Isolation_level, On_error, Qualify_owners, Fire_triggers, ...
Types
    - Integer, Char, Varchar, Date, DateTime, Timestamp, ...

4.2 Dynamic Mode sql-completion-dynamic

Dynamic mode populates the popups with data directly from a database. In
order for the dynamic feature to be enabled you must have the dbext.vim
plugin installed, (http://vim.sourceforge.net/script.php?script_id=356).

Dynamic mode is used by several features of the SQL completion plugin.
After installing the dbext plugin see the dbext-tutorial for additional
configuration and usage. The dbext plugin allows the SQL completion plugin
to display a list of tables, procedures, views and columns.

Table List
    - All tables for all schema owners
Procedure List
    - All stored procedures for all schema owners
View List
    - All stored procedures for all schema owners
Column List
    - For the selected table, the columns that are part of the table

To enable the popup, while in INSERT mode, use the following key combinations
for each group (where <C-C> means hold the CTRL key down while pressing
the space bar):

```
Table List            - <C-C>t
                      - <C-X><C-O> (the default map assumes tables)
Stored Procedure List - <C-C>p
View List             - <C-C>v
Column List           - <C-C>c
```

Drilling In / Out - When viewing a popup window displaying the list of tables, you can press <Right>, this will replace the table currently highlighted with the column list for that table.
- When viewing a popup window displaying the list of columns, you can press <Left>, this will replace the column list with the list of tables.
- This allows you to quickly drill down into a table to view its columns and back again.
- <Right> and <Left> can be also be chosen via your .vimrc

```
let g:ftplugin_sql_omni_key_right = '<Right>'
let g:ftplugin_sql_omni_key_left  = '<Left>'
```

The SQL completion plugin caches various lists that are displayed in the popup window. This makes the re-displaying of these lists very fast. If new tables or columns are added to the database it may become necessary to clear the plugins cache. The default map for this is:

```
imap <buffer> <C-C>R <C-\><C-O>:call sqlcomplete#Map('ResetCache')<CR><C-X><C-O>
```

4.3 SQL Tutorial sql-completion-tutorial

This tutorial is designed to take you through the common features of the SQL completion plugin so that:

a) You gain familiarity with the plugin
b) You are introduced to some of the more common features
c) Show how to customize it to your preferences
d) Demonstrate "Best of Use" of the plugin (easiest way to configure).

First, create a new buffer:

```
:e tutorial.sql
```

Static features

To take you through the various lists, simply enter insert mode, hit:

```
<C-C>s   (show SQL statements)
```

At this point, you can page down through the list until you find "select". If you are familiar with the item you are looking for, for example you know the statement begins with the letter "s". You can type ahead (without the quotes) "se" then press:

```
<C-Space>t
```

Assuming "select" is highlighted in the popup list press <Enter> to choose the entry. Now type:

```
* fr<C-C>a (show all syntax items)
```

choose "from" from the popup list.

When writing stored procedures using the "type" list is useful. It contains a list of all the database supported types. This may or may not be true depending on the syntax file you are using. The SQL Anywhere syntax file (sqlanywhere.vim) has support for this:

```
BEGIN
   DECLARE customer_id <C-C>T <-- Choose a type from the list
```

Dynamic features

To take advantage of the dynamic features you must first install the dbext.vim plugin (http://vim.sourceforge.net/script.php?script_id=356). It also comes with a tutorial. From the SQL completion plugin's perspective, the main feature dbext provides is a connection to a database. dbext connection profiles are the most efficient mechanism to define connection information. Once connections have been setup, the SQL completion plugin uses the features of dbext in the background to populate the popups.

What follows assumes dbext.vim has been correctly configured, a simple test is to run the command, :DBListTable. If a list of tables is shown, you know dbext.vim is working as expected. If not, please consult the dbext.txt documentation.

Assuming you have followed the dbext-tutorial you can press <C-C>t to display a list of tables. There is a delay while dbext is creating the table list. After the list is displayed press <C-W>. This will remove both the popup window and the table name already chosen when the list became active.

4.3.1 Table Completion: *sql-completion-tables*

Press <C-C>t to display a list of tables from within the database you have connected via the dbext plugin.
NOTE: All of the SQL completion popups support typing a prefix before pressing the key map. This will limit the contents of the popup window to just items beginning with those characters.

4.3.2 Column Completion: *sql-completion-columns*

The SQL completion plugin can also display a list of columns for particular tables. The column completion is trigger via <C-C>c.

NOTE: The following example uses <Right> to trigger a column list while the popup window is active.

Example of using column completion:

- Press <C-C>t again to display the list of tables.
- When the list is displayed in the completion window, press <Right>, this will replace the list of tables, with a list of columns for the table highlighted (after the same short delay).
- If you press <Left>, this will again replace the column list with the list of tables. This allows you to drill into tables and column lists very quickly.
- Press <Right> again while the same table is highlighted. You will notice there is no delay since the column list has been cached. If you change the schema of a cached table you can press <C-C>R, which clears the SQL completion cache.
- NOTE: <Right> and <Left> have been designed to work while the completion window is active. If the completion popup window is

not active, a normal <Right> or <Left> will be executed.

Let's look at how we can build a SQL statement dynamically. A select statement requires a list of columns. There are two ways to build a column list using the SQL completion plugin.

One column at a time:

1. After typing SELECT press <C-C>t to display a list of tables.
2. Choose a table from the list.
3. Press <Right> to display a list of columns.
4. Choose the column from the list and press enter.
5. Enter a "," and press <C-C>c. Generating a column list generally requires having the cursor on a table name. The plugin uses this name to determine what table to retrieve the column list. In this step, since we are pressing <C-C>c without the cursor on a table name the column list displayed will be for the previous table. Choose a different column and move on.
6. Repeat step 5 as often as necessary.

All columns for a table:

1. After typing SELECT press <C-C>t to display a list of tables.
2. Highlight the table you need the column list for.
3. Press <Enter> to choose the table from the list.
4. Press <C-C>l to request a comma separated list of all columns for this table.
5. Based on the table name chosen in step 3, the plugin attempts to decide on a reasonable table alias. You are then prompted to either accept of change the alias. Press OK.
6. The table name is replaced with the column list of the table is replaced with the comma separate list of columns with the alias prepended to each of the columns.
7. Step 3 and 4 can be replaced by pressing <C-C>L, which has a <C-Y> embedded in the map to choose the currently highlighted table in the list.

There is a special provision when writing select statements. Consider the following statement:

```
select *
  from customer c,
       contact cn,
       department as dp,
       employee e,
       site_options so
 where c.
```

In INSERT mode after typing the final "c." which is an alias for the "customer" table, you can press either <C-C>c or <C-X><C-O>. This will popup a list of columns for the customer table. It does this by looking back to the beginning of the select statement and finding a list of the tables specified in the FROM clause. In this case it notes that in the string "customer c", "c" is an alias for the customer table. The optional "AS" keyword is also supported, "customer AS c".

4.3.3 Procedure Completion: *sql-completion-procedures*

Similar to the table list, <C-C>p, will display a list of stored
procedures stored within the database.

4.3.4 View Completion: *sql-completion-views*

Similar to the table list, <C-C>v, will display a list of views in the
database.

4.4 Completion Customization sql-completion-customization

The SQL completion plugin can be customized through various options set in
your vimrc :

omni_sql_no_default_maps
- Default: This variable is not defined
- If this variable is defined, no maps are created for OMNI
  completion. See sql-completion-maps for further discussion.

omni_sql_use_tbl_alias
- Default: a
- This setting is only used when generating a comma separated
  column list. By default the map is <C-C>l. When generating
  a column list, an alias can be prepended to the beginning of each
  column, for example: e.emp_id, e.emp_name. This option has three
  settings:
  n - do not use an alias
  d - use the default (calculated) alias
  a - ask to confirm the alias name

  An alias is determined following a few rules:
  1. If the table name has an '_', then use it as a separator:
     MY_TABLE_NAME --> MTN
     my_table_name --> mtn
     My_table_NAME --> MtN
  2. If the table name does NOT contain an '_', but DOES use
     mixed case then the case is used as a separator:
     MyTableName --> MTN
  3. If the table name does NOT contain an '_', and does NOT
     use mixed case then the first letter of the table is used:
     mytablename --> m
     MYTABLENAME --> M

omni_sql_ignorecase
- Default: Current setting for 'ignorecase'
- Valid settings are 0 or 1.
- When entering a few letters before initiating completion, the list
  will be filtered to display only the entries which begin with the
  list of characters. When this option is set to 0, the list will be
  filtered using case sensitivity.

omni_sql_include_owner
- Default: 0, unless dbext.vim 3.00 has been installed
- Valid settings are 0 or 1.

- When completing tables, procedure or views and using dbext.vim 3.00
  or higher the list of objects will also include the owner name.
  When completing these objects and omni_sql_include_owner is enabled
  the owner name will be replaced.

omni_sql_precache_syntax_groups
- Default:
  ['syntax','sqlKeyword','sqlFunction','sqlOption','sqlType','sqlStatement']
- sqlcomplete can be used in conjunction with other completion
  plugins. This is outlined at sql-completion-filetypes . When the
  filetype is changed temporarily to SQL, the sqlcompletion plugin
  will cache the syntax groups listed in the List specified in this
  option.

4.5 SQL Maps sql-completion-maps

The default SQL maps have been described in other sections of this document in greater detail. Here is a list of the maps with a brief description of each.

Static Maps

These are maps which use populate the completion list using Vim's syntax highlighting rules.

<C-C>a
- Displays all SQL syntax items.

<C-C>k
- Displays all SQL syntax items defined as 'sqlKeyword'.

<C-C>f
- Displays all SQL syntax items defined as 'sqlFunction.

<C-C>o
- Displays all SQL syntax items defined as 'sqlOption'.

<C-C>T
- Displays all SQL syntax items defined as 'sqlType'.

<C-C>s
- Displays all SQL syntax items defined as 'sqlStatement'.

Dynamic Maps

These are maps which use populate the completion list using the dbext.vim plugin.

<C-C>t
- Displays a list of tables.

<C-C>p
- Displays a list of procedures.

<C-C>v
- Displays a list of views.

<C-C>c
- Displays a list of columns for a specific table.

<C-C>l
- Displays a comma separated list of columns for a specific table.

<C-C>L
- Displays a comma separated list of columns for a specific table.

This should only be used when the completion window is active.

<Right>
- Displays a list of columns for the table currently highlighted in the completion window. <Right> is not recognized on most Unix systems, so this maps is only created on the Windows platform. If you would like the same feature on Unix, choose a different key and make the same map in your vimrc.

<Left>
- Displays the list of tables. <Left> is not recognized on most Unix systems, so this maps is only created on the Windows platform. If you would like the same feature on Unix, choose a different key and make the same map in your vimrc.

<C-C>R
- This maps removes all cached items and forces the SQL completion to regenerate the list of items.

Customizing Maps

You can create as many additional key maps as you like. Generally, the maps will be specifying different syntax highlight groups.

If you do not wish the default maps created or the key choices do not work on your platform (often a case on *nix) you define the following variable in your vimrc :

```
let g:omni_sql_no_default_maps = 1
```

Do no edit ftplugin/sql.vim directly! If you change this file your changes will be over written on future updates. Vim has a special directory structure which allows you to make customizations without changing the files that are included with the Vim distribution. If you wish to customize the maps create an after/ftplugin/sql.vim (see after-directory) and place the same maps from the ftplugin/sql.vim in it using your own key strokes. <C-C> was chosen since it will work on both Windows and *nix platforms. On the windows platform you can also use <C-Space> or ALT keys.

4.6 Using with other filetypes sql-completion-filetypes

Many times SQL can be used with different filetypes. For example Perl, Java, PHP, Javascript can all interact with a database. Often you need both the SQL completion and the completion capabilities for the current language you are editing.

This can be enabled easily with the following steps (assuming a Perl file):

1. :e test.pl
2. :set filetype=sql
3. :set ft=perl

Step 1

Begins by editing a Perl file. Vim automatically sets the filetype to "perl". By default, Vim runs the appropriate filetype file

ftplugin/perl.vim. If you are using the syntax completion plugin by following the directions at ft-syntax-omni then the 'omnifunc' option has been set to "syntax#Complete". Pressing <C-X><C-O> will display the omni popup containing the syntax items for Perl.

Step 2

Manually setting the filetype to 'sql' will also fire the appropriate filetype files ftplugin/sql.vim. This file will define a number of buffer specific maps for SQL completion, see sql-completion-maps . Now these maps have been created and the SQL completion plugin has been initialized. All SQL syntax items have been cached in preparation. The SQL filetype script detects we are attempting to use two different completion plugins. Since the SQL maps begin with <C-C>, the maps will toggle the 'omnifunc' when in use. So you can use <C-X><C-O> to continue using the completion for Perl (using the syntax completion plugin) and <C-C> to use the SQL completion features.

Step 3

Setting the filetype back to Perl sets all the usual "perl" related items back as they were.

vim:tw=78:ts=8:noet:ft=help:norl:

hangulin.txt For Vim version 8.1. Last change: 2015 Nov 24

VIM REFERENCE MANUAL by Chi-Deok Hwang and Sung-Hyun Nam

Introduction hangul

It is to input hangul, the Korean language, with Vim GUI version.
If you have a XIM program, you can use another +xim feature.
Basically, it is for anybody who has no XIM program.

Compile

Next is a basic option. You can add any other configure option.

```
./configure --with-x --enable-multibyte --enable-hangulinput \
        --disable-xim
```

And you should check feature.h. If +hangul_input feature is enabled
by configure, you can select more options such as keyboard type, 2 bulsik
or 3 bulsik. You can find keywords like next in there.

```
#define HANGUL_DEFAULT_KEYBOARD 2
#define ESC_CHG_TO_ENG_MODE
/* #define X_LOCALE */
```

Environment variables

You should set LANG variable to Korean locale such as ko, ko_KR.eucKR
or ko_KR.UTF-8.
If you set LC_ALL variable, it should be set to Korean locale also.

Vim resource

You may want to set 'encoding' and 'fileencodings'.
Next are examples:

```
:set encoding=euc-kr
:set encoding=utf-8
:set fileencodings=ucs-bom,utf-8,cp949,euc-kr,latin1
```

Keyboard

You can change keyboard type (2 bulsik or 3 bulsik) using VIM_KEYBOARD
or HANGUL_KEYBOARD_TYPE environment variables. For sh, just do (2 bulsik):

```
export VIM_KEYBOARD="2"
```
or
```
export HANGUL_KEYBOARD_TYPE="2"
```

If both are set, VIM_KEYBOARD has higher priority.

Hangul Fonts

```
------------
If you use GTK version of gvim, you should set 'guifont' and 'guifontwide'.
For example:
    set guifont=Courier\ 12
    set guifontwide=NanumGothicCoding\ 12

If you use Motif or Athena version of gvim, you should set 'guifontset' in
your vimrc.  You can set fontset in the .Xdefaults file.

$HOME/.gvimrc:
    set guifontset=english_font,hangul_font

$HOME/.Xdefaults:
    Vim.font: english_font

    ! Nexts are for hangul menu with Athena
    *international: True
    Vim*fontSet: english_font,hangul_font

    ! Nexts are for hangul menu with Motif
    *international: True
    Vim*fontList: english_font;hangul_font:

attention! the , (comma) or ; (semicolon)

And there should be no ':set guifont'.  If it exists, then gvim ignores
':set guifontset'.  It means Vim runs without fontset supporting.
So, you can see only English.  Hangul does not be correctly displayed.

After "fontset" feature is enabled, Vim does not allow using english
font only in "font" setting for syntax.
For example, if you use
   :set guifontset=eng_font,your_font
in your .gvimrc, then you should do for syntax
   :hi Comment guifg=Cyan font=another_eng_font,another_your_font
If you just do
   :hi Comment font=another_eng_font
then you can see a error message.  Be careful!

hangul_font width should be twice than english_font width.

Unsupported Feature
-------------------
We don't support Johab font.
We don't support Hanja input.
And We don't have any plan to support them.

If you really need such features, you can use console version of Vim with a
capable terminal emulator.

vim:tw=78:ts=8:noet:ft=help:norl:

rileft.txt For Vim version 8.1. Last change: 2006 Apr 24

VIM REFERENCE MANUAL by Avner Lottem
updated by Nadim Shaikli

Right to Left display mode for Vim rileft

These functions were originally created by Avner Lottem:
E-mail: alottem@iil.intel.com
Phone: +972-4-8307322

{Vi does not have any of these commands}

E26
{only available when compiled with the |+rightleft| feature}

Introduction

Some languages such as Arabic, Farsi, Hebrew (among others) require the ability to display their text from right-to-left. Files in those languages are stored conventionally and the right-to-left requirement is only a function of the display engine (per the Unicode specification). In right-to-left oriented files the characters appear on the screen from right to left.

Bidirectionality (or bidi for short) is what Unicode offers as a full solution to these languages. Bidi offers the user the ability to view both right-to-left as well as left-to-right text properly at the same time within the same window. Vim currently, due to simplicity, does not offer bidi and is merely opting to present a functional means to display/enter/use right-to-left languages. An older hybrid solution in which direction is encoded for every character (or group of characters) are not supported either as this kind of support is out of the scope of a simple addition to an existing editor (and it's not sanctioned by Unicode either).

Highlights

- Editing left-to-right files as in the original Vim, no change.
- Viewing and editing files in right-to-left windows. File orientation is per window, so it is possible to view the same file in right-to-left and left-to-right modes, simultaneously. (Useful for editing mixed files in which both right-to-left and left-to-right text exist).
- Compatibility to the original Vim. Almost all features work in right-to-left mode (see Bugs below).
- Backing from reverse insert mode to the correct place in the file (if possible).

o No special terminal with right-to-left capabilities is required. The
   right-to-left changes are completely hardware independent.

o Many languages use and require right-to-left support. These languages
   can quite easily be supported given the inclusion of their required
   keyboard mappings and some possible minor code change. Some of the
   current supported languages include - arabic.txt , farsi.txt and
    hebrew.txt .

Of Interest...
----

o Invocations

   + 'rightleft' ('rl') sets window orientation to right-to-left.
   + 'delcombine' ('deco'), boolean, if editing UTF-8 encoded languages,
     allows one to remove a composing character which gets superimposed
     on those that proceeded them (some languages require this).
   + 'rightleftcmd' ('rlc') sets the command-line within certain modes
     (such as search) to be utilized in right-to-left orientation as well.

o Typing backwards   ins-reverse

   In lieu of using full-fledged the 'rightleft' option, one can opt for
   reverse insertion. When the 'revins' (reverse insert) option is set,
   inserting happens backwards. This can be used to type right-to-left
   text. When inserting characters the cursor is not moved and the text
   moves rightwards. A <BS> deletes the character under the cursor.
   CTRL-W and CTRL-U also work in the opposite direction. <BS>, CTRL-W
   and CTRL-U do not stop at the start of insert or end of line, no matter
   how the 'backspace' option is set.

   There is no reverse replace mode (yet).

   If the 'showmode' option is set, "-- REVERSE INSERT --" will be shown
   in the status line when reverse Insert mode is active.

o Pasting when in a rightleft window

   When cutting text with the mouse and pasting it in a rightleft window
   the text will be reversed, because the characters come from the cut buffer
   from the left to the right, while inserted in the file from the right to
   the left.   In order to avoid it, toggle 'revins' before pasting.

Bugs
----
o Does not handle CTRL-A and CTRL-X commands (add and subtract) correctly
   when in rightleft window.

o Does not support reverse insert and rightleft modes on the command-line.
   However, functionality of the editor is not reduced, because it is

possible to enter mappings, abbreviations and searches typed from the left to the right on the command-line.

- Somewhat slower in right-to-left mode, because right-to-left motion is emulated inside Vim, not by the controlling terminal.

- When the Athena GUI is used, the bottom scrollbar works in the wrong direction. This is difficult to fix.

- When both 'rightleft' and 'revins' are on: 'textwidth' does not work. Lines do not wrap at all; you just get a single, long line.

- There is no full bidirectionality (bidi) support.

vim:tw=78:ts=8:noet:ft=help:norl:

channel.txt For Vim version 8.1. Last change: 2018 Apr 18

VIM REFERENCE MANUAL by Bram Moolenaar

Inter-process communication channel

Vim uses channels to communicate with other processes.
A channel uses a socket or pipes. socket-interface
Jobs can be used to start processes and communicate with them.
The Netbeans interface also uses a channel. netbeans

{Vi does not have any of these features}
{only when compiled with the |+channel| feature for channel stuff}
        You can check this with: `has('channel')`
{only when compiled with the |+job| feature for job stuff}
        You can check this with: `has('job')`

==
1. Overview job-channel-overview

There are four main types of jobs:
1. A daemon, serving several Vim instances.
   Vim connects to it with a socket.
2. One job working with one Vim instance, asynchronously.
   Uses a socket or pipes.
3. A job performing some work for a short time, asynchronously.
   Uses a socket or pipes.
4. Running a filter, synchronously.
   Uses pipes.

For when using sockets See job-start , job-start-nochannel and
 channel-open . For 2 and 3, one or more jobs using pipes, see job-start .
For 4 use the ":{range}!cmd" command, see filter .

Over the socket and pipes these protocols are available:
RAW   nothing known, Vim cannot tell where a message ends
NL   every message ends in a NL (newline) character
JSON   JSON encoding json_encode()
JS   JavaScript style JSON-like encoding js_encode()

Common combination are:
- Using a job connected through pipes in NL mode. E.g., to run a style
  checker and receive errors and warnings.
- Using a daemon, connecting over a socket in JSON mode. E.g. to lookup
  cross-references in a database.

==
2. Channel demo   channel-demo   demoserver.py

This requires Python. The demo program can be found in
$VIMRUNTIME/tools/demoserver.py
Run it in one terminal. We will call this T1.

Run Vim in another terminal. Connect to the demo server with:
```
let channel = ch_open('localhost:8765')
```

In T1 you should see:
```
=== socket opened ===
```

You can now send a message to the server:
```
echo ch_evalexpr(channel, 'hello!')
```

The message is received in T1 and a response is sent back to Vim.
You can see the raw messages in T1. What Vim sends is:
```
[1,"hello!"]
```
And the response is:
```
[1,"got it"]
```
The number will increase every time you send a message.

The server can send a command to Vim. Type this on T1 (literally, including
the quotes):
```
["ex","echo 'hi there'"]
```
And you should see the message in Vim. You can move the cursor a word forward:
```
["normal","w"]
```

To handle asynchronous communication a callback needs to be used:
```
func MyHandler(channel, msg)
  echo "from the handler: " . a:msg
endfunc
call ch_sendexpr(channel, 'hello!', {'callback': "MyHandler"})
```
Vim will not wait for a response. Now the server can send the response later
and MyHandler will be invoked.

Instead of giving a callback with every send call, it can also be specified
when opening the channel:
```
call ch_close(channel)
let channel = ch_open('localhost:8765', {'callback': "MyHandler"})
call ch_sendexpr(channel, 'hello!')
```

When trying out channels it's useful to see what is going on. You can tell
Vim to write lines in log file:
```
call ch_logfile('channellog', 'w')
```
See ch_logfile() .

```
==============================================================================
3. Opening a channel                                            channel-open

To open a channel:
    let channel = ch_open({address} [, {options}])
    if ch_status(channel) == "open"
      " use the channel

Use  ch_status()  to see if the channel could be opened.

{address} has the form "hostname:port".  E.g., "localhost:8765".

{options} is a dictionary with optional entries:         channel-open-options

"mode" can be:                                                  channel-mode
        "json" - Use JSON, see below; most convenient way. Default.
        "js"   - Use JS (JavaScript) encoding, more efficient than JSON.
        "nl"   - Use messages that end in a NL character
        "raw"  - Use raw messages
                                                  channel-callback   E921
"callback"      A function that is called when a message is received that is
                not handled otherwise.  It gets two arguments: the channel
                and the received message. Example:
        func Handle(channel, msg)
          echo 'Received: ' . a:msg
        endfunc
        let channel = ch_open("localhost:8765", {"callback": "Handle"})

                When "mode" is "json" or "js" the "msg" argument is the body
                of the received message, converted to Vim types.
                When "mode" is "nl" the "msg" argument is one message,
                excluding the NL.
                When "mode" is "raw" the "msg" argument is the whole message
                as a string.

                For all callbacks: Use  function()  to bind it to arguments
                and/or a Dictionary.  Or use the form "dict.function" to bind
                the Dictionary.

                Callbacks are only called at a "safe" moment, usually when Vim
                is waiting for the user to type a character.  Vim does not use
                multi-threading.

                                                                close_cb
"close_cb"      A function that is called when the channel gets closed, other
                than by calling ch_close().  It should be defined like this:
        func MyCloseHandler(channel)
               Vim will invoke callbacks that handle data before invoking
                close_cb, thus when this function is called no more data will
                be passed to the callbacks.
                                                                channel-drop
"drop"          Specifies when to drop messages:
                    "auto"      When there is no callback to handle a message.
```

The "close_cb" is also considered for this.
"never" All messages will be kept.

waittime
"waittime" The time to wait for the connection to be made in milliseconds. A negative number waits forever.

The default is zero, don't wait, which is useful if a local server is supposed to be running already. On Unix Vim actually uses a 1 msec timeout, that is required on many systems. Use a larger value for a remote server, e.g. 10 msec at least.

channel-timeout
"timeout" The time to wait for a request when blocking, E.g. when using ch_evalexpr(). In milliseconds. The default is 2000 (2 seconds).

When "mode" is "json" or "js" the "callback" is optional. When omitted it is only possible to receive a message after sending one.

To change the channel options after opening it use ch_setoptions() . The arguments are similar to what is passed to ch_open() , but "waittime" cannot be given, since that only applies to opening the channel.

For example, the handler can be added or changed:
```
call ch_setoptions(channel, {'callback': callback})
```
When "callback" is empty (zero or an empty string) the handler is removed.

After a callback has been invoked Vim will update the screen and put the cursor back where it belongs. Thus the callback should not need to do `:redraw`.

The timeout can be changed:
```
call ch_setoptions(channel, {'timeout': msec})
```

channel-close E906
Once done with the channel, disconnect it like this:
```
call ch_close(channel)
```
When a socket is used this will close the socket for both directions. When pipes are used (stdin/stdout/stderr) they are all closed. This might not be what you want! Stopping the job with job_stop() might be better.
All readahead is discarded, callbacks will no longer be invoked.

Note that a channel is closed in three stages:
- The I/O ends, log message: "Closing channel". There can still be queued messages to read or callbacks to invoke.
- The readahead is cleared, log message: "Clearing channel". Some variables may still reference the channel.
- The channel is freed, log message: "Freeing channel".

When the channel can't be opened you will get an error message. There is a difference between MS-Windows and Unix: On Unix when the port doesn't exist ch_open() fails quickly. On MS-Windows "waittime" applies.
E898 E901 E902

If there is an error reading or writing a channel it will be closed.
E630 E631

==
4. Using a JSON or JS channel channel-use

If mode is JSON then a message can be sent synchronously like this:
```
    let response = ch_evalexpr(channel, {expr})
```
This awaits a response from the other side.

When mode is JS this works the same, except that the messages use
JavaScript encoding. See js_encode() for the difference.

To send a message, without handling a response or letting the channel callback
handle the response:
```
    call ch_sendexpr(channel, {expr})
```

To send a message and letting the response handled by a specific function,
asynchronously:
```
    call ch_sendexpr(channel, {expr}, {'callback': Handler})
```

Vim will match the response with the request using the message ID. Once the
response is received the callback will be invoked. Further responses with the
same ID will be ignored. If your server sends back multiple responses you
need to send them with ID zero, they will be passed to the channel callback.

The {expr} is converted to JSON and wrapped in an array. An example of the
message that the receiver will get when {expr} is the string "hello":
```
        [12,"hello"]
```

The format of the JSON sent is:
```
    [{number},{expr}]
```

In which {number} is different every time. It must be used in the response
(if any):

```
    [{number},{response}]
```

This way Vim knows which sent message matches with which received message and
can call the right handler. Also when the messages arrive out of order.

A newline character is terminating the JSON text. This can be used to
separate the read text. For example, in Python:
```
        splitidx = read_text.find('\n')
        message = read_text[:splitidx]
        rest = read_text[splitidx + 1:]
```

The sender must always send valid JSON to Vim. Vim can check for the end of
the message by parsing the JSON. It will only accept the message if the end
was received. A newline after the message is optional.

When the process wants to send a message to Vim without first receiving a
message, it must use the number zero:

```
    [0,{response}]

Then channel handler will then get {response} converted to Vim types.  If the
channel does not have a handler the message is dropped.

It is also possible to use ch_sendraw() and ch_evalraw() on a JSON or JS
channel.  The caller is then completely responsible for correct encoding and
decoding.

==============================================================================
5. Channel commands                                     channel-commands

With a JSON channel the process can send commands to Vim that will be
handled by Vim internally, it does not require a handler for the channel.

Possible commands are:                              E903   E904   E905
    ["redraw", {forced}]
    ["ex",     {Ex command}]
    ["normal", {Normal mode command}]
    ["expr",   {expression}, {number}]
    ["expr",   {expression}]
    ["call",   {func name}, {argument list}, {number}]
    ["call",   {func name}, {argument list}]

With all of these: Be careful what these commands do!  You can easily
interfere with what the user is doing.  To avoid trouble use  mode()  to check
that the editor is in the expected state.  E.g., to send keys that must be
inserted as text, not executed as a command:
    ["ex","if mode() == 'i' | call feedkeys('ClassName') | endif"]

Errors in these commands are normally not reported to avoid them messing up
the display.  If you do want to see them, set the 'verbose' option to 3 or
higher.

Command "redraw"

The other commands do not update the screen, so that you can send a sequence
of commands without the cursor moving around.  You must end with the "redraw"
command to show any changed text and show the cursor where it belongs.

The argument is normally an empty string:
        ["redraw", ""]
To first clear the screen pass "force":
        ["redraw", "force"]

Command "ex"

The "ex" command is executed as any Ex command.  There is no response for
completion or error.  You could use functions in an  autoload  script:
        ["ex","call myscript#MyFunc(arg)"]

You can also use "call  feedkeys() " to insert any key sequence.
```

When there is an error a message is written to the channel log, if it exists,
and v:errmsg is set to the error.

Command "normal"

The "normal" command is executed like with ":normal!", commands are not
mapped. Example to open the folds under the cursor:
```
["normal" "zO"]
```

Command "expr" with response

The "expr" command can be used to get the result of an expression. For
example, to get the number of lines in the current buffer:
```
["expr","line('$')", -2]
```

It will send back the result of the expression:
```
[-2, "last line"]
```
The format is:
```
[{number}, {result}]
```

Here {number} is the same as what was in the request. Use a negative number
to avoid confusion with message that Vim sends. Use a different number on
every request to be able to match the request with the response.

{result} is the result of the evaluation and is JSON encoded. If the
evaluation fails or the result can't be encoded in JSON it is the string
"ERROR".

Command "expr" without a response

This command is similar to "expr" above, but does not send back any response.
Example:
```
["expr","setline('$', ['one', 'two', 'three'])"]
```
There is no third argument in the request.

Command "call"

This is similar to "expr", but instead of passing the whole expression as a
string this passes the name of a function and a list of arguments. This
avoids the conversion of the arguments to a string and escaping and
concatenating them. Example:
```
["call", "line", ["$"], -2]
```

Leave out the fourth argument if no response is to be sent:
```
["call", "setline", ["$", ["one", "two", "three"]]]
```

==
6. Using a RAW or NL channel channel-raw

If mode is RAW or NL then a message can be sent like this:
    let response = ch_evalraw(channel, {string})

The {string} is sent as-is. The response will be what can be read from the channel right away. Since Vim doesn't know how to recognize the end of the message you need to take care of it yourself. The timeout applies for reading the first byte, after that it will not wait for anything more.

If mode is "nl" you can send a message in a similar way. You are expected to put in the NL after each message. Thus you can also send several messages ending in a NL at once. The response will be the text up to and including the first NL. This can also be just the NL for an empty response.
If no NL was read before the channel timeout an empty string is returned.

To send a message, without expecting a response:
    call ch_sendraw(channel, {string})
The process can send back a response, the channel handler will be called with it.

To send a message and letting the response handled by a specific function, asynchronously:
    call ch_sendraw(channel, {string}, {'callback': 'MyHandler'})

This {string} can also be JSON, use json_encode() to create it and json_decode() to handle a received JSON message.

It is not possible to use ch_evalexpr() or ch_sendexpr() on a raw channel.

A String in Vim cannot contain NUL bytes. To send or receive NUL bytes read or write from a buffer. See in_io-buffer and out_io-buffer .

==
7. More channel functions   channel-more

To obtain the status of a channel: ch_status(channel). The possible results are:
        "fail"   Failed to open the channel.
        "open"   The channel can be used.
        "buffered"   The channel was closed but there is data to read.
        "closed"   The channel was closed.

To obtain the job associated with a channel: ch_getjob(channel)

To read one message from a channel:
        let output = ch_read(channel)
This uses the channel timeout. To read without a timeout, just get any message that is available:
        let output = ch_read(channel, {'timeout': 0})
When no message was available then the result is v:none for a JSON or JS mode channels, an empty string for a RAW or NL channel. You can use ch_canread() to check if there is something to read.

Note that when there is no callback, messages are dropped. To avoid that add a close callback to the channel.

To read all output from a RAW channel that is available:
        let output = ch_readraw(channel)
To read the error output:
        let output = ch_readraw(channel, {"part": "err"})

ch_read() and ch_readraw() use the channel timeout. When there is nothing to
read within that time an empty string is returned. To specify a different
timeout in msec use the "timeout" option:
        {"timeout": 123}
To read from the error output use the "part" option:
        {"part": "err"}
To read a message with a specific ID, on a JS or JSON channel:
        {"id": 99}
When no ID is specified or the ID is -1, the first message is returned. This
overrules any callback waiting for this message.

For a RAW channel this returns whatever is available, since Vim does not know
where a message ends.
For a NL channel this returns one message.
For a JS or JSON channel this returns one decoded message.
This includes any sequence number.

==
8. Starting a job with a channel   job-start   job

To start a job and open a channel for stdin/stdout/stderr:
    let job = job_start(command, {options})

You can get the channel with:
    let channel = job_getchannel(job)

The channel will use NL mode. If you want another mode it's best to specify
this in {options}. When changing the mode later some text may have already
been received and not parsed correctly.

If the command produces a line of output that you want to deal with, specify
a handler for stdout:
    let job = job_start(command, {"out_cb": "MyHandler"})
The function will be called with the channel and a message. You would define
it like this:
    func MyHandler(channel, msg)

Without the handler you need to read the output with ch_read() or
 ch_readraw() . You can do this in the close callback, see read-in-close-cb .

Note that if the job exits before you read the output, the output may be lost.
This depends on the system (on Unix this happens because closing the write end
of a pipe causes the read end to get EOF). To avoid this make the job sleep
for a short while before it exits.

The handler defined for "out_cb" will not receive stderr. If you want to
handle that separately, add an "err_cb" handler:
    let job = job_start(command, {"out_cb": "MyHandler",

```
            \                    "err_cb": "ErrHandler"})
```

If you want to handle both stderr and stdout with one handler use the "callback" option:

```
    let job = job_start(command, {"callback": "MyHandler"})
```

Depending on the system, starting a job can put Vim in the background, the started job gets the focus. To avoid that, use the `foreground()` function. This might not always work when called early, put in the callback handler or use a timer to call it after the job has started.

You can send a message to the command with ch_evalraw(). If the channel is in JSON or JS mode you can use ch_evalexpr().

There are several options you can use, see job-options .
For example, to start a job and write its output in buffer "dummy":

```
        let logjob = job_start("tail -f /tmp/log",
                        \ {'out_io': 'buffer', 'out_name': 'dummy'})
        sbuf dummy
```

Job input from a buffer

in_io-buffer

To run a job that reads from a buffer:

```
        let job = job_start({command},
            \ {'in_io': 'buffer', 'in_name': 'mybuffer'})
```

E915 E918

The buffer is found by name, similar to bufnr() . The buffer must exist and be loaded when job_start() is called.

By default this reads the whole buffer. This can be changed with the "in_top" and "in_bot" options.

A special mode is when "in_top" is set to zero and "in_bot" is not set: Every time a line is added to the buffer, the last-but-one line will be sent to the job stdin. This allows for editing the last line and sending it when pressing Enter.

channel-close-in

When not using the special mode the pipe or socket will be closed after the last line has been written. This signals the reading end that the input finished. You can also use ch_close_in() to close it sooner.

NUL bytes in the text will be passed to the job (internally Vim stores these as NL bytes).

Reading job output in the close callback

read-in-close-cb

If the job can take some time and you don't need intermediate results, you can add a close callback and read the output there:

```
        func! CloseHandler(channel)
          while ch_status(a:channel, {'part': 'out'}) == 'buffered'
```

```
            echomsg ch_read(a:channel)
          endwhile
        endfunc
        let job = job_start(command, {'close_cb': 'CloseHandler'})
```

You will want to do something more useful than "echomsg".

==
9. Starting a job without a channel   job-start-nochannel

To start another process without creating a channel:

```
    let job = job_start(command,
        \ {"in_io": "null", "out_io": "null", "err_io": "null"})
```

This starts {command} in the background, Vim does not wait for it to finish.

When Vim sees that neither stdin, stdout or stderr are connected, no channel will be created. Often you will want to include redirection in the command to avoid it getting stuck.

There are several options you can use, see job-options .

                                                       job-start-if-needed
To start a job only when connecting to an address does not work, do something like this:

```
        let channel = ch_open(address, {"waittime": 0})
        if ch_status(channel) == "fail"
          let job = job_start(command)
          let channel = ch_open(address, {"waittime": 1000})
        endif
```

Note that the waittime for ch_open() gives the job one second to make the port available.

==
10. Job options   job-options

The {options} argument in job_start() is a dictionary. All entries are optional. Some options can be used after the job has started, using job_setoptions(job, {options}). Many options can be used with the channel related to the job, using ch_setoptions(channel, {options}).
See job_setoptions() and ch_setoptions() .

                                                  in_mode out_mode err_mode
"in_mode"   mode specifically for stdin, only when using pipes
"out_mode"   mode specifically for stdout, only when using pipes
"err_mode"   mode specifically for stderr, only when using pipes
                       See channel-mode for the values.

                       Note: when setting "mode" the part specific mode is
                       overwritten. Therefore set "mode" first and the part
                       specific mode later.

                       Note: when writing to a file or buffer and when

reading from a buffer NL mode is used by default.

job-callback
"callback": handler Callback for something to read on any part of the channel.

job-out_cb *out_cb*
"out_cb": handler Callback for when there is something to read on stdout. Only for when the channel uses pipes. When "out_cb" wasn't set the channel callback is used. The two arguments are the channel and the message.

job-err_cb *err_cb*
"err_cb": handler Callback for when there is something to read on stderr. Only for when the channel uses pipes. When "err_cb" wasn't set the channel callback is used. The two arguments are the channel and the message.

job-close_cb
"close_cb": handler Callback for when the channel is closed. Same as "close_cb" on ch_open() , see close_cb .

job-drop
"drop": when Specifies when to drop messages. Same as "drop" on ch_open() , see channel-drop . For "auto" the exit_cb is not considered.

job-exit_cb
"exit_cb": handler Callback for when the job ends. The arguments are the job and the exit status.
Vim checks up to 10 times per second for jobs that ended. The check can also be triggered by calling job_status() , which may then invoke the exit_cb handler.
Note that data can be buffered, callbacks may still be called after the process ends.

job-timeout
"timeout": time The time to wait for a request when blocking, E.g. when using ch_evalexpr(). In milliseconds. The default is 2000 (2 seconds).

out_timeout *err_timeout*
"out_timeout": time Timeout for stdout. Only when using pipes.
"err_timeout": time Timeout for stderr. Only when using pipes.
Note: when setting "timeout" the part specific mode is overwritten. Therefore set "timeout" first and the part specific mode later.

job-stoponexit
"stoponexit": {signal} Send {signal} to the job when Vim exits. See job_stop() for possible values.
"stoponexit": "" Do not stop the job when Vim exits.
The default is "term".

job-term
"term": "open" Start a terminal in a new window and connect the job stdin/stdout/stderr to it. Similar to using `:terminal`.
NOTE: Not implemented yet!

```
"channel": {channel}    Use an existing channel instead of creating a new one.
                        The parts of the channel that get used for the new job
                        will be disconnected from what they were used before.
                        If the channel was still used by another job this may
                        cause I/O errors.
                        Existing callbacks and other settings remain.

"pty": 1                Use a pty (pseudo-tty) instead of a pipe when
                        possible.  This is most useful in combination with a
                        terminal window, see  terminal .
                        {only on Unix and Unix-like systems}

                                job-in_io   in_top   in_bot   in_name   in_buf
"in_io": "null"         disconnect stdin (read from /dev/null)
"in_io": "pipe"         stdin is connected to the channel (default)
"in_io": "file"         stdin reads from a file
"in_io": "buffer"       stdin reads from a buffer
"in_top": number        when using "buffer": first line to send (default: 1)
"in_bot": number        when using "buffer": last line to send (default: last)
"in_name": "/path/file" the name of the file or buffer to read from
"in_buf": number        the number of the buffer to read from

                                job-out_io   out_name   out_buf
"out_io": "null"        disconnect stdout (goes to /dev/null)
"out_io": "pipe"        stdout is connected to the channel (default)
"out_io": "file"        stdout writes to a file
"out_io": "buffer"      stdout appends to a buffer (see below)
"out_name": "/path/file" the name of the file or buffer to write to
"out_buf": number       the number of the buffer to write to
"out_modifiable": 0     when writing to a buffer, 'modifiable' will be off
                        (see below)
"out_msg": 0            when writing to a new buffer, the first line will be
                        set to "Reading from channel output..."

                                job-err_io   err_name   err_buf
"err_io": "out"         stderr messages to go to stdout
"err_io": "null"        disconnect stderr  (goes to /dev/null)
"err_io": "pipe"        stderr is connected to the channel (default)
"err_io": "file"        stderr writes to a file
"err_io": "buffer"      stderr appends to a buffer (see below)
"err_name": "/path/file" the name of the file or buffer to write to
"err_buf": number       the number of the buffer to write to
"err_modifiable": 0     when writing to a buffer, 'modifiable' will be off
                        (see below)
"err_msg": 0            when writing to a new buffer, the first line will be
                        set to "Reading from channel error..."

"block_write": number   only for testing: pretend every other write to stdin
                        will block

"env": dict             environment variables for the new process
"cwd": "/path/to/dir"   current working directory for the new process;
                        if the directory does not exist an error is given
```

Writing to a buffer

out_io-buffer

When the out_io or err_io mode is "buffer" and there is a callback, the text is appended to the buffer before invoking the callback.

When a buffer is used both for input and output, the output lines are put above the last line, since the last line is what is written to the channel input. Otherwise lines are appended below the last line.

When using JS or JSON mode with "buffer", only messages with zero or negative ID will be added to the buffer, after decoding + encoding. Messages with a positive number will be handled by a callback, commands are handled as usual.

The name of the buffer from "out_name" or "err_name" is compared the full name of existing buffers, also after expanding the name for the current directory. E.g., when a buffer was created with ":edit somename" and the buffer name is "somename" it will use that buffer.

If there is no matching buffer a new buffer is created. Use an empty name to always create a new buffer. ch_getbufnr() can then be used to get the buffer number.

For a new buffer 'buftype' is set to "nofile" and 'bufhidden' to "hide". If you prefer other settings, create the buffer first and pass the buffer number.

out_modifiable err_modifiable

The "out_modifiable" and "err_modifiable" options can be used to set the 'modifiable' option off, or write to a buffer that has 'modifiable' off. That means that lines will be appended to the buffer, but the user can't easily change the buffer.

out_msg err_msg

The "out_msg" option can be used to specify whether a new buffer will have the first line set to "Reading from channel output...". The default is to add the message. "err_msg" does the same for channel error.

When an existing buffer is to be written where 'modifiable' is off and the "out_modifiable" or "err_modifiable" options is not zero, an error is given and the buffer will not be written to.

When the buffer written to is displayed in a window and the cursor is in the first column of the last line, the cursor will be moved to the newly added line and the window is scrolled up to show the cursor if needed.

Undo is synced for every added line. NUL bytes are accepted (internally Vim stores these as NL bytes).

Writing to a file

E920

The file is created with permissions 600 (read-write for the user, not accessible for others). Use setfperm() to change this.

If the file already exists it is truncated.

==
11. Controlling a job   job-control

To get the status of a job:
        echo job_status(job)

To make a job stop running:
        job_stop(job)

This is the normal way to end a job. On Unix it sends a SIGTERM to the job.
It is possible to use other ways to stop the job, or even send arbitrary
signals. E.g. to force a job to stop, "kill it":
        job_stop(job, "kill")

For more options see job_stop() .

==
12. Using a prompt buffer   prompt-buffer

If you want to type input for the job in a Vim window you have a few options:
- Use a normal buffer and handle all possible commands yourself.
  This will be complicated, since there are so many possible commands.
- Use a terminal window. This works well if what you type goes directly to
  the job and the job output is directly displayed in the window.
  See terminal-window .
- Use a prompt window. This works well when entering a line for the job in Vim
  while displaying (possibly filtered) output from the job.

A prompt buffer is created by setting 'buftype' to "prompt". You would
normally only do that in a newly created buffer.

The user can edit and enter one line of text at the very last line of the
buffer. When pressing Enter in the prompt line the callback set with
 prompt_setcallback() is invoked. It would normally send the line to a job.
Another callback would receive the output from the job and display it in the
buffer, below the prompt (and above the next prompt).

Only the text in the last line, after the prompt, is editable. The rest of the
buffer is not modifiable with Normal mode commands. It can be modified by
calling functions, such as append() . Using other commands may mess up the
buffer.

After setting 'buftype' to "prompt" Vim does not automatically start Insert
mode, use `:startinsert` if you want to enter Insert mode, so that the user
can start typing a line.

The text of the prompt can be set with the prompt_setprompt() function.

The user can go to Normal mode and navigate through the buffer. This can be
useful see older output or copy text.

The CTRL-W key can be used to start a window command, such as CTRL-W w to
switch to the next window. This also works in Insert mode (use Shift-CTRL-W

to delete a word). When leaving the window Insert mode will be stopped. When coming back to the prompt window Insert mode will be restored.

Any command that starts Insert mode, such as "a", "i", "A" and "I", will move the cursor to the last line. "A" will move to the end of the line, "I" to the start of the line.

gui.txt For Vim version 8.1. Last change: 2018 Mar 06

VIM REFERENCE MANUAL by Bram Moolenaar

Vim's Graphical User Interface gui GUI

Other GUI documentation:
gui_x11.txt For specific items of the X11 GUI.
gui_w32.txt For specific items of the Win32 GUI.

{Vi does not have any of these commands}

==========

1. Starting the GUI gui-start E229 E233

First you must make sure you actually have a version of Vim with the GUI code included. You can check this with the ":version" command, it says "with xxx GUI", where "xxx" is X11-Motif, X11-Athena, Photon, GTK2, GTK3, etc., or "MS-Windows 32 bit GUI version".

How to start the GUI depends on the system used. Mostly you can run the GUI version of Vim with:

```
gvim [options] [files...]
```

The X11 version of Vim can run both in GUI and in non-GUI mode. See gui-x11-start .

gui-init gvimrc .gvimrc _gvimrc $MYGVIMRC
The gvimrc file is where GUI-specific startup commands should be placed. It is always sourced after the vimrc file. If you have one then the $MYGVIMRC environment variable has its name.

When the GUI starts up initializations are carried out, in this order:
- The 'term' option is set to "builtin_gui" and terminal options are reset to their default value for the GUI terminal-options .
- If the system menu file exists, it is sourced. The name of this file is normally "$VIMRUNTIME/menu.vim". You can check this with ":version". Also see $VIMRUNTIME . To skip loading the system menu include 'M' in 'guioptions'. buffers-menu no_buffers_menu
  The system menu file includes a "Buffers" menu. If you don't want this, set the "no_buffers_menu" variable in your .vimrc (not .gvimrc!):
  ```
  :let no_buffers_menu = 1
  ```
  NOTE: Switching on syntax highlighting also loads the menu file, thus disabling the Buffers menu must be done before ":syntax on".

  The path names are truncated to 35 characters. You can truncate them at a
  different length, for example 50, like this:
        :let bmenu_max_pathlen = 50
- If the "-U {gvimrc}" command-line option has been used when starting Vim,
  the {gvimrc} file will be read for initializations. The following
  initializations are skipped. When {gvimrc} is "NONE" no file will be read
  for initializations.
- For Unix and MS-Windows, if the system gvimrc exists, it is sourced. The
  name of this file is normally "$VIM/gvimrc". You can check this with
  ":version". Also see $VIM .
- The following are tried, and only the first one that exists is used:
  - If the GVIMINIT environment variable exists and is not empty, it is
    executed as an Ex command.
  - If the user gvimrc file exists, it is sourced. The name of this file is
    normally "$HOME/.gvimrc". You can check this with ":version".
  - For Win32, $HOME is set by Vim if needed, see $HOME-windows .
  - When a "_gvimrc" file is not found, ".gvimrc" is tried too. And vice
    versa.
  The name of the first file found is stored in $MYGVIMRC, unless it was
  already set.
- If the 'exrc' option is set (which is NOT the default) the file ./.gvimrc
  is sourced, if it exists and isn't the same file as the system or user
  gvimrc file. If this file is not owned by you, some security restrictions
  apply. When ".gvimrc" is not found, "_gvimrc" is tried too. For Macintosh
  and DOS/Win32 "_gvimrc" is tried first.

NOTE: All but the first one are not carried out if Vim was started with
"-u NONE" or "-u DEFAULTS" and no "-U" argument was given, or when started
with "-U NONE".

All this happens AFTER the normal Vim initializations, like reading your
.vimrc file. See initialization .
But the GUI window is only opened after all the initializations have been
carried out. If you want some commands to be executed just after opening the
GUI window, use the GUIEnter autocommand event. Example:
        :autocmd GUIEnter * winpos 100 50

You can use the gvimrc files to set up your own customized menus (see :menu)
and initialize other things that you may want to set up differently from the
terminal version.

Recommended place for your personal GUI initializations:
        Unix $HOME/.gvimrc or $HOME/.vim/gvimrc
        OS/2 $HOME/.gvimrc, $HOME/vimfiles/gvimrc
                            or $VIM/.gvimrc
        MS-DOS and Win32 $HOME/_gvimrc, $HOME/vimfiles/gvimrc
                            or $VIM/_gvimrc
        Amiga   s:.gvimrc, home:.gvimrc, home:vimfiles:gvimrc
                            or $VIM/.gvimrc

The personal initialization files are searched in the order specified above
and only the first one that is found is read.

There are a number of options which only have meaning in the GUI version of

Vim. These are 'guicursor', 'guifont', 'guipty' and 'guioptions'. They are documented in options.txt with all the other options.

If using the Motif or Athena version of the GUI (but not for the GTK+ or Win32 version), a number of X resources are available. See gui-resources .

Another way to set the colors for different occasions is with highlight groups. The "Normal" group is used to set the background and foreground colors. Example (which looks nice):

```
:highlight Normal guibg=grey90
```

The "guibg" and "guifg" settings override the normal background and foreground settings. The other settings for the Normal highlight group are not used. Use the 'guifont' option to set the font.

Also check out the 'guicursor' option, to set the colors for the cursor in various modes.

Vim tries to make the window fit on the screen when it starts up. This avoids that you can't see part of it. On the X Window System this requires a bit of guesswork. You can change the height that is used for the window title and a task bar with the 'guiheadroom' option.

:winp :winpos E188

:winp[os]
Display current position of the top left corner of the GUI vim window in pixels. Does not work in all versions.
Also see getwinpos() , getwinposx() and getwinposy() .

:winp[os] {X} {Y} E466
Put the GUI vim window at the given {X} and {Y} coordinates. The coordinates should specify the position in pixels of the top left corner of the window. Does not work in all versions.
Does work in an (new) xterm xterm-color .
When the GUI window has not been opened yet, the values are remembered until the window is opened. The position is adjusted to make the window fit on the screen (if possible).

:win :winsize E465

:win[size] {width} {height}
Set the window height to {width} by {height} characters.
Obsolete, use ":set lines=11 columns=22".
If you get less lines than expected, check the 'guiheadroom' option.

If you are running the X Window System, you can get information about the window Vim is running in with these commands:

```
:!xwininfo -id $WINDOWID
:!xprop -id $WINDOWID
:execute '!xwininfo -id ' . v:windowid
:execute '!xprop -id ' . v:windowid
```

gui-IME iBus

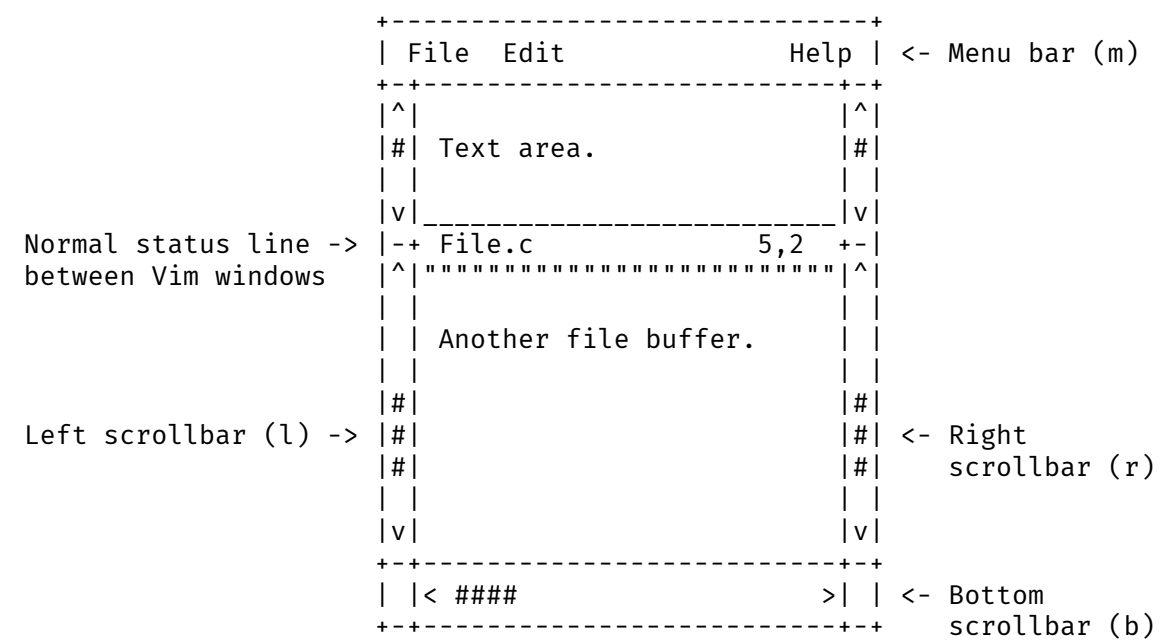
Input methods for international characters in X that rely on the XIM framework, most notably iBus, have been known to produce undesirable results in gvim. These may include an inability to enter spaces, or long delays between typing a character and it being recognized by the application.

One workaround that has been successful, for unknown reasons, is to prevent gvim from forking into the background by starting it with the `-f` argument.

==
2. Scrollbars gui-scrollbars

There are vertical scrollbars and a horizontal scrollbar. You may configure which ones appear with the 'guioptions' option.

The interface looks like this (with ":set guioptions=mlrb"):



Any of the scrollbar or menu components may be turned off by not putting the appropriate letter in the 'guioptions' string. The bottom scrollbar is only useful when 'nowrap' is set.

VERTICAL SCROLLBARS gui-vert-scroll

Each Vim window has a scrollbar next to it which may be scrolled up and down to move through the text in that buffer. The size of the scrollbar-thumb indicates the fraction of the buffer which can be seen in the window. When the scrollbar is dragged all the way down, the last line of the file will appear in the top of the window.

If a window is shrunk to zero height (by the growth of another window) its scrollbar disappears. It reappears when the window is restored.

If a window is vertically split, it will get a scrollbar when it is the

current window and when, taking the middle of the current window and drawing a vertical line, this line goes through the window.
When there are scrollbars on both sides, and the middle of the current window is on the left half, the right scrollbar column will contain scrollbars for the rightmost windows. The same happens on the other side.

HORIZONTAL SCROLLBARS gui-horiz-scroll

The horizontal scrollbar (at the bottom of the Vim GUI) may be used to scroll text sideways when the 'wrap' option is turned off. The scrollbar-thumb size is such that the text of the longest visible line may be scrolled as far as possible left and right. The cursor is moved when necessary, it must remain on a visible character (unless 'virtualedit' is set).

Computing the length of the longest visible line takes quite a bit of computation, and it has to be done every time something changes. If this takes too much time or you don't like the cursor jumping to another line, include the 'h' flag in 'guioptions'. Then the scrolling is limited by the text of the current cursor line.

athena-intellimouse

If you have an Intellimouse and an X server that supports using the wheel, then you can use the wheel to scroll the text up and down in gvim. This works with XFree86 4.0 and later, and with some older versions when you add patches. See scroll-mouse-wheel .

For older versions of XFree86 you must patch your X server. The following page has a bit of information about using the Intellimouse on Linux as well as links to the patches and X server binaries (may not have the one you need though):
    http://www.inria.fr/koala/colas/mouse-wheel-scroll/

==
3. Mouse Control gui-mouse

The mouse only works if the appropriate flag in the 'mouse' option is set. When the GUI is switched on, and 'mouse' wasn't set yet, the 'mouse' option is automatically set to "a", enabling it for all modes except for the hit-enter prompt. If you don't want this, a good place to change the 'mouse' option is the "gvimrc" file.

Other options that are relevant:
'mousefocus'   window focus follows mouse pointer gui-mouse-focus
'mousemodel'   what mouse button does which action
'mousehide'   hide mouse pointer while typing text
'selectmode'   whether to start Select mode or Visual mode

A quick way to set these is with the ":behave" command.

:behave :be
:be[have] {model}   Set behavior for mouse and selection. Valid
                        arguments are:
                           mswin   MS-Windows behavior

```
   xterm        Xterm behavior

Using ":behave" changes these options:
option          mswin                   xterm
'selectmode'    "mouse,key"             ""
'mousemodel'    "popup"                 "extend"
'keymodel'      "startsel,stopsel"      ""
'selection'     "exclusive"             "inclusive"
```

In the $VIMRUNTIME directory, there is a script called mswin.vim , which will also map a few keys to the MS-Windows cut/copy/paste commands. This is NOT compatible, since it uses the CTRL-V, CTRL-X and CTRL-C keys. If you don't mind, use this command:

```
:so $VIMRUNTIME/mswin.vim
```

For scrolling with a wheel on a mouse, see scroll-mouse-wheel .

3.1 Moving Cursor with Mouse gui-mouse-move

Click the left mouse button somewhere in a text buffer where you want the cursor to go, and it does!

This works in	when 'mouse' contains
Normal mode	'n' or 'a'
Visual mode	'v' or 'a'
Insert mode	'i' or 'a'

Select mode is handled like Visual mode.

You may use this with an operator such as 'd' to delete text from the current cursor position to the position you point to with the mouse. That is, you hit 'd' and then click the mouse somewhere.

gui-mouse-focus

The 'mousefocus' option can be set to make the keyboard focus follow the mouse pointer. This means that the window where the mouse pointer is, is the active window. Warning: this doesn't work very well when using a menu, because the menu command will always be applied to the top window.

If you are on the ':' line (or '/' or '?'), then clicking the left or right mouse button will position the cursor on the ':' line (if 'mouse' contains 'c', 'a' or 'A').

In any situation the middle mouse button may be clicked to paste the current selection.

3.2 Selection with Mouse gui-mouse-select

The mouse can be used to start a selection. How depends on the 'mousemodel' option:

'mousemodel' is "extend": use the right mouse button
'mousemodel' is "popup": use the left mouse button, while keeping the Shift key pressed.

If there was no selection yet, this starts a selection from the old cursor position to the position pointed to with the mouse. If there already is a selection then the closest end will be extended.

If 'selectmode' contains "mouse", then the selection will be in Select mode. This means that typing normal text will replace the selection. See Select-mode . Otherwise, the selection will be in Visual mode.

Double clicking may be done to make the selection word-wise, triple clicking makes it line-wise, and quadruple clicking makes it rectangular block-wise.

See gui-selections on how the selection is used.

3.3 Other Text Selection with Mouse gui-mouse-modeless modeless-selection

A different kind of selection is used when:
- in Command-line mode
- in the Command-line window and pointing in another window
- at the hit-enter prompt
- whenever the current mode is not in the 'mouse' option
- when holding the CTRL and SHIFT keys in the GUI

Since Vim continues like the selection isn't there, and there is no mode associated with the selection, this is called modeless selection. Any text in the Vim window can be selected. Select the text by pressing the left mouse button at the start, drag to the end and release. To extend the selection, use the right mouse button when 'mousemodel' is "extend", or the left mouse button with the shift key pressed when 'mousemodel' is "popup".
The selection is removed when the selected text is scrolled or changed.

On the command line CTRL-Y can be used to copy the selection into the clipboard. To do this from Insert mode, use CTRL-O : CTRL-Y <CR>. When 'guioptions' contains a or A (default on X11), the selection is automatically copied to the "* register.

The middle mouse button can then paste the text. On non-X11 systems, you can use CTRL-R +.

3.4 Using Mouse on Status Lines gui-mouse-status

Clicking the left or right mouse button on the status line below a Vim window makes that window the current window. This actually happens on button release (to be able to distinguish a click from a drag action).

With the left mouse button a status line can be dragged up and down, thus resizing the windows above and below it. This does not change window focus.

The same can be used on the vertical separator: click to give the window left of it focus, drag left and right to make windows wider and narrower.

3.5 Various Mouse Clicks gui-mouse-various

<S-LeftMouse>	Search forward for the word under the mouse click. When 'mousemodel' is "popup" this starts or extends a selection.
<S-RightMouse>	Search backward for the word under the mouse click.
<C-LeftMouse>	Jump to the tag name under the mouse click.
<C-RightMouse>	Jump back to position before the previous tag jump (same as "CTRL-T")

3.6 Mouse Mappings gui-mouse-mapping

The mouse events, complete with modifiers, may be mapped. Eg:

```
:map <S-LeftMouse>     <RightMouse>
:map <S-LeftDrag>      <RightDrag>
:map <S-LeftRelease>   <RightRelease>
:map <2-S-LeftMouse>   <2-RightMouse>
:map <2-S-LeftDrag>    <2-RightDrag>
:map <2-S-LeftRelease> <2-RightRelease>
:map <3-S-LeftMouse>   <3-RightMouse>
:map <3-S-LeftDrag>    <3-RightDrag>
:map <3-S-LeftRelease> <3-RightRelease>
:map <4-S-LeftMouse>   <4-RightMouse>
:map <4-S-LeftDrag>    <4-RightDrag>
:map <4-S-LeftRelease> <4-RightRelease>
```

These mappings make selection work the way it probably should in a Motif application, with shift-left mouse allowing for extending the visual area rather than the right mouse button.

Mouse mapping with modifiers does not work for modeless selection.

3.7 Drag and drop drag-n-drop

You can drag and drop one or more files into the Vim window, where they will be opened as if a :drop command was used.

If you hold down Shift while doing this, Vim changes to the first dropped file's directory. If you hold Ctrl Vim will always split a new window for the file. Otherwise it's only done if the current buffer has been changed.

You can also drop a directory on Vim. This starts the explorer plugin for that directory (assuming it was enabled, otherwise you'll get an error message). Keep Shift pressed to change to the directory instead.

If Vim happens to be editing a command line, the names of the dropped files and directories will be inserted at the cursor. This allows you to use these names with any Ex command. Special characters (space, tab, double quote and '|'; backslash on non-MS-Windows systems) will be escaped.

==========

4. Making GUI Selections gui-selections

quotestar

You may make selections with the mouse (see gui-mouse-select), or by using Vim's Visual mode (see v). If 'a' is present in 'guioptions', then whenever a selection is started (Visual or Select mode), or when the selection is changed, Vim becomes the owner of the windowing system's primary selection (on MS-Windows the gui-clipboard is used; under X11, the x11-selection is used - you should read whichever of these is appropriate now).

clipboard

There is a special register for storing this selection, it is the "* register. Nothing is put in here unless the information about what text is selected is about to change (e.g. with a left mouse click somewhere), or when another application wants to paste the selected text. Then the text is put in the "* register. For example, to cut a line and make it the current selection/put it on the clipboard:

```
"*dd
```

Similarly, when you want to paste a selection from another application, e.g., by clicking the middle mouse button, the selection is put in the "* register first, and then 'put' like any other register. For example, to put the selection (contents of the clipboard):

```
"*p
```

When using this register under X11, also see x11-selection . This also explains the related "+ register.

Note that when pasting text from one Vim into another separate Vim, the type of selection (character, line, or block) will also be copied. For other applications the type is always character. However, if the text gets transferred via the x11-cut-buffer , the selection type is ALWAYS lost.

When the "unnamed" string is included in the 'clipboard' option, the unnamed register is the same as the "* register. Thus you can yank to and paste the selection without prepending "* to commands.

==

5. Menus menus

For an introduction see usr_42.txt in the user manual.

5.1 Using Menus using-menus

Basically, menus can be used just like mappings. You can define your own menus, as many as you like.
Long-time Vim users won't use menus much. But the power is in adding your own menus and menu items. They are most useful for things that you can't remember what the key sequence was.

For creating menus in a different language, see :menutrans .
If you don't want to use menus at all, see 'go-M' .

menu.vim

The default menus are read from the file "$VIMRUNTIME/menu.vim". See
$VIMRUNTIME for where the path comes from. You can set up your own menus.
Starting off with the default set is a good idea. You can add more items, or,
if you don't like the defaults at all, start with removing all menus
:unmenu-all . You can also avoid the default menus being loaded by adding
this line to your .vimrc file (NOT your .gvimrc file!):

```
:let did_install_default_menus = 1
```

If you also want to avoid the Syntax menu:

```
:let did_install_syntax_menu = 1
```

The first item in the Syntax menu can be used to show all available filetypes
in the menu (which can take a bit of time to load). If you want to have all
filetypes already present at startup, add:

```
:let do_syntax_sel_menu = 1
```

The following menuitems show all available color schemes, keymaps and compiler
settings:

```
Edit > Color Scheme
Edit > Keymap
Tools > Set Compiler
```

However, they can also take a bit of time to load, because they search all
related files from the directories in 'runtimepath'. Therefore they are
loaded lazily (by the CursorHold event), or you can also load them manually.
If you want to have all these items already present at startup, add:

```
:let do_no_lazyload_menus = 1
```

Note that the menu.vim is sourced when `:syntax on` or `:filetype on` is
executed or after your .vimrc file is sourced. This means that the 'encoding'
option and the language of messages (`:language messages`) must be set before
that (if you want to change them).

console-menus

Although this documentation is in the GUI section, you can actually use menus
in console mode too. You will have to load menu.vim explicitly then, it is
not done by default. You can use the :emenu command and command-line
completion with 'wildmenu' to access the menu entries almost like a real menu
system. To do this, put these commands in your .vimrc file:

```
:source $VIMRUNTIME/menu.vim
:set wildmenu
:set cpo-=<
:set wcm=<C-Z>
:map <F4> :emenu <C-Z>
```

Pressing <F4> will start the menu. You can now use the cursor keys to select
a menu entry. Hit <Enter> to execute it. Hit <Esc> if you want to cancel.
This does require the +menu feature enabled at compile time.

tear-off-menus

GTK+ 2 and Motif support Tear-off menus. These are sort of sticky menus or
pop-up menus that are present all the time. If the resizing does not work
correctly, this may be caused by using something like "Vim*geometry" in the
defaults. Use "Vim.geometry" instead.

As to GTK+ 3, tear-off menus have been deprecated since GTK+ 3.4.
Accordingly, they are disabled if gvim is linked against GTK+ 3.4 or later.

The Win32 GUI version emulates Motif's tear-off menus. Actually, a Motif user will spot the differences easily, but hopefully they're just as useful. You can also use the :tearoff command together with hidden-menus to create floating menus that do not appear on the main menu bar.

5.2 Creating New Menus creating-menus

:me	:menu	:noreme	:noremenu
:am	:amenu	:an	:anoremenu
:nme	:nmenu	:nnoreme	:nnoremenu
:ome	:omenu	:onoreme	:onoremenu
:vme	:vmenu	:vnoreme	:vnoremenu
:xme	:xmenu	:xnoreme	:xnoremenu
:sme	:smenu	:snoreme	:snoremenu
:ime	:imenu	:inoreme	:inoremenu
:cme	:cmenu	:cnoreme	:cnoremenu
E330	E327	E331	E336	E333
E328	E329	E337	E792	

To create a new menu item, use the ":menu" commands. They are mostly like the ":map" set of commands but the first argument is a menu item name, given as a path of menus and submenus with a '.' between them, e.g.:

```
:menu File.Save  :w<CR>
:inoremenu File.Save  <C-O>:w<CR>
:menu Edit.Big\ Changes.Delete\ All\ Spaces  :%s/[ ^I]//g<CR>
```

This last one will create a new item in the menu bar called "Edit", holding the mouse button down on this will pop up a menu containing the item "Big Changes", which is a sub-menu containing the item "Delete All Spaces", which when selected, performs the operation.

Special characters in a menu name:

&	The next character is the shortcut key. Make sure each shortcut key is only used once in a (sub)menu. If you want to insert a literal "&" in the menu name use "&&".
<Tab>	Separates the menu name from right-aligned text. This can be used to show the equivalent typed command. The text "<Tab>" can be used here for convenience. If you are using a real tab, don't forget to put a backslash before it!

Example:

```
:amenu &File.&Open<Tab>:e  :browse e<CR>
```

[typed literally]
With the shortcut "F" (while keeping the <Alt> key pressed), and then "O", this menu can be used. The second part is shown as "Open :e". The ":e" is right aligned, and the "O" is underlined, to indicate it is the shortcut.

The ":amenu" command can be used to define menu entries for all modes at once. To make the command work correctly, a character is automatically inserted for some modes:

```
        mode            inserted        appended
        Normal          nothing         nothing
        Visual          <C-C>           <C-\><C-G>
        Insert          <C-\><C-O>
        Cmdline         <C-C>           <C-\><C-G>
        Op-pending      <C-C>           <C-\><C-G>
```

Appending CTRL-\ CTRL-G is for going back to insert mode when 'insertmode' is set. CTRL-_CTRL-G

Example:

```
   :amenu File.Next     :next^M
```

is equal to:

```
   :nmenu File.Next     :next^M
   :vmenu File.Next     ^C:next^M^\^G
   :imenu File.Next     ^\^O:next^M
   :cmenu File.Next     ^C:next^M^\^G
   :omenu File.Next     ^C:next^M^\^G
```

Careful: In Insert mode this only works for a SINGLE Normal mode command, because of the CTRL-O. If you have two or more commands, you will need to use the ":imenu" command. For inserting text in any mode, you can use the expression register:

```
   :amenu Insert.foobar   "='foobar'<CR>P
```

Note that the '<' and 'k' flags in 'cpoptions' also apply here (when included they make the <> form and raw key codes not being recognized).

Note that <Esc> in Cmdline mode executes the command, like in a mapping. This is Vi compatible. Use CTRL-C to quit Cmdline mode.

:menu-<silent> :menu-silent

To define a menu which will not be echoed on the command line, add "<silent>" as the first argument. Example:

```
        :menu <silent> Settings.Ignore\ case  :set ic<CR>
```

The ":set ic" will not be echoed when using this menu. Messages from the executed command are still given though. To shut them up too, add a ":silent" in the executed command:

```
        :menu <silent> Search.Header :exe ":silent normal /Header\r"<CR>
```

"<silent>" may also appear just after "<special>" or "<script>".

:menu-<special> :menu-special

Define a menu with <> notation for special keys, even though the "<" flag may appear in 'cpoptions'. This is useful if the side effect of setting 'cpoptions' is not desired. Example:

```
        :menu <special> Search.Header /Header<CR>
```

"<special>" must appear as the very first argument to the ":menu" command or just after "<silent>" or "<script>".

:menu-<script> :menu-script

The "to" part of the menu will be inspected for mappings. If you don't want
this, use the ":noremenu" command (or the similar one for a specific mode).
If you do want to use script-local mappings, add "<script>" as the very first
argument to the ":menu" command or just after "<silent>" or "<special>".

menu-priority

You can give a priority to a menu. Menus with a higher priority go more to
the right. The priority is given as a number before the ":menu" command.
Example:

```
:80menu Buffer.next :bn<CR>
```

The default menus have these priorities:

```
File            10
Edit            20
Tools           40
Syntax          50
Buffers         60
Window          70
Help            9999
```

When no or zero priority is given, 500 is used.
The priority for the PopUp menu is not used.

The Help menu will be placed on the far right side of the menu bar on systems
which support this (Motif and GTK+). For GTK+ 2 and 3, this is not done
anymore because right-aligning the Help menu is now discouraged UI design.

You can use a priority higher than 9999, to make it go after the Help menu,
but that is non-standard and is discouraged. The highest possible priority is
about 32000. The lowest is 1.

sub-menu-priority

The same mechanism can be used to position a sub-menu. The priority is then
given as a dot-separated list of priorities, before the menu name:

```
:menu 80.500 Buffer.next :bn<CR>
```

Giving the sub-menu priority is only needed when the item is not to be put
in a normal position. For example, to put a sub-menu before the other items:

```
:menu 80.100 Buffer.first :brew<CR>
```

Or to put a sub-menu after the other items, and further items with default
priority will be put before it:

```
:menu 80.900 Buffer.last :blast<CR>
```

When a number is missing, the default value 500 will be used:

```
:menu .900 myMenu.test :echo "text"<CR>
```

The menu priority is only used when creating a new menu. When it already
existed, e.g., in another mode, the priority will not change. Thus, the
priority only needs to be given the first time a menu is used.
An exception is the PopUp menu. There is a separate menu for each mode
(Normal, Op-pending, Visual, Insert, Cmdline). The order in each of these
menus can be different. This is different from menu-bar menus, which have
the same order for all modes.
NOTE: sub-menu priorities currently don't work for all versions of the GUI.

menu-separator E332

Menu items can be separated by a special item that inserts some space between

items. Depending on the system this is displayed as a line or a dotted line.
These items must start with a '-' and end in a '-'. The part in between is
used to give it a unique name. Priorities can be used as with normal items.
Example:

```
        :menu Example.item1     :do something
        :menu Example.-Sep-     :
        :menu Example.item2     :do something different
```

Note that the separator also requires a rhs. It doesn't matter what it is,
because the item will never be selected. Use a single colon to keep it
simple.

gui-toolbar

The toolbar is currently available in the Win32, Athena, Motif, GTK+ (X11),
and Photon GUI. It should turn up in other GUIs in due course. The
default toolbar is setup in menu.vim.
The display of the toolbar is controlled by the 'guioptions' letter 'T'. You
can thus have menu & toolbar together, or either on its own, or neither.
The appearance is controlled by the 'toolbar' option. You can choose between
an image, text or both.

toolbar-icon

The toolbar is defined as a special menu called ToolBar, which only has one
level. Vim interprets the items in this menu as follows:

1) If an "icon=" argument was specified, the file with this name is used.
    The file can either be specified with the full path or with the base name.
    In the last case it is searched for in the "bitmaps" directory in
    'runtimepath', like in point 3. Examples:

```
        :amenu icon=/usr/local/pixmaps/foo_icon.xpm ToolBar.Foo :echo "Foo"<CR>
        :amenu icon=FooIcon ToolBar.Foo :echo "Foo"<CR>
```

    Note that in the first case the extension is included, while in the second
    case it is omitted.
    If the file cannot be opened the next points are tried.
    A space in the file name must be escaped with a backslash.
    A menu priority must come _after_ the icon argument:

```
        :amenu icon=foo 1.42 ToolBar.Foo :echo "42!"<CR>
```

2) An item called 'BuiltIn##', where ## is a number, is taken as number ## of
    the built-in bitmaps available in Vim. Currently there are 31 numbered
    from 0 to 30 which cover most common editing operations builtin-tools .

```
        :amenu ToolBar.BuiltIn22 :call SearchNext("back")<CR>
```

3) An item with another name is first searched for in the directory
    "bitmaps" in 'runtimepath'. If found, the bitmap file is used as the
    toolbar button image. Note that the exact filename is OS-specific: For
    example, under Win32 the command

```
        :amenu ToolBar.Hello :echo "hello"<CR>
```

    would find the file 'hello.bmp'. Under GTK+/X11 it is 'Hello.xpm'. With
    GTK+ 2 the files 'Hello.png', 'Hello.xpm' and 'Hello.bmp' are checked for
    existence, and the first one found would be used.
    For MS-Windows and GTK+ 2 the bitmap is scaled to fit the button. For
    MS-Windows a size of 18 by 18 pixels works best.
    For MS-Windows the bitmap should have 16 colors with the standard palette.
    The light grey pixels will be changed to the Window frame color and the
    dark grey pixels to the window shadow color. More colors might also work,
    depending on your system.
4) If the bitmap is still not found, Vim checks for a match against its list

of built-in names. Each built-in button image has a name.
So the command
:amenu ToolBar.Open :e
will show the built-in "open a file" button image if no open.bmp exists.
All the built-in names can be seen used in menu.vim.
5) If all else fails, a blank, but functioning, button is displayed.

builtin-tools

nr	Name	Normal action
00	New	open new window
01	Open	browse for file to open in current window
02	Save	write buffer to file
03	Undo	undo last change
04	Redo	redo last undone change
05	Cut	delete selected text to clipboard
06	Copy	copy selected text to clipboard
07	Paste	paste text from clipboard
08	Print	print current buffer
09	Help	open a buffer on Vim's builtin help
10	Find	start a search command
11	SaveAll	write all modified buffers to file
12	SaveSesn	write session file for current situation
13	NewSesn	write new session file
14	LoadSesn	load session file
15	RunScript	browse for file to run as a Vim script
16	Replace	prompt for substitute command
17	WinClose	close current window
18	WinMax	make current window use many lines
19	WinMin	make current window use few lines
20	WinSplit	split current window
21	Shell	start a shell
22	FindPrev	search again, backward
23	FindNext	search again, forward
24	FindHelp	prompt for word to search help for
25	Make	run make and jump to first error
26	TagJump	jump to tag under the cursor
27	RunCtags	build tags for files in current directory
28	WinVSplit	split current window vertically
29	WinMaxWidth	make current window use many columns
30	WinMinWidth	make current window use few columns

hidden-menus win32-hidden-menus

In the Win32 and GTK+ GUI, starting a menu name with ']' excludes that menu from the main menu bar. You must then use the :popup or :tearoff command to display it.

window-toolbar WinBar

Each window can have a local toolbar. This uses the first line of the window, thus reduces the space for the text by one line. The items in the toolbar must start with "WinBar".

Only text can be used. When using Unicode, special characters can be used to make the items look like icons.

If the items do not fit then the last ones cannot be used. The toolbar does not wrap.

Note that Vim may be in any mode when executing these commands. The menu should be defined for Normal mode and will be executed without changing the current mode. Thus if the current window is in Visual mode and the menu command does not intentionally change the mode, Vim will remain in Visual mode. Best is to use `:nnoremenu` to avoid side effects.

Example for debugger tools:
```
        nnoremenu 1.10 WinBar.Step :Step<CR>
        nnoremenu 1.20 WinBar.Next :Next<CR>
        nnoremenu 1.30 WinBar.Finish :Finish<CR>
        nnoremenu 1.40 WinBar.Cont :Continue<CR>
```

The window toolbar uses the ToolbarLine and ToolbarButton highlight groups.

When splitting the window the window toolbar is not copied to the new window.

popup-menu

In the Win32, GTK+, Motif, Athena and Photon GUI, you can define the special menu "PopUp". This is the menu that is displayed when the right mouse button is pressed, if 'mousemodel' is set to popup or popup_setpos.
Example:
```
    nnoremenu 1.40 PopUp.&Paste "+gP
    menu PopUp
```

5.3 Showing What Menus Are Mapped To showing-menus

To see what an existing menu is mapped to, use just one argument after the menu commands (just like you would with the ":map" commands). If the menu specified is a submenu, then all menus under that hierarchy will be shown. If no argument is given after :menu at all, then ALL menu items are shown for the appropriate mode (e.g., Command-line mode for :cmenu).

Special characters in the list, just before the rhs:
```
*       The menu was defined with "nore" to disallow remapping.
&       The menu was defined with "<script>" to allow remapping script-local
        mappings only.
-       The menu was disabled.
```

Note that hitting <Tab> while entering a menu name after a menu command may be used to complete the name of the menu item.

5.4 Executing Menus execute-menus

:em :emenu E334 E335

:[range]em[enu] {menu} Execute {menu} from the command line.
The default is to execute the Normal mode menu. If a range is specified, it executes the Visual mode menu.
If used from <c-o>, it executes the

insert-mode menu Eg:

```
:emenu File.Exit
```

If the console-mode vim has been compiled with WANT_MENU defined, you can use :emenu to access useful menu items you may have got used to from GUI mode. See 'wildmenu' for an option that works well with this. See console-menus for an example.

When using a range, if the lines match with '<,'>, then the menu is executed using the last visual selection.

5.5 Deleting Menus delete-menus

:unme :unmenu
:aun :aunmenu
:nunme :nunmenu
:ounme :ounmenu
:vunme :vunmenu
:xunme :xunmenu
:sunme :sunmenu
:iunme :iunmenu
:cunme :cunmenu

To delete a menu item or a whole submenu, use the unmenu commands, which are analogous to the unmap commands. Eg:

```
:unmenu! Edit.Paste
```

This will remove the Paste item from the Edit menu for Insert and Command-line modes.

Note that hitting <Tab> while entering a menu name after an umenu command may be used to complete the name of the menu item for the appropriate mode.

To remove all menus use: :unmenu-all

```
:unmenu *       " remove all menus in Normal and visual mode
:unmenu! *      " remove all menus in Insert and Command-line mode
:aunmenu *      " remove all menus in all modes
```

If you want to get rid of the menu bar:

```
:set guioptions-=m
```

5.6 Disabling Menus disable-menus

:menu-disable :menu-enable

If you do not want to remove a menu, but disable it for a moment, this can be done by adding the "enable" or "disable" keyword to a ":menu" command. Examples:

```
:menu disable &File.&Open\.\.\.
:amenu enable *
:amenu disable &Tools.*
```

The command applies to the modes as used with all menu commands. Note that characters like "&" need to be included for translated names to be found.

When the argument is "*", all menus are affected. Otherwise the given menu name and all existing submenus below it are affected.

5.7 Examples for Menus menu-examples

Here is an example on how to add menu items with menu's! You can add a menu item for the keyword under the cursor. The register "z" is used.

```
:nmenu Words.Add\ Var         wb"zye:menu! Words.<C-R>z <C-R>z<CR>
:nmenu Words.Remove\ Var      wb"zye:unmenu! Words.<C-R>z<CR>
:vmenu Words.Add\ Var         "zy:menu! Words.<C-R>z <C-R>z <CR>
:vmenu Words.Remove\ Var      "zy:unmenu! Words.<C-R>z<CR>
:imenu Words.Add\ Var         <Esc>wb"zye:menu! Words.<C-R>z <C-R>z<CR>a
:imenu Words.Remove\ Var      <Esc>wb"zye:unmenu! Words.<C-R>z<CR>a
```

(the rhs is in <> notation, you can copy/paste this text to try out the mappings, or put these lines in your gvimrc; "<C-R>" is CTRL-R, "<CR>" is the <CR> key. <>)

5.8 Tooltips & Menu tips

See section 42.4 in the user manual.

:tmenu :tm

:tm[enu] {menupath} {rhs} Define a tip for a menu or tool. {only in X11 and Win32 GUI}

:tm[enu] [menupath] List menu tips. {only in X11 and Win32 GUI}

:tunmenu :tu

:tu[nmenu] {menupath} Remove a tip for a menu or tool. {only in X11 and Win32 GUI}

When a tip is defined for a menu item, it appears in the command-line area when the mouse is over that item, much like a standard Windows menu hint in the status bar. (Except when Vim is in Command-line mode, when of course nothing is displayed.)
When a tip is defined for a ToolBar item, it appears as a tooltip when the mouse pauses over that button, in the usual fashion. Use the hl-Tooltip highlight group to change its colors.

A "tip" can be defined for each menu item. For example, when defining a menu item like this:

```
:amenu MyMenu.Hello :echo "Hello"<CR>
```

The tip is defined like this:

```
:tmenu MyMenu.Hello Displays a greeting.
```

And delete it with:

```
:tunmenu MyMenu.Hello
```

Tooltips are currently only supported for the X11 and Win32 GUI. However, they should appear for the other gui platforms in the not too distant future.

The ":tmenu" command works just like other menu commands, it uses the same arguments. ":tunmenu" deletes an existing menu tip, in the same way as the other unmenu commands.

If a menu item becomes invalid (i.e. its actions in all modes are deleted) Vim deletes the menu tip (and the item) for you. This means that :aunmenu deletes a menu item - you don't need to do a :tunmenu as well.

5.9 Popup Menus

In the Win32 and GTK+ GUI, you can cause a menu to popup at the cursor. This behaves similarly to the PopUp menus except that any menu tree can be popped up.

This command is for backwards compatibility, using it is discouraged, because it behaves in a strange way.

:popup :popu

:popu[p] {name} Popup the menu {name}. The menu named must have at least one subentry, but need not appear on the menu-bar (see hidden-menus). {only available for Win32 and GTK GUI or in the terminal when compiled with +insert_expand}

:popu[p]! {name} Like above, but use the position of the mouse pointer instead of the cursor. In the terminal this is the last known position, which is usually at the last click or release (mouse movement is irrelevant).

Example:

```
:popup File
```

will make the "File" menu (if there is one) appear at the text cursor (mouse pointer if ! was used).

```
:amenu ]Toolbar.Make    :make<CR>
:popup ]Toolbar
```

This creates a popup menu that doesn't exist on the main menu-bar.

Note that in the GUI the :popup command will return immediately, before a selection has been made. In the terminal the commands waits for the user to make a selection.

Note that a menu that starts with ']' will not be displayed.

==========

6. Extras gui-extras

This section describes other features which are related to the GUI.

- With the GUI, there is no wait for one second after hitting escape, because the key codes don't start with <Esc>.

- Typing ^V followed by a special key in the GUI will insert "<Key>", since
  the internal string used is meaningless. Modifiers may also be held down to
  get "<Modifiers-Key>".

- In the GUI, the modifiers SHIFT, CTRL, and ALT (or META) may be used within
  mappings of special keys and mouse events. E.g.: :map <M-LeftDrag> <LeftDrag>

- In the GUI, several normal keys may have modifiers in mappings etc, these
  are <Space>, <Tab>, <NL>, <CR>, <Esc>.

- To check in a Vim script if the GUI is being used, you can use something
  like this:

```
if has("gui_running")
   echo "yes, we have a GUI"
else
   echo "Boring old console"
endif
```

setting-guifont

- When you use the same vimrc file on various systems, you can use something
  like this to set options specifically for each type of GUI:

```
if has("gui_running")
    if has("gui_gtk2")
        :set guifont=Luxi\ Mono\ 12
    elseif has("x11")
        " Also for GTK 1
        :set guifont=*-lucidatypewriter-medium-r-normal-*-*-180-*-*-m-*-*
    elseif has("gui_win32")
        :set guifont=Luxi_Mono:h12:cANSI
    endif
endif
```

A recommended Japanese font is MS Mincho. You can find info here:
http://www.lexikan.com/mincho.htm

==
7. Shell Commands gui-shell

For the X11 GUI the external commands are executed inside the gvim window.
See gui-pty .

WARNING: Executing an external command from the X11 GUI will not always
work. "normal" commands like "ls", "grep" and "make" mostly work fine.
Commands that require an intelligent terminal like "less" and "ispell" won't
work. Some may even hang and need to be killed from another terminal. So be
careful!

For the Win32 GUI the external commands are executed in a separate window.
See gui-shell-win32 .

vim:tw=78:sw=4:ts=8:noet:ft=help:norl:

gui_w32.txt For Vim version 8.1. Last change: 2017 Oct 27

VIM REFERENCE MANUAL by Bram Moolenaar

Vim's Win32 Graphical User Interface gui-w32 win32-gui

Other relevant documentation:
gui.txt For generic items of the GUI.
os_win32.txt For Win32 specific items.

{Vi does not have a Windows GUI}

==========

1. Starting the GUI gui-w32-start

The Win32 GUI version of Vim will always start the GUI, no matter how you start it or what it's called.

The GUI will always run in the Windows subsystem. Mostly shells automatically return with a command prompt after starting gvim. If not, you should use the "start" command:

```
start gvim [options] file ..
```

Note: All fonts (bold, italic) must be of the same size!!! If you don't do this, text will disappear or mess up the display. Vim does not check the font sizes. It's the size in screen pixels that must be the same. Note that some fonts that have the same point size don't have the same pixel size! Additionally, the positioning of the fonts must be the same (ascent and descent).

The Win32 GUI has an extra menu item: "Edit/Select Font". It brings up the standard Windows font selector.

Setting the menu height doesn't work for the Win32 GUI.

gui-win32-maximized

If you want Vim to start with a maximized window, add this command to your vimrc or gvimrc file:

```
au GUIEnter * simalt ~x
```

Using Vim as a plugin gui-w32-windowid

When gvim starts up normally, it creates its own top level window. If you
pass Vim the command-line option --windowid with a decimal or hexadecimal
value, Vim will create a window that is a child of the window with the given
ID. This enables Vim to act as a plugin in another application. This really
is a programmer's interface, and is of no use without a supporting application
to spawn Vim correctly.

==
2. Vim as default editor   vim-default-editor

To set Vim as the default editor for a file type:
1. Start a Windows Explorer
2. Choose View/Options -> File Types
3. Select the path to gvim for every file type that you want to use it for.
   (you can also use three spaces in the file type field, for files without an
   extension).
   In the "open" action, use:
        gvim "%1"
  The quotes are required for using file names with embedded spaces.
   You can also use this:
        gvim "%L"
  This should avoid short (8.3 character) file names in some situations. But
   I'm not sure if this works everywhere.

When you open a file in Vim by double clicking it, Vim changes to that
file's directory.

If you want Vim to start full-screen, use this for the Open action:
        gvim -c "simalt ~x" "%1"

Another method, which also works when you put Vim in another directory (e.g.,
when you have got a new version):
1. select a file you want to use Vim with
2. <Shift-F10>
3. select "Open With..." menu entry
4. click "Other..."
5. browse to the (new) location of Vim and click "Open"
6. make "Always Use this program..." checked
7. <OK>

                                                send-to-menu   sendto
You can also install Vim in the "Send To" menu:
1. Start a Windows Explorer
2. Navigate to your sendto directory:
   Windows NT: %windir%\profiles\%user%\sendto (e.g.
               "c:\winnt\profiles\mattha\sendto")
   Windows XP: C:\Documents and Settings\%user%\SendTo
   Windows Vista: C:\Users\%user%\AppData\Roaming\Microsoft\Windows\SendTo .
3. Right-click in the file pane and select New->Shortcut
4. Follow the shortcut wizard, using the full path to VIM/GVIM.

When you 'send a file to Vim', Vim changes to that file's directory. Note,
however, that any long directory names will appear in their short (MS-DOS)
form. This is a limitation of the Windows "Send To" mechanism.

notepad

You could replace notepad.exe with gvim.exe, but that has a few side effects. Some programs rely on notepad arguments, which are not recognized by Vim. For example "notepad -p" is used by some applications to print a file. It's better to leave notepad where it is and use another way to start Vim.

win32-popup-menu

A more drastic approach is to install an "Edit with Vim" entry in the popup menu for the right mouse button. With this you can edit any file with Vim.

This can co-exist with the file associations mentioned above. The difference is that the file associations will make starting Vim the default action. With the "Edit with Vim" menu entry you can keep the existing file association for double clicking on the file, and edit the file with Vim when you want. For example, you can associate "*.mak" with your make program. You can execute the makefile by double clicking it and use the "Edit with Vim" entry to edit the makefile.

You can select any files and right-click to see a menu option called "Edit with gvim". Choosing this menu option will invoke gvim with the file you have selected. If you select multiple files, you will find two gvim-related menu options:
"Edit with multiple gvims" -- one gvim for each file in the selection
"Edit with single gvim" -- one gvim for all the files in the selection
And if there already is a gvim running:
"Edit with existing gvim" -- edit the file with the running gvim

The "edit with existing Vim" entries can be disabled by adding an entry in the registry under HKLM\Software\Vim\Gvim, named DisableEditWithExisting, and with any value.

install-registry

You can add the "Edit with Vim" menu entry in an easy way by using the "install.exe" program. It will add several registry entries for you.

You can also do this by hand. This is complicated! Use the install.exe if you can.

1. Start the registry editor with "regedit".
2. Add these keys:

key	value name	value
HKEY_CLASSES_ROOT\CLSID\{51EEE242-AD87-11d3-9C1E-0090278BBD99}		
	{default}	Vim Shell Extension
HKEY_CLASSES_ROOT\CLSID\{51EEE242-AD87-11d3-9C1E-0090278BBD99}\InProcServer32		
	{default}	{path}\gvimext.dll
	ThreadingModel	Apartment
HKEY_CLASSES_ROOT*\shellex\ContextMenuHandlers\gvim		
	{default}	{51EEE242-AD87-11d3-9C1E-0090278BBD99}
HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Shell Extensions\Approved		
	{51EEE242-AD87-11d3-9C1E-0090278BBD99}	
		Vim Shell Extension
HKEY_LOCAL_MACHINE\Software\Vim\Gvim		
	path	{path}\gvim.exe
HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Uninstall\vim 5.6		

```
                DisplayName                Vim 5.6: Edit with Vim popup menu entry
                UninstallString            {path}\uninstal.exe
```

   Replace {path} with the path that leads to the executable.
   Don't type {default}, this is the value for the key itself.

To remove "Edit with Vim" from the popup menu, just remove the registry entries mentioned above. The "uninstal.exe" program can do this for you. You can also use the entry in the Windows standard "Add/Remove Programs" list.

If you notice that this entry overrules other file type associations, set those associations again by hand (using Windows Explorer, see above). This only seems to happen on some Windows NT versions (Windows bug?). Procedure:
1. Find the name of the file type. This can be done by starting the registry editor, and searching for the extension in \\HKEY_CLASSES_ROOT
2. In a Windows Explorer, use View/Options/File Types. Search for the file type in the list and click "Edit". In the actions list, you can select on to be used as the default (normally the "open" action) and click on the "Set Default" button.

Vim in the "Open With..." context menu *win32-open-with-menu*

If you use the Vim install program you have the choice to add Vim to the "Open With..." menu. This means you can use Vim to edit many files. Not every file (for unclear reasons...), thus the "Edit with Vim" menu entry is still useful.

One reason to add this is to be able to edit HTML files directly from Internet Explorer. To enable this use the "Tools" menu, "Internet Options..." entry. In the dialog select the "Programs" tab and select Vim in the "HTML editor" choice. If it's not there than installing didn't work properly.

Doing this manually can be done with this script:

```
------------------------------------------------------------
REGEDIT4

[HKEY_CLASSES_ROOT\Applications\gvim.exe]

[HKEY_CLASSES_ROOT\Applications\gvim.exe\shell]

[HKEY_CLASSES_ROOT\Applications\gvim.exe\shell\edit]

[HKEY_CLASSES_ROOT\Applications\gvim.exe\shell\edit\command]
@="c:\\vim\\vim62\\gvim.exe \"%1\""

[HKEY_CLASSES_ROOT\.htm\OpenWithList\gvim.exe]

[HKEY_CLASSES_ROOT\*\OpenWithList\gvim.exe]

------------------------------------------------------------
```

Change the "c:\\vim\\vim62" bit to where gvim.exe is actually located.

To uninstall this run the Vim uninstall program or manually delete the
registry entries with "regedit".

==
3. Using the clipboard   gui-clipboard

Windows has a clipboard, where you can copy text to, and paste text from. Vim
supports this in several ways. For other systems see gui-selections .

The "* register reflects the contents of the clipboard.   quotestar

When the "unnamed" string is included in the 'clipboard' option, the unnamed
register is the same. Thus you can yank to and paste from the clipboard
without prepending "* to commands.

The 'a' flag in 'guioptions' is not included by default. This means that text
is only put on the clipboard when an operation is performed on it. Just
Visually selecting text doesn't put it on the clipboard. When the 'a' flag is
included, the text is copied to the clipboard even when it is not operated
upon.

                                                        mswin.vim
To use the standard MS-Windows way of CTRL-X, CTRL-C and CTRL-V, use the
$VIMRUNTIME/mswin.vim script. You could add this line to your _vimrc file:
        source $VIMRUNTIME/mswin.vim

Since CTRL-C is used to copy the text to the clipboard, it can't be used to
cancel an operation. Use CTRL-Break for that.

CTRL-Z is used for undo. This means you can't suspend Vim with this key, use
 :suspend instead (if it's supported at all).

                                              CTRL-V-alternative   CTRL-Q
Since CTRL-V is used to paste, you can't use it to start a blockwise Visual
selection. You can use CTRL-Q instead. You can also use CTRL-Q in Insert
mode and Command-line mode to get the old meaning of CTRL-V. But CTRL-Q
doesn't work for terminals when it's used for control flow.

NOTE: The clipboard support still has a number of bugs. See todo .

==
4. Shell Commands   gui-shell-win32

Vim uses another window for external commands, to make it possible to run any
command. The external command gets its own environment for running, just like
it was started from a DOS prompt.

                                                        win32-vimrun
Executing an external command is done indirectly by the "vimrun" command. The
"vimrun.exe" must be in the path for this to work. Or it must be in the same
directory as the Vim executable. If "vimrun" cannot be found, the command is
executed directly, but then the DOS window closes immediately after the
external command has finished.
WARNING: If you close this window with the "X" button, and confirm the

question if you really want to kill the application, Vim may be killed too!
(This does not apply to commands run asynchronously with ":!start".)

The window in which the commands are executed will be the default you have set up for "Console" in Control Panel.

win32-!start

Normally, Vim waits for a command to complete before continuing (this makes sense for most shell commands which produce output for Vim to use). If you want Vim to start a program and return immediately, you can use the following syntax:

```
:!start [/min] {command}
```

The optional "/min" causes the window to be minimized.

==

5. Special colors win32-colors

On Win32, the normal DOS colors can be used. See dos-colors .

Additionally the system configured colors can also be used. These are known by the names Sys_XXX, where XXX is the appropriate system color name, from the following list (see the Win32 documentation for full descriptions). Case is ignored.

Sys_3DDKShadow	Sys_3DFace	Sys_BTNFace
Sys_3DHilight	Sys_3DHighlight	Sys_BTNHilight
Sys_BTNHighlight	Sys_3DLight	Sys_3DShadow
Sys_BTNShadow	Sys_ActiveBorder	Sys_ActiveCaption
Sys_AppWorkspace	Sys_Background	Sys_Desktop
Sys_BTNText	Sys_CaptionText	Sys_GrayText
Sys_Highlight	Sys_HighlightText	Sys_InactiveBorder
Sys_InactiveCaption	Sys_InactiveCaptionText	Sys_InfoBK
Sys_InfoText	Sys_Menu	Sys_MenuText
Sys_ScrollBar	Sys_Window	Sys_WindowFrame
Sys_WindowText		

Probably the most useful values are

Sys_Window	Normal window background
Sys_WindowText	Normal window text
Sys_Highlight	Highlighted background
Sys_HighlightText	Highlighted text

These extra colors are also available:
Gray, Grey, LightYellow, SeaGreen, Orange, Purple, SlateBlue, Violet,

rgb.txt

Additionally, colors defined by a "rgb.txt" file can be used. This file is well known from X11. A few lines from it:

```
  255 218 185             peach puff
  205 133  63             peru
  255 181 197             pink
```

This shows the layout of the file: First the R, G and B value as a decimal

number, followed by the name of the color. The four fields are separated by spaces.

You can get an rgb.txt file from any X11 distribution. It is located in a directory like "/usr/X11R6/lib/X11/". For Vim it must be located in the $VIMRUNTIME directory. Thus the file can be found with "$VIMRUNTIME/rgb.txt".

==
gui-w32-dialogs dialog

6. Windows dialogs & browsers

The Win32 GUI can use familiar Windows components for some operations, as well as the traditional interface shared with the console version.

6.1 Dialogs

The dialogs displayed by the "confirm" family (i.e. the 'confirm' option, :confirm command and confirm() function) are GUI-based rather than the console-based ones used by other versions. The 'c' flag in 'guioptions' changes this.

6.2 File Browsers

When prepending ":browse" before file editing commands, a file requester is used to allow you to select an existing file. See :browse .

6.3 Tearoff Menus

The Win32 GUI emulates Motif's tear-off menus. At the top of each menu you will see a small graphic "rip here" sign. Selecting it will cause a floating window to be created with the same menu entries on it. The floating menu can then be accessed just as if it was the original (including sub-menus), but without having to go to the menu bar each time.
This is most useful if you find yourself using a command buried in a sub-menu over and over again.
The tearoff menus can be positioned where you like, and always stay just above the Main Vim window. You can get rid of them by closing them as usual; they also of course close when you exit Vim.

:tearoff :te

:te[aroff] {name} Tear-off the menu {name}. The menu named must have at least one subentry, but need not appear on the menu-bar (see win32-hidden-menus).

Example:

```
:tearoff File
```

will make the "File" menu (if there is one) appear as a tearoff menu.

```
:amenu ]Toolbar.Make    :make<CR>
:tearoff ]Toolbar
```

This creates a floating menu that doesn't exist on the main menu-bar.

Note that a menu that starts with ']' will not be displayed.

==
7. Command line arguments   gui-w32-cmdargs

Command line arguments behave the same way as with the console application,
see win32-cmdargs .

==
8. Various   gui-w32-various

                                                            gui-w32-printing
The "File/Print" menu prints the text with syntax highlighting, see
 :hardcopy . If you just want to print the raw text and have a default
printer installed this should also work:
        :w >>prn

Vim supports a number of standard MS Windows features. Some of these are
detailed elsewhere: see 'mouse' , win32-hidden-menus .

                                                            drag-n-drop-win32
You can drag and drop one or more files into the Vim window, where they will
be opened as normal. See drag-n-drop .

                                                            :simalt   :sim
:sim[alt] {key}   simulate pressing {key} while holding Alt pressed.
                        {not in Vi} {only for Win32 versions}
                        Note: ":si" means ":s" with the "i" flag.

Normally, Vim takes control of all Alt-<Key> combinations, to increase the
number of possible mappings. This clashes with the standard use of Alt as the
key for accessing menus.
The quick way of getting standard behavior is to set the 'winaltkeys' option
to "yes". This however prevents you from mapping Alt keys at all.
Another way is to set 'winaltkeys' to "menu". Menu shortcut keys are then
handled by windows, other ALT keys can be mapped. This doesn't allow a
dependency on the current state though.
To get round this, the :simalt command allows Vim (when 'winaltkeys' is not
"yes") to fake a Windows-style Alt keypress. You can use this to map Alt key
combinations (or anything else for that matter) to produce standard Windows
actions. Here are some examples:

        :map <M-f> :simalt f<CR>
This makes Alt-F pop down the 'File' menu (with the stock Menu.vim) by
simulating the keystrokes Alt, F.
        :map <M-Space> :simalt ~<CR>
This maps Alt-Space to pop down the system menu for the Vim window. Note that
~ is used by simalt to represent the <Space> character.
        :map <C-n> :simalt ~n<CR>
Maps Control-N to produce the keys Alt-Space followed by N. This minimizes the
Vim window via the system menu.

Note that the key changes depending on the language you are using.

intellimouse-wheel-problems

When using the Intellimouse mouse wheel causes Vim to stop accepting input, go to:
	ControlPanel - Mouse - Wheel - UniversalScrolling - Exceptions

And add gvim to the list of applications. This problem only appears to happen with the Intellimouse driver 2.2 and when "Universal Scrolling" is turned on.

XPM support w32-xpm-support

GVim can be build on MS-Windows with support for XPM files. +xpm_w32
See the Make_mvc.mak file for instructions, search for XPM.

To try out if XPM support works do this:

```
:help
:exe 'sign define vimxpm icon=' . $VIMRUNTIME . '\\vim16x16.xpm'
:exe 'sign place 1 line=1 name=vimxpm file=' . expand('%:p')
```

vim:tw=78:sw=4:ts=8:noet:ft=help:norl:

gui_x11.txt For Vim version 8.1. Last change: 2018 May 06

VIM REFERENCE MANUAL by Bram Moolenaar

Vim's Graphical User Interface gui-x11 GUI-X11
Athena Motif

Other relevant documentation:
gui.txt For generic items of the GUI.

{Vi does not have any of these commands}

==========

1. Starting the X11 GUI gui-x11-start E665

Then you can run the GUI version of Vim in either of these ways:

```
gvim [options] [files...]
vim -g [options] [files...]
```

So if you call the executable "gvim", or make "gvim" a link to the executable, then the GUI version will automatically be used. Additional characters may be added after "gvim", for example "gvim-5".

You may also start up the GUI from within the terminal version by using one of these commands:

```
:gui [++opt] [+cmd] [-f|-b] [files...]  :gu  :gui
:gvim [++opt] [+cmd] [-f|-b] [files...]  :gv  :gvim
```

The "-f" option runs Vim in the foreground.
The "-b" option runs Vim in the background (this is the default).
Also see ++opt and +cmd .

gui-fork

When the GUI is started, it does a fork() and exits the current process. When gvim was started from a shell this makes the shell accept further commands. If you don't want this (e.g. when using gvim for a mail program that waits for gvim to exit), start gvim with "gvim -f", "vim -gf" or use ":gui -f". Don't use "vim -fg", because "-fg" specifies the foreground color.

When using "gvim -f" and then ":gui", Vim will run in the foreground. The "-f" argument will be remembered. To force running Vim in the background use ":gui -b".

"gvim --nofork" does the same as "gvim -f".

When there are running jobs Vim will not fork, because the processes would no
longer be child processes.
                                                                E851 E852
When starting the GUI fails Vim will try to continue running in the terminal.

If you want the GUI to run in the foreground always, include the 'f'
flag in 'guioptions'. -f .

==
2. GUI Resources   gui-resources .Xdefaults

If using the Motif or Athena version of the GUI (not for the KDE, GTK+ or Win32
version), a number of X resources are available. You should use Vim's class
"Vim" when setting these. They are as follows:

    Resource name   Meaning

    reverseVideo   Boolean: should reverse video be used?
    background   Color of background.
    foreground   Color of normal text.
    scrollBackground   Color of trough portion of scrollbars.
    scrollForeground   Color of slider and arrow portions of scrollbars.
    menuBackground   Color of menu backgrounds.
    menuForeground   Color of menu foregrounds.
    tooltipForeground   Color of tooltip and balloon foreground.
    tooltipBackground   Color of tooltip and balloon background.

    font   Name of font used for normal text.
    boldFont   Name of font used for bold text.
    italicFont   Name of font used for italic text.
    boldItalicFont   Name of font used for bold, italic text.
    menuFont   Name of font used for the menus, used when compiled
                        without the +xfontset feature
    menuFontSet   Name of fontset used for the menus, used when compiled
                        with the +xfontset feature
    tooltipFont   Name of the font used for the tooltip and balloons.
                        When compiled with the +xfontset feature this is a
                        fontset name.

    geometry   Initial geometry to use for gvim's window (default
                        is same size as terminal that started it).
    scrollbarWidth   Thickness of scrollbars.
    borderWidth   Thickness of border around text area.
    menuHeight   Height of the menu bar (only for Athena).

A special font for italic, bold, and italic-bold text will only be used if
the user has specified one via a resource. No attempt is made to guess what
fonts should be used for these based on the normal text font.

Note that the colors can also be set with the ":highlight" command, using the
"Normal", "Menu", "Tooltip", and "Scrollbar" groups. Example:
        :highlight Menu guibg=lightblue

```
        :highlight Tooltip guibg=yellow
        :highlight Scrollbar guibg=lightblue guifg=blue
        :highlight Normal guibg=grey90
```

font-sizes

Note: All fonts (except for the menu and tooltip) must be of the same size!!! If you don't do this, text will disappear or mess up the display. Vim does not check the font sizes. It's the size in screen pixels that must be the same. Note that some fonts that have the same point size don't have the same pixel size! Additionally, the positioning of the fonts must be the same (ascent and descent). You can check this with "xlsfonts -l {fontname}".

If any of these things are also set with Vim commands, e.g. with ":set guifont=Screen15", then this will override the X resources (currently 'guifont' is the only option that is supported).

Here is an example of what you might put in your ~/.Xdefaults file:

```
        Vim*useSchemes:                 all
        Vim*sgiMode:                    true
        Vim*useEnhancedFSB:             true
        Vim.foreground:                 Black
        Vim.background:                 Wheat
        Vim*fontList:                   7x13
```

The first three of these are standard resources on Silicon Graphics machines which make Motif applications look even better, highly recommended!

The "Vim*fontList" is to set the menu font for Motif. Example:

```
        Vim*menuBar*fontList:        -*-courier-medium-r-*-*-10-*-*-*-*-*-*-*
```

With Athena:

```
        Vim*menuBar*SmeBSB*font:     -*-courier-medium-r-*-*-10-*-*-*-*-*-*-*
        Vim*menuBar*MenuButton*font: -*-courier-medium-r-*-*-10-*-*-*-*-*-*-*
```

NOTE: A more portable, and indeed more correct, way to specify the menu font in either Motif or Athena is through the resource:

```
        Vim.menuFont:        -*-courier-medium-r-*-*-10-*-*-*-*-*-*-*
```

Or, when compiled with the +xfontset feature:

```
        Vim.menuFontSet:     -*-courier-medium-r-*-*-10-*-*-*-*-*-*-*
```

Don't use "Vim*geometry" in the defaults. This will break the menus. Use "Vim.geometry" instead.

If you get an error message "Cannot allocate colormap entry for "gray60", try adding this to your Vim resources (change the colors to your liking):

```
        Vim*scrollBackground:           Black
        Vim*scrollForeground:           Blue
```

The resources can also be set with arguments to Vim:

argument	meaning	
		-gui
-display {display}	Run vim on {display}	-display

```
    -iconic              Start vim iconified              -iconic
    -background {color}  Use {color} for the background   -background
    -bg {color}          idem                             -bg
    -foreground {color}  Use {color} for normal text      -foreground
    -fg {color}          idem                             -fg
    -ul {color}          idem                             -ul
    -font {font}         Use {font} for normal text       -font
    -fn {font}           idem                             -fn
    -boldfont {font}     Use {font} for bold text         -boldfont
    -italicfont {font}   Use {font} for italic text       -italicfont
    -menufont {font}     Use {font} for menu items        -menufont
    -menufontset {fontset} Use {fontset} for menu items   -menufontset
    -mf {font}           idem                             -mf
    -geometry {geom}     Use {geom} for initial geometry  -geometry
    -geom {geom}         idem, see  -geometry-example     -geom
    -borderwidth {width} Use a border width of {width}    -borderwidth
    -bw {width}          idem                             -bw
                                                          -scrollbarwidth
    -scrollbarwidth {width}      Use a scrollbar width of {width}
    -sw {width}          idem                             -sw
    -menuheight {height} Use a menu bar height of {height}  -menuheight
    -mh {height}         idem                             -mh
                         NOTE: On Motif the value is ignored, the menu height
                         is computed to fit the menus.
    -reverse             Use reverse video                -reverse
    -rv                  idem                             -rv
    +reverse             Don't use reverse video          -+reverse
    +rv                  idem                             -+rv
    -xrm {resource}      Set the specified resource       -xrm
```

Note about reverse video: Vim checks that the result is actually a light text on a dark background. The reason is that some X11 versions swap the colors, and some don't. These two examples will both give yellow text on a blue background:

```
    gvim -fg Yellow -bg Blue -reverse
    gvim -bg Yellow -fg Blue -reverse
```

-geometry-example

An example for the geometry argument:

```
        gvim -geometry 80x63+8+100
```

This creates a window with 80 columns and 63 lines at position 8 pixels from the left and 100 pixels from the top of the screen.

==

3. Shell Commands gui-pty

WARNING: Executing an external command from the GUI will not always work. "normal" commands like "ls", "grep" and "make" mostly work fine. Commands that require an intelligent terminal like "less" and "ispell" won't work. Some may even hang and need to be killed from another terminal. So be careful!

There are two ways to do the I/O with a shell command: Pipes and a pseudo-tty. The default is to use a pseudo-tty. This should work best on most systems.

Unfortunately, the implementation of the pseudo-tty is different on every Unix system. And some systems require root permission. To avoid running into problems with a pseudo-tty when you least expect it, test it when not editing a file. Be prepared to "kill" the started command or Vim. Commands like ":r !cat" may hang!

If using a pseudo-tty does not work for you, reset the 'guipty' option:

```
:set noguipty
```

Using a pipe should work on any Unix system, but there are disadvantages:
- Some shell commands will notice that a pipe is being used and behave differently. E.g., ":!ls" will list the files in one column.
- The ":sh" command won't show a prompt, although it will sort of work.
- When using ":make" it's not possible to interrupt with a CTRL-C.

Typeahead while the external command is running is often lost. This happens both with a pipe and a pseudo-tty. This is a known problem, but it seems it can't be fixed (or at least, it's very difficult).

gui-pty-erase

When your erase character is wrong for an external command, you should fix this in your "~/.cshrc" file, or whatever file your shell uses for initializations. For example, when you want to use backspace to delete characters, but hitting backspaces produces "^H" instead, try adding this to your "~/.cshrc":

```
stty erase ^H
```

The ^H is a real CTRL-H, type it as CTRL-V CTRL-H.

==

4. Various gui-x11-various

gui-x11-printing

The "File/Print" menu simply sends the current buffer to "lpr". No options or whatever. If you want something else, you can define your own print command. For example:

```
:10amenu File.Print :w !lpr -Php3
:10vmenu File.Print :w !lpr -Php3
```

X11-icon

Vim uses a black&white icon by default when compiled with Motif or Athena. A colored Vim icon is included as $VIMRUNTIME/vim32x32.xpm. For GTK+, this is the builtin icon used. Unfortunately, how you should install it depends on your window manager. When you use this, remove the 'i' flag from 'guioptions', to remove the black&white icon:

```
:set guioptions-=i
```

If you use one of the fvwm* family of window managers simply add this line to your .fvwm2rc configuration file:

```
Style "vim"           Icon vim32x32.xpm
```

Make sure the icon file's location is consistent with the window manager's ImagePath statement. Either modify the ImagePath from within your .fvwm2rc or drop the icon into one the pre-defined directories:

```
  ImagePath /usr/X11R6/include/X11/pixmaps:/usr/X11R6/include/X11/bitmaps
```

Note: older versions of fvwm use "IconPath" instead of "ImagePath".

For CDE "dtwm" (a derivative of Motif) add this line in the .Xdefaults:

```
   Dtwm*Vim*iconImage: /usr/local/share/vim/vim32x32.xpm
```

For "mwm" (Motif window manager) the line would be:

```
   Mwm*Vim*iconImage: /usr/local/share/vim/vim32x32.xpm
```

Mouse Pointers Available in X11

X11_mouse_shapes

By using the 'mouseshape' option, the mouse pointer can be automatically changed whenever Vim enters one of its various modes (e.g., Insert or Command). Currently, the available pointers are:

arrow	an arrow pointing northwest
beam	a I-like vertical bar
size	an arrow pointing up and down
busy	a wristwatch
blank	an invisible pointer
crosshair	a thin "+" sign
hand1	a dark hand pointing northeast
hand2	a light hand pointing northwest
pencil	a pencil pointing southeast
question	question_arrow
right_arrow	an arrow pointing northeast
up_arrow	an arrow pointing upwards

Additionally, any of the mouse pointers that are built into X11 may be used by specifying an integer from the X11/cursorfont.h include file.

If a name is used that exists on other systems, but not in X11, the default "arrow" pointer is used.

==

5. GTK version

gui-gtk GTK+ GTK GTK3

The GTK version of the GUI works a little bit different.

GTK does _not_ use the traditional X resource settings. Thus items in your ~/.Xdefaults or app-defaults files are not used.
Many of the traditional X command line arguments are not supported. (e.g., stuff like -bg, -fg, etc). The ones that are supported are:

command line argument	resource name	meaning
-fn or -font	.font	font name for the text
-geom or -geometry	.geometry	size of the gvim window
-rv or -reverse	*reverseVideo	white text on black background

```
    -display                                    display to be used
    -fg -foreground {color}                     foreground color
    -bg -background {color}                     background color
```

To set the font, see 'guifont'. For GTK, there's also a menu option that does this.

Additionally, there are these command line arguments, which are handled by GTK internally. Look in the GTK documentation for how they are used:

```
        --sync
        --gdk-debug
        --gdk-no-debug
        --no-xshm       (not in GTK+ 2)
        --xim-preedit   (not in GTK+ 2)
        --xim-status    (not in GTK+ 2)
        --gtk-debug
        --gtk-no-debug
        --g-fatal-warnings
        --gtk-module
        --display       (GTK+ counterpart of -display; works the same way.)
        --screen        (The screen number; for GTK+ 2.2 multihead support.)
```

These arguments are ignored when the +netbeans_intg feature is used:

```
        -xrm
        -mf
```

As for colors, Vim's color settings (for syntax highlighting) is still done the traditional Vim way. See :highlight for more help.

If you want to set the colors of remaining gui components (e.g., the menubar, scrollbar, whatever), those are GTK specific settings and you need to set those up in some sort of gtkrc file. You'll have to refer to the GTK documentation, however little there is, on how to do this. See http://developer.gnome.org/doc/API/2.0/gtk/gtk-Resource-Files.html for more information.

Tooltip Colors

gtk-tooltip-colors

Example, which sets the tooltip colors to black on light-yellow:

```
        style "tooltips"
        {
                bg[NORMAL] = "#ffffcc"
                fg[NORMAL] = "#000000"
        }

        widget "gtk-tooltips*"          style "tooltips"
```

Write this in the file ~/.gtkrc and it will be used by GTK+. For GTK+ 2 you might have to use the file ~/.gtkrc-2.0 instead, depending on your distribution.

For GTK+ 3, an effect similar to the above can be obtained by adding the

following snippet of CSS code to $XDG_HOME_DIR/gtk-3.0/gtk.css (usually, $HOME/.config/gtk-3.0/gtk.css):

For GTK+ 3 < 3.20:

```
        .tooltip {
                background-color: #ffffcc;
                color: #000000;
        }
```

For GTK+ 3 >= 3.20:

```
        tooltip {
            background-color: #ffffcc;
            text-shadow: none;
        }

        tooltip label {
            color: #2e3436;
        }
```

A Quick Look at GTK+ CSS

gtk-css

The contents of this subsection apply to GTK+ 3.20 or later which provides stable support for GTK+ CSS:

        https://developer.gnome.org/gtk3/stable/theming.html

GTK+ uses CSS for styling and layout of widgets. In this subsection, we'll have a quick look at GTK+ CSS through simple, illustrative examples.

Example 1. Empty Space Adjustment

By default, the toolbar and the tabline of the GTK+ 3 GUI are somewhat larger than those of the GTK+ 2 GUI. Some people may want to make them look similar to the GTK+ 2 GUI in size.

To do that, we'll try reducing empty space around icons and labels that looks apparently superfluous.

Add the following lines to $XDG_HOME_DIR/gtk-3.0/gtk.css (usually, $HOME/.config/gtk-3.0/gtk.css):

```
        toolbar button {
            margin-top: -2px;
            margin-right: 0px;
            margin-bottom: -2px;
            margin-left: 0px;

            padding-top: 0px;
            padding-right: 0px;
            padding-bottom: 0px;
            padding-left: 0px
```

```
        }

        notebook tab {
            margin-top: -1px;
            margin-right: 3px;
            margin-bottom: -1px;
            margin-left: 3px;

            padding-top: 0px;
            padding-right: 0px;
            padding-bottom: 0px;
            padding-left: 0px
        }
```

Since it's a CSS, they can be rewritten using shorthand:

```
        toolbar button {
            margin: -2px 0px;
            padding: 0px;
        }

        notebook tab {
            margin: -1px 3px;
            padding: 0px
        }
```

Note: You might want to use 'toolbariconsize' to adjust the icon size, too.

Note: Depending on the icon theme and/or the font in use, some extra tweaks may be needed for a satisfactory result.

Note: In addition to margin and padding, you can use border. For details, refer to the box model of CSS, e.g.,

```
        https://www.w3schools.com/css/css_boxmodel.asp
```

Example 2. More Than Just Colors

GTK+ CSS supports gradients as well:

```
        tooltip {
            background-image: -gtk-gradient(linear,
                                            0 0, 0 1,
                                            color-stop(0, #344752),
                                            color-stop(0.5, #546772),
                                            color-stop(1, #243742));
        }

        tooltip label {
            color: #f3f3f3;
        }
```

Gradients can be used to make a GUI element visually distinguishable from others without relying on high contrast. Accordingly, effective use of them is

a useful technique to give a theme a sense of unity in color and luminance.

Note: Theming can be difficult since it must make every application look equally good; making a single application more charming often gets others unexpectedly less attractive or even deteriorates their usability. Keep this in mind always when you try improving a theme.

Using Vim as a GTK+ plugin

gui-gtk-socketid

When the GTK+ version of Vim starts up normally, it creates its own top level window (technically, a 'GtkWindow'). GTK+ provides an embedding facility with its GtkSocket and GtkPlug widgets. If one GTK+ application creates a GtkSocket widget in one of its windows, an entirely different GTK+ application may embed itself into the first application by creating a top-level GtkPlug widget using the socket's ID.

If you pass Vim the command-line option '--socketid' with a decimal or hexadecimal value, Vim will create a GtkPlug widget using that value instead of the normal GtkWindow. This enables Vim to act as a GTK+ plugin.

This really is a programmer's interface, and is of no use without a supporting application to spawn the Vim correctly. For more details on GTK+ sockets, see http://www.gtk.org/api/

Note that this feature requires the latest GTK version. GTK 1.2.10 still has a small problem. The socket feature has not yet been tested with GTK+ 2 -- feel free to volunteer.

==
6. GNOME version

gui-gnome Gnome GNOME

The GNOME GUI works just like the GTK+ version. See GTK+ above for how it works. It looks a bit different though, and implements one important feature that's not available in the plain GTK+ GUI: Interaction with the session manager. gui-gnome-session

These are the different looks:
- Uses GNOME dialogs (GNOME 1 only). The GNOME 2 GUI uses the same nice dialogs as the GTK+ 2 version.
- Uses the GNOME dock, so that the toolbar and menubar can be moved to different locations other than the top (e.g., the toolbar can be placed on the left, right, top, or bottom). The placement of the menubar and toolbar is only saved in the GNOME 2 version.
- That means the menubar and toolbar handles are back! Yeah! And the resizing grid still works too.

GNOME is compiled with if it was found by configure and the --enable-gnome-check argument was used.

Note: Avoid use of --enable-gnome-check with GTK+ 3 GUI build. The functionality mentioned above is consolidated in GTK+ 3.

GNOME session support
                                                gui-gnome-session gnome-session
On logout, Vim shows the well-known exit confirmation dialog if any buffers
are modified. Clicking [Cancel] will stop the logout process. Otherwise the
current session is stored to disk by using the :mksession command, and
restored the next time you log in.

The GNOME session support should also work with the KDE session manager.
If you are experiencing any problems please report them as bugs.

Note: The automatic session save works entirely transparent, in order to
avoid conflicts with your own session files, scripts and autocommands. That
means in detail:
- The session file is stored to a separate directory (usually $HOME/.gnome2).
- 'sessionoptions' is ignored, and a hardcoded set of appropriate flags is
  used instead:
        blank,curdir,folds,globals,help,options,tabpages,winsize
- The internal variable v:this_session is not changed when storing the
  session. Also, it is restored to its old value when logging in again.

The position and size of the GUI window is not saved by Vim since doing so
is the window manager's job. But if compiled with GTK+ 2 support, Vim helps
the WM to identify the window by restoring the window role (using the --role
command line argument).

==
7. KDE version   gui-kde kde KDE KVim
                                                          gui-x11-kde
There is no KDE version of Vim. There has been some work on a port using the
Qt toolkit, but it never worked properly and it has been abandoned. Work
continues on Yzis: https://github.com/chrizel/Yzis.

==
8. Compiling   gui-x11-compiling

If using X11, Vim's configure will by default first try to find the necessary
GTK+ files on your system. When both GTK+ 2 and GTK+ 3 are available, GTK+ 2
will be chosen unless --enable-gui=gtk3 is passed explicitly to configure.

If the GTK+ files cannot be found, then the Motif files will be searched for.
Finally, if this fails, the Athena files will be searched for. If all three
fail, the GUI will be disabled.

For GTK+, Vim's configuration process uses pkg-config(1) to check if the
GTK+ required for a specified build is properly installed and usable.
Accordingly, it is a good idea to make sure before running configure that
your system has a working pkg-config together with the .pc file of the
required GTK+. For that, say, run the following on the command line to see if
your pkg-config works with your GTK+ 2:

    $ pkg-config --modversion gtk+-2.0

Replace gtk+-2.0 with gtk+-3.0 for GTK+ 3. If you get the correct version
number of your GTK+, you can proceed; if not, you probably need to do some

system administration chores to set up pkg-config and GTK+ correctly.

The GTK+ 2 GUI is built by default. Therefore, you usually don't need to pass any options such as --enable-gui=gtk2 to configure and build that.

Optionally, the GTK+ 2 GUI can consolidate the GNOME 2 support. This support is enabled by passing --enable-gnome-check to configure.

If you want to build the GTK+ 3 GUI, you have to pass --enable-gui=gtk3 explicitly to configure, and avoid passing --enable-gnome-check to that, as the functionality of the GNOME 2 support has already been consolidated in GTK+ 3.

Otherwise, if you are using Motif or Athena, when you have the Motif or Athena files in a directory where configure doesn't look, edit the Makefile to enter the names of the directories. Search for "GUI_INC_LOC" for an example to set the Motif directories, "CONF_OPT_X" for Athena.

gui-x11-gtk

Currently, Vim supports both GTK+ 2 and GTK+ 3.

The GTK+ 2 GUI requires GTK+ 2.2 or later.

Although the GTK+ 3 GUI is written in such a way that the source code can be compiled against all versions of the 3.x series, we recommend GTK+ 3.10 or later because of its substantial implementation changes in redraw done at that version.

gui-x11-motif

For Motif, you need at least Motif version 1.2 and/or X11R5. Motif 2.0 and X11R6 are OK. Motif 1.1 and X11R4 might work, no guarantee (there may be a few problems, but you might make it compile and run with a bit of work, please send me the patches if you do). The newest releases of LessTif have been reported to work fine too.

gui-x11-athena

The Athena version uses the Xaw widget set by default. If you have the 3D version, you might want to link with Xaw3d instead. This will make the menus look a bit better. Edit the Makefile and look for "XAW_LIB". The scrollbars will remain the same, because Vim has its own, which are already 3D (in fact, they look more like Motif).

gui-x11-neXtaw

The neXtaw version is mostly like Athena, but uses different widgets.

gui-x11-misc

In general, do not try to mix files from different GTK+, Motif, Athena and X11 versions. This will cause problems. For example, using header files for X11R5 with a library for X11R6 probably doesn't work (although the linking won't give an error message, Vim will crash later).

==
9. X11 selection mechanism   x11-selection

If using X11, in either the GUI or an xterm with an X11-aware Vim, then Vim provides varied access to the X11 selection and clipboard. These are accessed by using the two selection registers "* and "+.

X11 provides two basic types of global store, selections and cut-buffers, which differ in one important aspect: selections are "owned" by an application, and disappear when that application (e.g., Vim) exits, thus losing the data, whereas cut-buffers, are stored within the X-server itself and remain until written over or the X-server exits (e.g., upon logging out).

The contents of selections are held by the originating application (e.g., upon a copy), and only passed on to another application when that other application asks for them (e.g., upon a paste).

The contents of cut-buffers are immediately written to, and are then accessible directly from the X-server, without contacting the originating application.

quoteplus quote+

There are three documented X selections: PRIMARY (which is expected to represent the current visual selection - as in Vim's Visual mode), SECONDARY (which is ill-defined) and CLIPBOARD (which is expected to be used for cut, copy and paste operations).

Of these three, Vim uses PRIMARY when reading and writing the "* register (hence when the X11 selections are available, Vim sets a default value for 'clipboard' of "autoselect"), and CLIPBOARD when reading and writing the "+ register. Vim does not access the SECONDARY selection.

Examples: (assuming the default option values)
- Select a URL in Visual mode in Vim. Go to your browser and click the middle mouse button in the URL text field. The selected text will be inserted (hopefully!). Note: in Firefox you can set the middlemouse.contentLoadURL preference to true in about:config, then the selected URL will be used when pressing middle mouse button in most places in the window.
- Select some text in your browser by dragging with the mouse. Go to Vim and press the middle mouse button: The selected text is inserted.
- Select some text in Vim and do "+y. Go to your browser, select some text in a textfield by dragging with the mouse. Now use the right mouse button and select "Paste" from the popup menu. The selected text is overwritten by the text from Vim.

Note that the text in the "+ register remains available when making a Visual selection, which makes other text available in the "* register. That allows overwriting selected text.

x11-cut-buffer

There are, by default, 8 cut-buffers: CUT_BUFFER0 to CUT_BUFFER7. Vim only uses CUT_BUFFER0, which is the one that xterm uses by default.

Whenever Vim is about to become unavailable (either via exiting or becoming suspended), and thus unable to respond to another application's selection request, it writes the contents of any owned selection to CUT_BUFFER0. If the "+ CLIPBOARD selection is owned by Vim, then this is written in preference, otherwise if the "* PRIMARY selection is owned by Vim, then that is written.

Similarly, when Vim tries to paste from "* or "+ (either explicitly, or, in the case of the "* register, when the middle mouse button is clicked), if the requested X selection is empty or unavailable, Vim reverts to reading the current value of the CUT_BUFFER0.

Note that when text is copied to CUT_BUFFER0 in this way, the type of selection (character, line or block) is always lost, even if it is a Vim which later pastes it.

Xterm, by default, always writes visible selections to both PRIMARY and CUT_BUFFER0. When it pastes, it uses PRIMARY if this is available, or else falls back upon CUT_BUFFER0. For this reason, when cutting and pasting between Vim and an xterm, you should use the "* register. Xterm doesn't use CLIPBOARD, thus the "+ doesn't work with xterm.

Most newer applications will provide their current selection via PRIMARY ("*) and use CLIPBOARD ("+) for cut/copy/paste operations. You thus have access to both by choosing to use either of the "* or "+ registers.

vim:tw=78:sw=4:ts=8:noet:ft=help:norl:

if_cscop.txt For Vim version 8.1. Last change: 2018 Jan 21

VIM REFERENCE MANUAL by Andy Kahn

cscope Cscope

This document explains how to use Vim's cscope interface.

Cscope is a tool like ctags, but think of it as ctags on steroids since it does a lot more than what ctags provides. In Vim, jumping to a result from a cscope query is just like jumping to any tag; it is saved on the tag stack so that with the right keyboard mappings, you can jump back and forth between functions as you normally would with tags .

This is currently for Unix and Win32 only.
{Vi does not have any of these commands}

==========

1. Cscope introduction cscope-intro

The following text is taken from a version of the cscope man page:

Cscope is an interactive screen-oriented tool that helps you:

Learn how a C program works without endless flipping through a thick listing.

Locate the section of code to change to fix a bug without having to learn the entire program.

Examine the effect of a proposed change such as adding a value to an enum variable.

Verify that a change has been made in all source files such as adding an argument to an existing function.

Rename a global variable in all source files.

Change a constant to a preprocessor symbol in selected lines of files.

It is designed to answer questions like:
Where is this symbol used?
Where is it defined?
Where did this variable get its value?

```
        What is this global symbol's definition?
        Where is this function in the source files?
        What functions call this function?
        What functions are called by this function?
        Where does the message "out of space" come from?
        Where is this source file in the directory structure?
        What files include this header file?

  Cscope answers these questions from a symbol database that it builds the
  first time it is used on the source files.  On a subsequent call, cscope
  rebuilds the database only if a source file has changed or the list of
  source files is different.  When the database is rebuilt the data for the
  unchanged files is copied from the old database, which makes rebuilding
  much faster than the initial build.

                                     -----

When cscope is normally invoked, you will get a full-screen selection
screen allowing you to make a query for one of the above questions.
However, once a match is found to your query and you have entered your
text editor to edit the source file containing match, you cannot simply
jump from tag to tag as you normally would with vi's Ctrl-] or :tag
command.

Vim's cscope interface is done by invoking cscope with its line-oriented
interface, and then parsing the output returned from a query.  The end
result is that cscope query results become just like regular tags, so
you can jump to them just like you do with normal tags (Ctrl-] or :tag)
and then go back by popping off the tagstack with Ctrl-T.  (Please note
however, that you don't actually jump to a cscope tag simply by doing
Ctrl-] or :tag without remapping these commands or setting an option.
See the remaining sections on how the cscope interface works and for
suggested use.)

==============================================================================
2. Cscope related commands                                cscope-commands

                :cscope   :cs   :scs   :scscope   E259   E262   E561   E560
All cscope commands are accessed through suboptions to the cscope commands.
        `:cscope` or `:cs` is the main command
        `:scscope` or `:scs` does the same and splits the window
        `:lcscope` or `:lcs` uses the location list, see  :lcscope

The available subcommands are:

                        E563   E564   E566   E568   E622   E623   E625
                        E626   E609
    add   : Add a new cscope database/connection.

        USAGE   :cs add {file|dir} [pre-path] [flags]

            [pre-path] is the pathname used with the -P command to cscope.
```

[flags] are any additional flags you want to pass to cscope.

EXAMPLES
```
:cscope add /usr/local/cdb/cscope.out
:cscope add /projects/vim/cscope.out /usr/local/vim
:cscope add cscope.out /usr/local/vim -C
```

cscope-find cs-find E567

find : Query cscope. All cscope query options are available except option #5 ("Change this grep pattern").

USAGE :cs find {querytype} {name}

{querytype} corresponds to the actual cscope line interface numbers as well as default nvi commands:

0 or s: Find this C symbol
1 or g: Find this definition
2 or d: Find functions called by this function
3 or c: Find functions calling this function
4 or t: Find this text string
6 or e: Find this egrep pattern
7 or f: Find this file
8 or i: Find files #including this file
9 or a: Find places where this symbol is assigned a value

For all types, except 4 and 6, leading white space for {name} is removed. For 4 and 6 there is exactly one space between {querytype} and {name}. Further white space is included in {name}.

EXAMPLES
```
:cscope find c vim_free
:cscope find 3  vim_free
```

These two examples perform the same query: functions calling "vim_free".

```
:cscope find t initOnce
:cscope find t  initOnce
```

The first one searches for the text "initOnce", the second one for " initOnce".

```
:cscope find 0 DEFAULT_TERM
```

Executing this example on the source code for Vim 5.1 produces the following output:

```
Cscope tag: DEFAULT_TERM
   #   line  filename / context / line
   1   1009  vim-5.1-gtk/src/term.c <<GLOBAL>>
             #define DEFAULT_TERM (char_u *)"amiga"
   2   1013  vim-5.1-gtk/src/term.c <<GLOBAL>>
             #define DEFAULT_TERM (char_u *)"win32"
```

```
            3   1017  vim-5.1-gtk/src/term.c <<GLOBAL>>
                      #define DEFAULT_TERM (char_u *)"pcterm"
            4   1021  vim-5.1-gtk/src/term.c <<GLOBAL>>
                      #define DEFAULT_TERM (char_u *)"ansi"
            5   1025  vim-5.1-gtk/src/term.c <<GLOBAL>>
                      #define DEFAULT_TERM (char_u *)"vt52"
            6   1029  vim-5.1-gtk/src/term.c <<GLOBAL>>
                      #define DEFAULT_TERM (char_u *)"os2ansi"
            7   1033  vim-5.1-gtk/src/term.c <<GLOBAL>>
                      #define DEFAULT_TERM (char_u *)"ansi"
            8   1037  vim-5.1-gtk/src/term.c <<GLOBAL>>
                      # undef DEFAULT_TERM
            9   1038  vim-5.1-gtk/src/term.c <<GLOBAL>>
                      #define DEFAULT_TERM (char_u *)"beos-ansi"
           10   1042  vim-5.1-gtk/src/term.c <<GLOBAL>>
                      #define DEFAULT_TERM (char_u *)"mac-ansi"
           11   1335  vim-5.1-gtk/src/term.c <<set_termname>>
                      term = DEFAULT_TERM;
           12   1459  vim-5.1-gtk/src/term.c <<set_termname>>
                      if (STRCMP(term, DEFAULT_TERM))
           13   1826  vim-5.1-gtk/src/term.c <<termcapinit>>
                      term = DEFAULT_TERM;
           14   1833  vim-5.1-gtk/src/term.c <<termcapinit>>
                      term = DEFAULT_TERM;
           15   3635  vim-5.1-gtk/src/term.c <<update_tcap>>
                      p = find_builtin_term(DEFAULT_TERM);
    Enter nr of choice (<CR> to abort):

    The output shows several pieces of information:
    1. The tag number (there are 15 in this example).
    2. The line number where the tag occurs.
    3. The filename where the tag occurs.
    4. The context of the tag (e.g., global, or the function name).
    5. The line from the file itself.

help  : Show a brief synopsis.

    USAGE   :cs help

                                                          E261
kill  : Kill a cscope connection (or kill all cscope connections).

    USAGE   :cs kill {num|partial_name}

    To kill a cscope connection, the connection number or a partial
    name must be specified.  The partial name is simply any part of
    the pathname of the cscope database.  Kill a cscope connection
    using the partial name with caution!

    If the specified connection number is -1, then _ALL_ cscope
    connections will be killed.

reset : Reinit all cscope connections.
```

USAGE	:cs reset

show : Show cscope connections.

USAGE	:cs show

:lcscope :lcs

This command is same as the ":cscope" command, except when the 'cscopequickfix' option is set, the location list for the current window is used instead of the quickfix list to show the cscope results.

:cstag E257 E562

If you use cscope as well as ctags, :cstag allows you to search one or the other before making a jump. For example, you can choose to first search your cscope database(s) for a match, and if one is not found, then your tags file(s) will be searched. The order in which this happens is determined by the value of csto . See cscope-options for more details.

:cstag performs the equivalent of ":cs find g" on the identifier when searching through the cscope database(s).

:cstag performs the equivalent of :tjump on the identifier when searching through your tags file(s).

==

3. Cscope options cscope-options

Use the :set command to set all cscope options. Ideally, you would do this in one of your startup files (e.g., .vimrc). Some cscope related variables are only valid within .vimrc . Setting them after vim has started will have no effect!

cscopeprg csprg

'cscopeprg' specifies the command to execute cscope. The default is "cscope". For example:

```
:set csprg=/usr/local/bin/cscope
```

cscopequickfix csqf E469

{not available when compiled without the |+quickfix| feature}

'cscopequickfix' specifies whether to use quickfix window to show cscope results. This is a list of comma-separated values. Each item consists of cscope-find command (s, g, d, c, t, e, f, i or a) and flag (+, - or 0). '+' indicates that results must be appended to quickfix window, '-' implies previous results clearance, '0' or command absence - don't use quickfix. Search is performed from start until first command occurrence. The default value is "" (don't use quickfix anyway). The following value seems to be useful:

```
:set cscopequickfix=s-,c-,d-,i-,t-,e-,a-
```

cscopetag cst

If 'cscopetag' is set, the commands ":tag" and CTRL-] as well as "vim -t" will always use :cstag instead of the default :tag behavior. Effectively,

by setting 'cst', you will always search your cscope databases as well as
your tag files. The default is off. Examples:
	:set cst
	:set nocst

cscoperelative csre
If 'cscoperelative' is set, then in absence of a prefix given to cscope
(prefix is the argument of -P option of cscope), basename of cscope.out
location (usually the project root directory) will be used as the prefix
to construct an absolute path. The default is off. Note: This option is
only effective when cscope (cscopeprg) is initialized without a prefix
path (-P). Examples:
	:set csre
	:set nocsre

cscopetagorder csto
The value of 'csto' determines the order in which :cstag performs a search.
If 'csto' is set to zero, cscope database(s) are searched first, followed
by tag file(s) if cscope did not return any matches. If 'csto' is set to
one, tag file(s) are searched before cscope database(s). The default is zero.
Examples:
	:set csto=0
	:set csto=1

cscopeverbose csverb
If 'cscopeverbose' is not set (the default), messages will not be printed
indicating success or failure when adding a cscope database. Ideally, you
should reset this option in your .vimrc before adding any cscope databases,
and after adding them, set it. From then on, when you add more databases
within Vim, you will get a (hopefully) useful message should the database fail
to be added. Examples:
	:set csverb
	:set nocsverb

cscopepathcomp cspc
The value of 'cspc' determines how many components of a file's path to
display. With the default value of zero the entire path will be displayed.
The value one will display only the filename with no path. Other values
display that many components. For example:
	:set cspc=3
will display the last 3 components of the file's path, including the file
name itself.

==
4. How to use cscope in Vim cscope-howtouse

The first thing you need to do is to build a cscope database for your
source files. For the most basic case, simply do "cscope -b". Please
refer to the cscope man page for more details.

Assuming you have a cscope database, you need to "add" the database to Vim.
This establishes a cscope "connection" and makes it available for Vim to use.
You can do this in your .vimrc file, or you can do it manually after starting
vim. For example, to add the cscope database "cscope.out", you would do:

```
        :cs add cscope.out
```

You can double-check the result of this by executing ":cs show". This will produce output which looks like this:

```
 # pid    database name                       prepend path
 0 28806  cscope.out                          <none>
```

Note:
Because of the Microsoft RTL limitations, Win32 version shows 0 instead of the real pid.

Once a cscope connection is established, you can make queries to cscope and the results will be printed to you. Queries are made using the command ":cs find". For example:

```
        :cs find g ALIGN_SIZE
```

This can get a little cumbersome since one ends up doing a significant amount of typing. Fortunately, there are ways around this by mapping shortcut keys. See cscope-suggestions for suggested usage.

If the results return only one match, you will automatically be taken to it. If there is more than one match, you will be given a selection screen to pick the match you want to go to. After you have jumped to the new location, simply hit Ctrl-T to get back to the previous one.

==
5. Limitations cscope-limitations

Cscope support for Vim is only available on systems that support these four system calls: fork(), pipe(), execl(), waitpid(). This means it is mostly limited to Unix systems.

Additionally Cscope support works for Win32. For more information and a cscope version for Win32 see:

```
        http://iamphet.nm.ru/cscope/index.html
```

The DJGPP-built version from http://cscope.sourceforge.net is known to not work with Vim.

Hard-coded limitation: doing a :tjump when :cstag searches the tag files is not configurable (e.g., you can't do a tselect instead).

==
6. Suggested usage cscope-suggestions

Put these entries in your .vimrc (adjust the pathname accordingly to your setup):

```
        if has("cscope")
```

```
            set csprg=/usr/local/bin/cscope
            set csto=0
            set cst
            set nocsverb
            " add any database in current directory
            if filereadable("cscope.out")
                cs add cscope.out
            " else add database pointed to by environment
            elseif $CSCOPE_DB != ""
                cs add $CSCOPE_DB
            endif
            set csverb
    endif
```

By setting 'cscopetag', we have effectively replaced all instances of the :tag command with :cstag. This includes :tag, Ctrl-], and "vim -t". In doing this, the regular tag command not only searches your ctags generated tag files, but your cscope databases as well.

Some users may want to keep the regular tag behavior and have a different shortcut to access :cstag. For example, one could map Ctrl-_ (underscore) to :cstag with the following command:

```
    map <C-_> :cstag <C-R>=expand("<cword>")<CR><CR>
```

A couple of very commonly used cscope queries (using ":cs find") is to find all functions calling a certain function and to find all occurrences of a particular C symbol. To do this, you can use these mappings as an example:

```
    map g<C-]> :cs find 3 <C-R>=expand("<cword>")<CR><CR>
    map g<C-\> :cs find 0 <C-R>=expand("<cword>")<CR><CR>
```

These mappings for Ctrl-] (right bracket) and Ctrl-\ (backslash) allow you to place your cursor over the function name or C symbol and quickly query cscope for any matches.

Or you may use the following scheme, inspired by Vim/Cscope tutorial from Cscope Home Page (http://cscope.sourceforge.net/):

```
    nmap <C-_>s :cs find s <C-R>=expand("<cword>")<CR><CR>
    nmap <C-_>g :cs find g <C-R>=expand("<cword>")<CR><CR>
    nmap <C-_>c :cs find c <C-R>=expand("<cword>")<CR><CR>
    nmap <C-_>t :cs find t <C-R>=expand("<cword>")<CR><CR>
    nmap <C-_>e :cs find e <C-R>=expand("<cword>")<CR><CR>
    nmap <C-_>f :cs find f <C-R>=expand("<cfile>")<CR><CR>
    nmap <C-_>i :cs find i ^<C-R>=expand("<cfile>")<CR>$<CR>
    nmap <C-_>d :cs find d <C-R>=expand("<cword>")<CR><CR>
    nmap <C-_>a :cs find a <C-R>=expand("<cword>")<CR><CR>

    " Using 'CTRL-spacebar' then a search type makes the vim window
    " split horizontally, with search result displayed in
    " the new window.
```

```
        nmap <C-Space>s :scs find s <C-R>=expand("<cword>")<CR><CR>
        nmap <C-Space>g :scs find g <C-R>=expand("<cword>")<CR><CR>
        nmap <C-Space>c :scs find c <C-R>=expand("<cword>")<CR><CR>
        nmap <C-Space>t :scs find t <C-R>=expand("<cword>")<CR><CR>
        nmap <C-Space>e :scs find e <C-R>=expand("<cword>")<CR><CR>
        nmap <C-Space>f :scs find f <C-R>=expand("<cfile>")<CR><CR>
        nmap <C-Space>i :scs find i ^<C-R>=expand("<cfile>")<CR>$<CR>
        nmap <C-Space>d :scs find d <C-R>=expand("<cword>")<CR><CR>
        nmap <C-Space>a :scs find a <C-R>=expand("<cword>")<CR><CR>

        " Hitting CTRL-space *twice* before the search type does a vertical
        " split instead of a horizontal one

        nmap <C-Space><C-Space>s
               \:vert scs find s <C-R>=expand("<cword>")<CR><CR>
        nmap <C-Space><C-Space>g
               \:vert scs find g <C-R>=expand("<cword>")<CR><CR>
        nmap <C-Space><C-Space>c
               \:vert scs find c <C-R>=expand("<cword>")<CR><CR>
        nmap <C-Space><C-Space>t
               \:vert scs find t <C-R>=expand("<cword>")<CR><CR>
        nmap <C-Space><C-Space>e
               \:vert scs find e <C-R>=expand("<cword>")<CR><CR>
        nmap <C-Space><C-Space>i
               \:vert scs find i ^<C-R>=expand("<cfile>")<CR>$<CR>
        nmap <C-Space><C-Space>d
               \:vert scs find d <C-R>=expand("<cword>")<CR><CR>
        nmap <C-Space><C-Space>a
               \:vert scs find a <C-R>=expand("<cword>")<CR><CR>
```

==========

7. Cscope availability and information cscope-info

If you do not already have cscope (it did not come with your compiler license or OS distribution), then you can download it for free from:

        http://cscope.sourceforge.net/

This is released by SCO under the BSD license.

In Solaris 2.x, if you have the C compiler license, you will also have cscope. Both are usually located under /opt/SUNWspro/bin

There is source to an older version of a cscope clone (called "cs") available on the net. Due to various reasons, this is not supported with Vim.

The cscope interface/support for Vim was originally written by Andy Kahn <ackahn@netapp.com>. The original structure (as well as a tiny bit of code) was adapted from the cscope interface in nvi.

cscope-win32

For a cscope version for Win32 see (seems abandoned):

        https://code.google.com/archive/p/cscope-win32/

Win32 support was added by Sergey Khorev <sergey.khorev@gmail.com>. Contact him if you have Win32-specific issues.

if_lua.txt For Vim version 8.1. Last change: 2015 Oct 16

VIM REFERENCE MANUAL by Luis Carvalho

The Lua Interface to Vim lua Lua

{Vi does not have any of these commands}

The Lua interface is available only when Vim was compiled with the
+lua feature.

==========

1. Commands lua-commands

:lua

:[range]lua {chunk}
Execute Lua chunk {chunk}. {not in Vi}

Examples:

```
:lua print("Hello, Vim!")
:lua local curbuf = vim.buffer() curbuf[7] = "line #7"
```

:[range]lua << {endmarker}
{script}
{endmarker}
Execute Lua script {script}. {not in Vi}
Note: This command doesn't work when the Lua
feature wasn't compiled in. To avoid errors, see
script-here .

{endmarker} must NOT be preceded by any white space. If {endmarker} is
omitted from after the "<<", a dot '.' must be used after {script}, like
for the :append and :insert commands.
This form of the :lua command is mainly useful for including Lua code
in Vim scripts.

Example:

```
function! CurrentLineInfo()
lua << EOF
```

```
        local linenr = vim.window().line
        local curline = vim.buffer()[linenr]
        print(string.format("Current line [%d] has %d chars",
                linenr, #curline))
        EOF
        endfunction
```

To see what version of Lua you have:

```
        :lua print(_VERSION)
```

If you use LuaJIT you can also use this:

```
        :lua print(jit.version)
```

:luado

:[range]luado {body} Execute Lua function "function (line, linenr) {body} end" for each line in the [range], with the function argument being set to the text of each line in turn, without a trailing <EOL>, and the current line number. If the value returned by the function is a string it becomes the text of the line in the current turn. The default for [range] is the whole file: "1,$". {not in Vi}

Examples:

```
        :luado return string.format("%s\t%d", line:reverse(), #line)

        :lua require"lpeg"
        :lua -- balanced parenthesis grammar:
        :lua bp = lpeg.P{ "(" * ((1 - lpeg.S"()") + lpeg.V(1))^0 * ")" }
        :luado if bp:match(line) then return "-->\t" .. line end
```

:luafile

:[range]luafile {file}
        Execute Lua script in {file}. {not in Vi}
        The whole argument is used as a single file name.

Examples:

```
        :luafile script.lua
        :luafile %
```

All these commands execute a Lua chunk from either the command line (:lua and :luado) or a file (:luafile) with the given line [range]. Similarly to the Lua interpreter, each chunk has its own scope and so only global variables are shared between command calls. All Lua default libraries are available. In addition, Lua "print" function has its output redirected to the Vim message area, with arguments separated by a white space instead of a tab.

Lua uses the "vim" module (see lua-vim) to issue commands to Vim and manage buffers (lua-buffer) and windows (lua-window). However,

procedures that alter buffer content, open new buffers, and change cursor position are restricted when the command is executed in the sandbox .

==
2. The vim module lua-vim

Lua interfaces Vim through the "vim" module. The first and last line of the input range are stored in "vim.firstline" and "vim.lastline" respectively. The module also includes routines for buffer, window, and current line queries, Vim evaluation and command execution, and others.

vim.list([arg])
Returns an empty list or, if "arg" is a Lua table with numeric keys 1, ..., n (a "sequence"), returns a list l such that l[i] = arg[i] for i = 1, ..., n (see List). Non-numeric keys are not used to initialize the list. See also lua-eval for conversion rules. Example:

```
:lua t = {math.pi, false, say = 'hi'}
:echo luaeval('vim.list(t)')
:" [3.141593, v:false], 'say' is ignored
```

vim.dict([arg])
Returns an empty dictionary or, if "arg" is a Lua table, returns a dict d such that d[k] = arg[k] for all string keys k in "arg" (see Dictionary). Number keys are converted to strings. Keys that are not strings are not used to initialize the dictionary. See also lua-eval for conversion rules. Example:

```
:lua t = {math.pi, false, say = 'hi'}
:echo luaeval('vim.dict(t)')
:" {'1': 3.141593, '2': v:false,
:" 'say': 'hi'}
```

vim.funcref({name})
Returns a Funcref to function {name} (see Funcref). It is equivalent to Vim's function().

vim.buffer([arg])
If "arg" is a number, returns buffer with number "arg" in the buffer list or, if "arg" is a string, returns buffer whose full or short name is "arg". In both cases, returns 'nil' (nil value, not string) if the buffer is not found. Otherwise, if "toboolean(arg)" is 'true' returns the first buffer in the buffer list or else the current buffer.

vim.window([arg])
If "arg" is a number, returns window with number "arg" or 'nil' (nil value, not string) if not found. Otherwise, if "toboolean(arg)" is 'true' returns the first window or else the current window.

vim.type({arg}) Returns the type of {arg}. It is equivalent to Lua's "type" function, but returns "list", "dict", "funcref", "buffer", or "window" if {arg} is a list, dictionary, funcref, buffer, or window, respectively. Examples:

```
:lua l = vim.list()
:lua print(type(l), vim.type(l))
:" list
```

vim.command({cmd}) Executes the vim (ex-mode) command {cmd}. Examples:

```
:lua vim.command"set tw=60"
:lua vim.command"normal ddp"
```

vim.eval({expr}) Evaluates expression {expr} (see expression), converts the result to Lua, and returns it. Vim strings and numbers are directly converted to Lua strings and numbers respectively. Vim lists and dictionaries are converted to Lua userdata (see lua-list and lua-dict). Examples:

```
:lua tw = vim.eval"&tw"
:lua print(vim.eval"{'a': 'one'}".a)
```

vim.line() Returns the current line (without the trailing <EOL>), a Lua string.

vim.beep() Beeps.

vim.open({fname}) Opens a new buffer for file {fname} and returns it. Note that the buffer is not set as current.

==
3. List userdata lua-list

List userdata represent vim lists, and the interface tries to follow closely Vim's syntax for lists. Since lists are objects, changes in list references in Lua are reflected in Vim and vice-versa. A list "l" has the following properties and methods:

Properties

- "#l" is the number of items in list "l", equivalent to "len(l)" in Vim.
- "l[k]" returns the k-th item in "l"; "l" is zero-indexed, as in Vim. To modify the k-th item, simply do "l[k] = newitem"; in particular, "l[k] = nil" removes the k-th item from "l".
- "l()" returns an iterator for "l".

Methods

- "l:add(item)" appends "item" to the end of "l".

- "l:insert(item[, pos])" inserts "item" at (optional) position "pos" in the list. The default value for "pos" is 0.

Examples:

```
:let l = [1, 'item']
:lua l = vim.eval('l') -- same 'l'
:lua l:add(vim.list())
:lua l[0] = math.pi
:echo l[0] " 3.141593
:lua l[0] = nil -- remove first item
:lua l:insert(true, 1)
:lua print(l, #l, l[0], l[1], l[-1])
:lua for item in l() do print(item) end
```

==
4. Dict userdata lua-dict

Similarly to list userdata, dict userdata represent vim dictionaries; since dictionaries are also objects, references are kept between Lua and Vim. A dict "d" has the following properties:

Properties

- "#d" is the number of items in dict "d", equivalent to "len(d)" in Vim.
- "d.key" or "d['key']" returns the value at entry "key" in "d". To modify the entry at this key, simply do "d.key = newvalue"; in particular, "d.key = nil" removes the entry from "d".
- "d()" returns an iterator for "d" and is equivalent to "items(d)" in Vim.

Examples:

```
:let d = {'n':10}
:lua d = vim.eval('d') -- same 'd'
:lua print(d, d.n, #d)
:let d.self = d
:lua for k, v in d() do print(d, k, v) end
:lua d.x = math.pi
:lua d.self = nil -- remove entry
:echo d
```

==
5. Funcref userdata lua-funcref

Funcref userdata represent funcref variables in Vim. Funcrefs that were defined with a "dict" attribute need to be obtained as a dictionary key in order to have "self" properly assigned to the dictionary (see examples below.) A funcref "f" has the following properties:

Properties

- "#f" is the name of the function referenced by "f"
- "f(...)" calls the function referenced by "f" (with arguments)

Examples:

```
:function I(x)
:  return a:x
:  endfunction
:let R = function('I')
:lua i1 = vim.funcref('I')
:lua i2 = vim.eval('R')
:lua print(#i1, #i2) -- both 'I'
:lua print(i1, i2, #i2(i1) == #i1(i2))
:function Mylen() dict
:  return len(self.data)
:  endfunction
:let mydict = {'data': [0, 1, 2, 3]}
:lua d = vim.eval('mydict'); d.len = vim.funcref('Mylen')
:echo mydict.len()
:lua l = d.len -- assign d as 'self'
:lua print(l())
```

==========

6. Buffer userdata lua-buffer

Buffer userdata represent vim buffers. A buffer userdata "b" has the following properties and methods:

Properties

- "b()" sets "b" as the current buffer.
- "#b" is the number of lines in buffer "b".
- "b[k]" represents line number k: "b[k] = newline" replaces line k with string "newline" and "b[k] = nil" deletes line k.
- "b.name" contains the short name of buffer "b" (read-only).
- "b.fname" contains the full name of buffer "b" (read-only).
- "b.number" contains the position of buffer "b" in the buffer list (read-only).

Methods

- "b:insert(newline[, pos])" inserts string "newline" at (optional) position "pos" in the buffer. The default value for "pos" is "#b + 1". If "pos == 0" then "newline" becomes the first line in the buffer.
- "b:next()" returns the buffer next to "b" in the buffer list.
- "b:previous()" returns the buffer previous to "b" in the buffer list.
- "b:isvalid()" returns 'true' (boolean) if buffer "b" corresponds to a "real" (not freed from memory) Vim buffer.

Examples:

```
:lua b = vim.buffer() -- current buffer
:lua print(b.name, b.number)
:lua b[1] = "first line"
:lua b:insert("FIRST!", 0)
:lua b[1] = nil -- delete top line
:lua for i=1,3 do b:insert(math.random()) end
:3,4lua for i=vim.lastline,vim.firstline,-1 do b[i] = nil end
:lua vim.open"myfile"() -- open buffer and set it as current

function! ListBuffers()
lua << EOF
local b = vim.buffer(true) -- first buffer in list
while b ~= nil do
        print(b.number, b.name, #b)
        b = b:next()
end
vim.beep()
EOF
endfunction
```

==
7. Window userdata   lua-window

Window objects represent vim windows. A window userdata "w" has the following properties and methods:

Properties

- "w()" sets "w" as the current window.
- "w.buffer" contains the buffer of window "w" (read-only).
- "w.line" represents the cursor line position in window "w".
- "w.col" represents the cursor column position in window "w".
- "w.width" represents the width of window "w".
- "w.height" represents the height of window "w".

Methods

- "w:next()" returns the window next to "w".
- "w:previous()" returns the window previous to "w".
- "w:isvalid()" returns 'true' (boolean) if window "w" corresponds to a "real" (not freed from memory) Vim window.

Examples:

```
:lua w = vim.window() -- current window
:lua print(w.buffer.name, w.line, w.col)
:lua w.width = w.width + math.random(10)
:lua w.height = 2 * math.random() * w.height
:lua n,w = 0,vim.window(true) while w~=nil do n,w = n + 1,w:next() end
:lua print("There are " .. n .. " windows")
```

==
8. The luaeval function   lua-luaeval lua-eval

The (dual) equivalent of "vim.eval" for passing Lua values to Vim is
"luaeval". "luaeval" takes an expression string and an optional argument and
returns the result of the expression. It is semantically equivalent in Lua to:

```
local chunkheader = "local _A = select(1, ...) return "
function luaeval (expstr, arg)
    local chunk = assert(loadstring(chunkheader .. expstr, "luaeval"))
    return chunk(arg) -- return typval
end
```

Note that "_A" receives the argument to "luaeval". Lua numbers, strings, and
list, dict, and funcref userdata are converted to their Vim respective types,
while Lua booleans are converted to numbers. An error is thrown if conversion
of any of the remaining Lua types, including userdata other than lists, dicts,
and funcrefs, is attempted.

Examples:

```
:echo luaeval('math.pi')
:lua a = vim.list():add('newlist')
:let a = luaeval('a')
:echo a[0] " 'newlist'
:function Rand(x,y) " random uniform between x and y
:  return luaeval('(_A.y-_A.x)*math.random()+_A.x', {'x':a:x,'y':a:y})
:  endfunction
:echo Rand(1,10)
```

==
9. Dynamic loading   lua-dynamic

On MS-Windows and Unix the Lua library can be loaded dynamically. The
:version output then includes +lua/dyn .

This means that Vim will search for the Lua DLL or shared library file only
when needed. When you don't use the Lua interface you don't need it, thus
you can use Vim without this file.

MS-Windows

To use the Lua interface the Lua DLL must be in your search path. In a
console window type "path" to see what directories are used. The 'luadll'
option can be also used to specify the Lua DLL. The version of the DLL must
match the Lua version Vim was compiled with.

Unix

The 'luadll' option can be used to specify the Lua shared library file instead
of DYNAMIC_LUA_DLL file what was specified at compile time. The version of

the shared library must match the Lua version Vim was compiled with.

==
 vim:tw=78:ts=8:noet:ft=help:norl:

if_mzsch.txt For Vim version 8.1. Last change: 2017 Oct 08

VIM REFERENCE MANUAL by Sergey Khorev

The MzScheme Interface to Vim mzscheme MzScheme

{Vi does not have any of these commands}

The MzScheme interface is available only if Vim was compiled with the
 +mzscheme feature.

Based on the work of Brent Fulgham.
Dynamic loading added by Sergey Khorev

MzScheme and PLT Scheme names have been rebranded as Racket. For more
information please check http://racket-lang.org

Futures and places of Racket version 5.x up to and including 5.3.1 do not
work correctly with processes created by Vim.
The simplest solution is to build Racket on your own with these features
disabled:
  ./configure --disable-futures --disable-places --prefix=your-install-prefix

To speed up the process, you might also want to use --disable-gracket and
--disable-docs

==
1. Commands mzscheme-commands

  :mzscheme :mz
:[range]mz[scheme] {stmt}
  Execute MzScheme statement {stmt}. {not in Vi}

:[range]mz[scheme] << {endmarker}
{script}
{endmarker}
  Execute inlined MzScheme script {script}.
  Note: This command doesn't work if the MzScheme
  feature wasn't compiled in. To avoid errors, see
   script-here .

  :mzfile :mzf
:[range]mzf[ile] {file} Execute the MzScheme script in {file}. {not in Vi}

All of these commands do essentially the same thing - they execute a piece of
MzScheme code, with the "current range" set to the given line
range.

In the case of :mzscheme, the code to execute is in the command-line.
In the case of :mzfile, the code to execute is the contents of the given file.

MzScheme interface defines exception exn:vim, derived from exn.
It is raised for various Vim errors.

During compilation, the MzScheme interface will remember the current MzScheme
collection path. If you want to specify additional paths use the
'current-library-collection-paths' parameter. E.g., to cons the user-local
MzScheme collection path:

```
    :mz << EOF
    (current-library-collection-paths
        (cons
            (build-path (find-system-path 'addon-dir) (version) "collects")
            (current-library-collection-paths)))
    EOF
```

All functionality is provided through module vimext.

The exn:vim is available without explicit import.

To avoid clashes with MzScheme, consider using prefix when requiring module,
e.g.:

```
        :mzscheme (require (prefix vim- vimext))
```

All the examples below assume this naming scheme.

mzscheme-sandbox

When executed in the sandbox, access to some filesystem and Vim interface
procedures is restricted.

==
2. Examples mzscheme-examples

```
        :mzscheme (display "Hello")
        :mz (display (string-append "Using MzScheme version " (version)))
        :mzscheme (require (prefix vim- vimext)) ; for MzScheme < 4.x
        :mzscheme (require (prefix-in vim- 'vimext)) ; MzScheme 4.x
        :mzscheme (vim-set-buff-line 10 "This is line #10")
```

To see what version of MzScheme you have:

```
        :mzscheme (display (version))
```

Inline script usage:

```
        function! <SID>SetFirstLine()
            :mz << EOF
            (display "!!!")
            (require (prefix vim- vimext))
```

```
            ; for newer versions (require (prefix-in vim- 'vimext))
            (vim-set-buff-line 1 "This is line #1")
            (vim-beep)
        EOF
        endfunction

        nmap <F9> :call <SID>SetFirstLine() <CR>
```

File execution:

```
        :mzfile supascript.scm
```

Vim exception handling:

```
        :mz << EOF
        (require (prefix vim- vimext))
        ; for newer versions (require (prefix-in vim- 'vimext))
        (with-handlers
          ([exn:vim? (lambda (e) (display (exn-message e)))])
          (vim-eval "nonsense-string"))
        EOF
```

Auto-instantiation of vimext module (can be placed in your vimrc):

```
    function! MzRequire()
        :redir => l:mzversion
        :mz (version)
        :redir END
        if strpart(l:mzversion, 1, 1) < "4"
            " MzScheme versions < 4.x:
            :mz (require (prefix vim- vimext))
        else
            " newer versions:
            :mz (require (prefix-in vim- 'vimext))
        endif
    endfunction

    if has("mzscheme")
        silent call MzRequire()
    endif
```

==

3. Threads mzscheme-threads

The MzScheme interface supports threads. They are independent from OS threads, thus scheduling is required. The option 'mzquantum' determines how often Vim should poll for available MzScheme threads.

NOTE
Thread scheduling in the console version of Vim is less reliable than in the GUI version.

==

4. Vim access from MzScheme mzscheme-vim

mzscheme-vimext

The 'vimext' module provides access to procedures defined in the MzScheme interface.

```
Common
------
    (command {command-string})      Perform the vim ":Ex" style command.
    (eval {expr-string})            Evaluate the vim expression into
                                    respective MzScheme object:  Lists  are
                                    represented as Scheme lists,
                                     Dictionaries  as hash tables,
                                     Funcref s as functions (see also
                                     mzscheme-funcref )
                                    NOTE the name clashes with MzScheme eval,
                                    use module qualifiers to overcome this.
    (range-start)                   Start/End of the range passed with
    (range-end)                     the Scheme command.
    (beep)                          beep
    (get-option {option-name} [buffer-or-window]) Get Vim option value (either
                                    local or global, see set-option).
    (set-option {string} [buffer-or-window])
                                    Set a Vim option. String must have option
                                    setting form (like optname=optval, or
                                    optname+=optval, etc.) When called with
                                    {buffer} or {window} the local option will
                                    be set. The symbol 'global can be passed
                                    as {buffer-or-window}. Then  :setglobal
                                    will be used.

Buffers                                                   mzscheme-buffer
-------
    (buff? {object})                Is object a buffer?
    (buff-valid? {object})          Is object a valid buffer? (i.e.
                                    corresponds to the real Vim buffer)
    (get-buff-line {linenr} [buffer])
                                    Get line from a buffer.
    (set-buff-line {linenr} {string} [buffer])
                                    Set a line in a buffer. If {string} is #f,
                                    the line gets deleted.  The [buffer]
                                    argument is optional. If omitted, the
                                    current buffer will be used.
    (get-buff-line-list {start} {end} [buffer])
                                    Get a list of lines in a buffer. {Start}
                                    and {end} are 1-based and inclusive.
    (set-buff-line-list {start} {end} {string-list} [buffer])
                                    Set a list of lines in a buffer. If
                                    string-list is #f or null, the lines get
                                    deleted. If a list is shorter than
                                    {end}-{start} the remaining lines will
                                    be deleted.
    (get-buff-name [buffer])        Get a buffer's text name.
    (get-buff-num [buffer])         Get a buffer's number.
    (get-buff-size [buffer])        Get buffer line count.
    (insert-buff-line-list {linenr} {string/string-list} [buffer])
                                    Insert a list of lines into a buffer after
                                    {linenr}. If {linenr} is 0, lines will be
                                    inserted at start.
```

```
    (curr-buff)                     Get the current buffer. Use other MzScheme
                                    interface procedures to change it.
    (buff-count)                    Get count of total buffers in the editor.
    (get-next-buff [buffer])        Get next buffer.
    (get-prev-buff [buffer])        Get previous buffer. Return #f when there
                                    are no more buffers.
    (open-buff {filename})          Open a new buffer (for file "name")
    (get-buff-by-name {buffername}) Get a buffer by its filename or #f
                                        if there is no such buffer.
    (get-buff-by-num {buffernum})   Get a buffer by its number (return #f if
                                    there is no buffer with this number).

Windows                                                     mzscheme-window
------
    (win? {object})                 Is object a window?
    (win-valid? {object})           Is object a valid window (i.e. corresponds
                                    to the real Vim window)?
    (curr-win)                      Get the current window.
    (win-count)                     Get count of windows.
    (get-win-num [window])          Get window number.
    (get-win-by-num {windownum})    Get window by its number.
    (get-win-buffer     [window])   Get the buffer for a given window.
    (get-win-height [window])
    (set-win-height {height} [window])  Get/Set height of window.
    (get-win-width [window])
    (set-win-width {width} [window])Get/Set width of window.
    (get-win-list [buffer])         Get list of windows for a buffer.
    (get-cursor [window])           Get cursor position in a window as
                                    a pair (linenr . column).
    (set-cursor (line . col) [window])  Set cursor position.

==============================================================================
5. mzeval() Vim function                                    mzscheme-mzeval

To facilitate bi-directional interface, you can use  mzeval()  function to
evaluate MzScheme expressions and pass their values to Vim script.

==============================================================================
6. Using Function references                                mzscheme-funcref

MzScheme interface allows use of  Funcref s so you can call Vim functions
directly from Scheme. For instance:
    function! MyAdd2(arg)
        return a:arg + 2
    endfunction
    mz (define f2 (vim-eval "function(\"MyAdd2\")"))
    mz (f2 7)
 or :
    :mz (define indent (vim-eval "function('indent')"))
    " return Vim indent for line 12
    :mz (indent 12)

==============================================================================
```

7. Dynamic loading mzscheme-dynamic E815

On MS-Windows the MzScheme libraries can be loaded dynamically. The :version output then includes +mzscheme/dyn .

This means that Vim will search for the MzScheme DLL files only when needed. When you don't use the MzScheme interface you don't need them, thus you can use Vim without these DLL files.
NOTE: Newer version of MzScheme (Racket) require earlier (trampolined) initialisation via scheme_main_setup. So Vim always loads the MzScheme DLL at startup if possible. This may make Vim startup slower.

To use the MzScheme interface the MzScheme DLLs must be in your search path. In a console window type "path" to see what directories are used.

On MS-Windows the options 'mzschemedll' and 'mzschemegcdll' are used for the name of the library to load. The initial value is specified at build time.

The version of the DLL must match the MzScheme version Vim was compiled with. For MzScheme version 209 they will be "libmzsch209_000.dll" and "libmzgc209_000.dll". To know for sure look at the output of the ":version" command, look for -DDYNAMIC_MZSCH_DLL="something" and -DDYNAMIC_MZGC_DLL="something" in the "Compilation" info.

For example, if MzScheme (Racket) is installed at C:\Racket63, you may need to set the environment variable as the following:

```
PATH=%PATH%;C:\Racket63\lib
PLTCOLLECTS=C:\Racket63\collects
PLTCONFIGDIR=C:\Racket63\etc
```

8. MzScheme setup mzscheme-setup E895

Vim requires "racket/base" module for if_mzsch core (fallback to "scheme/base" if it doesn't exist), "r5rs" module for test and "raco ctool" command for building Vim. If MzScheme did not have them, you can install them with MzScheme's raco command:

```
raco pkg install scheme-lib       # scheme/base module
raco pkg install r5rs-lib         # r5rs module
raco pkg install cext-lib         # raco ctool command
```

vim:tw=78:ts=8:noet:sts=4:ft=help:norl:

if_perl.txt For Vim version 8.1. Last change: 2017 Nov 24

VIM REFERENCE MANUAL by Sven Verdoolaege
and Matt Gerassimof

Perl and Vim perl Perl

{Vi does not have any of these commands}

The Perl interface only works when Vim was compiled with the +perl feature.

==========

1. Editing Perl files perl-editing

Vim syntax highlighting supports Perl and POD files. Vim assumes a file is Perl code if the filename has a .pl or .pm suffix. Vim also examines the first line of a file, regardless of the filename suffix, to check if a file is a Perl script (see scripts.vim in Vim's syntax directory). Vim assumes a file is POD text if the filename has a .POD suffix.

To use tags with Perl, you need a recent version of Exuberant ctags. Look here:
http://ctags.sourceforge.net

Alternatively, you can use the Perl script pltags.pl, which is shipped with Vim in the $VIMRUNTIME/tools directory. This script has currently more features than Exuberant ctags' Perl support.

==========

2. Compiling Vim with Perl interface perl-compiling

To compile Vim with Perl interface, you need Perl 5.004 (or later). Perl must be installed before you compile Vim. Vim's Perl interface does NOT work with the 5.003 version that has been officially released! It will probably work with Perl 5.003_05 and later.

The Perl patches for Vim were made by:
Sven Verdoolaege <skimo@breughel.ufsia.ac.be>
Matt Gerassimof

Perl for MS-Windows (and other platforms) can be found at:
http://www.perl.org/ The ActiveState one should work, Strawberry Perl is a good alternative.

==========

3. Using the Perl interface perl-using

:perl :pe

:pe[rl] {cmd}		Execute Perl command {cmd}. The current package
		is "main". Simple example to test if `:perl` is
		working:
			:perl VIM::Msg("Hello")

:pe[rl] << {endpattern}
{script}
{endpattern}
		Execute Perl script {script}.
		{endpattern} must NOT be preceded by any white space.
		If {endpattern} is omitted, it defaults to a dot '.'
		like for the :append and :insert commands. Using
		'.' helps when inside a function, because "$i;" looks
		like the start of an :insert command to Vim.
		This form of the :perl command is mainly useful for
		including perl code in vim scripts.
		Note: This command doesn't work when the Perl feature
		wasn't compiled in. To avoid errors, see
		 script-here .

Example vim script:

```
	function! WhitePearl()
	perl << EOF
		VIM::Msg("pearls are nice for necklaces");
		VIM::Msg("rubys for rings");
		VIM::Msg("pythons for bags");
		VIM::Msg("tcls????");
	EOF
	endfunction
```

To see what version of Perl you have:

```
	:perl print $^V
```

:perldo :perld

:[range]perld[o] {cmd}	Execute Perl command {cmd} for each line in the
		[range], with $_ being set to the text of each line in
		turn, without a trailing <EOL>. Setting $_ will change
		the text, but note that it is not possible to add or
		delete lines using this command.
		The default for [range] is the whole file: "1,$".

Here are some things you can try:

```
  :perl $a=1
  :perldo $_ = reverse($_);1
  :perl VIM::Msg("hello")
  :perl $line = $curbuf->Get(42)
```

E299

Executing Perl commands in the sandbox is limited. ":perldo" will not be
possible at all. ":perl" will be evaluated in the Safe environment, if

possible.

perl-overview

Here is an overview of the functions that are available to Perl:

```
:perl VIM::Msg("Text")               # displays a message
:perl VIM::Msg("Wrong!", "ErrorMsg")  # displays an error message
:perl VIM::Msg("remark", "Comment")   # displays a highlighted message
:perl VIM::SetOption("ai")            # sets a vim option
:perl $nbuf = VIM::Buffers()          # returns the number of buffers
:perl @buflist = VIM::Buffers()       # returns array of all buffers
:perl $mybuf = (VIM::Buffers('qq.c'))[0] # returns buffer object for 'qq.c'
:perl @winlist = VIM::Windows()       # returns array of all windows
:perl $nwin = VIM::Windows()          # returns the number of windows
:perl ($success, $v) = VIM::Eval('&path') # $v: option 'path', $success: 1
:perl ($success, $v) = VIM::Eval('&xyz')  # $v: '' and $success: 0
:perl $v = VIM::Eval('expand("<cfile>")') # expands <cfile>
:perl $curwin->SetHeight(10)          # sets the window height
:perl @pos = $curwin->Cursor()        # returns (row, col) array
:perl @pos = (10, 10)
:perl $curwin->Cursor(@pos)           # sets cursor to @pos
:perl $curwin->Cursor(10,10)          # sets cursor to row 10 col 10
:perl $mybuf = $curwin->Buffer()      # returns the buffer object for window
:perl $curbuf->Name()                 # returns buffer name
:perl $curbuf->Number()               # returns buffer number
:perl $curbuf->Count()                # returns the number of lines
:perl $l = $curbuf->Get(10)           # returns line 10
:perl @l = $curbuf->Get(1 .. 5)       # returns lines 1 through 5
:perl $curbuf->Delete(10)             # deletes line 10
:perl $curbuf->Delete(10, 20)         # delete lines 10 through 20
:perl $curbuf->Append(10, "Line")     # appends a line
:perl $curbuf->Append(10, "Line1", "Line2", "Line3") # appends 3 lines
:perl @l = ("L1", "L2", "L3")
:perl $curbuf->Append(10, @l)         # appends L1, L2 and L3
:perl $curbuf->Set(10, "Line")        # replaces line 10
:perl $curbuf->Set(10, "Line1", "Line2")      # replaces lines 10 and 11
:perl $curbuf->Set(10, @l)            # replaces 3 lines
```

perl-Msg

VIM::Msg({msg}, {group}?)
Displays the message {msg}. The optional {group} argument specifies a highlight group for Vim to use for the message.

perl-SetOption

VIM::SetOption({arg}) Sets a vim option. {arg} can be any argument that the ":set" command accepts. Note that this means that no spaces are allowed in the argument! See :set .

perl-Buffers

VIM::Buffers([{bn}...]) With no arguments, returns a list of all the buffers in an array context or returns the number of buffers in a scalar context. For a list of buffer names or

numbers {bn}, returns a list of the buffers matching {bn}, using the same rules as Vim's internal bufname() function.
WARNING: the list becomes invalid when :bwipe is used. Using it anyway may crash Vim.

perl-Windows
VIM::Windows([{wn}...]) With no arguments, returns a list of all the windows in an array context or returns the number of windows in a scalar context. For a list of window numbers {wn}, returns a list of the windows with those numbers.
WARNING: the list becomes invalid when a window is closed. Using it anyway may crash Vim.

perl-DoCommand
VIM::DoCommand({cmd}) Executes Ex command {cmd}.

perl-Eval
VIM::Eval({expr}) Evaluates {expr} and returns (success, value) in list context or just value in scalar context.
success=1 indicates that val contains the value of {expr}; success=0 indicates a failure to evaluate the expression. '@x' returns the contents of register x, '&x' returns the value of option x, 'x' returns the value of internal variables x, and '$x' is equivalent to perl's $ENV{x}. All functions accessible from the command-line are valid for {expr}.
A List is turned into a string by joining the items and inserting line breaks.

perl-SetHeight
Window->SetHeight({height})
Sets the Window height to {height}, within screen limits.

perl-GetCursor
Window->Cursor({row}?, {col}?)
With no arguments, returns a (row, col) array for the current cursor position in the Window. With {row} and {col} arguments, sets the Window's cursor position to {row} and {col}. Note that {col} is numbered from 0, Perl-fashion, and thus is one less than the value in Vim's ruler.

Window->Buffer() perl-Buffer
Returns the Buffer object corresponding to the given Window.

perl-Name
Buffer->Name() Returns the filename for the Buffer.

perl-Number
Buffer->Number() Returns the number of the Buffer.

perl-Count
Buffer->Count()		Returns the number of lines in the Buffer.

perl-Get
Buffer->Get({lnum}, {lnum}?, ...)
			Returns a text string of line {lnum} in the Buffer
			for each {lnum} specified. An array can be passed
			with a list of {lnum}'s specified.

perl-Delete
Buffer->Delete({lnum}, {lnum}?)
			Deletes line {lnum} in the Buffer. With the second
			{lnum}, deletes the range of lines from the first
			{lnum} to the second {lnum}.

perl-Append
Buffer->Append({lnum}, {line}, {line}?, ...)
			Appends each {line} string after Buffer line {lnum}.
			The list of {line}s can be an array.

perl-Set
Buffer->Set({lnum}, {line}, {line}?, ...)
			Replaces one or more Buffer lines with specified
			{lines}s, starting at Buffer line {lnum}. The list of
			{line}s can be an array. If the arguments are
			invalid, replacement does not occur.

$main::curwin
			The current window object.

$main::curbuf
			The current buffer object.

script-here
When using a script language in-line, you might want to skip this when the
language isn't supported. But this mechanism doesn't work:
>
   if has('perl')
     perl << EOF
       this will NOT work!
   EOF
   endif
<
Instead, put the Perl/Python/Ruby/etc. command in a function and call that
function:
>
    if has('perl')
      function DefPerl()
        perl << EOF
          this works
    EOF
      endfunction
      call DefPerl()
    endif
<
Note that "EOF" must be at the start of the line.

==
4. Dynamic loading   perl-dynamic

On MS-Windows and Unix the Perl library can be loaded dynamically. The
 :version output then includes +perl/dyn .

This means that Vim will search for the Perl DLL or shared library file only
when needed. When you don't use the Perl interface you don't need it, thus
you can use Vim without this file.

MS-Windows

You can download Perl from http://www.perl.org. The one from ActiveState was
used for building Vim.

To use the Perl interface the Perl DLL must be in your search path.
If Vim reports it cannot find the perl512.dll, make sure your $PATH includes
the directory where it is located. The Perl installer normally does that.
In a console window type "path" to see what directories are used. The
'perldll' option can be also used to specify the Perl DLL.

The name of the DLL must match the Perl version Vim was compiled with.
Currently the name is "perl512.dll". That is for Perl 5.12. To know for
sure edit "gvim.exe" and search for "perl\d*.dll\c".

Unix

The 'perldll' option can be used to specify the Perl shared library file
instead of DYNAMIC_PERL_DLL file what was specified at compile time. The
version of the shared library must match the Perl version Vim was compiled
with.

if_pyth.txt For Vim version 8.1. Last change: 2018 Jan 30

VIM REFERENCE MANUAL by Paul Moore

The Python Interface to Vim python Python

{Vi does not have any of these commands}

The Python 2.x interface is available only when Vim was compiled with the
+python feature.
The Python 3 interface is available only when Vim was compiled with the
+python3 feature.
Both can be available at the same time, but read python-2-and-3 .

==========
1. Commands python-commands

:python :py E263 E264 E887
:[range]py[thon] {stmt}
Execute Python statement {stmt}. A simple check if
the `:python` command is working:
:python print "Hello"

:[range]py[thon] << {endmarker}
{script}
{endmarker}
Execute Python script {script}.
Note: This command doesn't work when the Python
feature wasn't compiled in. To avoid errors, see
script-here .

{endmarker} must NOT be preceded by any white space. If {endmarker} is
omitted from after the "<<", a dot '.' must be used after {script}, like
for the :append and :insert commands.
This form of the :python command is mainly useful for including python code
in Vim scripts.

Example:
```
function! IcecreamInitialize()
```

```
        python << EOF
        class StrawberryIcecream:
                def __call__(self):
                        print 'EAT ME'
        EOF
        endfunction
```

To see what version of Python you have:

```
        :python import sys
        :python print(sys.version)
```

Note: Python is very sensitive to the indenting. Make sure the "class" line and "EOF" do not have any indent.

:[range]pydo {body} :pydo

Execute Python function "def _vim_pydo(line, linenr): {body}" for each line in the [range], with the function arguments being set to the text of each line in turn, without a trailing <EOL>, and the current line number. The function should return a string or None. If a string is returned, it becomes the text of the line in the current turn. The default for [range] is the whole file: "1,$". {not in Vi}

Examples:

```
        :pydo return "%s\t%d" % (line[::-1], len(line))
        :pydo if line: return "%4d: %s" % (linenr, line)
```

:[range]pyf[ile] {file} :pyfile :pyf

Execute the Python script in {file}. The whole argument is used as a single file name. {not in Vi}

Both of these commands do essentially the same thing - they execute a piece of Python code, with the "current range" python-range set to the given line range.

In the case of :python, the code to execute is in the command-line.
In the case of :pyfile, the code to execute is the contents of the given file.

Python commands cannot be used in the sandbox .

To pass arguments you need to set sys.argv[] explicitly. Example:

```
        :python import sys
        :python sys.argv = ["foo", "bar"]
        :pyfile myscript.py
```

Here are some examples python-examples

```
        :python from vim import *
        :python from string import upper
```

```
:python current.line = upper(current.line)
:python print "Hello"
:python str = current.buffer[42]
```

(Note that changes - like the imports - persist from one command to the next,
just like in the Python interpreter.)

==
2. The vim module   python-vim

Python code gets all of its access to vim (with one exception - see
python-output below) via the "vim" module. The vim module implements two
methods, three constants, and one error object. You need to import the vim
module before using it:

```
:python import vim
```

Overview

```
:py print "Hello"               # displays a message
:py vim.command(cmd)            # execute an Ex command
:py w = vim.windows[n]          # gets window "n"
:py cw = vim.current.window     # gets the current window
:py b = vim.buffers[n]          # gets buffer "n"
:py cb = vim.current.buffer     # gets the current buffer
:py w.height = lines            # sets the window height
:py w.cursor = (row, col)       # sets the window cursor position
:py pos = w.cursor              # gets a tuple (row, col)
:py name = b.name               # gets the buffer file name
:py line = b[n]                 # gets a line from the buffer
:py lines = b[n:m]              # gets a list of lines
:py num = len(b)                # gets the number of lines
:py b[n] = str                  # sets a line in the buffer
:py b[n:m] = [str1, str2, str3] # sets a number of lines at once
:py del b[n]                    # deletes a line
:py del b[n:m]                  # deletes a number of lines
```

Methods of the "vim" module

vim.command(str)   python-command

Executes the vim (ex-mode) command str. Returns None.
Examples:

```
:py vim.command("set tw=72")
:py vim.command("%s/aaa/bbb/g")
```

The following definition executes Normal mode commands:

```
def normal(str):
        vim.command("normal "+str)
# Note the use of single quotes to delimit a string containing
# double quotes
normal('"a2dd"aP')
```

E659

The ":python" command cannot be used recursively with Python 2.2 and
older. This only works with Python 2.3 and later:

```
:py vim.command("python print 'Hello again Python'")
```

```
vim.eval(str)                                                python-eval
        Evaluates the expression str using the vim internal expression
        evaluator (see  expression ).  Returns the expression result as:
        - a string if the Vim expression evaluates to a string or number
        - a list if the Vim expression evaluates to a Vim list
        - a dictionary if the Vim expression evaluates to a Vim dictionary
        Dictionaries and lists are recursively expanded.
        Examples:
            :py text_width = vim.eval("&tw")
            :py str = vim.eval("12+12")         # NB result is a string! Use
                                                # string.atoi() to convert to
                                                # a number.

            :py tagList = vim.eval('taglist("eval_expr")')
       The latter will return a python list of python dicts, for instance:
        [{'cmd': '/^eval_expr(arg, nextcmd)$/', 'static': 0, 'name':
        'eval_expr', 'kind': 'f', 'filename': './src/eval.c'}]

vim.bindeval(str)                                            python-bindeval
        Like  python-eval , but returns special objects described in
         python-bindeval-objects . These python objects let you modify ( List
        or  Dictionary ) or call ( Funcref ) vim objects.

vim.strwidth(str)                                            python-strwidth
        Like  strwidth() : returns number of display cells str occupies, tab
        is counted as one cell.

vim.foreach_rtp(callable)                                    python-foreach_rtp
        Call the given callable for each path in 'runtimepath' until either
        callable returns something but None, the exception is raised or there
        are no longer paths. If stopped in case callable returned non-None,
        vim.foreach_rtp function returns the value returned by callable.

vim.chdir(*args, **kwargs)                                   python-chdir
vim.fchdir(*args, **kwargs)                                  python-fchdir
        Run os.chdir or os.fchdir, then all appropriate vim stuff.
        Note: you should not use these functions directly, use os.chdir and
              os.fchdir instead. Behavior of vim.fchdir is undefined in case
              os.fchdir does not exist.

Error object of the "vim" module

vim.error                                                    python-error
        Upon encountering a Vim error, Python raises an exception of type
        vim.error.
        Example:
                try:
                        vim.command("put a")
                except vim.error:
                        # nothing in register a

Constants of the "vim" module

        Note that these are not actually constants - you could reassign them.
```

But this is silly, as you would then lose access to the vim objects to which the variables referred.

vim.buffers python-buffers

A mapping object providing access to the list of vim buffers. The object supports the following operations:

```
:py b = vim.buffers[i]      # Indexing (read-only)
:py b in vim.buffers        # Membership test
:py n = len(vim.buffers)    # Number of elements
:py for b in vim.buffers:   # Iterating over buffer list
```

vim.windows python-windows

A sequence object providing access to the list of vim windows. The object supports the following operations:

```
:py w = vim.windows[i]      # Indexing (read-only)
:py w in vim.windows        # Membership test
:py n = len(vim.windows)    # Number of elements
:py for w in vim.windows:   # Sequential access
```

Note: vim.windows object always accesses current tab page. python-tabpage .windows objects are bound to parent python-tabpage object and always use windows from that tab page (or throw vim.error in case tab page was deleted). You can keep a reference to both without keeping a reference to vim module object or python-tabpage , they will not lose their properties in this case.

vim.tabpages python-tabpages

A sequence object providing access to the list of vim tab pages. The object supports the following operations:

```
:py t = vim.tabpages[i]     # Indexing (read-only)
:py t in vim.tabpages       # Membership test
:py n = len(vim.tabpages)   # Number of elements
:py for t in vim.tabpages:  # Sequential access
```

vim.current python-current

An object providing access (via specific attributes) to various "current" objects available in vim:

vim.current.line	The current line (RW)	String
vim.current.buffer	The current buffer (RW)	Buffer
vim.current.window	The current window (RW)	Window
vim.current.tabpage	The current tab page (RW)	TabPage
vim.current.range	The current line range (RO)	Range

The last case deserves a little explanation. When the :python or :pyfile command specifies a range, this range of lines becomes the "current range". A range is a bit like a buffer, but with all access restricted to a subset of lines. See python-range for more details.

Note: When assigning to vim.current.{buffer,window,tabpage} it expects valid python-buffer , python-window or python-tabpage objects respectively. Assigning triggers normal (with autocommand s) switching to given buffer, window or tab page. It is the only way to switch UI objects in python: you can't assign to python-tabpage .window attribute. To switch without triggering autocommands use

```
            py << EOF
            saved_eventignore = vim.options['eventignore']
            vim.options['eventignore'] = 'all'
            try:
                vim.current.buffer = vim.buffers[2] # Switch to buffer 2
            finally:
                vim.options['eventignore'] = saved_eventignore
            EOF
```

vim.vars python-vars
vim.vvars python-vvars
Dictionary-like objects holding dictionaries with global (g:) and vim (v:) variables respectively. Identical to `vim.bindeval("g:")`, but faster.

vim.options python-options
Object partly supporting mapping protocol (supports setting and getting items) providing a read-write access to global options. Note: unlike :set this provides access only to global options. You cannot use this object to obtain or set local options' values or access local-only options in any fashion. Raises KeyError if no global option with such name exists (i.e. does not raise KeyError for global-local options and global only options, but does for window- and buffer-local ones). Use python-buffer objects to access to buffer-local options and python-window objects to access to window-local options.

Type of this object is available via "Options" attribute of vim module.

Output from Python python-output
Vim displays all Python code output in the Vim message area. Normal output appears as information messages, and error output appears as error messages.

In implementation terms, this means that all output to sys.stdout (including the output from print statements) appears as information messages, and all output to sys.stderr (including error tracebacks) appears as error messages.

python-input
Input (via sys.stdin, including input() and raw_input()) is not supported, and may cause the program to crash. This should probably be fixed.

python2-directory python3-directory pythonx-directory
Python 'runtimepath' handling python-special-path

In python vim.VIM_SPECIAL_PATH special directory is used as a replacement for the list of paths found in 'runtimepath': with this directory in sys.path and vim.path_hooks in sys.path_hooks python will try to load module from {rtp}/python2 (or python3) and {rtp}/pythonx (for both python versions) for each {rtp} found in 'runtimepath'.

Implementation is similar to the following, but written in C:

```
    from imp import find_module, load_module
    import vim
    import sys

    class VimModuleLoader(object):
        def __init__(self, module):
            self.module = module

        def load_module(self, fullname, path=None):
            return self.module

    def _find_module(fullname, oldtail, path):
        idx = oldtail.find('.')
        if idx > 0:
            name = oldtail[:idx]
            tail = oldtail[idx+1:]
            fmr = find_module(name, path)
            module = load_module(fullname[:-len(oldtail)] + name, *fmr)
            return _find_module(fullname, tail, module.__path__)
        else:
            fmr = find_module(fullname, path)
            return load_module(fullname, *fmr)

    # It uses vim module itself in place of VimPathFinder class: it does not
    # matter for python which object has find_module function attached to as
    # an attribute.
    class VimPathFinder(object):
        @classmethod
        def find_module(cls, fullname, path=None):
            try:
                return VimModuleLoader(_find_module(fullname, fullname, path or vim._get_pa
            except ImportError:
                return None

        @classmethod
        def load_module(cls, fullname, path=None):
            return _find_module(fullname, fullname, path or vim._get_paths())

    def hook(path):
        if path == vim.VIM_SPECIAL_PATH:
            return VimPathFinder
        else:
            raise ImportError

    sys.path_hooks.append(hook)
```

vim.VIM_SPECIAL_PATH   python-VIM_SPECIAL_PATH

String constant used in conjunction with vim path hook. If path hook installed by vim is requested to handle anything but path equal to vim.VIM_SPECIAL_PATH constant it raises ImportError. In the only other case it uses special loader.

Note: you must not use value of this constant directly, always use
vim.VIM_SPECIAL_PATH object.

vim.find_module(...) python-find_module
vim.path_hook(path) python-path_hook
Methods or objects used to implement path loading as described above.
You should not be using any of these directly except for vim.path_hook
in case you need to do something with sys.meta_path. It is not
guaranteed that any of the objects will exist in the future vim
versions.

vim._get_paths python-_get_paths
Methods returning a list of paths which will be searched for by path
hook. You should not rely on this method being present in future
versions, but can use it for debugging.

It returns a list of {rtp}/python2 (or {rtp}/python3) and
{rtp}/pythonx directories for each {rtp} in 'runtimepath'.

==
3. Buffer objects python-buffer

Buffer objects represent vim buffers. You can obtain them in a number of ways:
- via vim.current.buffer (python-current)
- from indexing vim.buffers (python-buffers)
- from the "buffer" attribute of a window (python-window)

Buffer objects have two read-only attributes - name - the full file name for
the buffer, and number - the buffer number. They also have three methods
(append, mark, and range; see below).

You can also treat buffer objects as sequence objects. In this context, they
act as if they were lists (yes, they are mutable) of strings, with each
element being a line of the buffer. All of the usual sequence operations,
including indexing, index assignment, slicing and slice assignment, work as
you would expect. Note that the result of indexing (slicing) a buffer is a
string (list of strings). This has one unusual consequence - b[:] is different
from b. In particular, "b[:] = None" deletes the whole of the buffer, whereas
"b = None" merely updates the variable b, with no effect on the buffer.

Buffer indexes start at zero, as is normal in Python. This differs from vim
line numbers, which start from 1. This is particularly relevant when dealing
with marks (see below) which use vim line numbers.

The buffer object attributes are:
b.vars Dictionary-like object used to access
buffer-variable s.
b.options Mapping object (supports item getting, setting and
deleting) that provides access to buffer-local options
and buffer-local values of global-local options. Use
python-window .options if option is window-local,
this object will raise KeyError. If option is
global-local and local value is missing getting it
will return None.

```
        b.name          String, RW. Contains buffer name (full path).
                        Note: when assigning to b.name  BufFilePre  and
                         BufFilePost  autocommands are launched.
        b.number        Buffer number. Can be used as  python-buffers  key.
                        Read-only.
        b.valid         True or False. Buffer object becomes invalid when
                        corresponding buffer is wiped out.

The buffer object methods are:
        b.append(str)   Append a line to the buffer
        b.append(str, nr)  Idem, below line "nr"
        b.append(list)  Append a list of lines to the buffer
                        Note that the option of supplying a list of strings to
                        the append method differs from the equivalent method
                        for Python's built-in list objects.
        b.append(list, nr)  Idem, below line "nr"
        b.mark(name)    Return a tuple (row,col) representing the position
                        of the named mark (can also get the []"<> marks)
        b.range(s,e)    Return a range object (see  python-range ) which
                        represents the part of the given buffer between line
                        numbers s and e  inclusive .

Note that when adding a line it must not contain a line break character '\n'.
A trailing '\n' is allowed and ignored, so that you can do:
        :py b.append(f.readlines())

Buffer object type is available using "Buffer" attribute of vim module.

Examples (assume b is the current buffer)
        :py print b.name                # write the buffer file name
        :py b[0] = "hello!!!"           # replace the top line
        :py b[:] = None                 # delete the whole buffer
        :py del b[:]                    # delete the whole buffer
        :py b[0:0] = [ "a line" ]       # add a line at the top
        :py del b[2]                    # delete a line (the third)
        :py b.append("bottom")          # add a line at the bottom
        :py n = len(b)                  # number of lines
        :py (row,col) = b.mark('a')     # named mark
        :py r = b.range(1,5)            # a sub-range of the buffer
        :py b.vars["foo"] = "bar"       # assign b:foo variable
        :py b.options["ff"] = "dos"     # set fileformat
        :py del b.options["ar"]         # same as :set autoread<

==============================================================================
4. Range objects                                              python-range

Range objects represent a part of a vim buffer.  You can obtain them in a
number of ways:
        - via vim.current.range ( python-current )
        - from a buffer's range() method ( python-buffer )

A range object is almost identical in operation to a buffer object.  However,
all operations are restricted to the lines within the range (this line range
can, of course, change as a result of slice assignments, line deletions, or
```

the range.append() method).

The range object attributes are:
```
        r.start         Index of first line into the buffer
        r.end           Index of last line into the buffer
```

The range object methods are:
```
        r.append(str)   Append a line to the range
        r.append(str, nr)  Idem, after line "nr"
        r.append(list)  Append a list of lines to the range
                        Note that the option of supplying a list of strings to
                        the append method differs from the equivalent method
                        for Python's built-in list objects.
        r.append(list, nr)  Idem, after line "nr"
```

Range object type is available using "Range" attribute of vim module.

Example (assume r is the current range):
```
        # Send all lines in a range to the default printer
        vim.command("%d,%dhardcopy!" % (r.start+1,r.end+1))
```

==
5. Window objects python-window

Window objects represent vim windows. You can obtain them in a number of ways:
- via vim.current.window (python-current)
- from indexing vim.windows (python-windows)
- from indexing "windows" attribute of a tab page (python-tabpage)
- from the "window" attribute of a tab page (python-tabpage)

You can manipulate window objects only through their attributes. They have no methods, and no sequence or other interface.

Window attributes are:

buffer (read-only)	The buffer displayed in this window
cursor (read-write)	The current cursor position in the window. This is a tuple, (row,col).
height (read-write)	The window height, in rows
width (read-write)	The window width, in columns
vars (read-only)	The window w: variables. Attribute is unassignable, but you can change window variables this way
options (read-only)	The window-local options. Attribute is unassignable, but you can change window options this way. Provides access only to window-local options, for buffer-local use python-buffer and for global ones use python-options . If option is global-local and local value is missing getting it will return None.
number (read-only)	Window number. The first window has number 1. This is zero in case it cannot be determined (e.g. when the window object belongs to other tab page).

```
        row, col (read-only)    On-screen window position in display cells.
                                First position is zero.
        tabpage (read-only)     Window tab page.
        valid (read-write)      True or False. Window object becomes invalid
                                when corresponding window is closed.

The height attribute is writable only if the screen is split horizontally.
The width attribute is writable only if the screen is split vertically.

Window object type is available using "Window" attribute of vim module.

==============================================================================
6. Tab page objects                                         python-tabpage

Tab page objects represent vim tab pages. You can obtain them in a number of
ways:
        - via vim.current.tabpage ( python-current )
        - from indexing vim.tabpages ( python-tabpages )

You can use this object to access tab page windows. They have no methods and
no sequence or other interfaces.

Tab page attributes are:
        number          The tab page number like the one returned by
                         tabpagenr() .
        windows         Like  python-windows , but for current tab page.
        vars            The tab page  t:  variables.
        window          Current tabpage window.
        valid           True or False. Tab page object becomes invalid when
                        corresponding tab page is closed.

TabPage object type is available using "TabPage" attribute of vim module.

==============================================================================
7. vim.bindeval objects                           python-bindeval-objects

vim.Dictionary object                             python-Dictionary
    Dictionary-like object providing access to vim  Dictionary  type.
    Attributes:
        Attribute  Description
        locked     One of                                 python-.locked
                    Value           Description
                    zero            Variable is not locked
                    vim.VAR_LOCKED  Variable is locked, but can be unlocked
                    vim.VAR_FIXED   Variable is locked and can't be unlocked
                   Read-write. You can unlock locked variable by assigning
                   `True` or `False` to this attribute. No recursive locking
                   is supported.
        scope      One of
                    Value              Description
                    zero               Dictionary is not a scope one
                    vim.VAR_DEF_SCOPE   g:  or  l:  dictionary
                    vim.VAR_SCOPE      Other scope dictionary,
                                       see  internal-variables
```

```
    Methods (note: methods do not support keyword arguments):
        Method      Description
        keys()      Returns a list with dictionary keys.
        values()    Returns a list with dictionary values.
        items()     Returns a list of 2-tuples with dictionary contents.
        update(iterable), update(dictionary), update(**kwargs)
                    Adds keys to dictionary.
        get(key[, default=None])
                    Obtain key from dictionary, returning the default if it is
                    not present.
        pop(key[, default])
                    Remove specified key from dictionary and return
                    corresponding value. If key is not found and default is
                    given returns the default, otherwise raises KeyError.
        popitem()
                    Remove random key from dictionary and return (key, value)
                    pair.
        has_key(key)
                    Check whether dictionary contains specified key, similar
                    to `key in dict`.

        __new__(), __new__(iterable), __new__(dictionary), __new__(update)
                    You can use `vim.Dictionary()` to create new vim
                    dictionaries. `d=vim.Dictionary(arg)` is the same as
                    `d=vim.bindeval('{}');d.update(arg)`. Without arguments
                    constructs empty dictionary.

    Examples:
        d = vim.Dictionary(food="bar")          # Constructor
        d['a'] = 'b'                            # Item assignment
        print d['a']                            # getting item
        d.update({'c': 'd'})                    # .update(dictionary)
        d.update(e='f')                         # .update(**kwargs)
        d.update((('g', 'h'), ('i', 'j')))      # .update(iterable)
        for key in d.keys():                    # .keys()
        for val in d.values():                  # .values()
        for key, val in d.items():              # .items()
        print isinstance(d, vim.Dictionary)     # True
        for key in d:                           # Iteration over keys
        class Dict(vim.Dictionary):             # Subclassing

    Note: when iterating over keys you should not modify dictionary.

vim.List object                                         python-List
    Sequence-like object providing access to vim  List  type.
    Supports `.locked` attribute, see  python-.locked . Also supports the
    following methods:
        Method          Description
        extend(item)    Add items to the list.

        __new__(), __new__(iterable)
                        You can use `vim.List()` to create new vim lists.
                        `l=vim.List(iterable)` is the same as
                        `l=vim.bindeval('[]');l.extend(iterable)`. Without
```

arguments constructs empty list.

Examples:

```
l = vim.List("abc")            # Constructor, result: ['a', 'b', 'c']
l.extend(['abc', 'def'])       # .extend() method
print l[1:]                    # slicing
l[:0] = ['ghi', 'jkl']         # slice assignment
print l[0]                     # getting item
l[0] = 'mno'                   # assignment
for i in l:                    # iteration
print isinstance(l, vim.List)  # True
class List(vim.List):          # Subclassing
```

vim.Function object python-Function

Function-like object, acting like vim Funcref object. Accepts special keyword argument `self`, see Dictionary-function . You can also use `vim.Function(name)` constructor, it is the same as `vim.bindeval('function(%s)'%json.dumps(name))`.

Attributes (read-only):

Attribute	Description
name	Function name.
args	`None` or a python-List object with arguments. Note that this is a copy of the arguments list, constructed each time you request this attribute. Modifications made to the list will be ignored (but not to the containers inside argument list: this is like copy() and not deepcopy()).
self	`None` or a python-Dictionary object with self dictionary. Note that explicit `self` keyword used when calling resulting object overrides this attribute.
auto_rebind	Boolean. True if partial created from this Python object and stored in the Vim script dictionary should be automatically rebound to the dictionary it is stored in when this dictionary is indexed. Exposes Vim internal difference between `dict.func` (auto_rebind=True) and `function(dict.func,dict)` (auto_rebind=False). This attribute makes no sense if `self` attribute is `None`.

Constructor additionally accepts `args`, `self` and `auto_rebind` keywords. If `args` and/or `self` argument is given then it constructs a partial, see function() . `auto_rebind` is only used when `self` argument is given, otherwise it is assumed to be `True` regardless of whether it was given or not. If `self` is given then it defaults to `False`.

Examples:

```
f = vim.Function('tr')                # Constructor
print f('abc', 'a', 'b')              # Calls tr('abc', 'a', 'b')
vim.command('''
    function DictFun() dict
        return self
    endfunction
''')
f = vim.bindeval('function("DictFun")')
```

```
        print f(self={})                         # Like call('DictFun', [], {})
        print isinstance(f, vim.Function)       # True

        p = vim.Function('DictFun', self={})
        print f()
        p = vim.Function('tr', args=['abc', 'a'])
        print f('b')
```

==
8. pyeval() and py3eval() Vim functions   python-pyeval

To facilitate bi-directional interface, you can use `pyeval()` and `py3eval()` functions to evaluate Python expressions and pass their values to Vim script. `pyxeval()` is also available.

The Python value "None" is converted to v:none.

==
9. Dynamic loading   python-dynamic

On MS-Windows and Unix the Python library can be loaded dynamically. The `:version` output then includes `+python/dyn` or `+python3/dyn` .

This means that Vim will search for the Python DLL or shared library file only when needed. When you don't use the Python interface you don't need it, thus you can use Vim without this file.

MS-Windows

To use the Python interface the Python DLL must be in your search path. In a console window type "path" to see what directories are used. The 'pythondll' or 'pythonthreedll' option can be also used to specify the Python DLL.

The name of the DLL should match the Python version Vim was compiled with. Currently the name for Python 2 is "python27.dll", that is for Python 2.7. That is the default value for 'pythondll'. For Python 3 it is python36.dll (Python 3.6). To know for sure edit "gvim.exe" and search for "python\d*.dll\c".

Unix

The 'pythondll' or 'pythonthreedll' option can be used to specify the Python shared library file instead of DYNAMIC_PYTHON_DLL or DYNAMIC_PYTHON3_DLL file what were specified at compile time. The version of the shared library must match the Python 2.x or Python 3 version Vim was compiled with.

==
10. Python 3   python3

                                                        :py3   :python3

The `:py3` and `:python3` commands work similar to `:python`. A simple check if the `:py3` command is working:

```
        :py3 print("Hello")

To see what version of Python you have:
        :py3 import sys
        :py3 print(sys.version)
                                                              :py3file
The `:py3file` command works similar to `:pyfile`.
                                                               :py3do
The `:py3do` command works similar to `:pydo`.

Vim can be built in four ways (:version output):
1. No Python support        (-python, -python3)
2. Python 2 support only    (+python or +python/dyn, -python3)
3. Python 3 support only    (-python, +python3 or +python3/dyn)
4. Python 2 and 3 support   (+python/dyn, +python3/dyn)

Some more details on the special case 4:   python-2-and-3

When Python 2 and Python 3 are both supported they must be loaded dynamically.

When doing this on Linux/Unix systems and importing global symbols, this leads
to a crash when the second Python version is used.  So either global symbols
are loaded but only one Python version is activated, or no global symbols are
loaded. The latter makes Python's "import" fail on libraries that expect the
symbols to be provided by Vim.
                                                          E836   E837
Vim's configuration script makes a guess for all libraries based on one
standard Python library (termios).  If importing this library succeeds for
both Python versions, then both will be made available in Vim at the same
time.  If not, only the version first used in a session will be enabled.
When trying to use the other one you will get the E836 or E837 error message.

Here Vim's behavior depends on the system in which it was configured.  In a
system where both versions of Python were configured with --enable-shared,
both versions of Python will be activated at the same time.  There will still
be problems with other third party libraries that were not linked to
libPython.

To work around such problems there are these options:
1. The problematic library is recompiled to link to the according
   libpython.so.
2. Vim is recompiled for only one Python version.
3. You undefine PY_NO_RTLD_GLOBAL in auto/config.h after configuration.  This
   may crash Vim though.

                                                              E880
Raising SystemExit exception in python isn't endorsed way to quit vim, use:
        :py vim.command("qall!")

                                                          has-python
You can test what Python version is available with:
        if has('python')
```

```
  echo 'there is Python 2.x'
endif
if has('python3')
  echo 'there is Python 3.x'
endif
```

Note however, that when Python 2 and 3 are both available and loaded
dynamically, these has() calls will try to load them. If only one can be
loaded at a time, just checking if Python 2 or 3 are available will prevent
the other one from being available.

To avoid loading the dynamic library, only check if Vim was compiled with
python support:

```
if has('python_compiled')
  echo 'compiled with Python 2.x support'
  if has('python_dynamic')
    echo 'Python 2.x dynamically loaded'
  endif
endif
if has('python3_compiled')
  echo 'compiled with Python 3.x support'
  if has('python3_dynamic')
    echo 'Python 3.x dynamically loaded'
  endif
endif
```

This also tells you whether Python is dynamically loaded, which will fail if
the runtime library cannot be found.

==
11. Python X   python_x pythonx

Because most python code can be written so that it works with python 2.6+ and
python 3 the pyx* functions and commands have been written. They work exactly
the same as the Python 2 and 3 variants, but select the Python version using
the 'pyxversion' setting.

You should set 'pyxversion' in your .vimrc to prefer Python 2 or Python 3
for Python commands. If you change this setting at runtime you may risk that
state of plugins (such as initialization) may be lost.

If you want to use a module, you can put it in the {rtp}/pythonx directory.
See pythonx-directory .

                                                              :pyx :pythonx
The `:pyx` and `:pythonx` commands work similar to `:python`. A simple check
if the `:pyx` command is working:

```
:pyx print("Hello")
```

To see what version of Python is being used:

```
:pyx import sys
:pyx print(sys.version)
```

                                              :pyxfile python_x-special-comments

The `:pyxfile` command works similar to `:pyfile`. However you can add one of these comments to force Vim using `:pyfile` or `:py3file`:

```
  #!/any string/python2         " Shebang. Must be the first line of the file.
  #!/any string/python3         " Shebang. Must be the first line of the file.
  # requires python 2.x         " Maximum lines depend on 'modelines'.
  # requires python 3.x         " Maximum lines depend on 'modelines'.
```

Unlike normal modelines, the bottom of the file is not checked.
If none of them are found, the 'pyxversion' setting is used.
W20 W21

If Vim does not support the selected Python version a silent message will be printed. Use `:messages` to read them.

:pyxdo

The `:pyxdo` command works similar to `:pydo`.

has-pythonx

You can test if pyx* commands are available with:

```
        if has('pythonx')
          echo 'pyx* commands are available. (Python ' . &pyx . ')'
        endif
```

When compiled with only one of +python or +python3 , the has() returns 1. When compiled with both +python and +python3 , the test depends on the 'pyxversion' setting. If 'pyxversion' is 0, it tests Python 3 first, and if it is not available then Python 2. If 'pyxversion' is 2 or 3, it tests only Python 2 or 3 respectively.

Note that for `has('pythonx')` to work it may try to dynamically load Python 3 or 2. This may have side effects, especially when Vim can only load one of the two.

If a user prefers Python 2 and want to fallback to Python 3, he needs to set 'pyxversion' explicitly in his .vimrc . E.g.:

```
        if has('python')
          set pyx=2
        elseif has('python3')
          set pyx=3
        endif
```

==
12. Building with Python support python-building

A few hints for building with Python 2 or 3 support.

UNIX

See src/Makefile for how to enable including the Python interface.

On Ubuntu you will want to install these packages for Python 2:

```
        python
        python-dev
```

For Python 3:

```
        python3
        python3-dev
```

```
For Python 3.6:
        python3.6
        python3.6-dev

If you have more than one version of Python 3, you need to link python3 to the
one you prefer, before running configure.

if_tcl.txt For Vim version 8.1. Last change: 2016 Jan 01

VIM REFERENCE MANUAL by Ingo Wilken

The Tcl Interface to Vim tcl Tcl TCL

{Vi does not have any of these commands} E280

The Tcl interface only works when Vim was compiled with the +tcl feature.

WARNING: There are probably still some bugs. Please send bug reports,
comments, ideas etc to <Ingo.Wilken@informatik.uni-oldenburg.de>

==
1. Commands tcl-ex-commands E571 E572

:tcl :tc

:tc[l] {cmd} Execute Tcl command {cmd}. A simple check if `:tcl`
is working:

```
:tcl puts "Hello"
```

:[range]tc[l] << {endmarker}
{script}
{endmarker}

Execute Tcl script {script}.
Note: This command doesn't work when the Tcl feature
wasn't compiled in. To avoid errors, see
script-here .

{endmarker} must NOT be preceded by any white space. If {endmarker} is
omitted from after the "<<", a dot '.' must be used after {script}, like for
the :append and :insert commands.
This form of the :tcl command is mainly useful for including tcl code in Vim
scripts.

Example:

```
function! DefineDate()
    tcl << EOF
    proc date {} {
        return [clock format [clock seconds]]
    }
EOF
```

```
        endfunction

To see what version of Tcl you have:
        :tcl puts [info patchlevel]

                                                        :tcldo   :tcld
:[range]tcld[o] {cmd}   Execute Tcl command {cmd} for each line in [range]
                        with the variable "line" being set to the text of each
                        line in turn, and "lnum" to the line number.  Setting
                        "line" will change the text, but note that it is not
                        possible to add or delete lines using this command.
                        If {cmd} returns an error, the command is interrupted.
                        The default for [range] is the whole file: "1,$".
                        See  tcl-var-line  and  tcl-var-lnum .  {not in Vi}

                                                        :tclfile   :tclf
:tclf[ile] {file}       Execute the Tcl script in {file}.  This is the same as
                        ":tcl source {file}", but allows file name completion.
                        {not in Vi}

Note that Tcl objects (like variables) persist from one command to the next,
just as in the Tcl shell.

Executing Tcl commands is not possible in the  sandbox .

==============================================================================
2. Tcl commands                                         tcl-commands

Tcl code gets all of its access to vim via commands in the "::vim" namespace.
The following commands are implemented:

        ::vim::beep                     # Guess.
        ::vim::buffer {n}               # Create Tcl command for one buffer.
        ::vim::buffer list              # Create Tcl commands for all buffers.
        ::vim::command [-quiet] {cmd}   # Execute an Ex command.
        ::vim::expr {expr}              # Use Vim's expression evaluator.
        ::vim::option {opt}             # Get vim option.
        ::vim::option {opt} {val}       # Set vim option.
        ::vim::window list              # Create Tcl commands for all windows.

Commands:
        ::vim::beep                                     tcl-beep
        Honk.  Does not return a result.

        ::vim::buffer {n}                               tcl-buffer
        ::vim::buffer exists {n}
        ::vim::buffer list
        Provides access to vim buffers.  With an integer argument, creates a
        buffer command (see  tcl-buffer-cmds ) for the buffer with that
        number, and returns its name as the result.  Invalid buffer numbers
        result in a standard Tcl error.  To test for valid buffer numbers,
        vim's internal functions can be used:
```

```
        set nbufs [::vim::expr bufnr("$")]
        set isvalid [::vim::expr "bufexists($n)"]
```
The "list" option creates a buffer command for each valid buffer, and returns a list of the command names as the result.
Example:
```
        set bufs [::vim::buffer list]
        foreach b $bufs { $b append end "The End!" }
```
The "exists" option checks if a buffer with the given number exists.
Example:
```
        if { [::vim::buffer exists $n] } { ::vim::command ":e #$n" }
```
This command might be replaced by a variable in future versions.
See also tcl-var-current for the current buffer.

::vim::command {cmd} tcl-command
::vim::command -quiet {cmd}
Execute the vim (ex-mode) command {cmd}. Any Ex command that affects a buffer or window uses the current buffer/current window. Does not return a result other than a standard Tcl error code. After this command is completed, the "::vim::current" variable is updated.
The "-quiet" flag suppresses any error messages from vim.
Examples:
```
        ::vim::command "set ts=8"
        ::vim::command "%s/foo/bar/g"
```
To execute normal-mode commands, use "normal" (see :normal):
```
        set cmd "jj"
        ::vim::command "normal $cmd"
```
See also tcl-window-command and tcl-buffer-command .

::vim::expr {expr} tcl-expr
Evaluates the expression {expr} using vim's internal expression evaluator (see expression). Any expression that queries a buffer or window property uses the current buffer/current window. Returns the result as a string. A List is turned into a string by joining the items and inserting line breaks.
Examples:
```
        set perl_available [::vim::expr has("perl")]
```
See also tcl-window-expr and tcl-buffer-expr .

::vim::option {opt} tcl-option
::vim::option {opt} {value}
Without second argument, queries the value of a vim option. With this argument, sets the vim option to {value}, and returns the previous value as the result. Any options that are marked as 'local to buffer' or 'local to window' affect the current buffer/current window. The global value is not changed, use the ":set" command for that. For boolean options, {value} should be "0" or "1", or any of the keywords "on", "off" or "toggle". See option-summary for a list of options.
Example:
```
        ::vim::option ts 8
```
See also tcl-window-option and tcl-buffer-option .

::vim::window {option} tcl-window
Provides access to vim windows. Currently only the "list" option is implemented. This creates a window command (see tcl-window-cmds) for

each window, and returns a list of the command names as the result.
Example:

```
set wins [::vim::window list]
foreach w $wins { $w height 4 }
```

This command might be replaced by a variable in future versions.
See also tcl-var-current for the current window.

==
3. Tcl variables tcl-variables

The ::vim namespace contains a few variables. These are created when the Tcl interpreter is called from vim and set to current values.

```
::vim::current          # array containing "current" objects
::vim::lbase            # number of first line
::vim::range            # array containing current range numbers
line                    # current line as a string (:tcldo only)
lnum                    # current line number (:tcldo only)
```

Variables:

::vim::current tcl-var-current
This is an array providing access to various "current" objects available in vim. The contents of this array are updated after "::vim::command" is called, as this might change vim's current settings (e.g., by deleting the current buffer).
The "buffer" element contains the name of the buffer command for the current buffer. This can be used directly to invoke buffer commands (see tcl-buffer-cmds). This element is read-only.
Example:

```
$::vim::current(buffer) insert begin "Hello world"
```

The "window" element contains the name of the window command for the current window. This can be used directly to invoke window commands (see tcl-window-cmds). This element is read-only.
Example:

```
$::vim::current(window) height 10
```

::vim::lbase tcl-var-lbase
This variable controls how Tcl treats line numbers. If it is set to '1', then lines and columns start at 1. This way, line numbers from Tcl commands and vim expressions are compatible. If this variable is set to '0', then line numbers and columns start at 0 in Tcl. This is useful if you want to treat a buffer as a Tcl list or a line as a Tcl string and use standard Tcl commands that return an index ("lsort" or "string first", for example). The default value is '1'. Currently, any non-zero values is treated as '1', but your scripts should not rely on this. See also tcl-linenumbers .

::vim::range tcl-var-range
This is an array with three elements, "start", "begin" and "end". It contains the line numbers of the start and end row of the current range. "begin" is the same as "start". This variable is read-only.
See tcl-examples .

line tcl-var-line

lnum   tcl-var-lnum
These global variables are only available if the ":tcldo" Ex command
is being executed. They contain the text and line number of the
current line. When the Tcl command invoked by ":tcldo" is completed,
the current line is set to the contents of the "line" variable, unless
the variable was unset by the Tcl command. The "lnum" variable is
read-only. These variables are not in the "::vim" namespace so they
can be used in ":tcldo" without much typing (this might be changed in
future versions). See also tcl-linenumbers .

==
4. Tcl window commands   tcl-window-cmds

Window commands represent vim windows. They are created by several commands:
        ::vim::window list   tcl-window
        "windows" option of a buffer command   tcl-buffer-windows
The ::vim::current(window) variable contains the name of the window command
for the current window. A window command is automatically deleted when the
corresponding vim window is closed.

Let's assume the name of the window command is stored in the Tcl variable "win",
i.e. "$win" calls the command. The following options are available:

```
$win buffer             # Create Tcl command for window's buffer.
$win command {cmd}      # Execute Ex command in windows context.
$win cursor             # Get current cursor position.
$win cursor {var}       # Set cursor position from array variable.
$win cursor {row} {col} # Set cursor position.
$win delcmd {cmd}       # Call Tcl command when window is closed.
$win expr {expr}        # Evaluate vim expression in windows context.
$win height             # Report the window's height.
$win height {n}         # Set the window's height.
$win option {opt} [val] # Get/Set vim option in windows context.
```

Options:
        $win buffer   tcl-window-buffer
        Creates a Tcl command for the window's buffer, and returns its name as
        the result. The name should be stored in a variable:
                set buf [$win buffer]
       $buf is now a valid Tcl command. See tcl-buffer-cmds for the
        available options.

        $win cursor   tcl-window-cursor
        $win cursor {var}
        $win cursor {row} {col}
        Without argument, reports the current cursor position as a string.
        This can be converted to a Tcl array variable:
                array set here [$win cursor]
      "here(row)" and "here(column)" now contain the cursor position.
        With a single argument, the argument is interpreted as the name of a
        Tcl array variable, which must contain two elements "row" and "column".
        These are used to set the cursor to the new position:
                $win cursor here   ;# not $here !
      With two arguments, sets the cursor to the specified row and column:

```
        $win cursor $here(row) $here(column)
```
Invalid positions result in a standard Tcl error, which can be caught with "catch". The row and column values depend on the "::vim::lbase" variable. See tcl-var-lbase .

$win delcmd {cmd} tcl-window-delcmd

Registers the Tcl command {cmd} as a deletion callback for the window. This command is executed (in the global scope) just before the window is closed. Complex commands should be build with "list":

```
        $win delcmd [list puts vimerr "window deleted"]
```
See also tcl-buffer-delcmd .

$win height tcl-window-height
$win height {n}

Without argument, reports the window's current height. With an argument, tries to set the window's height to {n}, then reports the new height (which might be different from {n}).

$win command [-quiet] {cmd} tcl-window-command
$win expr {expr} tcl-window-expr
$win option {opt} [val] tcl-window-option

These are similar to "::vim::command" etc., except that everything is done in the context of the window represented by $win, instead of the current window. For example, setting an option that is marked 'local to window' affects the window $win. Anything that affects or queries a buffer uses the buffer displayed in this window (i.e. the buffer that is represented by "$win buffer"). See tcl-command , tcl-expr and tcl-option for more information.

Example:

```
        $win option number on
```

==

5. Tcl buffer commands tcl-buffer-cmds

Buffer commands represent vim buffers. They are created by several commands:

::vim::buffer {N}	tcl-buffer
::vim::buffer list	tcl-buffer
"buffer" option of a window command	tcl-window-buffer

The ::vim::current(buffer) variable contains the name of the buffer command for the current buffer. A buffer command is automatically deleted when the corresponding vim buffer is destroyed. Whenever the buffer's contents are changed, all marks in the buffer are automatically adjusted. Any changes to the buffer's contents made by Tcl commands can be undone with the "undo" vim command (see undo).

Let's assume the name of the buffer command is stored in the Tcl variable "buf", i.e. "$buf" calls the command. The following options are available:

```
        $buf append {n} {str}   # Append a line to buffer, after line {n}.
        $buf command {cmd}      # Execute Ex command in buffers context.
        $buf count              # Report number of lines in buffer.
        $buf delcmd {cmd}       # Call Tcl command when buffer is deleted.
        $buf delete {n}         # Delete a single line.
        $buf delete {n} {m}     # Delete several lines.
```

```
        $buf expr {expr}        # Evaluate vim expression in buffers context.
        $buf get {n}            # Get a single line as a string.
        $buf get {n} {m}        # Get several lines as a list.
        $buf insert {n} {str}   # Insert a line in buffer, as line {n}.
        $buf last               # Report line number of last line in buffer.
        $buf mark {mark}        # Report position of buffer mark.
        $buf name               # Report name of file in buffer.
        $buf number             # Report number of this buffer.
        $buf option {opt} [val] # Get/Set vim option in buffers context.
        $buf set {n} {text}     # Replace a single line.
        $buf set {n} {m} {list} # Replace several lines.
        $buf windows            # Create Tcl commands for buffer's windows.
```

tcl-linenumbers

Most buffer commands take line numbers as arguments. How Tcl treats these numbers depends on the "::vim::lbase" variable (see tcl-var-lbase). Instead of line numbers, several keywords can be also used: "top", "start", "begin", "first", "bottom", "end" and "last".

Options:

$buf append {n} {str} tcl-buffer-append
$buf insert {n} {str} tcl-buffer-insert

Add a line to the buffer. With the "insert" option, the string becomes the new line {n}, with "append" it is inserted after line {n}. Example:

```
        $buf insert top "This is the beginning."
        $buf append end "This is the end."
```

To add a list of lines to the buffer, use a loop:

```
        foreach line $list { $buf append $num $line ; incr num }
```

$buf count tcl-buffer-count

Reports the total number of lines in the buffer.

$buf delcmd {cmd} tcl-buffer-delcmd

Registers the Tcl command {cmd} as a deletion callback for the buffer. This command is executed (in the global scope) just before the buffer is deleted. Complex commands should be build with "list":

```
        $buf delcmd [list puts vimerr "buffer [$buf number] gone"]
```

See also tcl-window-delcmd .

$buf delete {n} tcl-buffer-delete
$buf delete {n} {m}

Deletes line {n} or lines {n} through {m} from the buffer. This example deletes everything except the last line:

```
        $buf delete first [expr [$buf last] - 1]
```

$buf get {n} tcl-buffer-get
$buf get {n} {m}

Gets one or more lines from the buffer. For a single line, the result is a string; for several lines, a list of strings. Example:

```
        set topline [$buf get top]
```

$buf last tcl-buffer-last

Reports the line number of the last line. This value depends on the
"::vim::lbase" variable. See tcl-var-lbase .

$buf mark {mark}   tcl-buffer-mark
Reports the position of the named mark as a string, similar to the
cursor position of the "cursor" option of a window command (see
 tcl-window-cursor). This can be converted to a Tcl array variable:
        array set mpos [$buf mark "a"]
"mpos(column)" and "mpos(row)" now contain the position of the mark.
If the mark is not set, a standard Tcl error results.

$buf name
Reports the name of the file in the buffer. For a buffer without a
file, this is an empty string.

$buf number
Reports the number of this buffer. See :buffers .
This example deletes a buffer from vim:
        ::vim::command "bdelete [$buf number]"

$buf set {n} {string}   tcl-buffer-set
$buf set {n} {m} {list}
Replace one or several lines in the buffer. If the list contains more
elements than there are lines to replace, they are inserted into the
buffer. If the list contains fewer elements, any unreplaced line is
deleted from the buffer.

$buf windows   tcl-buffer-windows
Creates a window command for each window that displays this buffer, and
returns a list of the command names as the result.
Example:
        set winlist [$buf windows]
        foreach win $winlist { $win height 4 }
See tcl-window-cmds for the available options.

$buf command [-quiet] {cmd}   tcl-buffer-command
$buf expr {expr}   tcl-buffer-expr
$buf option {opt} [val]   tcl-buffer-option
These are similar to "::vim::command" etc., except that everything is
done in the context of the buffer represented by $buf, instead of the
current buffer. For example, setting an option that is marked 'local
to buffer' affects the buffer $buf. Anything that affects or queries
a window uses the first window in vim's window list that displays this
buffer (i.e. the first entry in the list returned by "$buf windows").
See tcl-command , tcl-expr and tcl-option for more information.
Example:
        if { [$buf option modified] } { $buf command "w" }

==
6. Miscellaneous; Output from Tcl   tcl-misc   tcl-output

The standard Tcl commands "exit" and "catch" are replaced by custom versions.
"exit" terminates the current Tcl script and returns to vim, which deletes the
Tcl interpreter. Another call to ":tcl" then creates a new Tcl interpreter.

"exit" does NOT terminate vim! "catch" works as before, except that it does not prevent script termination from "exit". An exit code != 0 causes the ex command that invoked the Tcl script to return an error.

Two new I/O streams are available in Tcl, "vimout" and "vimerr". All output directed to them is displayed in the vim message area, as information messages and error messages, respectively. The standard Tcl output streams stdout and stderr are mapped to vimout and vimerr, so that a normal "puts" command can be used to display messages in vim.

==
7. Known bugs & problems   tcl-bugs

Calling one of the Tcl Ex commands from inside Tcl (via "::vim::command") may have unexpected side effects. The command creates a new interpreter, which has the same abilities as the standard interpreter - making "::vim::command" available in a safe child interpreter therefore makes the child unsafe. (It would be trivial to block nested :tcl* calls or ensure that such calls from a safe interpreter create only new safe interpreters, but quite pointless - depending on vim's configuration, "::vim::command" may execute arbitrary code in any number of other scripting languages.) A call to "exit" within this new interpreter does not affect the old interpreter; it only terminates the new interpreter, then script processing continues normally in the old interpreter.

Input from stdin is currently not supported.

==
8. Examples: tcl-examples

Here are a few small (and maybe useful) Tcl scripts.

This script sorts the lines of the entire buffer (assume it contains a list of names or something similar):

```
        set buf $::vim::current(buffer)
        set lines [$buf get top bottom]
        set lines [lsort -dictionary $lines]
        $buf set top bottom $lines
```

This script reverses the lines in the buffer. Note the use of "::vim::lbase" and "$buf last" to work with any line number setting.

```
        set buf $::vim::current(buffer)
        set t $::vim::lbase
        set b [$buf last]
        while { $t < $b } {
                set tl [$buf get $t]
                set bl [$buf get $b]
                $buf set $t $bl
                $buf set $b $tl
                incr t
                incr b -1
        }
```

This script adds a consecutive number to each line in the current range:

```
        set buf $::vim::current(buffer)
```

```
        set i $::vim::range(start)
        set n 1
        while { $i <= $::vim::range(end) } {
                set line [$buf get $i]
                $buf set $i "$n\t$line"
                incr i ; incr n
        }
```

The same can also be done quickly with two Ex commands, using ":tcldo":

```
        :tcl set n 1
        :[range]tcldo set line "$n\t$line" ; incr n
```

This procedure runs an Ex command on each buffer (idea stolen from Ron Aaron):

```
        proc eachbuf { cmd } {
                foreach b [::vim::buffer list] {
                        $b command $cmd
                }
        }
```

Use it like this:

```
        :tcl eachbuf %s/foo/bar/g
```

Be careful with Tcl's string and backslash substitution, tough. If in doubt, surround the Ex command with curly braces.

If you want to add some Tcl procedures permanently to vim, just place them in a file (e.g. "~/.vimrc.tcl" on Unix machines), and add these lines to your startup file (usually "~/.vimrc" on Unix):

```
        if has("tcl")
                tclfile ~/.vimrc.tcl
        endif
```

==

9. Dynamic loading tcl-dynamic

On MS-Windows and Unix the Tcl library can be loaded dynamically. The :version output then includes +tcl/dyn .

This means that Vim will search for the Tcl DLL or shared library file only when needed. When you don't use the Tcl interface you don't need it, thus you can use Vim without this file.

MS-Windows

To use the Tcl interface the Tcl DLL must be in your search path. In a console window type "path" to see what directories are used. The 'tcldll' option can be also used to specify the Tcl DLL.

The name of the DLL must match the Tcl version Vim was compiled with. Currently the name is "tcl86.dll". That is for Tcl 8.6. To know for sure edit "gvim.exe" and search for "tcl\d*.dll\c".

Unix

The 'tcldll' option can be used to specify the Tcl shared library file instead
of DYNAMIC_TCL_DLL file what was specified at compile time. The version of
the shared library must match the Tcl version Vim was compiled with.

==

if_ole.txt For Vim version 8.1. Last change: 2008 Aug 16

VIM REFERENCE MANUAL by Paul Moore

The OLE Interface to Vim ole-interface

{Vi does not have any of these commands}

OLE is only available when compiled with the +ole feature. See src/if_ole.INSTALL.
An alternative is using the client-server communication clientserver .

==========
1. Activation ole-activation

Vim acts as an OLE automation server, accessible from any automation client, for example, Visual Basic, Python, or Perl. The Vim application "name" (its "ProgID", in OLE terminology) is "Vim.Application".

Hence, in order to start a Vim instance (or connect to an already running instance), code similar to the following should be used:

[Visual Basic]
```
Dim Vim As Object
Set Vim = CreateObject("Vim.Application")
```

[Python]
```
from win32com.client.dynamic import Dispatch
vim = Dispatch('Vim.Application')
```

[Perl]
```
use Win32::OLE;
$vim = new Win32::OLE 'Vim.Application';
```

[C#]
```
// Add a reference to Vim in your project.
// Choose the COM tab.
// Select "Vim Ole Interface 1.1 Type Library"
Vim.Vim vimobj = new Vim.Vim();
```

Vim does not support acting as a "hidden" OLE server, like some other OLE Automation servers. When a client starts up an instance of Vim, that instance is immediately visible. Simply closing the OLE connection to the Vim instance is not enough to shut down the Vim instance - it is necessary to explicitly execute a quit command (for example, :qa!, :wqa).

==
2. Methods   ole-methods

Vim exposes four methods for use by clients.

                                                              ole-sendkeys
SendKeys(keys)   Execute a series of keys.

This method takes a single parameter, which is a string of keystrokes. These keystrokes are executed exactly as if they had been types in at the keyboard. Special keys can be given using their <..> names, as for the right hand side of a mapping. Note: Execution of the Ex "normal" command is not supported - see below ole-normal .

Examples (Visual Basic syntax)
        Vim.SendKeys "ihello<Esc>"
        Vim.SendKeys "ma1GV4jy`a"

These examples assume that Vim starts in Normal mode. To force Normal mode, start the key sequence with CTRL-\ CTRL-N as in

        Vim.SendKeys "<C-\><C-N>ihello<Esc>"

CTRL-\ CTRL-N returns Vim to Normal mode, when in Insert or Command-line mode. Note that this doesn't work halfway a Vim command

                                                              ole-eval
Eval(expr)   Evaluate an expression.

This method takes a single parameter, which is an expression in Vim's normal format (see expression). It returns a string, which is the result of evaluating the expression. A List is turned into a string by joining the items and inserting line breaks.

Examples (Visual Basic syntax)
        Line20 = Vim.Eval("getline(20)")
        Twelve = Vim.Eval("6 + 6")   ' Note this is a STRING
        Font = Vim.Eval("&guifont")

                                                              ole-setforeground
SetForeground()   Make the Vim window come to the foreground

This method takes no arguments. No value is returned.

Example (Visual Basic syntax)
        Vim.SetForeground

                                                              ole-gethwnd
GetHwnd()   Return the handle of the Vim window.

This method takes no arguments. It returns the hwnd of the main Vimwindow. You can use this if you are writing something which needs to manipulate the Vim window, or to track it in the z-order, etc.

Example (Visual Basic syntax)

```
Vim_Hwnd = Vim.GetHwnd
```

==

3. The "normal" command ole-normal

Due to the way Vim processes OLE Automation commands, combined with the method of implementation of the Ex command :normal, it is not possible to execute the :normal command via OLE automation. Any attempt to do so will fail, probably harmlessly, although possibly in unpredictable ways.

There is currently no practical way to trap this situation, and users must simply be aware of the limitation.

==

4. Registration ole-registration E243

Before Vim will act as an OLE server, it must be registered in the system registry. In order to do this, Vim should be run with a single parameter of "-register".

-register

```
gvim -register
```

If gvim with OLE support is run and notices that no Vim OLE server has been registered, it will present a dialog and offers you the choice to register by clicking "Yes".

In some situations registering is not possible. This happens when the registry is not writable. If you run into this problem you need to run gvim as "Administrator".

Once vim is registered, the application path is stored in the registry. Before moving, deleting, or upgrading Vim, the registry entries should be removed using the "-unregister" switch.

-unregister

```
gvim -unregister
```

The OLE mechanism will use the first registered Vim it finds. If a Vim is already running, this one will be used. If you want to have (several) Vim sessions open that should not react to OLE commands, use the non-OLE version, and put it in a different directory. The OLE version should then be put in a directory that is not in your normal path, so that typing "gvim" will start the non-OLE version.

-silent

To avoid the message box that pops up to report the result, prepend "-silent":

```
gvim -silent -register
gvim -silent -unregister
```

==

5. MS Visual Studio integration MSVisualStudio VisVim

The OLE version can be used to run Vim as the editor in Microsoft Visual
Studio. This is called "VisVim". It is included in the archive that contains
the OLE version. The documentation can be found in the runtime directory, the
README_VisVim.txt file.

Using Vim with Visual Studio .Net

With .Net you no longer really need VisVim, since .Net studio has support for
external editors. Follow these directions:

In .Net Studio choose from the menu Tools->External Tools...
Add
     Title   - Vim
     Command   - c:\vim\vim63\gvim.exe
     Arguments - --servername VS_NET --remote-silent "+call cursor($(CurLine), $(CurCol))"
     Init Dir - Empty

Now, when you open a file in .Net, you can choose from the .Net menu:
Tools->Vim

That will open the file in Vim.
You can then add this external command as an icon and place it anywhere you
like. You might also be able to set this as your default editor.

If you refine this further, please post back to the Vim maillist so we have a
record of it.

--servername VS_NET
This will create a new instance of vim called VS_NET. So if you open multiple
files from VS, they will use the same instance of Vim. This allows you to
have multiple copies of Vim running, but you can control which one has VS
files in it.

--remote-silent "+call cursor(10, 27)"
              - Places the cursor on line 10 column 27
In Vim
   :h --remote-silent for more details

[.Net remarks provided by Dave Fishburn and Brian Sturk]

 vim:tw=78:ts=8:noet:ft=help:norl:

if_ruby.txt For Vim version 8.1. Last change: 2018 Mar 15

VIM REFERENCE MANUAL by Shugo Maeda

The Ruby Interface to Vim ruby Ruby

{Vi does not have any of these commands}
E266 E267 E268 E269 E270 E271 E272 E273

The Ruby interface only works when Vim was compiled with the +ruby feature.

The home page for ruby is http://www.ruby-lang.org/. You can find links for downloading Ruby there.

==========

1. Commands ruby-commands

:ruby :rub

:rub[y] {cmd} Execute Ruby command {cmd}. A command to try it out:
:ruby print "Hello"

:rub[y] << {endpattern}
{script}
{endpattern}

Execute Ruby script {script}.
{endpattern} must NOT be preceded by any white space.
If {endpattern} is omitted, it defaults to a dot '.'
like for the :append and :insert commands. This
form of the :ruby command is mainly useful for
including ruby code in vim scripts.
Note: This command doesn't work when the Ruby feature
wasn't compiled in. To avoid errors, see
script-here .

Example Vim script:

```
function! RedGem()
ruby << EOF
class Garnet
        def initialize(s)
                @buffer = Vim::Buffer.current
                vimputs(s)
        end
        def vimputs(s)
                @buffer.append(@buffer.count,s)
```

```
            end
        end
        gem = Garnet.new("pretty")
        EOF
        endfunction
```

To see what version of Ruby you have:

```
        :ruby print RUBY_VERSION
```

:rubydo :rubyd E265

:[range]rubyd[o] {cmd} Evaluate Ruby command {cmd} for each line in the [range], with $_ being set to the text of each line in turn, without a trailing <EOL>. Setting $_ will change the text, but note that it is not possible to add or delete lines using this command. The default for [range] is the whole file: "1,$".

:rubyfile :rubyf

:rubyf[ile] {file} Execute the Ruby script in {file}. This is the same as `:ruby load 'file'`, but allows file name completion.

Executing Ruby commands is not possible in the sandbox .

==

2. The Vim module ruby-vim

Ruby code gets all of its access to vim via the "Vim" module.

Overview:

```
        print "Hello"                          # displays a message
        Vim.command(cmd)                      # execute an Ex command
        num = Vim::Window.count               # gets the number of windows
        w = Vim::Window[n]                    # gets window "n"
        cw = Vim::Window.current              # gets the current window
        num = Vim::Buffer.count               # gets the number of buffers
        b = Vim::Buffer[n]                    # gets buffer "n"
        cb = Vim::Buffer.current              # gets the current buffer
        w.height = lines                      # sets the window height
        w.cursor = [row, col]                 # sets the window cursor position
        pos = w.cursor                        # gets an array [row, col]
        name = b.name                         # gets the buffer file name
        line = b[n]                           # gets a line from the buffer
        num = b.count                         # gets the number of lines
        b[n] = str                            # sets a line in the buffer
        b.delete(n)                           # deletes a line
        b.append(n, str)                      # appends a line after n
        line = Vim::Buffer.current.line       # gets the current line
        num = Vim::Buffer.current.line_number # gets the current line number
        Vim::Buffer.current.line = "test"     # sets the current line number
```

Module Functions:

ruby-message
Vim::message({msg})
        Displays the message {msg}.

ruby-set_option
Vim::set_option({arg})
        Sets a vim option. {arg} can be any argument that the ":set" command
        accepts. Note that this means that no spaces are allowed in the
        argument! See :set .

ruby-command
Vim::command({cmd})
        Executes Ex command {cmd}.

ruby-evaluate
Vim::evaluate({expr})
        Evaluates {expr} using the vim internal expression evaluator (see
         expression). Returns the expression result as:
        - a Integer if the Vim expression evaluates to a number
        - a Float if the Vim expression evaluates to a float
        - a String if the Vim expression evaluates to a string
        - a Array if the Vim expression evaluates to a Vim list
        - a Hash if the Vim expression evaluates to a Vim dictionary
        Dictionaries and lists are recursively expanded.

==
3. Vim::Buffer objects   ruby-buffer

Vim::Buffer objects represent vim buffers.

Class Methods:

current   Returns the current buffer object.
count   Returns the number of buffers.
self[{n}]   Returns the buffer object for the number {n}. The first number
                is 0.

Methods:

name   Returns the full name of the buffer.
number   Returns the number of the buffer.
count   Returns the number of lines.
length   Returns the number of lines.
self[{n}]   Returns a line from the buffer. {n} is the line number.
self[{n}] = {str}
                Sets a line in the buffer. {n} is the line number.
delete({n})   Deletes a line from the buffer. {n} is the line number.
append({n}, {str})
                Appends a line after the line {n}.
line   Returns the current line of the buffer if the buffer is
                active.
line = {str}   Sets the current line of the buffer if the buffer is active.
line_number   Returns the number of the current line if the buffer is
                active.

```
==============================================================================
4. Vim::Window objects                                          ruby-window

Vim::Window objects represent vim windows.

Class Methods:

current         Returns the current window object.
count           Returns the number of windows.
self[{n}]       Returns the window object for the number {n}.  The first number
                is 0.

Methods:

buffer          Returns the buffer displayed in the window.
height          Returns the height of the window.
height = {n}    Sets the window height to {n}.
width           Returns the width of the window.
width = {n}     Sets the window width to {n}.
cursor          Returns a [row, col] array for the cursor position.
                First line number is 1 and first column number is 0.
cursor = [{row}, {col}]
                Sets the cursor position to {row} and {col}.

==============================================================================
5. Global variables                                             ruby-globals

There are two global variables.

$curwin         The current window object.
$curbuf         The current buffer object.

==============================================================================
6. Dynamic loading                                              ruby-dynamic

On MS-Windows and Unix the Ruby library can be loaded dynamically.  The
 :version  output then includes  +ruby/dyn .

This means that Vim will search for the Ruby DLL file or shared library only
when needed.  When you don't use the Ruby interface you don't need it, thus
you can use Vim even though this library file is not on your system.

MS-Windows

You need to install the right version of Ruby for this to work.  You can find
the package to download from:
http://rubyinstaller.org/downloads/
Currently that is rubyinstaller-2.2.5.exe

To use the Ruby interface the Ruby DLL must be in your search path.  In a
console window type "path" to see what directories are used.  The 'rubydll'
option can be also used to specify the Ruby DLL.
```

The name of the DLL must match the Ruby version Vim was compiled with.
Currently the name is "msvcrt-ruby220.dll". That is for Ruby 2.2.X. To know
for sure edit "gvim.exe" and search for "ruby\d*.dll\c".

If you want to build Vim with RubyInstaller 1.9 or 2.X using MSVC, you need
some tricks. See the src/INSTALLpc.txt for detail.

If Vim is built with RubyInstaller 2.4 or later, you may also need to add
"C:\Ruby<version>\bin\ruby_builtin_dlls" to the PATH environment variable.

Unix

The 'rubydll' option can be used to specify the Ruby shared library file
instead of DYNAMIC_RUBY_DLL file what was specified at compile time. The
version of the shared library must match the Ruby version Vim was compiled
with.

==
 vim:tw=78:ts=8:noet:ft=help:norl:

VIM REFERENCE MANUAL by Gordon Prieur

Debugger Support Features debugger-support

{Vi does not have any of these features}

==
1. Debugger Features debugger-features

The following features are available for an integration with a debugger or an Integrated Programming Environment (IPE) or Integrated Development Environment (IDE):

Alternate Command Input	alt-input
Debug Signs	debug-signs
Debug Source Highlight	debug-highlight
Message Footer	gui-footer
Balloon Evaluation	balloon-eval

These features were added specifically for use in the Motif version of gvim. However, the alt-input and debug-highlight were written to be usable in both vim and gvim. Some of the other features could be used in the non-GUI vim with slight modifications. However, I did not do this nor did I test the reliability of building for vim or non Motif GUI versions.

1.1 Alternate Command Input alt-input

For Vim to work with a debugger there must be at least an input connection with a debugger or external tool. In many cases there will also be an output connection but this isn't absolutely necessary.

The purpose of the input connection is to let the external debugger send commands to Vim. The commands sent by the debugger should give the debugger enough control to display the current debug environment and state.

The current implementation is based on the X Toolkit dispatch loop and the XtAddInput() function call.

1.2 Debug Signs debug-signs

Many debuggers mark specific lines by placing a small sign or color highlight on the line. The :sign command lets the debugger set this graphic mark. Some examples where this feature would be used would be a debugger showing an arrow representing the Program Counter (PC) of the program being debugged. Another

example would be a small stop sign for a line with a breakpoint. These visible highlights let the user keep track of certain parts of the state of the debugger.

This feature can be used with more than debuggers, too. An IPE can use a sign to highlight build errors, searched text, or other things. The sign feature can also work together with the `debug-highlight` to ensure the mark is highly visible.

Debug signs are defined and placed using the `:sign` command.

1.3 Debug Source Highlight `debug-highlight`

This feature allows a line to have a predominant highlight. The highlight is intended to make a specific line stand out. The highlight could be made to work for both vim and gvim, whereas the debug sign is, in most cases, limited to gvim. The one exception to this is Sun Microsystem's dtterm. The dtterm from Sun has a "sign gutter" for showing signs.

1.4 Message Footer `gui-footer`

The message footer can be used to display messages from a debugger or IPE. It can also be used to display menu and toolbar tips. The footer area is at the bottom of the GUI window, below the line used to display colon commands.

The display of the footer is controlled by the `'guioptions'` letter 'F'.

1.5 Balloon Evaluation `balloon-eval`

This feature allows a debugger, or other external tool, to display dynamic information based on where the mouse is pointing. The purpose of this feature was to allow Sun's Visual WorkShop debugger to display expression evaluations. However, the feature was implemented in as general a manner as possible and could be used for displaying other information as well.

The Balloon Evaluation has some settable parameters too. For Motif the font list and colors can be set via X resources (XmNballoonEvalFontList, XmNballoonEvalBackground, and XmNballoonEvalForeground).
The `'balloondelay'` option sets the delay before an attempt is made to show a balloon.
The `'ballooneval'` and/or the `'balloonevalterm'` option needs to be set to switch it on.

Balloon evaluation is only available in the GUI when compiled with the `+balloon_eval` feature. For the terminal the `+balloon_eval_term` feature matters.

The Balloon evaluation functions are also used to show a tooltip for the toolbar. The `'ballooneval'` option does not need to be set for this. But the other settings apply.

Another way to use the balloon is with the 'balloonexpr' option. This is
completely user definable.

==
2. Vim Compile Options   debugger-compilation

The debugger features were added explicitly for use with Sun's Visual
WorkShop Integrated Programming Environment (ipe). However, they were done
in as generic a manner as possible so that integration with other debuggers
could also use some or all of the tools used with Sun's ipe.

The following compile time preprocessor variables control the features:

    Alternate Command Input   ALT_X_INPUT
    Debug Glyphs   FEAT_SIGNS
    Debug Highlights   FEAT_SIGNS
    Message Footer   FEAT_FOOTER
    Balloon Evaluation   FEAT_BEVAL

The first integration with a full IPE/IDE was with Sun Visual WorkShop. To
compile a gvim which interfaces with VWS set the following flag, which sets
all the above flags:

    Sun Visual WorkShop   FEAT_SUN_WORKSHOP

==
3. Integrated Debuggers   debugger-integration

One fully integrated debugger/IPE/IDE is Sun's Visual WorkShop Integrated
Programming Environment.

For Sun NetBeans support see netbeans .

 vim:tw=78:sw=4:ts=8:noet:ft=help:norl:

workshop.txt For Vim version 8.1. Last change: 2013 Jul 06

VIM REFERENCE MANUAL by Gordon Prieur

Sun Visual WorkShop Features workshop workshop-support

{Vi does not have any of these features}
{only available when compiled with the |+sun_workshop| feature}

==========
1. Introduction workshop-intro

Sun Visual WorkShop has an "Editor of Choice" feature designed to let users debug using their favorite editors. For the 6.0 release we have added support for gvim. A workshop debug session will have a debugging window and an editor window (possibly others as well). The user can do many debugging operations from the editor window, minimizing the need to switch from window to window.

The version of vim shipped with Sun Visual WorkShop 6 (also called Forte Developer 6) is vim 5.3. The features in this release are much more reliable than the vim/gvim shipped with Visual WorkShop. VWS users wishing to use vim as their editor should compile these sources and install them in their workshop release tree.

==========
2. Commands workshop-commands

:ws :wsverb

:ws[verb] verb Pass the verb to the verb executor

Pass the verb to a workshop function which gathers some arguments and sends the verb and data to workshop over an IPC connection.

==========
3. Compiling vim/gvim for WorkShop workshop-compiling

Compiling vim with FEAT_SUN_WORKSHOP turns on all compile time flags necessary for building a vim to work with Visual WorkShop. The features required for VWS have been built and tested using the Sun compilers from the VWS release. They have not been built or tested using Gnu compilers. This does not mean the features won't build and run if compiled with gcc, just that nothing is guaranteed with gcc!

==========
4. Configuring gvim for a WorkShop release tree workshop-configure

There are several assumptions which must be met in order to compile a gvim for use with Sun Visual WorkShop 6.

- You should use the compiler in VWS rather than gcc. We have neither built nor tested with gcc and cannot guarantee it will build properly.

- You must supply your own XPM library. See workshop-xpm below for details on obtaining the latest version of XPM.

- Edit the Makefile in the src directory and uncomment the lines for Sun Visual WorkShop. You can easily find these by searching for the string FEAT_SUN_WORKSHOP

- We also suggest you use Motif for your gui. This will provide gvim with the same look-and-feel as the rest of Sun Visual WorkShop.

The following configuration line can be used to configure vim to build for use with Sun Visual WorkShop:

```
$ CC=cc configure --enable-workshop --enable-gui=motif \
    -prefix=<VWS-install-dir>/contrib/contrib6/<vim-version>
```

The VWS-install-dir should be the base directory where your Sun Visual WorkShop was installed. By default this is /opt/SUNWspro. It will normally require root permissions to install the vim release. You will also need to change the symlink <VWS-install-dir>/bin/gvim to point to the vim in your newly installed directory. The <vim-version> should be a unique version string. I use "vim" concatenated with the equivalent of version.h's VIM_VERSION_SHORT.

==
5. Obtaining the latest version of the XPM library workshop-xpm

The XPM library is required to show images within Vim with Motif or Athena. Without it the toolbar and signs will be disabled.

The XPM library is provided by Arnaud Le Hors of the French National Institute for Research in Computer Science and Control. It can be downloaded from http://cgit.freedesktop.org/xorg/lib/libXpm. The current release, as of this writing, is xpm-3.4k-solaris.tgz, which is a gzip'ed tar file. If you create the directory /usr/local/xpm and untar the file there you can use the uncommented lines in the Makefile without changing them. If you use another xpm directory you will need to change the XPM_DIR in src/Makefile.

netbeans.txt For Vim version 8.1. Last change: 2016 Jul 15

VIM REFERENCE MANUAL by Gordon Prieur et al.

netbeans netbeans-support

Vim NetBeans Protocol: a socket interface for Vim integration into an IDE.

{Vi does not have any of these features}
{only available when compiled with the |+netbeans_intg| feature}

==
1. Introduction netbeans-intro

The NetBeans interface was initially developed to integrate Vim into the NetBeans Java IDE, using the external editor plugin. This NetBeans plugin no longer exists for recent versions of NetBeans but the protocol was developed in such a way that any IDE can use it to integrate Vim.

The NetBeans protocol of Vim is a text based communication protocol, over a classical TCP socket. There is no dependency on Java or NetBeans. Any language or environment providing a socket interface can control Vim using this protocol. There are existing implementations in C, C++, Python and Java. The name NetBeans is kept today for historical reasons.

Current projects using the NetBeans protocol of Vim are:
- VimIntegration, description of various projects doing Vim Integration:
  http://www.freehackers.org/VimIntegration
- Agide, an IDE for the AAP project, written in Python:
  http://www.a-a-p.org
- Clewn, a gdb integration into Vim, written in C:
  http://clewn.sourceforge.net/
- Pyclewn, a gdb integration into Vim, written in Python:
  http://pyclewn.sourceforge.net/
- VimPlugin, integration of Vim inside Eclipse:
  http://vimplugin.sourceforge.net/wiki/pmwiki.php

- PIDA, IDE written in Python integrating Vim:
  http://pida.co.uk/
- VimWrapper, library to easy Vim integration into IDE:
  http://www.freehackers.org/VimWrapper

Check the specific project pages to see how to use Vim with these projects.

An alternative is to use a channel, see channel .

In the rest of this help page, we will use the term "Vim Controller" to
describe the program controlling Vim through the NetBeans socket interface.

About the NetBeans IDE

NetBeans is an open source Integrated Development Environment developed
jointly by Sun Microsystems, Inc. and the netbeans.org developer community.
Initially just a Java IDE, NetBeans has had C, C++, and Fortran support added
in recent releases.

For more information visit the main NetBeans web site http://www.netbeans.org.
The External Editor is now, unfortunately, declared obsolete. See
http://externaleditor.netbeans.org.

Sun Microsystems, Inc. also ships NetBeans under the name Sun ONE Studio.
Visit http://www.sun.com for more information regarding the Sun ONE Studio
product line.

Current releases of NetBeans provide full support for Java and limited support
for C, C++, and Fortran. Current releases of Sun ONE Studio provide full
support for Java, C, C++, and Fortran.

==
2. Integration features netbeans-integration

The NetBeans socket interface of Vim allows to get information from Vim or to
ask Vim to perform specific actions:
- get information about buffer: buffer name, cursor position, buffer content,
  etc.
- be notified when buffers are open or closed
- be notified of how the buffer content is modified
- load and save files
- modify the buffer content
- installing special key bindings
- raise the window, control the window geometry

For sending key strokes to Vim or for evaluating functions in Vim, you must
use the clientserver interface.

==
3. Configuring Vim for NetBeans netbeans-configure

For more help about installing Vim, please read usr_90.txt in the Vim User

Manual.

On Unix:

When running configure without arguments the NetBeans interface should be
included. That is, if the configure check to find out if your system supports
the required features succeeds.

In case you do not want the NetBeans interface you can disable it by
uncommenting a line with "--disable-netbeans" in the Makefile.

Currently the NetBeans interface is supported by Vim running in a terminal and
by gvim when it is run with one of the following GUIs: GTK, GNOME, Windows,
Athena and Motif.

If Motif support is required the user must supply XPM libraries. See
 workshop-xpm for details on obtaining the latest version of XPM.

On MS-Windows:

The Win32 support is now in beta stage.

To use XPM signs on Win32 (e.g. when using with NetBeans) you can compile
XPM by yourself or use precompiled libraries from http://iamphet.nm.ru/misc/
(for MS Visual C++) or http://gnuwin32.sourceforge.net (for MinGW).

Enable debugging:

To enable debugging of Vim and of the NetBeans protocol, the "NBDEBUG" macro
needs to be defined. Search in the Makefile of the platform you are using for
"NBDEBUG" to see what line needs to be uncommented. This effectively adds
"-DNBDEBUG" to the compile command. Also see netbeans-debugging

==
4. Error Messages   netbeans-messages

These error messages are specific to NetBeans socket protocol:

                                                                E463
Region is guarded, cannot modify
                The Vim Controller has defined guarded areas in the text,
                which you cannot change. Also sets the current buffer, if
                necessary.

                                                                E532
The defineAnnoType highlighting color name is too long
                The maximum length of the "fg" or "bg" color argument in the
                defineAnnoType command is 32 characters.
                New in version 2.5.

E656

Writes of unmodified buffers forbidden
		Writes of unmodified buffers that were opened from the
		Vim Controller are not possible.

E657

Partial writes disallowed
		Partial writes for buffers that were opened from the
		Vim Controller are not allowed.

E658

Connection lost for this buffer
		The Vim Controller has become confused about the state of
		this file. Rather than risk data corruption, it has severed
		the connection for this file. Vim will take over
		responsibility for saving changes to this file and the
		Vim Controller will no longer know of these changes.

E744

Read-only file
		Vim normally allows changes to a read-only file and only
		enforces the read-only rule if you try to write the file.
		However, NetBeans does not let you make changes to a file
		which is read-only and becomes confused if Vim does this.
		So Vim does not allow modifications to files when run
		in NetBeans mode.

==
5. Running Vim in NetBeans mode		netbeans-run

There are two different ways to run Vim in NetBeans mode:

	+ an IDE may start Vim with the -nb command line argument
	+ NetBeans can be started from within Vim with the :nbstart command

Vim uses a 3 second timeout on trying to make the connection.

netbeans-parameters

Three forms can be used to setup the NetBeans connection parameters.
When started from the command line, the -nb command line argument may be:

	-nb={fname}				from a file
	-nb:{hostname}:{addr}:{password}	directly
	-nb					from a file or environment

When started from within Vim, the :nbstart optional argument may be:

	={fname}				from a file
	:{hostname}:{addr}:{password}		directly
	<MISSING ARGUMENT>			from a file or environment

E660 E668

When NetBeans is started from the command line, for security reasons, the best

method is to write the information in a file readable only by the user. The name of the file can be passed with the "-nb={fname}" argument or, when "-nb" is used without a parameter, the environment variable "__NETBEANS_CONINFO". The file must contain these three lines, in any order:

```
host={hostname}
port={addr}
auth={password}
```

Other lines are ignored. The Vim Controller is responsible for deleting the file afterwards.

{hostname} is the name of the machine where Vim Controller is running. When omitted the environment variable "__NETBEANS_HOST" is used or the default "localhost".

{addr} is the port number for the NetBeans interface. When omitted the environment variable "__NETBEANS_SOCKET" is used or the default 3219.

{password} is the password for connecting to NetBeans. When omitted the environment variable "__NETBEANS_VIM_PASSWORD" is used or "changeme".

Vim will initiate a socket connection (client side) to the specified host and port upon startup. The password will be sent with the AUTH event when the connection has been established.

==
6. NetBeans protocol netbeans-protocol

The communication between the Vim Controller and Vim uses plain text messages. This protocol was first designed to work with the external editor module of NetBeans. Later it was extended to work with Agide (A-A-P GUI IDE, see http://www.a-a-p.org) and then with other IDE. The extensions are marked with "version 2.1".

Version 2.2 of the protocol has several minor changes which should only affect NetBeans users (ie, not Agide users). However, a bug was fixed which could cause confusion. The netbeans_saved() function sent a "save" protocol command. In protocol version 2.1 and earlier this was incorrectly interpreted as a notification that a write had taken place. In reality, it told NetBeans to save the file so multiple writes were being done. This caused various problems and has been fixed in 2.2. To decrease the likelihood of this confusion happening again, netbeans_saved() has been renamed to netbeans_save_buffer().

We are now at version 2.5. For the differences between 2.4 and 2.5 search for "2.5" below.

The messages are currently sent over a socket. Since the messages are in plain UTF-8 text this protocol could also be used with any other communication mechanism.

Netbeans messages are processed when Vim is idle, waiting for user input.

When Vim is run in non-interactive mode, for example when running an automated test case that sources a Vim script, the idle loop may not be called often enough. In that case, insert :sleep commands in the Vim script. The :sleep command does invoke Netbeans messages processing.

6.1 Kinds of messages nb-messages

There are four kinds of messages:

kind	direction	comment
Command	IDE -> editor	no reply necessary
Function	IDE -> editor	editor must send back a reply
Reply	editor -> IDE	only in response to a Function
Event	editor -> IDE	no reply necessary

The messages are sent as a single line with a terminating newline character. Arguments are separated by a single space. The first item of the message depends on the kind of message:

kind	first item	example
Command	bufID:name!seqno	11:showBalloon!123 "text"
Function	bufID:name/seqno	11:getLength/123
Reply	seqno	123 5000
Event	bufID:name=seqno	11:keyCommand=123 "S-F2"

6.2 Terms nb-terms

bufID Buffer number. A message may be either for a specific buffer or generic. Generic messages use a bufID of zero. NOTE: this buffer ID is assigned by the IDE, it is not Vim's buffer number. The bufID must be a sequentially rising number, starting at one. When the 'switchbuf' option is set to "usetab" and the "bufID" buffer is not found in the current tab page, the netbeans commands and functions that set this buffer as the current buffer will jump to the first open window that contains this buffer in other tab pages instead of replacing the buffer in the current window.

seqno The IDE uses a sequence number for Commands and Functions. A Reply must use the sequence number of the Function that it is associated with. A zero sequence number can be used for Events (the seqno of the last received Command or Function can also be used).

string		Argument in double quotes. Text is in UTF-8 encoding. This
		means ASCII is passed as-is. Special characters are
		represented with a backslash:
			\"	double quote
			\n	newline
			\r	carriage-return
			\t	tab (optional, also works literally)
			\\	backslash
		NUL bytes are not allowed!

boolean		Argument with two possible values:
			T	true
			F	false

number		Argument with a decimal number.

color		Argument with either a decimal number, "none" (without the
		quotes) or the name of a color (without the quotes) defined
		both in the color list in highlight-ctermfg and in the color
		list in gui-colors .
		New in version 2.5.

offset		A number argument that indicates a byte position in a buffer.
		The first byte has offset zero. Line breaks are counted for
		how they appear in the file (CR/LF counts for two bytes).
		Note that a multi-byte character is counted for the number of
		bytes it takes.

lnum/col	Argument with a line number and column number position. The
		line number starts with one, the column is the byte position,
		starting with zero. Note that a multi-byte character counts
		for several columns.

pathname	String argument: file name with full path.

6.3 Commands   nb-commands

actionMenuItem Not implemented.

actionSensitivity
		Not implemented.

addAnno serNum typeNum off len
		Place an annotation in this buffer.
		Arguments:
		   serNum	number	serial number of this placed
					annotation, used to be able to remove
					it
		   typeNum	number	sequence number of the annotation
					defined with defineAnnoType for this
					buffer
		   off		number	offset where annotation is to be placed

```
                   len          number  not used
                In version 2.1 "lnum/col" can be used instead of "off".

balloonResult text
                Not implemented.

close           Close the buffer.  This leaves us without current buffer, very
                dangerous to use!

create          Creates a buffer without a name.  Replaces the current buffer
                (it's hidden when it was changed).
                The Vim Controller should use this as the first command for a
                file that is being opened.  The sequence of commands could be:
                        create
                        setCaretListener        (ignored)
                        setModified             (no effect)
                        setContentType          (ignored)
                        startDocumentListen
                        setTitle
                        setFullName

defineAnnoType typeNum typeName tooltip glyphFile fg bg
                Define a type of annotation for this buffer.
                Arguments:
                   typeNum      number  sequence number (not really used)
                   typeName     string  name that identifies this annotation
                   tooltip      string  not used
                   glyphFile    string  name of icon file
                   fg           color   foreground color for line highlighting
                   bg           color   background color for line highlighting
                Vim will define a sign for the annotation.
                When color is a number, this is the "#rrggbb" Red, Green and
                Blue values of the color (see  gui-colors ) and the
                highlighting is only defined for gVim.
                When color is a name, this color is defined both for Vim
                running in a color terminal and for gVim.
                When both "fg" and "bg" are "none" no line highlighting is
                used (new in version 2.1).
                When "glyphFile" is empty, no text sign is used (new in
                version 2.1).
                When "glyphFile" is one or two characters long, a text sign is
                defined (new in version 2.1).
                Note: the annotations will be defined in sequence, and the
                sequence number is later used with addAnno.

editFile pathname
                Set the name for the buffer and edit the file "pathname", a
                string argument.
                Normal way for the IDE to tell the editor to edit a file.

                You must set a bufId different of 0 with this command to
                assign a bufId to the buffer. It will trigger an event
                fileOpened with a bufId of 0 but the buffer has been assigned.
```

```
                If the IDE is going to pass the file text to the editor use
                these commands instead:
                        setFullName
                        insert
                        initDone
                New in version 2.1.

enableBalloonEval
                Not implemented.

endAtomic       End an atomic operation.  The changes between "startAtomic"
                and "endAtomic" can be undone as one operation.  But it's not
                implemented yet.  Redraw when necessary.

guard off len
                Mark an area in the buffer as guarded.  This means it cannot
                be edited.  "off" and "len" are numbers and specify the text
                to be guarded.

initDone        Mark the buffer as ready for use.  Implicitly makes the buffer
                the current buffer.  Fires the BufReadPost autocommand event.

insertDone
                Sent by Vim Controller to tell Vim an initial file insert is
                done.  This triggers a read message being printed.  Prior to
                version 2.3, no read messages were displayed after opening a
                file.  New in version 2.3.

moveAnnoToFront serNum
                Not implemented.

netbeansBuffer isNetbeansBuffer
                If "isNetbeansBuffer" is "T" then this buffer is "owned" by
                NetBeans.
                New in version 2.2.

putBufferNumber pathname
                Associate a buffer number with the Vim buffer by the name
                "pathname", a string argument.  To be used when the editor
                reported editing another file to the IDE and the IDE needs to
                tell the editor what buffer number it will use for this file.
                Also marks the buffer as initialized.
                New in version 2.1.

raise           Bring the editor to the foreground.
                Only when Vim is run with a GUI.
                New in version 2.1.

removeAnno serNum
                Remove a previously placed annotation for this buffer.
                "serNum" is the same number used in addAnno.

save            Save the buffer when it was modified.  The other side of the
                interface is expected to write the buffer and invoke
```

"setModified" to reset the "changed" flag of the buffer.
The writing is skipped when one of these conditions is true:
- 'write' is not set
- the buffer is read-only
- the buffer does not have a file name
- 'buftype' disallows writing
New in version 2.2.

saveDone
Sent by Vim Controller to tell Vim a save is done. This triggers a save message being printed. Prior to version 2.3, no save messages were displayed after a save.
New in version 2.3.

setAsUser Not implemented.

setBufferNumber pathname
Associate a buffer number with Vim buffer by the name "pathname". To be used when the editor reported editing another file to the IDE and the IDE needs to tell the editor what buffer number it will use for this file.
Has the side effect of making the buffer the current buffer.
See "putBufferNumber" for a more useful command.

setContentType
Not implemented.

setDot off Make the buffer the current buffer and set the cursor at the specified position. If the buffer is open in another window than make that window the current window.
If there are folds they are opened to make the cursor line visible.
In version 2.1 "lnum/col" can be used instead of "off".

setExitDelay seconds
Set the delay for exiting to "seconds", a number.
This delay is used to give the IDE a chance to handle things before really exiting. The default delay is two seconds.
New in version 2.1.
Obsolete in version 2.3.

setFullName pathname
Set the file name to be used for a buffer to "pathname", a string argument.
Used when the IDE wants to edit a file under control of the IDE. This makes the buffer the current buffer, but does not read the file. "insert" commands will be used next to set the contents.

setLocAndSize Not implemented.

setMark Not implemented.

setModified modified

When the boolean argument "modified" is "T" mark the buffer as
modified, when it is "F" mark it as unmodified.

setModtime time
Update a buffers modification time after the file has been
saved directly by the Vim Controller.
New in version 2.3.

setReadOnly
Set a file as readonly
Implemented in version 2.3.

setStyle Not implemented.

setTitle name
Set the title for the buffer to "name", a string argument.
The title is only used for the Vim Controller functions, not
by Vim.

setVisible visible
When the boolean argument "visible" is "T", goto the buffer.
The "F" argument does nothing.

showBalloon text
Show a balloon (popup window) at the mouse pointer position,
containing "text", a string argument. The balloon should
disappear when the mouse is moved more than a few pixels.
Only when Vim is run with a GUI.
New in version 2.1.

specialKeys
Map a set of keys (mostly function keys) to be passed back
to the Vim Controller for processing. This lets regular IDE
hotkeys be used from Vim.
Implemented in version 2.3.

startAtomic Begin an atomic operation. The screen will not be updated
until "endAtomic" is given.

startCaretListen
Not implemented.

startDocumentListen
Mark the buffer to report changes to the IDE with the
"insert" and "remove" events. The default is to report
changes.

stopCaretListen
Not implemented.

stopDocumentListen
Mark the buffer to stop reporting changes to the IDE.
Opposite of startDocumentListen.
NOTE: if "netbeansBuffer" was used to mark this buffer as a

NetBeans buffer, then the buffer is deleted in Vim. This is
for compatibility with Sun Studio 10.

unguard off len
Opposite of "guard", remove guarding for a text area.
Also sets the current buffer, if necessary.

version Not implemented.

6.4 Functions and Replies nb-functions

getDot Not implemented.

getCursor Return the current buffer and cursor position.
The reply is:
seqno bufID lnum col off
seqno = sequence number of the function
bufID = buffer ID of the current buffer (if this is unknown -1
is used)
lnum = line number of the cursor (first line is one)
col = column number of the cursor (in bytes, zero based)
off = offset of the cursor in the buffer (in bytes)
New in version 2.1.

getLength Return the length of the buffer in bytes.
Reply example for a buffer with 5000 bytes:
123 5000
TODO: explain use of partial line.

getMark Not implemented.

getAnno serNum
Return the line number of the annotation in the buffer.
Argument:
serNum serial number of this placed annotation
The reply is:
123 lnum line number of the annotation
123 0 invalid annotation serial number
New in version 2.4.

getModified When a buffer is specified: Return zero if the buffer does not
have changes, one if it does have changes.
When no buffer is specified (buffer number zero): Return the
number of buffers with changes. When the result is zero it's
safe to tell Vim to exit.
New in version 2.1.

getText Return the contents of the buffer as a string.
Reply example for a buffer with two lines
123 "first line\nsecond line\n"
NOTE: docs indicate an offset and length argument, but this is
not implemented.

```
insert off text
                Insert "text" before position "off".  "text" is a string
                argument, "off" a number.
                "text" should have a "\n" (newline) at the end of each line.
                Or "\r\n" when 'fileformat' is "dos".  When using "insert" in
                an empty buffer Vim will set 'fileformat' accordingly.
                When "off" points to the start of a line the text is inserted
                above this line.  Thus when "off" is zero lines are inserted
                before the first line.
                When "off" points after the start of a line, possibly on the
                NUL at the end of a line, the first line of text is appended
                to this line.  Further lines come below it.
                Possible replies:
                        123             no problem
                        123 !message    failed
                Note that the message in the reply is not quoted.
                Also sets the current buffer, if necessary.
                Does not move the cursor to the changed text.
                Resets undo information.

remove off length
                Delete "length" bytes of text at position "off".  Both
                arguments are numbers.
                Possible replies:
                        123             no problem
                        123 !message    failed
                Note that the message in the reply is not quoted.
                Also sets the current buffer, if necessary.

saveAndExit     Perform the equivalent of closing Vim: ":confirm qall".
                If there are no changed files or the user does not cancel the
                operation Vim exits and no result is sent back.  The IDE can
                consider closing the connection as a successful result.
                If the user cancels the operation the number of modified
                buffers that remains is returned and Vim does not exit.
                New in version 2.1.

6.5 Events                                                  nb-events

balloonEval off len type
                The mouse pointer rests on text for a short while.  When "len"
                is zero, there is no selection and the pointer is at position
                "off".  When "len" is non-zero the text from position "off" to
                "off" + "len" is selected.
                Only sent after "enableBalloonEval" was used for this buffer.
                "type" is not yet defined.
                Not implemented yet.

balloonText text
                Used when 'balooneval' is set and the mouse pointer rests on
                some text for a moment.  "text" is a string, the text under
                the mouse pointer.
                Only when Vim is run with a GUI.
```

New in version 2.1.

buttonRelease button lnum col
Report which button was pressed and the location of the cursor at the time of the release. Only for buffers that are owned by the Vim Controller. This event is not sent if the button was released while the mouse was in the status line or in a separator line. If col is less than 1 the button release was in the sign area.
New in version 2.2.

disconnect
Tell the Vim Controller that Vim is exiting and not to try and read or write more commands.
New in version 2.3.

fileClosed Not implemented.

fileModified Not implemented.

fileOpened pathname open modified
A file was opened by the user.
Arguments:

pathname	string	name of the file
open	boolean	always "T"
modified	boolean	always "F"

geometry cols rows x y
Report the size and position of the editor window.
Arguments:

cols	number	number of text columns
rows	number	number of text rows
x	number	pixel position on screen
y	number	pixel position on screen

Only works for Motif.

insert off text
Text "text" has been inserted in Vim at position "off".
Only fired when enabled, see "startDocumentListen".

invokeAction Not implemented.

keyCommand keyName
Reports a special key being pressed with name "keyName", which is a string.
Supported key names:

F1	function key 1
F2	function key 2
...	
F12	function key 12
' '	space (without the quotes)
!	exclamation mark
...	any other ASCII printable character

```
                        ~               tilde

                        X               any unrecognized key

                The key may be prepended by "C", "S" and/or "M" for Control,
                Shift and Meta (Alt) modifiers.  If there is a modifier a dash
                is used to separate it from the key name.  For example:
                "C-F2".
                ASCII characters are new in version 2.1.

keyAtPos keyName lnum/col
                Like "keyCommand" and also report the line number and column
                of the cursor.
                New in version 2.1.

killed          A file was deleted or wiped out by the user and the buffer
                annotations have been removed.  The bufID number for this
                buffer has become invalid.  Only for files that have been
                assigned a bufID number by the IDE.

newDotAndMark off off
                Reports the position of the cursor being at "off" bytes into
                the buffer.  Only sent just before a "keyCommand" event.

quit            Not implemented.

remove off len
                Text was deleted in Vim at position "off" with byte length
                "len".
                Only fired when enabled, see "startDocumentListen".

revert          Not implemented.

save            The buffer has been saved and is now unmodified.
                Only fired when enabled, see "startDocumentListen".

startupDone     The editor has finished its startup work and is ready for
                editing files.
                New in version 2.1.

unmodified      The buffer is now unmodified.
                Only fired when enabled, see "startDocumentListen".

version vers    Report the version of the interface implementation.  Vim
                reports "2.4" (including the quotes).

6.6 Special messages                                    nb-special

These messages do not follow the style of the messages above.  They are
terminated by a newline character.

ACCEPT          Not used.
```

AUTH password editor -> IDE: First message that the editor sends to the IDE.
               Must contain the password for the socket server, as specified
               with the -nb argument. No quotes are used!

DISCONNECT   IDE -> editor: break the connection. The editor will exit.
               The IDE must only send this message when there are no unsaved
               changes!

DETACH   IDE -> editor: break the connection without exiting the
               editor. Used when the IDE exits without bringing down the
               editor as well.
               New in version 2.1.

REJECT   Not used.

6.7 Protocol errors nb-protocol_errors

These errors occur when a message violates the protocol:
E627 E628 E629 E632 E633 E634 E635 E636
E637 E638 E639 E640 E641 E642 E643 E644 E645 E646
E647 E648 E649 E650 E651 E652

7. NetBeans commands netbeans-commands

:nbstart E511 E838
:nbs[tart] {connection} Start a new Netbeans session with {connection} as the
                         socket connection parameters. The format of
                         {connection} is described in netbeans-parameters .
                         At any time, one may check if the netbeans socket is
                         connected by running the command:
                         ':echo has("netbeans_enabled")'

:nbclose
:nbc[lose]   Close the current NetBeans session. Remove all placed
                         signs.

:nbkey
:nb[key] {key}   Pass the {key} to the Vim Controller for processing.
                         When a hot-key has been installed with the specialKeys
                         command, this command can be used to generate a hotkey
                         message to the Vim Controller.
                         This command can also be used to pass any text to the
                         Vim Controller. It is used by Pyclewn, for example,
                         to build the complete set of gdb commands as Vim user
                         commands.
                         The events newDotAndMark, keyCommand and keyAtPos are
                         generated (in this order).

8. Known problems netbeans-problems

NUL bytes are not possible. For editor -> IDE they will appear as NL
characters. For IDE -> editor they cannot be inserted.

A NetBeans session may be initiated with Vim running in a terminal, and
continued later in a GUI environment after running the :gui command. In this
case, the highlighting defined for the NetBeans annotations may be cleared
when the ":gui" command sources .gvimrc and this file loads a colorscheme
that runs the command ":highlight clear".
New in version 2.5.

==
9. Debugging NetBeans protocol   netbeans-debugging

To debug the Vim protocol, you must first compile Vim with debugging support
and NetBeans debugging support. See netbeans-configure for instructions
about Vim compiling and how to enable debug support.

When running Vim, set the following environment variables:

```
export SPRO_GVIM_DEBUG=netbeans.log
export SPRO_GVIM_DLEVEL=0xffffffff
```

Vim will then log all the incoming and outgoing messages of the NetBeans
protocol to the file netbeans.log .

The content of netbeans.log after a session looks like this:

```
Tue May 20 17:19:27 2008
EVT: 0:startupDone=0
CMD 1: (1) create
CMD 2: (1) setTitle "testfile1.txt"
CMD 3: (1) setFullName "testfile1.txt"
EVT(suppressed): 1:remove=3 0 -1
EVT: 1:fileOpened=0 "d:\\work\\vimWrapper\\vimWrapper2\\pyvimwrapper\\tests\\testfile1.txt"
CMD 4: (1) initDone
FUN 5: (0) getCursor
REP 5: 1 1 0 0
CMD 6: (2) create
CMD 7: (2) setTitle "testfile2.txt"
CMD 8: (2) setFullName "testfile2.txt"
EVT(suppressed): 2:remove=8 0 -1
EVT: 2:fileOpened=0 "d:\\work\\vimWrapper\\vimWrapper2\\pyvimwrapper\\tests\\testfile2.txt"
CMD 9: (2) initDone
```

==
10. NetBeans External Editor

NOTE: This information is obsolete! Only relevant if you are using an old
version of NetBeans.

10.1. Downloading NetBeans   netbeans-download

The NetBeans IDE is available for download from netbeans.org. You can download a released version, download sources, or use CVS to download the current source tree. If you choose to download sources, follow directions from netbeans.org on building NetBeans.

Depending on the version of NetBeans you download, you may need to do further work to get the required External Editor module. This is the module which lets NetBeans work with gvim (or xemacs :-). See http://externaleditor.netbeans.org for details on downloading this module if your NetBeans release does not have it.

For C, C++, and Fortran support you will also need the cpp module. See http://cpp.netbeans.org for information regarding this module.

You can also download Sun ONE Studio from Sun Microsystems, Inc for a 30 day free trial. See http://www.sun.com for further details.

10.2. NetBeans Key Bindings netbeans-keybindings

Vim understands a number of key bindings that execute NetBeans commands. These are typically all the Function key combinations. To execute a NetBeans command, the user must press the Pause key followed by a NetBeans key binding. For example, in order to compile a Java file, the NetBeans key binding is "F9". So, while in vim, press "Pause F9" to compile a java file. To toggle a breakpoint at the current line, press "Pause Shift F8".

The Pause key is Function key 21. If you don't have a working Pause key and want to use F8 instead, use:

```
:map <F8> <F21>
```

The External Editor module dynamically reads the NetBeans key bindings so vim should always have the latest key bindings, even when NetBeans changes them.

10.3. Preparing NetBeans for Vim netbeans-preparation

In order for NetBeans to work with vim, the NetBeans External Editor module must be loaded and enabled. If you have a Sun ONE Studio Enterprise Edition then this module should be loaded and enabled. If you have a NetBeans release you may need to find another way of obtaining this open source module.

You can check if you have this module by opening the Tools->Options dialog and drilling down to the "Modules" list (IDE Configuration->System->Modules). If your Modules list has an entry for "External Editor" you must make sure it is enabled (the "Enabled" property should have the value "True"). If your Modules list has no External Editor see the next section on obtaining-exted .

10.4. Obtaining the External Editor Module obtaining-exted

There are 2 ways of obtaining the External Editor module. The easiest way

is to use the NetBeans Update Center to download and install the module. Unfortunately, some versions do not have this module in their update center. If you cannot download via the update center you will need to download sources and build the module. I will try and get the module available from the NetBeans Update Center so building will be unnecessary. Also check http://externaleditor.netbeans.org for other availability options.

To download the External Editor sources via CVS and build your own module, see http://externaleditor.netbeans.org and http://www.netbeans.org. Unfortunately, this is not a trivial procedure.

10.5. Setting up NetBeans to run with Vim netbeans-setup

Assuming you have loaded and enabled the NetBeans External Editor module as described in netbeans-preparation all you need to do is verify that the gvim command line is properly configured for your environment.

Open the Tools->Options dialog and open the Editing category. Select the External Editor. The right hand pane should contain a Properties tab and an Expert tab. In the Properties tab make sure the "Editor Type" is set to "Vim". In the Expert tab make sure the "Vim Command" is correct.

You should be careful if you change the "Vim Command". There are command line options there which must be there for the connection to be properly set up. You can change the command name but that's about it. If your gvim can be found by your $PATH then the Vim Command can start with "gvim". If you don't want gvim searched from your $PATH then hard code in the full Unix path name. At this point you should get a gvim for any source file you open in NetBeans.

If some files come up in gvim and others (with different file suffixes) come up in the default NetBeans editor you should verify the MIME type in the Expert tab MIME Type property. NetBeans is MIME oriented and the External Editor will only open MIME types specified in this property.

sign.txt For Vim version 8.1. Last change: 2016 Aug 17

VIM REFERENCE MANUAL by Gordon Prieur
and Bram Moolenaar

Sign Support Features sign-support

{Vi does not have any of these features}
{only available when compiled with the |+signs| feature}

==========
1. Introduction sign-intro signs

When a debugger or other IDE tool is driving an editor it needs to be able to give specific highlights which quickly tell the user useful information about the file. One example of this would be a debugger which had an icon in the left-hand column denoting a breakpoint. Another example might be an arrow representing the Program Counter (PC). The sign features allow both placement of a sign, or icon, in the left-hand side of the window and definition of a highlight which will be applied to that line. Displaying the sign as an image is most likely only feasible in gvim (although Sun Microsystem's dtterm does support this it's the only terminal emulator I know of which does). A text sign and the highlight should be feasible in any color terminal emulator.

Signs and highlights are not useful just for debuggers. Sun's Visual WorkShop uses signs and highlights to mark build errors and SourceBrowser hits. Additionally, the debugger supports 8 to 10 different signs and highlight colors. workshop Same for Netbeans netbeans .

There are two steps in using signs:

1. Define the sign. This specifies the image, text and highlighting. For example, you can define a "break" sign with an image of a stop roadsign and text "!!".

2. Place the sign. This specifies the file and line number where the sign is displayed. A defined sign can be placed several times in different lines and files.

When signs are defined for a file, Vim will automatically add a column of two characters to display them in. When the last sign is unplaced the column disappears again. This behavior can be changed with the 'signcolumn' option.

The color of the column is set with the SignColumn group hl-SignColumn .
Example to set the color:

```
:highlight SignColumn guibg=darkgrey
```

Here is an example that places a sign "piet", displayed with the text ">>", in
line 23 of the current file:
```
:sign define piet text=>> texthl=Search
:exe ":sign place 2 line=23 name=piet file=" . expand("%:p")
```

And here is the command to delete it again:
```
:sign unplace 2
```

Note that the ":sign" command cannot be followed by another command or a
comment. If you do need that, use the :execute command.

DEFINING A SIGN. :sign-define E255 E160 E612

:sign define {name} {argument}...
Define a new sign or set attributes for an existing sign.
The {name} can either be a number (all digits) or a name
starting with a non-digit. Leading digits are ignored, thus
"0012", "012" and "12" are considered the same name.
About 120 different signs can be defined.

Accepted arguments:

icon={bitmap}
Define the file name where the bitmap can be found. Should be
a full path. The bitmap should fit in the place of two
characters. This is not checked. If the bitmap is too big it
will cause redraw problems. Only GTK 2 can scale the bitmap
to fit the space available.

toolkit	supports
GTK 1	pixmap (.xpm)
GTK 2	many
Motif	pixmap (.xpm)
Win32	.bmp, .ico, .cur
	pixmap (.xpm) +xpm_w32

linehl={group}
Highlighting group used for the whole line the sign is placed
in. Most useful is defining a background color.

text={text} E239
Define the text that is displayed when there is no icon or the
GUI is not being used. Only printable characters are allowed
and they must occupy one or two display cells.

texthl={group}
Highlighting group used for the text item.

DELETING A SIGN :sign-undefine E155

:sign undefine {name}
Deletes a previously defined sign. If signs with this {name} are still placed this will cause trouble.

LISTING SIGNS :sign-list E156

:sign list Lists all defined signs and their attributes.

:sign list {name}
Lists one defined sign and its attributes.

PLACING SIGNS :sign-place E158

:sign place {id} line={lnum} name={name} file={fname}
Place sign defined as {name} at line {lnum} in file {fname}.
:sign-fname
The file {fname} must already be loaded in a buffer. The exact file name must be used, wildcards, $ENV and ~ are not expanded, white space must not be escaped. Trailing white space is ignored.

The sign is remembered under {id}, this can be used for further manipulation. {id} must be a number.
It's up to the user to make sure the {id} is used only once in each file (if it's used several times unplacing will also have to be done several times and making changes may not work as expected).

:sign place {id} line={lnum} name={name} buffer={nr}
Same, but use buffer {nr}.

E885
:sign place {id} name={name} file={fname}
Change the placed sign {id} in file {fname} to use the defined sign {name}. See remark above about {fname} :sign-fname .
This can be used to change the displayed sign without moving it (e.g., when the debugger has stopped at a breakpoint).

:sign place {id} name={name} buffer={nr}
Same, but use buffer {nr}.

REMOVING SIGNS :sign-unplace E159

:sign unplace {id} file={fname}
Remove the previously placed sign {id} from file {fname}.
See remark above about {fname} :sign-fname .

:sign unplace * file={fname}
Remove all placed signs in file {fname}.

:sign unplace {id} buffer={nr}

Remove the previously placed sign {id} from buffer {nr}.

:sign unplace * buffer={nr}
Remove all placed signs in buffer {nr}.

:sign unplace {id}
Remove the previously placed sign {id} from all files it appears in.

:sign unplace *
Remove all placed signs.

:sign unplace
Remove the placed sign at the cursor position.

LISTING PLACED SIGNS :sign-place-list

:sign place file={fname}
List signs placed in file {fname}.
See remark above about {fname} :sign-fname .

:sign place buffer={nr}
List signs placed in buffer {nr}.

:sign place List placed signs in all files.

JUMPING TO A SIGN :sign-jump E157

:sign jump {id} file={fname}
Open the file {fname} or jump to the window that contains {fname} and position the cursor at sign {id}.
See remark above about {fname} :sign-fname .
If the file isn't displayed in window and the current file can not be abandon ed this fails.

:sign jump {id} buffer={nr} E934
Same, but use buffer {nr}. This fails if buffer {nr} does not have a name.

vim:tw=78:ts=8:noet:ft=help:norl:

vi_diff.txt For Vim version 8.1. Last change: 2016 Aug 16

VIM REFERENCE MANUAL by Bram Moolenaar

Differences between Vim and Vi vi-differences

Throughout the help files differences between Vim and Vi/Ex are given in curly braces, like "{not in Vi}". This file only lists what has not been mentioned in other files and gives an overview.

Vim is mostly POSIX 1003.2-1 compliant. The only command known to be missing is ":open". There are probably a lot of small differences (either because Vim is missing something or because Posix is beside the mark).

==
1. Simulated command simulated-command

This command is in Vi, but Vim only simulates it:

  :o :op :open
:[range]o[pen] Works like :visual : end Ex mode.
  {Vi: start editing in open mode}

:[range]o[pen] /pattern/ As above, additionally move the cursor to the column where "pattern" matches in the cursor line.

Vim does not support open mode, since it's not really useful. For those situations where ":open" would start open mode Vim will leave Ex mode, which allows executing the same commands, but updates the whole screen instead of only one line.

==
2. Missing options missing-options

These options are in the Unix Vi, but not in Vim. If you try to set one of them you won't get an error message, but the value is not used and cannot be printed.

autoprint (ap)	boolean (default on)	'autoprint' 'ap'
beautify (bf)	boolean (default off)	'beautify' 'bf'
flash (fl)	boolean (default ??)	'flash' 'fl'
graphic (gr)	boolean (default off)	'graphic' 'gr'
hardtabs (ht)	number (default 8)	'hardtabs' 'ht'

```
        number of spaces that a <Tab> moves on the display
mesg                    boolean (default on)            'mesg'
novice                  boolean (default off)           'novice'
open                    boolean (default on)            'open'
optimize (op)           boolean (default off)           'optimize'   'op'
redraw                  boolean (default off)           'redraw'
slowopen (slow)         boolean (default off)           'slowopen'   'slow'
sourceany               boolean (default off)           'sourceany'
w300                    number  (default 23)            'w300'
w1200                   number  (default 23)            'w1200'
w9600                   number  (default 23)            'w9600'

==============================================================================
3. Limits                                                       limits

Vim has only a few limits for the files that can be edited {Vi: can not handle
<Nul> characters and characters above 128, has limited line length, many other
limits}.
                                                                E340
Maximum line length         On machines with 16-bit ints (Amiga and MS-DOS real
                            mode): 32767, otherwise 2147483647 characters.
                            Longer lines are split.
Maximum number of lines     2147483647 lines.
Maximum file size           2147483647 bytes (2 Gbyte) when a long integer is
                            32 bits.  Much more for 64 bit longs.  Also limited
                            by available disk space for the  swap-file .
                                                                E75
Length of a file path       Unix and Win32: 1024 characters, otherwise 256
                            characters (or as much as the system supports).
Length of an expanded string option
                            Unix and Win32: 1024 characters, otherwise 256
                            characters
Maximum display width       Unix and Win32: 1024 characters, otherwise 255
                            characters
Maximum lhs of a mapping    50 characters.
Number of different highlighting types: over 30000
Range of a Number variable:  -2147483648 to 2147483647 (might be more on 64
                            bit systems)
Maximum length of a line in a tags file: 512 bytes.

Information for undo and text in registers is kept in memory, thus when making
(big) changes the amount of (virtual) memory available limits the number of
undo levels and the text that can be kept in registers.  Other things are also
kept in memory:  Command-line history, error messages for Quickfix mode, etc.

Memory usage limits
-------------------

The option 'maxmem' ('mm') is used to set the maximum memory used for one
buffer (in kilobytes).  'maxmemtot' is used to set the maximum memory used for
all buffers (in kilobytes).  The defaults depend on the system used.  For the
Amiga and MS-DOS, 'maxmemtot' is set depending on the amount of memory
available.
These are not hard limits, but tell Vim when to move text into a swap file.
```

If you don't like Vim to swap to a file, set 'maxmem' and 'maxmemtot' to a very large value. The swap file will then only be used for recovery. If you don't want a swap file at all, set 'updatecount' to 0, or use the "-n" argument when starting Vim.

==
4. The most interesting additions   vim-additions

Vi compatibility.   'compatible'
	Although Vim is 99% Vi compatible, some things in Vi can be considered to be a bug, or at least need improvement. But still, Vim starts in a mode which behaves like the "real" Vi as much as possible. To make Vim behave a little bit better, try resetting the 'compatible' option:
		:set nocompatible
	Or start Vim with the "-N" argument:
		vim -N
	Vim starts with 'nocompatible' automatically if you have a .vimrc file. See startup .
	The 'cpoptions' option can be used to set Vi compatibility on/off for a number of specific items.

Support for different systems.
	Vim can be used on:
	- All Unix systems (it works on all systems it was tested on, although the GUI and Perl interface may not work everywhere).
	- Amiga (500, 1000, 1200, 2000, 3000, 4000, ...).
	- MS-DOS in real-mode (no additional drivers required).
	- In protected mode on Windows 3.1 and MS-DOS (DPMI driver required).
	- Windows 95 and Windows NT, with support for long file names.
	- OS/2 (needs emx.dll)
	- Atari MiNT
	- VMS
	- BeOS
	- Macintosh
	- Risc OS
	- IBM OS/390
	Note that on some systems features need to be disabled to reduce resource usage, esp. on MS-DOS. For some outdated systems you need to use an older Vim version.

Multi level persistent undo.   undo
	'u' goes backward in time, 'CTRL-R' goes forward again. Set option 'undolevels' to the number of changes to be remembered (default 1000). Set 'undolevels' to 0 for a Vi-compatible one level undo. Set it to -1 for no undo at all.
	When all changes in a buffer have been undone, the buffer is not considered changed anymore. You can exit it with :q, without <!>.
	When undoing a few changes and then making a new change Vim will create a branch in the undo tree. This means you can go back to any state of the text, there is no risk of a change causing text to be lost forever. undo-tree
	The undo information is stored in a file when the 'undofile' option is set. This means you can exit Vim, start Vim on a previously edited

file and undo changes that were made before exiting Vim.

Graphical User Interface (GUI). gui
Included support for GUI: menu's, mouse, scrollbars, etc. You can define your own menus. Better support for CTRL/SHIFT/ALT keys in combination with special keys and mouse. Supported for various platforms, such as X11 (with Motif and Athena interfaces), GTK, Win32 (Windows 95 and later), BeOS, Amiga and Macintosh.

Multiple windows and buffers. windows.txt
Vim can split the screen into several windows, each editing a different buffer or the same buffer at a different location. Buffers can still be loaded (and changed) but not displayed in a window. This is called a hidden buffer. Many commands and options have been added for this facility.
Vim can also use multiple tab pages, each with one or more windows. A line with tab labels can be used to quickly switch between these pages. tab-page

Syntax highlighting. :syntax
Vim can highlight keywords, patterns and other things. This is defined by a number of :syntax commands, and can be made to highlight most languages and file types. A number of files are included for highlighting the most common languages, like C, C++, Java, Pascal, Makefiles, shell scripts, etc. The colors used for highlighting can be defined for ordinary terminals, color terminals and the GUI with the :highlight command. A convenient way to do this is using a :colorscheme command.
The highlighted text can be exported as HTML. convert-to-HTML
Other items that can be highlighted are matches with the search string 'hlsearch' , matching parens matchparen and the cursor line and column 'cursorline' 'cursorcolumn' .

Spell checking. spell
When the 'spell' option is set Vim will highlight spelling mistakes. About 50 languages are currently supported, selected with the 'spelllang' option. In source code only comments and strings are checked for spelling.

Folding. folding
A range of lines can be shown as one "folded" line. This allows overviewing a file and moving blocks of text around quickly.
Folds can be created manually, from the syntax of the file, by indent, etc.

Diff mode. diff
Vim can show two versions of a file with the differences highlighted. Parts of the text that are equal are folded away. Commands can be used to move text from one version to the other.

Plugins. add-plugin
The functionality can be extended by dropping a plugin file in the right directory. That's an easy way to start using Vim scripts written by others. Plugins can be for all kind of files, or

specifically for a filetype.
Packages make this even easier. packages

Asynchronous communication and timers. channel job timer
Vim can exchange messages with other processes in the background.
This makes it possible to have servers do work and send back the
results to Vim. channel
Vim can start a job, communicate with it and stop it. job
Timers can fire once or repeatedly and invoke a function to do any
work. timer

Repeat a series of commands. q
"q{c}" starts recording typed characters into named register {c}.
A subsequent "q" stops recording. The register can then be executed
with the "@{c}" command. This is very useful to repeat a complex
action.

Flexible insert mode. ins-special-special
The arrow keys can be used in insert mode to move around in the file.
This breaks the insert in two parts as far as undo and redo is
concerned.

CTRL-O can be used to execute a single Normal mode command. This is
almost the same as hitting <Esc>, typing the command and doing a .

Visual mode. Visual-mode
Visual mode can be used to first highlight a piece of text and then
give a command to do something with it. This is an (easy to use)
alternative to first giving the operator and then moving to the end of
the text to be operated upon.
 v and V are used to start Visual mode. v works on characters
and V on lines. Move the cursor to extend the Visual area. It is
shown highlighted on the screen. By typing "o" the other end of the
Visual area can be moved. The Visual area can be affected by an
operator:
        d   delete
        c   change
        y   yank
        > or < insert or delete indent
        !   filter through external program
        =   filter through indent
        :   start : command for the Visual lines.
        gq   format text to 'textwidth' columns
        J   join lines
        ~   swap case
        u   make lowercase
        U   make uppercase

Block operators. visual-block
With Visual mode a rectangular block of text can be selected. Start
Visual mode with CTRL-V. The block can be deleted ("d"), yanked ("y")
or its case can be changed ("~", "u" and "U"). A deleted or yanked
block can be put into the text with the "p" and "P" commands.

```
Help system.                                                    :help
        Help is displayed in a window.  The usual commands can be used to
        move around, search for a string, etc.  Tags can be used to jump
        around in the help files, just like hypertext links.  The  :help
        command takes an argument to quickly jump to the info on a subject.
        <F1> is the quick access to the help system.  The name of the help
        index file can be set with the 'helpfile' option.

Command-line editing and history.                       cmdline-editing
        You can insert or delete at any place in the command-line using the
        cursor keys.  The right/left cursor keys can be used to move
        forward/backward one character.  The shifted right/left cursor keys
        can be used to move forward/backward one word.  CTRL-B/CTRL-E can be
        used to go to the begin/end of the command-line.
                                                        cmdline-history
        The command-lines are remembered.  The up/down cursor keys can be used
        to recall previous command-lines.  The 'history' option can be set to
        the number of lines that will be remembered.  There is a separate
        history for commands and for search patterns.
