help.txt For Vim version 8.1. Last change: 2017 Oct 28

VIM - main help file

```
                                                                    k
     Move around:  Use the cursor keys, or "h" to go left,        h   l
                   "j" to go down, "k" to go up, "l" to go right.   j
Close this window: Use ":q<Enter>".
   Get out of Vim: Use ":qa!<Enter>" (careful, all changes are lost!).

Jump to a subject: Position the cursor on a tag (e.g. bars ) and hit CTRL-].
   With the mouse: ":set mouse=a" to enable the mouse (in xterm or GUI).
                   Double-click the left mouse button on a tag, e.g. bars .
        Jump back: Type CTRL-T or CTRL-O.  Repeat to go further back.

Get specific help: It is possible to go directly to whatever you want help
                   on, by giving an argument to the :help command.
                   Prepend something to specify the context:  help-context

                        WHAT                PREPEND    EXAMPLE
                    Normal mode command                :help x
                    Visual mode command       v_       :help v_u
                    Insert mode command       i_       :help i_<Esc>
                    Command-line command      :        :help :quit
                    Command-line editing      c_       :help c_<Del>
                    Vim command argument      -        :help -r
                    Option                    '        :help 'textwidth'
                    Regular expression        /        :help /[
                   See help-summary for more contexts and an explanation.

  Search for help: Type ":help word", then hit CTRL-D to see matching
                   help entries for "word".
                   Or use ":helpgrep word".  :helpgrep
```

Vim stands for Vi IMproved. Most of Vim was made by Bram Moolenaar, but only through the help of many others. See credits .

REFERENCE MANUAL: These files explain every detail of Vim.	reference_toc

General subjects
intro.txt	general introduction to Vim; notation used in help files
help.txt	overview and quick reference (this file)
helphelp.txt	about using the help files
index.txt	alphabetical index of all commands
help-tags	all the tags you can jump to (index of tags)
howto.txt	how to do the most common editing tasks
tips.txt	various tips on using Vim
message.txt	(error) messages and explanations
quotes.txt	remarks from users of Vim
todo.txt	known problems and desired extensions
develop.txt	development of Vim
debug.txt	debugging Vim itself
uganda.txt	Vim distribution conditions and what to do with your money

Basic editing

starting.txt	starting Vim, Vim command arguments, initialisation
editing.txt	editing and writing files
motion.txt	commands for moving around
scroll.txt	scrolling the text in the window
insert.txt	Insert and Replace mode
change.txt	deleting and replacing text
indent.txt	automatic indenting for C and other languages
undo.txt	Undo and Redo
repeat.txt	repeating commands, Vim scripts and debugging
visual.txt	using the Visual mode (selecting a text area)
various.txt	various remaining commands
recover.txt	recovering from a crash

Advanced editing

cmdline.txt	Command-line editing
options.txt	description of all options
pattern.txt	regexp patterns and search commands
map.txt	key mapping and abbreviations
tagsrch.txt	tags and special searches
quickfix.txt	commands for a quick edit-compile-fix cycle
windows.txt	commands for using multiple windows and buffers
tabpage.txt	commands for using multiple tab pages
syntax.txt	syntax highlighting
spell.txt	spell checking
diff.txt	working with two to four versions of the same file
autocmd.txt	automatically executing commands on an event
filetype.txt	settings done specifically for a type of file
eval.txt	expression evaluation, conditional commands
channel.txt	Jobs, Channels, inter-process communication
fold.txt	hide (fold) ranges of lines

Special issues

print.txt	printing
remote.txt	using Vim as a server or client
term.txt	using different terminals and mice
terminal.txt	Terminal window support
digraph.txt	list of available digraphs
mbyte.txt	multi-byte text support
mlang.txt	non-English language support
arabic.txt	Arabic language support and editing
farsi.txt	Farsi (Persian) editing
hebrew.txt	Hebrew language support and editing
russian.txt	Russian language support and editing
ft_ada.txt	Ada (the programming language) support
ft_rust.txt	Filetype plugin for Rust
ft_sql.txt	about the SQL filetype plugin
hangulin.txt	Hangul (Korean) input mode
rileft.txt	right-to-left editing mode

GUI

gui.txt	Graphical User Interface (GUI)
gui_w32.txt	Win32 GUI
gui_x11.txt	X11 GUI

Interfaces
 if_cscop.txt   using Cscope with Vim
 if_lua.txt   Lua interface
 if_mzsch.txt   MzScheme interface
 if_perl.txt   Perl interface
 if_pyth.txt   Python interface
 if_tcl.txt   Tcl interface
 if_ole.txt   OLE automation interface for Win32
 if_ruby.txt   Ruby interface
 debugger.txt   Interface with a debugger
 workshop.txt   Sun Visual Workshop interface
 netbeans.txt   NetBeans External Editor interface
 sign.txt   debugging signs

Versions
 vi_diff.txt   Main differences between Vim and Vi
 version4.txt   Differences between Vim version 3.0 and 4.x
 version5.txt   Differences between Vim version 4.6 and 5.x
 version6.txt   Differences between Vim version 5.7 and 6.x
 version7.txt   Differences between Vim version 6.4 and 7.x
 version8.txt   Differences between Vim version 7.4 and 8.x
                                                sys-file-list
Remarks about specific systems
 os_390.txt   OS/390 Unix
 os_amiga.txt   Amiga
 os_beos.txt   BeOS and BeBox
 os_dos.txt   MS-DOS and MS-Windows NT/95 common items
 os_mac.txt   Macintosh
 os_mint.txt   Atari MiNT
 os_msdos.txt   MS-DOS (plain DOS and DOS box under Windows)

Standard plugins
 pi_getscript.txt Downloading latest version of Vim scripts
 pi_gzip.txt   Reading and writing compressed files
 pi_logipat.txt   Logical operators on patterns
 pi_netrw.txt   Reading and writing files over a network
 pi_paren.txt   Highlight matching parens
 pi_spec.txt   Filetype plugin to work with rpm spec files
 pi_tar.txt   Tar file explorer
 pi_vimball.txt   Create a self-installing Vim script
 pi_zip.txt   Zip archive explorer

LOCAL ADDITIONS: local-additions
 vim_faq.txt   Frequently asked questions

----
 bars   Bars example

Now that you've jumped here with CTRL-] or a double mouse click, you can use CTRL-T, CTRL-O, g<RightMouse>, or <C-RightMouse> to go back to where you were.

Note that tags are within | characters, but when highlighting is enabled these characters are hidden. That makes it easier to read a command.

Anyway, you can use CTRL-] on any word, also when it is not within |, and Vim will try to find help for it. Especially for options in single quotes, e.g. 'compatible'.

quickref.txt For Vim version 8.1. Last change: 2018 Apr 18

VIM REFERENCE MANUAL by Bram Moolenaar

Quick reference guide

quickref Contents

N is used to indicate an optional count that can be given before the command.

Q_lr Left-right motions

h	N	h	left (also: CTRL-H, <BS>, or <Left> key)
l	N	l	right (also: <Space> or <Right> key)
0		0	to first character in the line (also: <Home> key)
^		^	to first non-blank character in the line
$	N	$	to the last character in the line (N-1 lines lower) (also: <End> key)
g0		g0	to first character in screen line (differs from "0" when lines wrap)
g^		g^	to first non-blank character in screen line (differs from "^" when lines wrap)
g$	N	g$	to last character in screen line (differs from "$" when lines wrap)
gm		gm	to middle of the screen line
bar	N	|	to column N (default: 1)
f	N	f{char}	to the Nth occurrence of {char} to the right
F	N	F{char}	to the Nth occurrence of {char} to the left
t	N	t{char}	till before the Nth occurrence of {char} to the right
T	N	T{char}	till before the Nth occurrence of {char} to the left

```
;       N  ;            repeat the last "f", "F", "t", or "T" N times
,       N  ,            repeat the last "f", "F", "t", or "T" N times in
                           opposite direction
-------------------------------------------------------------------------------
Q_ud            Up-down motions

k       N  k            up N lines (also: CTRL-P and <Up>)
j       N  j            down N lines (also: CTRL-J, CTRL-N, <NL>, and <Down>)
-       N  -            up N lines, on the first non-blank character
+       N  +            down N lines, on the first non-blank character (also:
                           CTRL-M and <CR>)
_       N  _            down N-1 lines, on the first non-blank character
G       N  G            goto line N (default: last line), on the first
                           non-blank character
gg      N  gg           goto line N (default: first line), on the first
                           non-blank character
N%      N  %            goto line N percentage down in the file; N must be
                           given, otherwise it is the  %  command
gk      N  gk           up N screen lines (differs from "k" when line wraps)
gj      N  gj           down N screen lines (differs from "j" when line wraps)
-------------------------------------------------------------------------------
Q_tm            Text object motions

w       N  w            N words forward

-------------------------------------------------------------------------------
Q_pa            Pattern searches
```

```
/       N  /{pattern}[/[offset]]<CR>
                        search forward for the Nth occurrence of {pattern}
?       N  ?{pattern}[?[offset]]<CR>
                        search backward for the Nth occurrence of {pattern}
/<CR>   N  /<CR>        repeat last search, in the forward direction
?<CR>   N  ?<CR>        repeat last search, in the backward direction
n       N  n            repeat last search
N       N  N            repeat last search, in opposite direction
star    N  *            search forward for the identifier under the cursor
#       N  #            search backward for the identifier under the cursor
gstar   N  g*           like "*", but also find partial matches
g#      N  g#           like "#", but also find partial matches
gd         gd           goto local declaration of identifier under the cursor
gD         gD           goto global declaration of identifier under the cursor

pattern                 Special characters in search patterns

                        meaning                 magic   nomagic
                matches any single character    .       \.
                       matches start of line    ^       ^
                               matches <EOL>    $       $
                       matches start of word    \<      \<
                         matches end of word    \>      \>
          matches a single char from the range  [a-z]   \[a-z]
       matches a single char not in the range   [^a-z]  \[^a-z]
                  matches an identifier char    \i      \i
                   idem but excluding digits    \I      \I
                 matches a keyword character    \k      \k
                   idem but excluding digits    \K      \K
               matches a file name character    \f      \f
                   idem but excluding digits    \F      \F
               matches a printable character    \p      \p
                   idem but excluding digits    \P      \P
              matches a white space character   \s      \s
           matches a non-white space character  \S      \S

                               matches <Esc>    \e      \e
                               matches <Tab>    \t      \t
                                matches <CR>    \r      \r
                                matches <BS>    \b      \b

      matches 0 or more of the preceding atom   *       \*
      matches 1 or more of the preceding atom   \+      \+
         matches 0 or 1 of the preceding atom   \=      \=
         matches 2 to 5 of the preceding atom   \{2,5}  \{2,5}
                   separates two alternatives   \|      \|
                  group a pattern into an atom  \(\)    \(\)

search-offset           Offsets allowed after search command

   [num]        [num] lines downwards, in column 1
   +[num]       [num] lines downwards, in column 1
   -[num]       [num] lines upwards, in column 1
```

```
   e[+num]     [num] characters to the right of the end of the match
   e[-num]     [num] characters to the left of the end of the match
   s[+num]     [num] characters to the right of the start of the match
   s[-num]     [num] characters to the left of the start of the match
   b[+num]     [num] identical to s[+num] above (mnemonic: begin)
   b[-num]     [num] identical to s[-num] above (mnemonic: begin)
   ;{search-command}   execute {search-command} next
-------------------------------------------------------------------------------
Q_ma           Marks and motions

m          m{a-zA-Z}    mark current position with mark {a-zA-Z}
`a         `{a-z}       go to mark {a-z} within current file
`A         `{A-Z}       go to mark {A-Z} in any file
`0         `{0-9}       go to the position where Vim was previously exited
``         ``           go to the position before the last jump
`quote     `"           go to the position when last editing this file
`[         `[           go to the start of the previously operated or put text
`]         `]           go to the end of the previously operated or put text
`<         `<           go to the start of the (previous) Visual area
`>         `>           go to the end of the (previous) Visual area
`.         `.           go to the position of the last change in this file
'          '{a-zA-Z0-9[]'"<>.}
                        same as `, but on the first non-blank in the line
:marks     :marks       print the active marks
CTRL-O     N  CTRL-O    go to Nth older position in jump list
CTRL-I     N  CTRL-I    go to Nth newer position in jump list
:ju        :ju[mps]     print the jump list
-------------------------------------------------------------------------------
Q_vm           Various motions

%          %            find the next brace, bracket, comment, or "#if"/
                           "#else"/"#endif" in this line and go to its match
H       N  H            go to the Nth line in the window, on the first
                           non-blank
M          M            go to the middle line in the window, on the first
                           non-blank
L       N  L            go to the Nth line from the bottom, on the first
                           non-blank

go      N  go                   go to Nth byte in the buffer
:go     :[range]go[to] [off]    go to [off] byte in the buffer
-------------------------------------------------------------------------------
Q_ta           Using tags

:ta        :ta[g][!] {tag}      jump to tag {tag}
:ta        :[count]ta[g][!]     jump to [count]'th newer tag in tag list
CTRL-]        CTRL-]            jump to the tag under cursor, unless changes
                                   have been made
:ts        :ts[elect][!] [tag]  list matching tags and select one to jump to
:tjump     :tj[ump][!] [tag]    jump to tag [tag] or select from list when
                                   there are multiple matches
:ltag      :lt[ag][!] [tag]     jump to tag [tag] and add matching tags to the
                                   location list
```

```
 :tags      :tags                 print tag list
 CTRL-T     N  CTRL-T             jump back from Nth older tag in tag list

 Q_sc            Scrolling

 CTRL-E          N  CTRL-E        window N lines downwards (default: 1)
 CTRL-D          N  CTRL-D        window N lines Downwards (default: 1/2 window)
 CTRL-F          N  CTRL-F        window N pages Forwards (downwards)
 CTRL-Y          N  CTRL-Y        window N lines upwards (default: 1)
 CTRL-U          N  CTRL-U        window N lines Upwards (default: 1/2 window)
 CTRL-B          N  CTRL-B        window N pages Backwards (upwards)
 z<CR>              z<CR> or zt   redraw, current line at top of window
 z.                 z.    or zz   redraw, current line at center of window
 z-                 z-    or zb   redraw, current line at bottom of window

These only work when 'wrap' is off:
 zh              N  zh            scroll screen N characters to the right
 zl              N  zl            scroll screen N characters to the left
 zH              N  zH            scroll screen half a screenwidth to the right
 zL              N  zL            scroll screen half a screenwidth to the left
-------------------------------------------------------------------------------
 Q_in            Inserting text

 a       N  a    append text after the cursor (N times)
 A       N  A    append text at the end of the line (N times)
 i       N  i    insert text before the cursor (N times) (also: <Insert>)
 I       N  I    insert text before the first non-blank in the line (N times)
 gI      N  gI   insert text in column 1 (N times)
 o       N  o    open a new line below the current line, append text (N times)
 O       N  O    open a new line above the current line, append text (N times)
 :startinsert   :star[tinsert][!]  start Insert mode, append when [!] used
 :startreplace  :startr[eplace][!]  start Replace mode, at EOL when [!] used

in Visual block mode:
 v_b_I      I    insert the same text in front of all the selected lines
 v_b_A      A    append the same text after all the selected lines
-------------------------------------------------------------------------------
 Q_ai            Insert mode keys

 insert-index    alphabetical index of Insert mode commands

leaving Insert mode:
```

```
 i_<Esc>        <Esc>             end Insert mode, back to Normal mode
 i_CTRL-C       CTRL-C            like <Esc>, but do not use an abbreviation
 i_CTRL-O       CTRL-O {command}  execute {command} and return to Insert mode

moving around:
 i_<Up>         cursor keys       move cursor left/right/up/down
 i_<S-Left>     shift-left/right  one word left/right
 i_<S-Up>       shift-up/down     one screenful backward/forward
 i_<End>        <End>             cursor after last character in the line
 i_<Home>       <Home>            cursor to first character in the line
-------------------------------------------------------------------------------
 Q_ss           Special keys in Insert mode

 i_CTRL-V       CTRL-V {char}..   insert character literally, or enter decimal
                                     byte value
 i_<NL>         <NL> or <CR> or CTRL-M or CTRL-J
                                  begin new line
 i_CTRL-E       CTRL-E            insert the character from below the cursor
 i_CTRL-Y       CTRL-Y            insert the character from above the cursor

 i_CTRL-A       CTRL-A            insert previously inserted text
 i_CTRL-@       CTRL-@            insert previously inserted text and stop
                                     Insert mode
 i_CTRL-R       CTRL-R {0-9a-z%#:.-="}  insert the contents of a register

 i_CTRL-N       CTRL-N            insert next match of identifier before the
                                     cursor
 i_CTRL-P       CTRL-P            insert previous match of identifier before
                                     the cursor
 i_CTRL-X       CTRL-X ...        complete the word before the cursor in
                                     various ways

 i_<BS>         <BS> or CTRL-H    delete the character before the cursor
 i_<Del>        <Del>             delete the character under the cursor
 i_CTRL-W       CTRL-W            delete word before the cursor
 i_CTRL-U       CTRL-U            delete all entered characters in the current
                                     line
 i_CTRL-T       CTRL-T            insert one shiftwidth of indent in front of
                                       the current line
 i_CTRL-D       CTRL-D            delete one shiftwidth of indent in front of
                                     the current line
 i_0_CTRL-D     0 CTRL-D          delete all indent in the current line
 i_^_CTRL-D     ^ CTRL-D          delete all indent in the current line,
                                     restore indent in next line
-------------------------------------------------------------------------------
 Q_di           Digraphs

 :dig      :dig[raphs]           show current list of digraphs
 :dig      :dig[raphs] {char1}{char2} {number} ...
                                 add digraph(s) to the list

In Insert or Command-line mode:
 i_CTRL-K       CTRL-K {char1} {char2}
                                  enter digraph
```

```
i_digraph      {char1} <BS> {char2}
                                  enter digraph if 'digraph' option set
------------------------------------------------------------------------------
Q_si           Special inserts

:r         :r [file]       insert the contents of [file] below the cursor
:r!        :r! {command}   insert the standard output of {command} below the
                              cursor
------------------------------------------------------------------------------
Q_de           Deleting text

x       N  x            delete N characters under and after the cursor
<Del>   N  <Del>        delete N characters under and after the cursor
X       N  X            delete N characters before the cursor
d       N  d{motion}    delete the text that is moved over with {motion}
v_d        {visual}d    delete the highlighted text
dd      N  dd           delete N lines
D       N  D            delete to the end of the line (and N-1 more lines)

                                       Command-line mode
:map_l        :ma[p] [lhs]          list mappings (starting with [lhs]) for
                                       Normal and Visual mode
:map_l!       :ma[p]! [lhs]         list mappings (starting with [lhs]) for
                                       Insert and Command-line mode
:cmap         :cmap/:cunmap/:cnoremap
                                    like ":map!"/":unmap!"/":noremap!" but for
                                       Command-line mode only
:imap         :imap/:iunmap/:inoremap
                                    like ":map!"/":unmap!"/":noremap!" but for
                                       Insert mode only
:nmap         :nmap/:nunmap/:nnoremap
                                    like ":map"/":unmap"/":noremap" but for
                                       Normal mode only
:vmap         :vmap/:vunmap/:vnoremap
                                    like ":map"/":unmap"/":noremap" but for
                                       Visual mode only
:omap         :omap/:ounmap/:onoremap
                                    like ":map"/":unmap"/":noremap" but only for
                                       when an operator is pending
:mapc         :mapc[lear]           remove mappings for Normal and Visual mode
```

```
:mapc       :mapc[lear]!          remove mappings for Insert and Cmdline mode
:imapc      :imapc[lear]          remove mappings for Insert mode
:vmapc      :vmapc[lear]          remove mappings for Visual mode
:omapc      :omapc[lear]          remove mappings for Operator-pending mode
:nmapc      :nmapc[lear]          remove mappings for Normal mode
:cmapc      :cmapc[lear]          remove mappings for Cmdline mode
:mkexrc     :mk[exrc][!] [file]   write current mappings, abbreviations, and
                                     settings to [file] (default: ".exrc";
                                     use ! to overwrite)
:mkvimrc    :mkv[imrc][!] [file]
                                  same as ":mkexrc", but with default ".vimrc"
:mksession  :mks[ession][!] [file]
                                  like ":mkvimrc", but store current files,
                                     windows, etc. too, to be able to continue
                                     this session later
------------------------------------------------------------------------------
Q_ab            Abbreviations

:abbreviate     :ab[breviate] {lhs} {rhs}  add abbreviation for {lhs} to {rhs}
:abbreviate     :ab[breviate] {lhs}        show abbr's that start with {lhs}
:abbreviate     :ab[breviate]              show all abbreviations
:unabbreviate   :una[bbreviate] {lhs}      remove abbreviation for {lhs}
:noreabbrev     :norea[bbrev] [lhs] [rhs]  like ":ab", but don't remap [rhs]
:iabbrev        :iab/:iunab/:inoreab       like ":ab", but only for Insert mode
:cabbrev        :cab/:cunab/:cnoreab       like ":ab", but only for
                                                Command-line mode
:abclear        :abc[lear]                 remove all abbreviations
:cabclear       :cabc[lear]                remove all abbr's for Cmdline mode
:iabclear       :iabc[lear]                remove all abbr's for Insert mode
------------------------------------------------------------------------------
Q_op            Options

:set            :se[t]                     show all modified options
:set            :se[t] all                 show all non-termcap options
:set            :se[t] termcap             show all termcap options
:set            :se[t] {option}            set boolean option (switch it on),
                                           show string or number option
:set            :se[t] no{option}          reset boolean option (switch it off)
:set            :se[t] inv{option}         invert boolean option
:set            :se[t] {option}={value}    set string/number option to {value}
:set            :se[t] {option}+={value}   append {value} to string option, add
                                           {value} to number option
:set            :se[t] {option}-={value}   remove {value} to string option,
                                           subtract {value} from number option
:set            :se[t] {option}?           show value of {option}
:set            :se[t] {option}&           reset {option} to its default value

:setlocal       :setl[ocal]                like ":set" but set the local value
                                           for options that have one
:setglobal      :setg[lobal]               like ":set" but set the global value
                                           of a local option

:fix            :fix[del]                  set value of 't_kD' according to
                                           value of 't_kb'
```

:options	:opt[ions]	open a new window to view and set options, grouped by functionality, a one line explanation and links to the help

Short explanation of each option: option-list

'aleph'	'al'	ASCII code of the letter Aleph (Hebrew)
'allowrevins'	'ari'	allow CTRL-_ in Insert and Command-line mode
'altkeymap'	'akm'	for default second language (Farsi/Hebrew)
'ambiwidth'	'ambw'	what to do with Unicode chars of ambiguous width
'antialias'	'anti'	Mac OS X: use smooth, antialiased fonts
'autochdir'	'acd'	change directory to the file in the current window
'arabic'	'arab'	for Arabic as a default second language
'arabicshape'	'arshape'	do shaping for Arabic characters
'autoindent'	'ai'	take indent for new line from previous line
'autoread'	'ar'	autom. read file when changed outside of Vim
'autowrite'	'aw'	automatically write file if changed
'autowriteall'	'awa'	as 'autowrite', but works with more commands
'background'	'bg'	"dark" or "light", used for highlight colors
'backspace'	'bs'	how backspace works at start of line
'backup'	'bk'	keep backup file after overwriting a file
'backupcopy'	'bkc'	make backup as a copy, don't rename the file
'backupdir'	'bdir'	list of directories for the backup file
'backupext'	'bex'	extension used for the backup file
'backupskip'	'bsk'	no backup for files that match these patterns
'balloondelay'	'bdlay'	delay in mS before a balloon may pop up
'balooneval'	'beval'	switch on balloon evaluation in the GUI
'balloonevalterm'	'bevalterm'	switch on balloon evaluation in the terminal
'balloonexpr'	'bexpr'	expression to show in balloon
'belloff'	'bo'	do not ring the bell for these reasons
'binary'	'bin'	read/write/edit file in binary mode
'bioskey'	'biosk'	MS-DOS: use bios calls for input characters
'bomb'		prepend a Byte Order Mark to the file
'breakat'	'brk'	characters that may cause a line break
'breakindent'	'bri'	wrapped line repeats indent
'breakindentopt'	'briopt'	settings for 'breakindent'
'browsedir'	'bsdir'	which directory to start browsing in
'bufhidden'	'bh'	what to do when buffer is no longer in window
'buflisted'	'bl'	whether the buffer shows up in the buffer list
'buftype'	'bt'	special type of buffer
'casemap'	'cmp'	specifies how case of letters is changed
'cdpath'	'cd'	list of directories searched with ":cd"
'cedit'		key used to open the command-line window
'charconvert'	'ccv'	expression for character encoding conversion
'cindent'	'cin'	do C program indenting
'cinkeys'	'cink'	keys that trigger indent when 'cindent' is set
'cinoptions'	'cino'	how to do indenting when 'cindent' is set
'cinwords'	'cinw'	words where 'si' and 'cin' add an indent
'clipboard'	'cb'	use the clipboard as the unnamed register
'cmdheight'	'ch'	number of lines to use for the command-line
'cmdwinheight'	'cwh'	height of the command-line window
'colorcolumn'	'cc'	columns to highlight
'columns'	'co'	number of columns in the display
'comments'	'com'	patterns that can start a comment line

'commentstring'	'cms'	template for comments; used for fold marker
'compatible'	'cp'	behave Vi-compatible as much as possible
'complete'	'cpt'	specify how Insert mode completion works
'completefunc'	'cfu'	function to be used for Insert mode completion
'completeopt'	'cot'	options for Insert mode completion
'concealcursor'	'cocu'	whether concealable text is hidden in cursor line
'conceallevel'	'cole'	whether concealable text is shown or hidden
'confirm'	'cf'	ask what to do about unsaved/read-only files
'conskey'	'consk'	get keys directly from console (MS-DOS only)
'copyindent'	'ci'	make 'autoindent' use existing indent structure
'cpoptions'	'cpo'	flags for Vi-compatible behavior
'cryptmethod'	'cm'	type of encryption to use for file writing
'cscopepathcomp'	'cspc'	how many components of the path to show
'cscopeprg'	'csprg'	command to execute cscope
'cscopequickfix'	'csqf'	use quickfix window for cscope results
'cscoperelative'	'csre'	Use cscope.out path basename as prefix
'cscopetag'	'cst'	use cscope for tag commands
'cscopetagorder'	'csto'	determines ":cstag" search order
'cscopeverbose'	'csverb'	give messages when adding a cscope database
'cursorbind'	'crb'	move cursor in window as it moves in other windows
'cursorcolumn'	'cuc'	highlight the screen column of the cursor
'cursorline'	'cul'	highlight the screen line of the cursor
'debug'		set to "msg" to see all error messages
'define'	'def'	pattern to be used to find a macro definition
'delcombine'	'deco'	delete combining characters on their own
'dictionary'	'dict'	list of file names used for keyword completion
'diff'		use diff mode for the current window
'diffexpr'	'dex'	expression used to obtain a diff file
'diffopt'	'dip'	options for using diff mode
'digraph'	'dg'	enable the entering of digraphs in Insert mode
'directory'	'dir'	list of directory names for the swap file
'display'	'dy'	list of flags for how to display text
'eadirection'	'ead'	in which direction 'equalalways' works
'edcompatible'	'ed'	toggle flags of ":substitute" command
'emoji'	'emo'	emoji characters are considered full width
'encoding'	'enc'	encoding used internally
'endofline'	'eol'	write <EOL> for last line in file
'equalalways'	'ea'	windows are automatically made the same size
'equalprg'	'ep'	external program to use for "=" command
'errorbells'	'eb'	ring the bell for error messages
'errorfile'	'ef'	name of the errorfile for the QuickFix mode
'errorformat'	'efm'	description of the lines in the error file
'esckeys'	'ek'	recognize function keys in Insert mode
'eventignore'	'ei'	autocommand events that are ignored
'expandtab'	'et'	use spaces when <Tab> is inserted
'exrc'	'ex'	read .vimrc and .exrc in the current directory
'fileencoding'	'fenc'	file encoding for multi-byte text
'fileencodings'	'fencs'	automatically detected character encodings
'fileformat'	'ff'	file format used for file I/O
'fileformats'	'ffs'	automatically detected values for 'fileformat'
'fileignorecase'	'fic'	ignore case when using file names
'filetype'	'ft'	type of file, used for autocommands
'fillchars'	'fcs'	characters to use for displaying special items
'fixendofline'	'fixeol'	make sure last line in file has <EOL>

'fkmap'	'fk'	Farsi keyboard mapping
'foldclose'	'fcl'	close a fold when the cursor leaves it
'foldcolumn'	'fdc'	width of the column used to indicate folds
'foldenable'	'fen'	set to display all folds open
'foldexpr'	'fde'	expression used when 'foldmethod' is "expr"
'foldignore'	'fdi'	ignore lines when 'foldmethod' is "indent"
'foldlevel'	'fdl'	close folds with a level higher than this
'foldlevelstart'	'fdls'	'foldlevel' when starting to edit a file
'foldmarker'	'fmr'	markers used when 'foldmethod' is "marker"
'foldmethod'	'fdm'	folding type
'foldminlines'	'fml'	minimum number of lines for a fold to be closed
'foldnestmax'	'fdn'	maximum fold depth
'foldopen'	'fdo'	for which commands a fold will be opened
'foldtext'	'fdt'	expression used to display for a closed fold
'formatexpr'	'fex'	expression used with "gq" command
'formatlistpat'	'flp'	pattern used to recognize a list header
'formatoptions'	'fo'	how automatic formatting is to be done
'formatprg'	'fp'	name of external program used with "gq" command
'fsync'	'fs'	whether to invoke fsync() after file write
'gdefault'	'gd'	the ":substitute" flag 'g' is default on
'grepformat'	'gfm'	format of 'grepprg' output
'grepprg'	'gp'	program to use for ":grep"
'guicursor'	'gcr'	GUI: settings for cursor shape and blinking
'guifont'	'gfn'	GUI: Name(s) of font(s) to be used
'guifontset'	'gfs'	GUI: Names of multi-byte fonts to be used
'guifontwide'	'gfw'	list of font names for double-wide characters
'guiheadroom'	'ghr'	GUI: pixels room for window decorations
'guioptions'	'go'	GUI: Which components and options are used
'guipty'		GUI: try to use a pseudo-tty for ":!" commands
'guitablabel'	'gtl'	GUI: custom label for a tab page
'guitabtooltip'	'gtt'	GUI: custom tooltip for a tab page
'helpfile'	'hf'	full path name of the main help file
'helpheight'	'hh'	minimum height of a new help window
'helplang'	'hlg'	preferred help languages
'hidden'	'hid'	don't unload buffer when it is abandon ed
'highlight'	'hl'	sets highlighting mode for various occasions
'history'	'hi'	number of command-lines that are remembered
'hkmap'	'hk'	Hebrew keyboard mapping
'hkmapp'	'hkp'	phonetic Hebrew keyboard mapping
'hlsearch'	'hls'	highlight matches with last search pattern
'icon'		let Vim set the text of the window icon
'iconstring'		string to use for the Vim icon text
'ignorecase'	'ic'	ignore case in search patterns
'imactivatefunc'	'imaf'	function to enable/disable the X input method
'imactivatekey'	'imak'	key that activates the X input method
'imcmdline'	'imc'	use IM when starting to edit a command line
'imdisable'	'imd'	do not use the IM in any mode
'iminsert'	'imi'	use :lmap or IM in Insert mode
'imsearch'	'ims'	use :lmap or IM when typing a search pattern
'imstatusfunc'	'imsf'	function to obtain X input method status
'imstyle'	'imst'	specifies the input style of the input method
'include'	'inc'	pattern to be used to find an include file
'includeexpr'	'inex'	expression used to process an include line
'incsearch'	'is'	highlight match while typing search pattern

'indentexpr'	'inde'	expression used to obtain the indent of a line
'indentkeys'	'indk'	keys that trigger indenting with 'indentexpr'
'infercase'	'inf'	adjust case of match for keyword completion
'insertmode'	'im'	start the edit of a file in Insert mode
'isfname'	'isf'	characters included in file names and pathnames
'isident'	'isi'	characters included in identifiers
'iskeyword'	'isk'	characters included in keywords
'isprint'	'isp'	printable characters
'joinspaces'	'js'	two spaces after a period with a join command
'key'		encryption key
'keymap'	'kmp'	name of a keyboard mapping
'keymodel'	'km'	enable starting/stopping selection with keys
'keywordprg'	'kp'	program to use for the "K" command
'langmap'	'lmap'	alphabetic characters for other language mode
'langmenu'	'lm'	language to be used for the menus
'langremap'	'lrm'	do apply 'langmap' to mapped characters
'laststatus'	'ls'	tells when last window has status lines
'lazyredraw'	'lz'	don't redraw while executing macros
'linebreak'	'lbr'	wrap long lines at a blank
'lines'		number of lines in the display
'linespace'	'lsp'	number of pixel lines to use between characters
'lisp'		automatic indenting for Lisp
'lispwords'	'lw'	words that change how lisp indenting works
'list'		show <Tab> and <EOL>
'listchars'	'lcs'	characters for displaying in list mode
'loadplugins'	'lpl'	load plugin scripts when starting up
'luadll'		name of the Lua dynamic library
'mzschemedll'		name of the MzScheme dynamic library
'mzschemegcdll'		name of the MzScheme dynamic library for GC
'macatsui'		Mac GUI: use ATSUI text drawing
'magic'		changes special characters in search patterns
'makeef'	'mef'	name of the errorfile for ":make"
'makeencoding'	'menc'	encoding of external make/grep commands
'makeprg'	'mp'	program to use for the ":make" command
'matchpairs'	'mps'	pairs of characters that "%" can match
'matchtime'	'mat'	tenths of a second to show matching paren
'maxcombine'	'mco'	maximum nr of combining characters displayed
'maxfuncdepth'	'mfd'	maximum recursive depth for user functions
'maxmapdepth'	'mmd'	maximum recursive depth for mapping
'maxmem'	'mm'	maximum memory (in Kbyte) used for one buffer
'maxmempattern'	'mmp'	maximum memory (in Kbyte) used for pattern search
'maxmemtot'	'mmt'	maximum memory (in Kbyte) used for all buffers
'menuitems'	'mis'	maximum number of items in a menu
'mkspellmem'	'msm'	memory used before :mkspell compresses the tree
'modeline'	'ml'	recognize modelines at start or end of file
'modelines'	'mls'	number of lines checked for modelines
'modifiable'	'ma'	changes to the text are not possible
'modified'	'mod'	buffer has been modified
'more'		pause listings when the whole screen is filled
'mouse'		enable the use of mouse clicks
'mousefocus'	'mousef'	keyboard focus follows the mouse
'mousehide'	'mh'	hide mouse pointer while typing
'mousemodel'	'mousem'	changes meaning of mouse buttons
'mouseshape'	'mouses'	shape of the mouse pointer in different modes

'mousetime'	'mouset'	max time between mouse double-click
'mzquantum'	'mzq'	the interval between polls for MzScheme threads
'nrformats'	'nf'	number formats recognized for CTRL-A command
'number'	'nu'	print the line number in front of each line
'numberwidth'	'nuw'	number of columns used for the line number
'omnifunc'	'ofu'	function for filetype-specific completion
'opendevice'	'odev'	allow reading/writing devices on MS-Windows
'operatorfunc'	'opfunc'	function to be called for g@ operator
'osfiletype'	'oft'	no longer supported
'packpath'	'pp'	list of directories used for packages
'paragraphs'	'para'	nroff macros that separate paragraphs
'paste'		allow pasting text
'pastetoggle'	'pt'	key code that causes 'paste' to toggle
'patchexpr'	'pex'	expression used to patch a file
'patchmode'	'pm'	keep the oldest version of a file
'path'	'pa'	list of directories searched with "gf" et.al.
'perldll'		name of the Perl dynamic library
'preserveindent'	'pi'	preserve the indent structure when reindenting
'previewheight'	'pvh'	height of the preview window
'previewwindow'	'pvw'	identifies the preview window
'printdevice'	'pdev'	name of the printer to be used for :hardcopy
'printencoding'	'penc'	encoding to be used for printing
'printexpr'	'pexpr'	expression used to print PostScript for :hardcopy
'printfont'	'pfn'	name of the font to be used for :hardcopy
'printheader'	'pheader'	format of the header used for :hardcopy
'printmbcharset'	'pmbcs'	CJK character set to be used for :hardcopy
'printmbfont'	'pmbfn'	font names to be used for CJK output of :hardcopy
'printoptions'	'popt'	controls the format of :hardcopy output
'prompt'	'prompt'	enable prompt in Ex mode
'pumheight'	'ph'	maximum height of the popup menu
'pumwidth'	'pw'	minimum width of the popup menu
'pythondll'		name of the Python 2 dynamic library
'pythonhome'		name of the Python 2 home directory
'pythonthreedll'		name of the Python 3 dynamic library
'pythonthreehome'		name of the Python 3 home directory
'pyxversion'	'pyx'	Python version used for pyx* commands
'quoteescape'	'qe'	escape characters used in a string
'readonly'	'ro'	disallow writing the buffer
'redrawtime'	'rdt'	timeout for 'hlsearch' and :match highlighting
'regexpengine'	're'	default regexp engine to use
'relativenumber'	'rnu'	show relative line number in front of each line
'remap'		allow mappings to work recursively
'renderoptions'	'rop'	options for text rendering on Windows
'report'		threshold for reporting nr. of lines changed
'restorescreen'	'rs'	Win32: restore screen when exiting
'revins'	'ri'	inserting characters will work backwards
'rightleft'	'rl'	window is right-to-left oriented
'rightleftcmd'	'rlc'	commands for which editing works right-to-left
'rubydll'		name of the Ruby dynamic library
'ruler'	'ru'	show cursor line and column in the status line
'rulerformat'	'ruf'	custom format for the ruler
'runtimepath'	'rtp'	list of directories used for runtime files
'scroll'	'scr'	lines to scroll with CTRL-U and CTRL-D
'scrollbind'	'scb'	scroll in window as other windows scroll

'scrolljump'	'sj'	minimum number of lines to scroll
'scrolloff'	'so'	minimum nr. of lines above and below cursor
'scrollopt'	'sbo'	how 'scrollbind' should behave
'sections'	'sect'	nroff macros that separate sections
'secure'		secure mode for reading .vimrc in current dir
'selection'	'sel'	what type of selection to use
'selectmode'	'slm'	when to use Select mode instead of Visual mode
'sessionoptions'	'ssop'	options for :mksession
'shell'	'sh'	name of shell to use for external commands
'shellcmdflag'	'shcf'	flag to shell to execute one command
'shellpipe'	'sp'	string to put output of ":make" in error file
'shellquote'	'shq'	quote character(s) for around shell command
'shellredir'	'srr'	string to put output of filter in a temp file
'shellslash'	'ssl'	use forward slash for shell file names
'shelltemp'	'stmp'	whether to use a temp file for shell commands
'shelltype'	'st'	Amiga: influences how to use a shell
'shellxescape'	'sxe'	characters to escape when 'shellxquote' is (
'shellxquote'	'sxq'	like 'shellquote', but include redirection
'shiftround'	'sr'	round indent to multiple of shiftwidth
'shiftwidth'	'sw'	number of spaces to use for (auto)indent step
'shortmess'	'shm'	list of flags, reduce length of messages
'shortname'	'sn'	non-MS-DOS: Filenames assumed to be 8.3 chars
'showbreak'	'sbr'	string to use at the start of wrapped lines
'showcmd'	'sc'	show (partial) command in status line
'showfulltag'	'sft'	show full tag pattern when completing tag
'showmatch'	'sm'	briefly jump to matching bracket if insert one
'showmode'	'smd'	message on status line to show current mode
'showtabline'	'stal'	tells when the tab pages line is displayed
'sidescroll'	'ss'	minimum number of columns to scroll horizontal
'sidescrolloff'	'siso'	min. nr. of columns to left and right of cursor
'signcolumn'	'scl'	when to display the sign column
'smartcase'	'scs'	no ignore case when pattern has uppercase
'smartindent'	'si'	smart autoindenting for C programs
'smarttab'	'sta'	use 'shiftwidth' when inserting <Tab>
'softtabstop'	'sts'	number of spaces that <Tab> uses while editing
'spell'		enable spell checking
'spellcapcheck'	'spc'	pattern to locate end of a sentence
'spellfile'	'spf'	files where zg and zw store words
'spelllang'	'spl'	language(s) to do spell checking for
'spellsuggest'	'sps'	method(s) used to suggest spelling corrections
'splitbelow'	'sb'	new window from split is below the current one
'splitright'	'spr'	new window is put right of the current one
'startofline'	'sol'	commands move cursor to first non-blank in line
'statusline'	'stl'	custom format for the status line
'suffixes'	'su'	suffixes that are ignored with multiple match
'suffixesadd'	'sua'	suffixes added when searching for a file
'swapfile'	'swf'	whether to use a swapfile for a buffer
'swapsync'	'sws'	how to sync the swap file
'switchbuf'	'swb'	sets behavior when switching to another buffer
'synmaxcol'	'smc'	maximum column to find syntax items
'syntax'	'syn'	syntax to be loaded for current buffer
'tabline'	'tal'	custom format for the console tab pages line
'tabpagemax'	'tpm'	maximum number of tab pages for -p and "tab all"
'tabstop'	'ts'	number of spaces that <Tab> in file uses

'tagbsearch'	'tbs'	use binary searching in tags files
'tagcase'	'tc'	how to handle case when searching in tags files
'taglength'	'tl'	number of significant characters for a tag
'tagrelative'	'tr'	file names in tag file are relative
'tags'	'tag'	list of file names used by the tag command
'tagstack'	'tgst'	push tags onto the tag stack
'tcldll'		name of the Tcl dynamic library
'term'		name of the terminal
'termbidi'	'tbidi'	terminal takes care of bi-directionality
'termencoding'	'tenc'	character encoding used by the terminal
'termguicolors'	'tgc'	use GUI colors for the terminal
'termwinkey'	'twk'	key that precedes a Vim command in a terminal
'termwinscroll'	'twsl'	max number of scrollback lines in a terminal window
'termwinsize'	'tws'	size of a terminal window
'terse'		shorten some messages
'textauto'	'ta'	obsolete, use 'fileformats'
'textmode'	'tx'	obsolete, use 'fileformat'
'textwidth'	'tw'	maximum width of text that is being inserted
'thesaurus'	'tsr'	list of thesaurus files for keyword completion
'tildeop'	'top'	tilde command "~" behaves like an operator
'timeout'	'to'	time out on mappings and key codes
'timeoutlen'	'tm'	time out time in milliseconds
'title'		let Vim set the title of the window
'titlelen'		percentage of 'columns' used for window title
'titleold'		old title, restored when exiting
'titlestring'		string to use for the Vim window title
'toolbar'	'tb'	GUI: which items to show in the toolbar
'toolbariconsize'	'tbis'	size of the toolbar icons (for GTK 2 only)
'ttimeout'		time out on mappings
'ttimeoutlen'	'ttm'	time out time for key codes in milliseconds
'ttybuiltin'	'tbi'	use built-in termcap before external termcap
'ttyfast'	'tf'	indicates a fast terminal connection
'ttymouse'	'ttym'	type of mouse codes generated
'ttyscroll'	'tsl'	maximum number of lines for a scroll
'ttytype'	'tty'	alias for 'term'
'undodir'	'udir'	where to store undo files
'undofile'	'udf'	save undo information in a file
'undolevels'	'ul'	maximum number of changes that can be undone
'undoreload'	'ur'	max nr of lines to save for undo on a buffer reload
'updatecount'	'uc'	after this many characters flush swap file
'updatetime'	'ut'	after this many milliseconds flush swap file
'varsofttabstop'	'vsts'	a list of number of spaces when typing <Tab>
'vartabstop'	'vts'	a list of number of spaces for <Tab>s
'verbose'	'vbs'	give informative messages
'verbosefile'	'vfile'	file to write messages in
'viewdir'	'vdir'	directory where to store files with :mkview
'viewoptions'	'vop'	specifies what to save for :mkview
'viminfo'	'vi'	use .viminfo file upon startup and exiting
'viminfofile'	'vif'	file name used for the viminfo file
'virtualedit'	've'	when to use virtual editing
'visualbell'	'vb'	use visual bell instead of beeping
'warn'		warn for shell command when buffer was changed
'weirdinvert'	'wiv'	for terminals that have weird inversion method
'whichwrap'	'ww'	allow specified keys to cross line boundaries

```
'wildchar'          'wc'      command-line character for wildcard expansion
'wildcharm'         'wcm'     like 'wildchar' but also works when mapped
'wildignore'        'wig'     files matching these patterns are not completed
'wildignorecase'    'wic'     ignore case when completing file names
'wildmenu'          'wmnu'    use menu for command line completion
'wildmode'          'wim'     mode for 'wildchar' command-line expansion
'wildoptions'       'wop'     specifies how command line completion is done
'winaltkeys'        'wak'     when the windows system handles ALT keys
'window'            'wi'      nr of lines to scroll for CTRL-F and CTRL-B
'winheight'         'wh'      minimum number of lines for the current window
'winfixheight'      'wfh'     keep window height when opening/closing windows
'winfixwidth'       'wfw'     keep window width when opening/closing windows
'winminheight'      'wmh'     minimum number of lines for any window
'winminwidth'       'wmw'     minimal number of columns for any window
'winptydll'                   name of the winpty dynamic library
'winwidth'          'wiw'     minimal number of columns for current window
'wrap'                        long lines wrap and continue on the next line
'wrapmargin'        'wm'      chars from the right where wrapping starts
'wrapscan'          'ws'      searches wrap around the end of the file
'write'                       writing to a file is allowed
'writeany'          'wa'      write to file with no need for "!" override
'writebackup'       'wb'      make a backup before overwriting a file
'writedelay'        'wd'      delay this many msec for each char (for debug)
-------------------------------------------------------------------------------
Q_ur            Undo/Redo commands

u         N  u          undo last N changes
CTRL-R    N  CTRL-R     redo last N undone changes
U            U          restore last changed line
-------------------------------------------------------------------------------
Q_et            External commands

:shell          :sh[ell]        start a shell
:!              :!{command}     execute {command} with a shell
K                  K            lookup keyword under the cursor with
                                   'keywordprg' program (default: "man")
-------------------------------------------------------------------------------
Q_qf            Quickfix commands

:cc             :cc [nr]        display error [nr] (default is the same again)
:cnext          :cn             display the next error
:cprevious      :cp             display the previous error
:clist          :cl             list all errors
:cfile          :cf             read errors from the file 'errorfile'
:cgetbuffer     :cgetb          like :cbuffer but don't jump to the first error
:cgetfile       :cg             like :cfile but don't jump to the first error
:cgetexpr       :cgete          like :cexpr but don't jump to the first error
:caddfile       :caddf          add errors from the error file to the current
                                   quickfix list
:caddexpr       :cad            add errors from an expression to the current
                                   quickfix list
:cbuffer        :cb             read errors from text in a buffer
:cexpr          :cex            read errors from an expression
:cquit          :cq             quit without writing and return error code (to
```

```
                                    the compiler)
:make           :make [args]    start make, read errors, and jump to first
                                    error
:grep           :gr[ep] [args]  execute 'grepprg' to find matches and jump to
                                    the first one
-------------------------------------------------------------------------------
Q_vc            Various commands

CTRL-L             CTRL-L       clear and redraw the screen
CTRL-G             CTRL-G       show current file name (with path) and cursor
                                    position
ga                 ga           show ascii value of character under cursor in
                                    decimal, hex, and octal
g8                 g8           for utf-8 encoding: show byte sequence for
                                    character under cursor in hex
g_CTRL-G           g CTRL-G     show cursor column, line, and character
                                    position
CTRL-C             CTRL-C       during searches: Interrupt the search
dos-CTRL-Break     CTRL-Break   MS-DOS: during searches: Interrupt the search
<Del>              <Del>        while entering a count: delete last character
:version        :ve[rsion]      show version information
:mode           :mode N         MS-DOS: set screen mode to N (number, C80,
                                    C4350, etc.)
:normal         :norm[al][!] {commands}
                                execute Normal mode commands
Q                  Q            switch to "Ex" mode

:redir          :redir >{file}          redirect messages to {file}
:silent         :silent[!] {command}    execute {command} silently
:confirm        :confirm {command}      quit, write, etc., asking about
                                        unsaved changes or read-only files
:browse         :browse {command}       open/read/write file, using a
                                        file selection dialog
-------------------------------------------------------------------------------
Q_ce            Command-line editing

c_<Esc>         <Esc>               abandon command-line (if 'wildchar' is
                                       <Esc>, type it twice)

c_CTRL-V        CTRL-V {char}       insert {char} literally
c_CTRL-V        CTRL-V {number}     enter decimal value of character (up to
                                       three digits)
c_CTRL-K        CTRL-K {char1} {char2}
                                    enter digraph (See  Q_di )
c_CTRL-R        CTRL-R {0-9a-z"%#:-=}
                                    insert the contents of a register

c_<Left>        <Left>/<Right>      cursor left/right
c_<S-Left>      <S-Left>/<S-Right>  cursor one word left/right
c_CTRL-B        CTRL-B/CTRL-E       cursor to beginning/end of command-line

c_<BS>          <BS>                delete the character in front of the cursor
c_<Del>         <Del>               delete the character under the cursor
c_CTRL-W        CTRL-W              delete the word in front of the cursor
```

```
 c_CTRL-U       CTRL-U              remove all characters

 c_<Up>         <Up>/<Down>         recall older/newer command-line that starts
                                       with current command
 c_<S-Up>       <S-Up>/<S-Down>     recall older/newer command-line from history
 c_CTRL-G       CTRL-G              next match when 'incsearch' is active
 c_CTRL-T       CTRL-T              previous match when 'incsearch' is active
 :history       :his[tory]          show older command-lines

Context-sensitive completion on the command-line:

 c_wildchar     'wildchar'  (default: <Tab>)
                                    do completion on the pattern in front of the
                                       cursor; if there are multiple matches,
                                       beep and show the first one; further
                                       'wildchar' will show the next ones
 c_CTRL-D       CTRL-D              list all names that match the pattern in
                                       front of the cursor
 c_CTRL-A       CTRL-A              insert all names that match pattern in front
                                       of cursor
 c_CTRL-L       CTRL-L              insert longest common part of names that
                                       match pattern
 c_CTRL-N       CTRL-N              after 'wildchar' with multiple matches: go
                                       to next match
 c_CTRL-P       CTRL-P              after 'wildchar' with multiple matches: go
                                       to previous match
------------------------------------------------------------------------------
 Q_ra           Ex ranges

 :range         ,                   separates two line numbers
 :range         ;                   idem, set cursor to the first line number
                                    before interpreting the second one

 :range         {number}            an absolute line number
 :range         .                   the current line
 :range         $                   the last line in the file
 :range         %                   equal to 1,$ (the entire file)
 :range         *                   equal to '<,'> (visual area)
 :range         't                  position of mark t
 :range         /{pattern}[/]       the next line where {pattern} matches
 :range         ?{pattern}[?]       the previous line where {pattern} matches

 :range         +[num]              add [num] to the preceding line number
                                       (default: 1)
 :range         -[num]              subtract [num] from the preceding line
                                       number (default: 1)
------------------------------------------------------------------------------
 Q_ex           Special Ex characters

 :bar       |           separates two commands (not for ":global" and ":!")
 :quote     "           begins comment

 :_%        %           current file name (only where a file name is expected)
 :_#        #[num]      alternate file name [num] (only where a file name is
```

```
                        expected)
        Note: The next seven are typed literally; these are not special keys!
 :<abuf>    <abuf>      buffer number, for use in an autocommand (only where a
                        file name is expected)
 :<afile>   <afile>     file name, for use in an autocommand (only where a
                        file name is expected)
 :<amatch>  <amatch>    what matched with the pattern, for use in an
                        autocommand (only where a file name is expected)
 :<cword>   <cword>     word under the cursor (only where a file name is
                        expected)
 :<cWORD>   <cWORD>     WORD under the cursor (only where a file name is
                        expected) (see  WORD )
 :<cfile>   <cfile>     file name under the cursor (only where a file name is
                        expected)
 :<sfile>   <sfile>     file name of a ":source"d file, within that file (only
                        where a file name is expected)

                After "%", "#", "<cfile>", "<sfile>" or "<afile>"
                 ::p        :p          full path
                 ::h        :h          head (file name removed)
                 ::t        :t          tail (file name only)
                 ::r        :r          root (extension removed)
                 ::e        :e          extension
                 ::s        :s/{pat}/{repl}/    substitute {pat} with {repl}
------------------------------------------------------------------------------
 Q_st            Starting Vim

 -vim       vim [options]                start editing with an empty buffer
 -file      vim [options] {file} ..      start editing one or more files
 --         vim [options] -              read file from stdin
 -tag       vim [options] -t {tag}       edit the file associated with {tag}
 -qf        vim [options] -q [fname]     start editing in QuickFix mode,
                                            display the first error

        Most useful Vim arguments (for full list see  startup-options )

 -gui    -g                  start GUI (also allows other options)

 -+      +[num]              put the cursor at line [num] (default: last line)
 -+c     +{command}          execute {command} after loading the file
 -+/     +/{pat} {file} ..   put the cursor at the first occurrence of {pat}
 -v      -v                  Vi mode, start ex in Normal mode
 -e      -e                  Ex mode, start vim in Ex mode
 -R      -R                  Read-only mode, implies -n
 -m      -m                  modifications not allowed (resets 'write' option)
 -d      -d                  diff mode  diff
 -b      -b                  binary mode
 -l      -l                  lisp mode
 -A      -A                  Arabic mode ('arabic' is set)
 -F      -F                  Farsi mode ('fkmap' and 'rightleft' are set)
 -H      -H                  Hebrew mode ('hkmap' and 'rightleft' are set)
 -V      -V                  Verbose, give informative messages
 -C      -C                  Compatible, set the 'compatible' option
 -N      -N                  Nocompatible, reset the 'compatible' option
```

```
-r      -r                  give list of swap files
-r      -r {file} ..        recover aborted edit session
-n      -n                  do not create a swap file
-o      -o [num]            open [num] windows (default: one for each file)
-f      -f                  GUI: foreground process, don't fork
                            Amiga: do not restart Vim to open a window (for
                                e.g., mail)
-s      -s {scriptin}       first read commands from the file {scriptin}
-w      -w {scriptout}      write typed chars to file {scriptout} (append)
-W      -W {scriptout}      write typed chars to file {scriptout} (overwrite)
-T      -T {terminal}       set terminal name
-d      -d {device}         Amiga: open {device} to be used as a console
-u      -u {vimrc}          read inits from {vimrc} instead of other inits
-U      -U {gvimrc}         idem, for when starting the GUI
-i      -i {viminfo}        read info from {viminfo} instead of other files
---     --                  end of options, other arguments are file names

                                   is set and [!] not given write the buffer
CTRL-Z      CTRL-Z              same as ":stop"
------------------------------------------------------------------------------
Q_ac            Automatic Commands

viminfo-file    read registers, marks, history at startup, save when exiting.

:rviminfo       :rv[iminfo] [file]      read info from viminfo file [file]
:rviminfo       :rv[iminfo]! [file]     idem, overwrite existing info
:wviminfo       :wv[iminfo] [file]      add info to viminfo file [file]
:wviminfo       :wv[iminfo]! [file]     write info to viminfo file [file]

modeline        Automatic option setting when editing a file

modeline        vim:{set-arg}: ..       In the first and last lines of the
```

```
                                        file (see 'ml' option), {set-arg} is
                                        given as an argument to ":set"

autocommand     Automatic execution of commands on certain events.

:autocmd        :au                       list all autocommands
:autocmd        :au {event}               list all autocommands for {event}
:autocmd        :au {event} {pat}         list all autocommands for {event}
                                          with {pat}
:autocmd        :au {event} {pat} {cmd}   enter new autocommands for {event}
                                          with {pat}
:autocmd        :au!                      remove all autocommands
:autocmd        :au! {event}              remove all autocommands for {event}
:autocmd        :au! * {pat}              remove all autocommands for {pat}
:autocmd        :au! {event} {pat}        remove all autocommands for {event}
                                          with {pat}
:autocmd        :au! {event} {pat} {cmd}  remove all autocommands for {event}
                                          with {pat} and enter new one
------------------------------------------------------------------------------
Q_wi            Multi-window commands

CTRL-W_s        CTRL-W s  or  :split    split window into two parts
:split_f        :split {file}           split window and edit {file} in one of
                                           them
:vsplit         :vsplit {file}          same, but split vertically
:vertical       :vertical {cmd}         make {cmd} split vertically

:sfind          :sf[ind] {file}         split window, find {file} in 'path'
                                           and edit it
:terminal       :terminal {cmd}         open a terminal window
CTRL-W_]        CTRL-W ]                split window and jump to tag under
                                           cursor
CTRL-W_f        CTRL-W f                split window and edit file name under
                                           the cursor
CTRL-W_^        CTRL-W ^                split window and edit alternate file
CTRL-W_n        CTRL-W n  or  :new      create new empty window
CTRL-W_q        CTRL-W q  or  :q[uit]   quit editing and close window
CTRL-W_c        CTRL-W c  or  :cl[ose]  make buffer hidden and close window
CTRL-W_o        CTRL-W o  or  :on[ly]   make current window only one on the
                                           screen

CTRL-W_j        CTRL-W j                move cursor to window below
CTRL-W_k        CTRL-W k                move cursor to window above
CTRL-W_CTRL-W   CTRL-W CTRL-W           move cursor to window below (wrap)
CTRL-W_W        CTRL-W W                move cursor to window above (wrap)
CTRL-W_t        CTRL-W t                move cursor to top window
CTRL-W_b        CTRL-W b                move cursor to bottom window
CTRL-W_p        CTRL-W p                move cursor to previous active window

CTRL-W_r        CTRL-W r                rotate windows downwards
CTRL-W_R        CTRL-W R                rotate windows upwards
CTRL-W_x        CTRL-W x                exchange current window with next one

CTRL-W_=        CTRL-W =                make all windows equal height & width
```

```
CTRL-W_-        CTRL-W -                decrease current window height
CTRL-W_+        CTRL-W +                increase current window height
CTRL-W__        CTRL-W _                set current window height (default:
                                           very high)

CTRL-W_<        CTRL-W <                decrease current window width
CTRL-W_>        CTRL-W >                increase current window width
CTRL-W_bar      CTRL-W |                set current window width (default:
                                           widest possible)
-------------------------------------------------------------------------------
Q_bu            Buffer list commands

:buffers        :buffers  or  :files    list all known buffer and file names

:ball           :ball     or  :sball    edit all args/buffers
:unhide         :unhide   or  :sunhide  edit all loaded buffers

:badd           :badd {fname}           add file name {fname} to the list
:bunload        :bunload[!] [N]         unload buffer [N] from memory
:bdelete        :bdelete[!] [N]         unload buffer [N] and delete it from
                                           the buffer list

                in current window  in new window
:buffer         :[N]buffer [N]     :[N]sbuffer [N]     to arg/buf N
:bnext          :[N]bnext [N]      :[N]sbnext [N]      to Nth next arg/buf
:bNext          :[N]bNext [N]      :[N]sbNext [N]      to Nth previous arg/buf
:bprevious      :[N]bprevious [N]  :[N]sbprevious [N]  to Nth previous arg/buf
:bfirst         :bfirst            :sbfirst            to first arg/buf
:blast          :blast             :sblast             to last arg/buf
:bmodified      :[N]bmod [N]       :[N]sbmod [N]       to Nth modified buf
-------------------------------------------------------------------------------
Q_sy            Syntax Highlighting

:syn-on         :syntax on              start using syntax highlighting
:syn-off        :syntax off             stop using syntax highlighting

:syn-keyword    :syntax keyword {group-name} {keyword} ..
                                        add a syntax keyword item
:syn-match      :syntax match {group-name} {pattern} ...
                                        add syntax match item
:syn-region     :syntax region {group-name} {pattern} ...
                                        add syntax region item
:syn-sync       :syntax sync [ccomment | lines {N} | ...]
                                        tell syntax how to sync
:syntax         :syntax [list]          list current syntax items
:syn-clear      :syntax clear           clear all syntax info

:highlight      :highlight clear        clear all highlight info
:highlight      :highlight {group-name} {key}={arg} ..
                                        set highlighting for {group-name}

:filetype       :filetype on            switch on file type detection, without
                                        syntax highlighting
:filetype       :filetype plugin indent on
```

```
                                        switch on file type detection, with
                                        automatic indenting and settings
------------------------------------------------------------------------------
Q_gu            GUI commands

:gui            :gui                    UNIX: start the GUI
:gui            :gui {fname} ..         idem, and edit {fname} ..

:menu           :menu                   list all menus
:menu           :menu {mpath}           list menus starting with {mpath}
:menu           :menu {mpath} {rhs}     add menu {mpath}, giving {rhs}
:menu           :menu {pri} {mpath} {rhs}
                                        idem, with priorities {pri}
:menu           :menu ToolBar.{name} {rhs}
                                        add toolbar item, giving {rhs}
:tmenu          :tmenu {mpath} {text}   add tooltip to menu {mpath}
:unmenu         :unmenu {mpath}         remove menu {mpath}
------------------------------------------------------------------------------
Q_fo            Folding

'foldmethod'    set foldmethod=manual   manual folding
                set foldmethod=indent   folding by indent
                set foldmethod=expr     folding by 'foldexpr'
                set foldmethod=syntax   folding by syntax regions
                set foldmethod=marker   folding by 'foldmarker'

zf              zf{motion}              operator: Define a fold manually
:fold           :{range}fold            define a fold for {range} lines
zd              zd                      delete one fold under the cursor
zD              zD                      delete all folds under the cursor

zo              zo                      open one fold under the cursor
zO              zO                      open all folds under the cursor
zc              zc                      close one fold under the cursor
zC              zC                      close all folds under the cursor

zm              zm                      fold more: decrease 'foldlevel'
zM              zM                      close all folds: make 'foldlevel' zero
zr              zr                      reduce folding: increase 'foldlevel'
zR              zR                      open all folds: make 'foldlevel' max.

zn              zn                      fold none: reset 'foldenable'
zN              zN                      fold normal set 'foldenable'
zi              zi                      invert 'foldenable'

VIM USER MANUAL - by Bram Moolenaar

About the manuals

This chapter introduces the manuals available with Vim. Read this to know the conditions under which the commands are explained.

Next chapter: usr_02.txt The first steps in Vim
Table of contents: usr_toc.txt

==

01.1 Two manuals

The Vim documentation consists of two parts:

1. The User manual
   Task oriented explanations, from simple to complex. Reads from start to end like a book.

2. The Reference manual
   Precise description of how everything in Vim works.

The notation used in these manuals is explained here: notation

JUMPING AROUND

The text contains hyperlinks between the two parts, allowing you to quickly jump between the description of an editing task and a precise explanation of the commands and options used for it. Use these two commands:

        Press CTRL-] to jump to a subject under the cursor.
        Press CTRL-O to jump back (repeat to go further back).

Many links are in vertical bars, like this: bars . The bars themselves may be hidden or invisible, see below. An option name, like 'number', a command in double quotes like ":write" and any other word can also be used as a link. Try it out: Move the cursor to CTRL-] and press CTRL-] on it.

Other subjects can be found with the ":help" command, see help.txt .

The bars and stars are usually hidden with the conceal feature. They also use hl-Ignore , using the same color for the text as the background. You can make them visible with:

```
:set conceallevel=0
:hi link HelpBar Normal
```

```
        :hi link HelpStar Normal
```

==
01.2 Vim installed

Most of the manuals assume that Vim has been properly installed. If you didn't do that yet, or if Vim doesn't run properly (e.g., files can't be found or in the GUI the menus do not show up) first read the chapter on installation: usr_90.txt .

not-compatible

The manuals often assume you are using Vim with Vi-compatibility switched off. For most commands this doesn't matter, but sometimes it is important, e.g., for multi-level undo. An easy way to make sure you are using a nice setup is to copy the example vimrc file. By doing this inside Vim you don't have to check out where it is located. How to do this depends on the system you are using:

Unix:
```
        :!cp -i $VIMRUNTIME/vimrc_example.vim ~/.vimrc
```
MS-DOS, MS-Windows, OS/2:
```
        :!copy $VIMRUNTIME/vimrc_example.vim $VIM/_vimrc
```
Amiga:
```
        :!copy $VIMRUNTIME/vimrc_example.vim $VIM/.vimrc
```

If the file already exists you probably want to keep it.

If you start Vim now, the 'compatible' option should be off. You can check it with this command:

```
        :set compatible?
```

If it responds with "nocompatible" you are doing well. If the response is "compatible" you are in trouble. You will have to find out why the option is still set. Perhaps the file you wrote above is not found. Use this command to find out:

```
        :scriptnames
```

If your file is not in the list, check its location and name. If it is in the list, there must be some other place where the 'compatible' option is switched back on.

For more info see vimrc and compatible-default .

        Note:
        This manual is about using Vim in the normal way. There is an alternative called "evim" (easy Vim). This is still Vim, but used in a way that resembles a click-and-type editor like Notepad. It always stays in Insert mode, thus it feels very different. It is not explained in the user manual, since it should be mostly self explanatory. See evim-keys for details.

==
01.3 Using the Vim tutor tutor vimtutor

Instead of reading the text (boring!) you can use the vimtutor to learn your first Vim commands. This is a 30 minute tutorial that teaches the most basic Vim functionality hands-on.

On Unix, if Vim has been properly installed, you can start it from the shell:

```
vimtutor
```

On MS-Windows you can find it in the Program/Vim menu. Or execute vimtutor.bat in the $VIMRUNTIME directory.

This will make a copy of the tutor file, so that you can edit it without the risk of damaging the original.
There are a few translated versions of the tutor. To find out if yours is available, use the two-letter language code. For French:

```
vimtutor fr
```

On Unix, if you prefer using the GUI version of Vim, use "gvimtutor" or "vimtutor -g" instead of "vimtutor".

For OpenVMS, if Vim has been properly installed, you can start vimtutor from a VMS prompt with:

```
@VIM:vimtutor
```

Optionally add the two-letter language code as above.

On other systems, you have to do a little work:

1. Copy the tutor file. You can do this with Vim (it knows where to find it):

```
vim --clean -c 'e $VIMRUNTIME/tutor/tutor' -c 'w! TUTORCOPY' -c 'q'
```

This will write the file "TUTORCOPY" in the current directory. To use a translated version of the tutor, append the two-letter language code to the filename. For French:

```
vim --clean -c 'e $VIMRUNTIME/tutor/tutor.fr' -c 'w! TUTORCOPY' -c 'q'
```

2. Edit the copied file with Vim:

```
vim --clean TUTORCOPY
```

The --clean argument makes sure Vim is started with nice defaults.

3. Delete the copied file when you are finished with it:

```
del TUTORCOPY
```

==
01.4 Copyright manual-copyright

frombook

Parts of the user manual come from the book "Vi IMproved - Vim" by Steve Oualline (published by New Riders Publishing, ISBN: 0735710015). The Open Publication License applies to this book. Only selected parts are included and these have been modified (e.g., by removing the pictures, updating the text for Vim 6.0 and later, fixing mistakes). The omission of the frombook tag does not mean that the text does not come from the book.

Many thanks to Steve Oualline and New Riders for creating this book and publishing it under the OPL! It has been a great help while writing the user manual. Not only by providing literal text, but also by setting the tone and style.

If you make money through selling the manuals, you are strongly encouraged to donate part of the profit to help AIDS victims in Uganda. See iccf .

VIM USER MANUAL - by Bram Moolenaar

The first steps in Vim

This chapter provides just enough information to edit a file with Vim. Not well or fast, but you can edit. Take some time to practice with these commands, they form the base for what follows.

Next chapter: usr_03.txt Moving around
Previous chapter: usr_01.txt About the manuals
Table of contents: usr_toc.txt

02.1 Running Vim for the First Time

To start Vim, enter this command:

```
gvim file.txt
```

In UNIX you can type this at any command prompt. If you are running Microsoft Windows, open an MS-DOS prompt window and enter the command.
In either case, Vim starts editing a file called file.txt. Because this is a new file, you get a blank window. This is what your screen will look like:

```
+----------------------------------------+
|#                                       |
|~                                       |
|~                                       |
|~                                       |
|~                                       |
|"file.txt" [New file]                   |
+----------------------------------------+
        ('#" is the cursor position.)
```

The tilde (~) lines indicate lines not in the file. In other words, when Vim runs out of file to display, it displays tilde lines. At the bottom of the screen, a message line indicates the file is named file.txt and shows that you are creating a new file. The message information is temporary and other information overwrites it.

THE VIM COMMAND

The gvim command causes the editor to create a new window for editing. If you use this command:

```
vim file.txt
```

the editing occurs inside your command window. In other words, if you are running inside an xterm, the editor uses your xterm window. If you are using an MS-DOS command prompt window under Microsoft Windows, the editing occurs inside this window. The text in the window will look the same for both versions, but with gvim you have extra features, like a menu bar. More about that later.

==========

02.2 Inserting text

The Vim editor is a modal editor. That means that the editor behaves differently, depending on which mode you are in. The two basic modes are called Normal mode and Insert mode. In Normal mode the characters you type are commands. In Insert mode the characters are inserted as text.

Since you have just started Vim it will be in Normal mode. To start Insert mode you type the "i" command (i for Insert). Then you can enter the text. It will be inserted into the file. Do not worry if you make mistakes; you can correct them later. To enter the following programmer's limerick, this is what you type:

```
iA very intelligent turtle
Found programming UNIX a hurdle
```

After typing "turtle" you press the <Enter> key to start a new line. Finally you press the <Esc> key to stop Insert mode and go back to Normal mode. You now have two lines of text in your Vim window:

```
+----------------------------------------+
|A very intelligent turtle               |
|Found programming UNIX a hurdle         |
|~                                       |
|~                                       |
|                                        |
+----------------------------------------+
```

WHAT IS THE MODE?

To be able to see what mode you are in, type this command:

```
:set showmode
```

You will notice that when typing the colon Vim moves the cursor to the last line of the window. That's where you type colon commands (commands that start with a colon). Finish this command by pressing the <Enter> key (all commands that start with a colon are finished this way).

Now, if you type the "i" command Vim will display --INSERT-- at the bottom

of the window. This indicates you are in Insert mode.

```
+----------------------------------------+
|A very intelligent turtle               |
|Found programming UNIX a hurdle         |
|~                                       |
|~                                       |
|-- INSERT --                            |
+----------------------------------------+
```

If you press <Esc> to go back to Normal mode the last line will be made blank.

GETTING OUT OF TROUBLE

One of the problems for Vim novices is mode confusion, which is caused by forgetting which mode you are in or by accidentally typing a command that switches modes. To get back to Normal mode, no matter what mode you are in, press the <Esc> key. Sometimes you have to press it twice. If Vim beeps back at you, you already are in Normal mode.

==
02.3 Moving around

After you return to Normal mode, you can move around by using these keys:

```
h   left                                                    hjkl
j   down
k   up
l   right
```

At first, it may appear that these commands were chosen at random. After all, who ever heard of using l for right? But actually, there is a very good reason for these choices: Moving the cursor is the most common thing you do in an editor, and these keys are on the home row of your right hand. In other words, these commands are placed where you can type them the fastest (especially when you type with ten fingers).

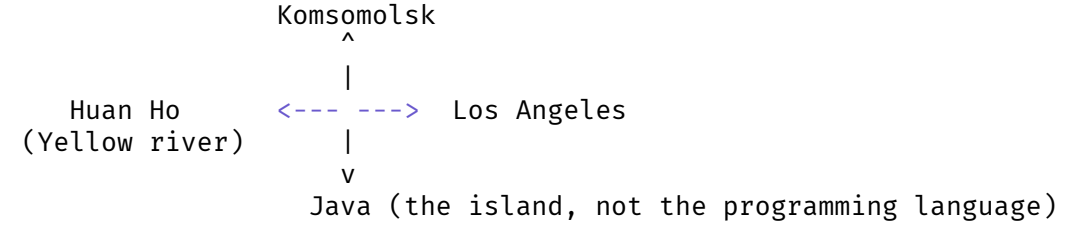
> Note:
> You can also move the cursor by using the arrow keys. If you do, however, you greatly slow down your editing because to press the arrow keys, you must move your hand from the text keys to the arrow keys. Considering that you might be doing it hundreds of times an hour, this can take a significant amount of time.
>
> Also, there are keyboards which do not have arrow keys, or which locate them in unusual places; therefore, knowing the use of the hjkl keys helps in those situations.

One way to remember these commands is that h is on the left, l is on the right and j points down. In a picture:

```
          k
     h    l
       j
```

The best way to learn these commands is by using them. Use the "i" command to insert some more lines of text. Then use the hjkl keys to move around and insert a word somewhere. Don't forget to press <Esc> to go back to Normal mode. The vimtutor is also a nice way to learn by doing.

For Japanese users, Hiroshi Iwatani suggested using this:



02.4 Deleting characters

To delete a character, move the cursor over it and type "x". (This is a throwback to the old days of the typewriter, when you deleted things by typing xxxx over them.) Move the cursor to the beginning of the first line, for example, and type xxxxxxx (seven x's) to delete "A very ". The result should look like this:

```
+----------------------------------------+
|intelligent turtle                      |
|Found programming UNIX a hurdle         |
|~                                       |
|~                                       |
|                                        |
+----------------------------------------+
```

Now you can insert new text, for example by typing:

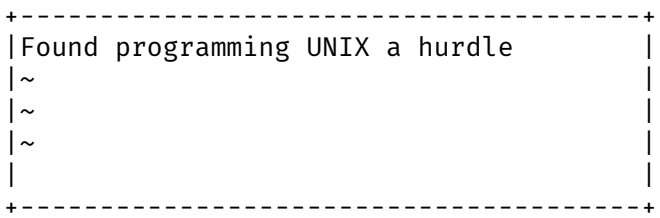
```
iA young <Esc>
```

This begins an insert (the i), inserts the words "A young", and then exits insert mode (the final <Esc>). The result:

```
+----------------------------------------+
|A young intelligent turtle              |
|Found programming UNIX a hurdle         |
|~                                       |
|~                                       |
|                                        |
+----------------------------------------+
```

DELETING A LINE

To delete a whole line use the "dd" command. The following line will then move up to fill the gap:



DELETING A LINE BREAK

In Vim you can join two lines together, which means that the line break between them is deleted. The "J" command does this.
Take these two lines:

```
A young intelligent
turtle
```

Move the cursor to the first line and press "J":

```
A young intelligent turtle
```

==========

02.5 Undo and Redo

Suppose you delete too much. Well, you can type it in again, but an easier way exists. The "u" command undoes the last edit. Take a look at this in action: After using "dd" to delete the first line, "u" brings it back.
Another one: Move the cursor to the A in the first line:

```
A young intelligent turtle
```

Now type xxxxxxx to delete "A young". The result is as follows:

```
 intelligent turtle
```

Type "u" to undo the last delete. That delete removed the g, so the undo restores the character.

```
g intelligent turtle
```

The next u command restores the next-to-last character deleted:

```
ng intelligent turtle
```

The next u command gives you the u, and so on:

```
ung intelligent turtle
oung intelligent turtle
young intelligent turtle
 young intelligent turtle
A young intelligent turtle
```

Note:

If you type "u" twice, and the result is that you get the same text back, you have Vim configured to work Vi compatible. Look here to fix this: not-compatible .
   This text assumes you work "The Vim Way". You might prefer to use the good old Vi way, but you will have to watch out for small differences in the text then.

REDO

If you undo too many times, you can press CTRL-R (redo) to reverse the preceding command. In other words, it undoes the undo. To see this in action, press CTRL-R twice. The character A and the space after it disappear:

```
        young intelligent turtle
```

There's a special version of the undo command, the "U" (undo line) command. The undo line command undoes all the changes made on the last line that was edited. Typing this command twice cancels the preceding "U".

```
        A very intelligent turtle
          xxxx                          Delete very

        A intelligent turtle
                      xxxxxx            Delete turtle

        A intelligent
                                        Restore line with "U"
        A very intelligent turtle
                                        Undo "U" with "u"
        A intelligent
```

The "U" command is a change by itself, which the "u" command undoes and CTRL-R redoes. This might be a bit confusing. Don't worry, with "u" and CTRL-R you can go to any of the situations you had. More about that in section 32.2 .

==
02.6 Other editing commands

Vim has a large number of commands to change the text. See Q_in and below. Here are a few often used ones.

APPENDING

The "i" command inserts a character before the character under the cursor. That works fine; but what happens if you want to add stuff to the end of the line? For that you need to insert text after the cursor. This is done with the "a" (append) command.
   For example, to change the line

```
        and that's not saying much for the turtle.
```

to

```
        and that's not saying much for the turtle!!!
```

move the cursor over to the dot at the end of the line. Then type "x" to delete the period. The cursor is now positioned at the end of the line on the e in turtle. Now type

```
a!!!<Esc>
```

to append three exclamation points after the e in turtle:

```
and that's not saying much for the turtle!!!
```

OPENING UP A NEW LINE

The "o" command creates a new, empty line below the cursor and puts Vim in Insert mode. Then you can type the text for the new line.
Suppose the cursor is somewhere in the first of these two lines:

```
A very intelligent turtle
Found programming UNIX a hurdle
```

If you now use the "o" command and type new text:

```
oThat liked using Vim<Esc>
```

The result is:

```
A very intelligent turtle
That liked using Vim
Found programming UNIX a hurdle
```

The "O" command (uppercase) opens a line above the cursor.

USING A COUNT

Suppose you want to move up nine lines. You can type "kkkkkkkkk" or you can enter the command "9k". In fact, you can precede many commands with a number. Earlier in this chapter, for instance, you added three exclamation points to the end of a line by typing "a!!!<Esc>". Another way to do this is to use the command "3a!<Esc>". The count of 3 tells the command that follows to triple its effect. Similarly, to delete three characters, use the command "3x". The count always comes before the command it applies to.

==
02.7 Getting out

To exit, use the "ZZ" command. This command writes the file and exits.

```
Note:
Unlike many other editors, Vim does not automatically make a backup
file. If you type "ZZ", your changes are committed and there's no
turning back. You can configure the Vim editor to produce backup
files, see 07.4 .
```

DISCARDING CHANGES

Sometimes you will make a sequence of changes and suddenly realize you were
better off before you started. Not to worry; Vim has a
quit-and-throw-things-away command. It is:

	:q!

Don't forget to press <Enter> to finish the command.

For those of you interested in the details, the three parts of this command
are the colon (:), which enters Command-line mode; the q command, which tells
the editor to quit; and the override command modifier (!).
   The override command modifier is needed because Vim is reluctant to throw
away changes. If you were to just type ":q", Vim would display an error
message and refuse to exit:

	E37: No write since last change (use ! to override)

By specifying the override, you are in effect telling Vim, "I know that what
I'm doing looks stupid, but I'm a big boy and really want to do this."

If you want to continue editing with Vim: The ":e!" command reloads the
original version of the file.

==
02.8	Finding help

Everything you always wanted to know can be found in the Vim help files.
Don't be afraid to ask!

If you know what you are looking for, it is usually easier to search for it
using the help system, instead of using Google. Because the subjects follow
a certain style guide.

Also the help has the advantage of belonging to your particular Vim version.
You won't see help for commands added later. These would not work for you.

To get generic help use this command:

	:help

You could also use the first function key <F1>. If your keyboard has a <Help>
key it might work as well.
   If you don't supply a subject, ":help" displays the general help window.
The creators of Vim did something very clever (or very lazy) with the help
system: They made the help window a normal editing window. You can use all
the normal Vim commands to move through the help information. Therefore h, j,
k, and l move left, down, up and right.
   To get out of the help window, use the same command you use to get out of
the editor: "ZZ". This will only close the help window, not exit Vim.

As you read the help text, you will notice some text enclosed in vertical bars (for example, |help|). This indicates a hyperlink. If you position the cursor anywhere between the bars and press CTRL-] (jump to tag), the help system takes you to the indicated subject. (For reasons not discussed here, the Vim terminology for a hyperlink is tag. So CTRL-] jumps to the location of the tag given by the word under the cursor.)

After a few jumps, you might want to go back. CTRL-T (pop tag) takes you back to the preceding position. CTRL-O (jump to older position) also works nicely here.

At the top of the help screen, there is the notation *help.txt*. This name between "*" characters is used by the help system to define a tag (hyperlink destination).

See 29.1 for details about using tags.

To get help on a given subject, use the following command:

```
:help {subject}
```

To get help on the "x" command, for example, enter the following:

```
:help x
```

To find out how to delete text, use this command:

```
:help deleting
```

To get a complete index of all Vim commands, use the following command:

```
:help index
```

When you need to get help for a control character command (for example, CTRL-A), you need to spell it with the prefix "CTRL-".

```
:help CTRL-A
```

The Vim editor has many different modes. By default, the help system displays the normal-mode commands. For example, the following command displays help for the normal-mode CTRL-H command:

```
:help CTRL-H
```

To identify other modes, use a mode prefix. If you want the help for the insert-mode version of a command, use "i_". For CTRL-H this gives you the following command:

```
:help i_CTRL-H
```

When you start the Vim editor, you can use several command-line arguments. These all begin with a dash (-). To find what the -t argument does, for example, use the command:

```
:help -t
```

The Vim editor has a number of options that enable you to configure and

customize the editor. If you want help for an option, you need to enclose it
in single quotation marks. To find out what the 'number' option does, for
example, use the following command:

	:help 'number'

The table with all mode prefixes can be found below: help-summary .

Special keys are enclosed in angle brackets. To find help on the up-arrow key
in Insert mode, for instance, use this command:

	:help i_<Up>

If you see an error message that you don't understand, for example:

	E37: No write since last change (use ! to override)

You can use the error ID at the start to find help about it:

	:help E37

Summary: help-summary

1) Use Ctrl-D after typing a topic and let Vim show all available topics.
   Or press Tab to complete:
	:help some<Tab>
   More information on how to use the help:
	:help helphelp

2) Follow the links in bars to related help. You can go from the detailed
   help to the user documentation, which describes certain commands more from
   a user perspective and less detailed. E.g. after:
	:help pattern.txt
   You can see the user guide topics 03.9 and usr_27.txt in the
   introduction.

3) Options are enclosed in single apostrophes. To go to the help topic for the
   list option:
	:help 'list'
   If you only know you are looking for a certain option, you can also do:
	:help options.txt
   to open the help page which describes all option handling and then search
   using regular expressions, e.g. textwidth.
   Certain options have their own namespace, e.g.:
	:help cpo-<letter>
   for the corresponding flag of the 'cpoptions' settings, substitute <letter>
   by a specific flag, e.g.:
	:help cpo-;
   And for the guioption flags:
	:help go-<letter>

4) Normal mode commands do not have a prefix. To go to the help page for the
   "gt" command:

```
        :help gt

5) Insert mode commands start with i_.  Help for deleting a word:
        :help i_CTRL-W

6) Visual mode commands start with v_.  Help for jumping to the other side of
   the Visual area:
        :help v_o

7) Command line editing and arguments start with c_.  Help for using the
   command argument %:
        :help c_%

8) Ex-commands always start with ":", so to go to the :s command help:
        :help :s

9) Commands specifically for debugging start with ">".  To go to the help
   for the "cont" debug command:
        :help >cont

10) Key combinations.  They usually start with a single letter indicating
    the mode for which they can be used.  E.g.:
        :help i_CTRL-X
    takes you to the family of Ctrl-X commands for insert mode which can be
    used to auto complete different things.  Note, that certain keys will
    always be written the same, e.g. Control will always be CTRL.
    For normal mode commands there is no prefix and the topic is available at
    :h CTRL-<Letter>. E.g.
        :help CTRL-W
    In contrast
        :help c_CTRL-R
    will describe what the Ctrl-R does when entering commands in the Command
    line and
        :help v_Ctrl-A
    talks about incrementing numbers in visual mode and
        :help g_CTRL-A
    talks about the g<C-A> command (e.g. you have to press "g" then <Ctrl-A>).
    Here the "g" stand for the normal command "g" which always expects a second
    key before doing something similar to the commands starting with "z"

11) Regexp items always start with /.  So to get help for the "\+" quantifier
    in Vim regexes:
        :help /\+
    If you need to know everything about regular expressions, start reading
    at:
        :help pattern.txt

12) Registers always start with "quote". To find out about the special ":"
    register:
        :help quote:

13) Vim script is available at
        :help eval.txt
   Certain aspects of the language are available at :h expr-X where "X" is a
```

single letter. E.g.
    :help expr-!
will take you to the topic describing the "!" (Not) operator for
VimScript.
Also important is
    :help function-list
to find a short description of all functions available. Help topics for
Vim script functions always include the "()", so:
    :help append()
talks about the append Vim script function rather than how to append text
in the current buffer.

14) Mappings are talked about in the help page :h map.txt . Use
    :help mapmode-i
    to find out about the :imap command. Also use :map-topic
    to find out about certain subtopics particular for mappings. e.g:
    :help :map-local
    for buffer-local mappings or
    :help map-bar
    for how the '|' is handled in mappings.

15) Command definitions are talked about :h command-topic, so use
    :help command-bar
    to find out about the '!' argument for custom commands.

16) Window management commands always start with CTRL-W, so you find the
    corresponding help at :h CTRL-W_letter. E.g.
    :help CTRL-W_p
    for moving the previous accessed window. You can also access
    :help windows.txt
    and read your way through if you are looking for window handling
    commands.

17) Use :helpgrep to search in all help pages (and also of any installed
    plugins). See :helpgrep for how to use it.
    To search for a topic:
    :helpgrep topic
    This takes you to the first match. To go to the next one:
    :cnext
    All matches are available in the quickfix window which can be opened
    with:
    :copen
    Move around to the match you like and press Enter to jump to that help.

18) The user manual. This describes help topics for beginners in a rather
    friendly way. Start at usr_toc.txt to find the table of content (as you
    might have guessed):
    :help usr_toc.txt
    Skim over the contents to find interesting topics. The "Digraphs" and
    "Entering special characters" items are in chapter 24, so to go to that
    particular help page:
    :help usr_24.txt
    Also if you want to access a certain chapter in the help, the chapter
    number can be accessed directly like this:

```
        :help 10.1
    goes to chapter 10.1 in  usr_10.txt  and talks about recording macros.

19) Highlighting groups.  Always start with hl-groupname.  E.g.
        :help hl-WarningMsg
    talks about the WarningMsg highlighting group.

20) Syntax highlighting is namespaced to :syn-topic e.g.
        :help :syn-conceal
    talks about the conceal argument for the :syn command.

21) Quickfix commands usually start with :c while location list commands
    usually start with :l

22) Autocommand events can be found by their name:
        :help BufWinLeave
    To see all possible events:
        :help autocommand-events

23) Command-line switches always start with "-".  So for the help of the -f
    command switch of Vim use:
        :help -f

24) Optional features always start with "+".  To find out about the
    conceal feature use:
        :help +conceal

25) Documentation for included filetype specific functionality is usually
    available  in the form ft-<filetype>-<functionality>.  So
        :help ft-c-syntax
    talks about the C syntax file and the option it provides.  Sometimes,
    additional sections for omni completion
        :help ft-php-omni
    or filetype plugins
        :help ft-tex-plugin
    are available.

26) Error and Warning codes can be looked up directly in the help.  So
        :help E297
    takes you exactly to the description of the swap error message and
        :help W10
    talks about the warning "Changing a readonly file".
    Sometimes however, those error codes are not described, but rather are
    listed at the Vim command that usually causes this.  So:
        :help E128
    takes you to the  :function  command

VIM USER MANUAL - by Bram Moolenaar

Moving around

Before you can insert or delete text the cursor has to be moved to the right place. Vim has a large number of commands to position the cursor. This chapter shows you how to use the most important ones. You can find a list of these commands below Q_lr .

Next chapter: usr_04.txt Making small changes
Previous chapter: usr_02.txt The first steps in Vim
Table of contents: usr_toc.txt

==========

03.1 Word movement

To move the cursor forward one word, use the "w" command. Like most Vim commands, you can use a numeric prefix to move past multiple words. For example, "3w" moves three words. This figure shows how it works:

```
        This is a line with example text
          --->-->->----------------->
           w  w  w    3w
```

Notice that "w" moves to the start of the next word if it already is at the start of a word.

The "b" command moves backward to the start of the previous word:

```
        This is a line with example text
        <----<--<-<---------<---
           b   b b    2b      b
```

There is also the "e" command that moves to the next end of a word and "ge", which moves to the previous end of a word:

```
        This is a line with example text
           <-   <--- ----->   ---->
           ge    ge     e       e
```

If you are at the last word of a line, the "w" command will take you to the

first word in the next line. Thus you can use this to move through a paragraph, much faster than using "l". "b" does the same in the other direction.

A word ends at a non-word character, such as a ".", "-" or ")". To change what Vim considers to be a word, see the 'iskeyword' option. If you try this out in the help directly, 'iskeyword' needs to be reset for the examples to work:

```
:set iskeyword&
```

It is also possible to move by white-space separated WORDs. This is not a word in the normal sense, that's why the uppercase is used. The commands for moving by WORDs are also uppercase, as this figure shows:

```
              ge      b          w                            e
              <-     <-         --->                         --->
        This is-a line, with special/separated/words (and some more).
           <----- <-----         --------------------->         ----->
             gE      B                   W                        E
```

With this mix of lowercase and uppercase commands, you can quickly move forward and backward through a paragraph.

==

03.2 Moving to the start or end of a line

The "$" command moves the cursor to the end of a line. If your keyboard has an <End> key it will do the same thing.

The "^" command moves to the first non-blank character of the line. The "0" command (zero) moves to the very first character of the line. The <Home> key does the same thing. In a picture:

```
                 ^
             <------------
        .....This is a line with example text
        <-----------------   --------------->
                0                 $
```

(the "....." indicates blanks here)

   The "$" command takes a count, like most movement commands. But moving to the end of the line several times doesn't make sense. Therefore it causes the editor to move to the end of another line. For example, "1$" moves you to the end of the first line (the one you're on), "2$" to the end of the next line, and so on.
   The "0" command doesn't take a count argument, because the "0" would be part of the count. Unexpectedly, using a count with "^" doesn't have any effect.

==

03.3 Moving to a character

One of the most useful movement commands is the single-character search command. The command "fx" searches forward in the line for the single

character x. Hint: "f" stands for "Find".
   For example, you are at the beginning of the following line. Suppose you want to go to the h of human. Just execute the command "fh" and the cursor will be positioned over the h:

```
        To err is human.  To really foul up you need a computer.
        ---------->--------------->
            fh           fy
```

This also shows that the command "fy" moves to the end of the word really.
   You can specify a count; therefore, you can go to the "l" of "foul" with "3fl":

```
        To err is human.  To really foul up you need a computer.
                  --------------------->
                           3fl
```

The "F" command searches to the left:

```
        To err is human.  To really foul up you need a computer.
                  <---------------------
                            Fh
```

The "tx" command works like the "fx" command, except it stops one character before the searched character. Hint: "t" stands for "To". The backward version of this command is "Tx".

```
        To err is human.  To really foul up you need a computer.
                   <------------  ------------->
                        Th              tn
```

These four commands can be repeated with ";". "," repeats in the other direction. The cursor is never moved to another line. Not even when the sentence continues.

Sometimes you will start a search, only to realize that you have typed the wrong command. You type "f" to search backward, for example, only to realize that you really meant "F". To abort a search, press <Esc>. So "f<Esc>" is an aborted forward search and doesn't do anything. Note: <Esc> cancels most operations, not just searches.

==
03.4 Matching a parenthesis

When writing a program you often end up with nested () constructs. Then the "%" command is very handy: It moves to the matching paren. If the cursor is on a "(" it will move to the matching ")". If it's on a ")" it will move to the matching "(".

```
                           %
                        <----->
                  if (a == (b * c) / d)
                     <---------------->
                           %
```

This also works for [] and {} pairs. (This can be defined with the
'matchpairs' option.)

When the cursor is not on a useful character, "%" will search forward to find
one. Thus if the cursor is at the start of the line of the previous example,
"%" will search forward and find the first "(". Then it moves to its match:

```
               if (a == (b * c) / d)
               ---+---------------->
                          %
```

==
03.5 Moving to a specific line

If you are a C or C++ programmer, you are familiar with error messages such as
the following:

```
        prog.c:33: j   undeclared (first use in this function)
```

This tells you that you might want to fix something on line 33. So how do you
find line 33? One way is to do "9999k" to go to the top of the file and "32j"
to go down thirty-two lines. It is not a good way, but it works. A much
better way of doing things is to use the "G" command. With a count, this
command positions you at the given line number. For example, "33G" puts you
on line 33. (For a better way of going through a compiler's error list, see
usr_30.txt , for information on the :make command.)
  With no argument, "G" positions you at the end of the file. A quick way to
go to the start of a file use "gg". "1G" will do the same, but is a tiny bit
more typing.

```
            |   first line of a file   ^
            |   text text text text    |
            |   text text text text    |  gg
        7G  |   text text text text    |
            |   text text text text
            |   text text text text
            V   text text text text    |
                text text text text    |  G
                text text text text    |
                last line of a file    V
```

Another way to move to a line is using the "%" command with a count. For
example "50%" moves you to halfway the file. "90%" goes to near the end.

The previous assumes that you want to move to a line in the file, no matter if
it's currently visible or not. What if you want to move to one of the lines
you can see? This figure shows the three commands you can use:

```
                       +---------------------------+
               H -->   | text sample text          |
                       | sample text               |
                       | text sample text          |
                       | sample text               |
```

```
              M -->   | text sample text          |
                      | sample text               |
                      | text sample text          |
                      | sample text               |
              L -->   | text sample text          |
                      +---------------------------+
```

Hints: "H" stands for Home, "M" for Middle and "L" for Last.

03.6 Telling where you are

To see where you are in a file, there are three ways:

1. Use the CTRL-G command. You get a message like this (assuming the 'ruler' option is off):

   "usr_03.txt" line 233 of 650 --35%-- col 45-52

   This shows the name of the file you are editing, the line number where the cursor is, the total number of lines, the percentage of the way through the file and the column of the cursor.
   Sometimes you will see a split column number. For example, "col 2-9". This indicates that the cursor is positioned on the second character, but because character one is a tab, occupying eight spaces worth of columns, the screen column is 9.

2. Set the 'number' option. This will display a line number in front of every line:

   :set number

   To switch this off again:

   :set nonumber

   Since 'number' is a boolean option, prepending "no" to its name has the effect of switching it off. A boolean option has only these two values, it is either on or off.
   Vim has many options. Besides the boolean ones there are options with a numerical value and string options. You will see examples of this where they are used.

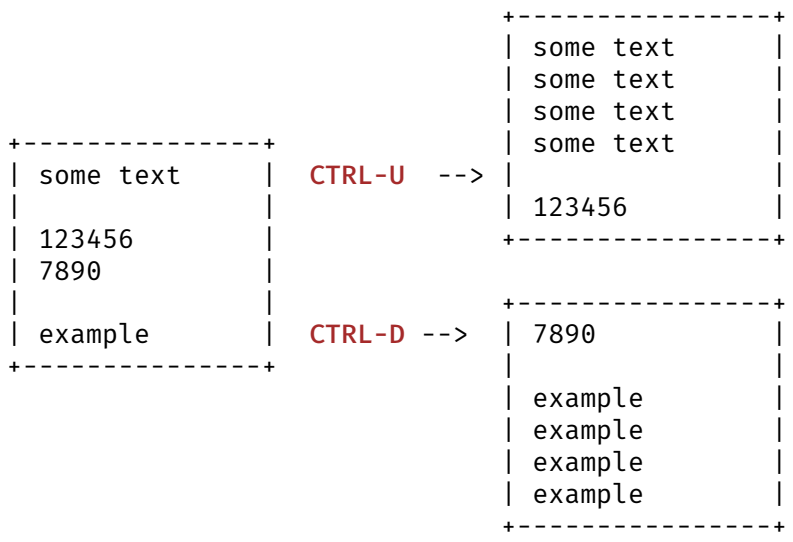
3. Set the 'ruler' option. This will display the cursor position in the lower right corner of the Vim window:

   :set ruler

Using the 'ruler' option has the advantage that it doesn't take much room, thus there is more space for your text.

03.7 Scrolling around

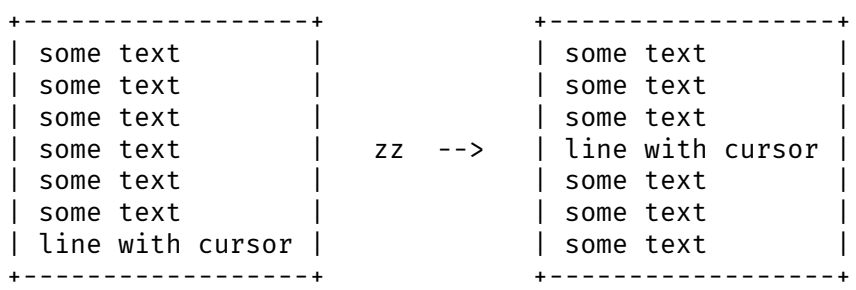
The CTRL-U command scrolls down half a screen of text. Think of looking
through a viewing window at the text and moving this window up by half the
height of the window. Thus the window moves up over the text, which is
backward in the file. Don't worry if you have a little trouble remembering
which end is up. Most users have the same problem.
   The CTRL-D command moves the viewing window down half a screen in the file,
thus scrolls the text up half a screen.



To scroll one line at a time use CTRL-E (scroll up) and CTRL-Y (scroll down).
Think of CTRL-E to give you one line Extra. (If you use MS-Windows compatible
key mappings CTRL-Y will redo a change instead of scroll.)

To scroll forward by a whole screen (except for two lines) use CTRL-F. The
other way is backward, CTRL-B is the command to use. Fortunately CTRL-F is
Forward and CTRL-B is Backward, that's easy to remember.

A common issue is that after moving down many lines with "j" your cursor is at
the bottom of the screen. You would like to see the context of the line with
the cursor. That's done with the "zz" command.



The "zt" command puts the cursor line at the top, "zb" at the bottom. There
are a few more scrolling commands, see Q_sc . To always keep a few lines of
context around the cursor, use the 'scrolloff' option.

==
 03.8   Simple searches

To search for a string, use the "/string" command. To find the word include,
for example, use the command:

	/include

You will notice that when you type the "/" the cursor jumps to the last line
of the Vim window, like with colon commands. That is where you type the word.
You can press the backspace key (backarrow or <BS>) to make corrections. Use
the <Left> and <Right> cursor keys when necessary.
   Pressing <Enter> executes the command.

	Note:
	The characters .*[]^%/\?~$ have special meanings. If you want to use
	them in a search you must put a \ in front of them. See below.

To find the next occurrence of the same string use the "n" command. Use this
to find the first #include after the cursor:

	/#include

And then type "n" several times. You will move to each #include in the text.
You can also use a count if you know which match you want. Thus "3n" finds
the third match. Using a count with "/" doesn't work.

The "?" command works like "/" but searches backwards:

	?word

The "N" command repeats the last search the opposite direction. Thus using
"N" after a "/" command searches backwards, using "N" after "?" searches
forward.

IGNORING CASE

Normally you have to type exactly what you want to find. If you don't care
about upper or lowercase in a word, set the 'ignorecase' option:

	:set ignorecase

If you now search for "word", it will also match "Word" and "WORD". To match
case again:

	:set noignorecase

HISTORY

Suppose you do three searches:

	/one
	/two
	/three

Now let's start searching by typing a simple "/" without pressing <Enter>. If you press <Up> (the cursor key), Vim puts "/three" on the command line. Pressing <Enter> at this point searches for three. If you do not press <Enter>, but press <Up> instead, Vim changes the prompt to "/two". Another press of <Up> moves you to "/one".
   You can also use the <Down> cursor key to move through the history of search commands in the other direction.

If you know what a previously used pattern starts with, and you want to use it again, type that character before pressing <Up>. With the previous example, you can type "/o<Up>" and Vim will put "/one" on the command line.

The commands starting with ":" also have a history. That allows you to recall a previous command and execute it again. These two histories are separate.

SEARCHING FOR A WORD IN THE TEXT

Suppose you see the word "TheLongFunctionName" in the text and you want to find the next occurrence of it. You could type "/TheLongFunctionName", but that's a lot of typing. And when you make a mistake Vim won't find it.
   There is an easier way: Position the cursor on the word and use the "*" command. Vim will grab the word under the cursor and use it as the search string.
   The "#" command does the same in the other direction. You can prepend a count: "3*" searches for the third occurrence of the word under the cursor.

SEARCHING FOR WHOLE WORDS

If you type "/the" it will also match "there". To only find words that end in "the" use:

```
/the\>
```

The "\>" item is a special marker that only matches at the end of a word. Similarly "\<" only matches at the beginning of a word. Thus to search for the word "the" only:

```
/\<the\>
```

This does not match "there" or "soothe". Notice that the "*" and "#" commands use these start-of-word and end-of-word markers to only find whole words (you can use "g*" and "g#" to match partial words).

HIGHLIGHTING MATCHES

While editing a program you see a variable called "nr". You want to check where it's used. You could move the cursor to "nr" and use the "*" command and press "n" to go along all the matches.
   There is another way. Type this command:

```
	:set hlsearch
```

If you now search for "nr", Vim will highlight all matches. That is a very good way to see where the variable is used, without the need to type commands.
   To switch this off:

```
	:set nohlsearch
```

Then you need to switch it on again if you want to use it for the next search command. If you only want to remove the highlighting, use this command:

```
	:nohlsearch
```

This doesn't reset the option. Instead, it disables the highlighting. As soon as you execute a search command, the highlighting will be used again. Also for the "n" and "N" commands.

TUNING SEARCHES

There are a few options that change how searching works. These are the essential ones:

```
	:set incsearch
```

This makes Vim display the match for the string while you are still typing it. Use this to check if the right match will be found. Then press <Enter> to really jump to that location. Or type more to change the search string.

```
	:set nowrapscan
```

This stops the search at the end of the file. Or, when you are searching backwards, at the start of the file. The 'wrapscan' option is on by default, thus searching wraps around the end of the file.

INTERMEZZO

If you like one of the options mentioned before, and set it each time you use Vim, you can put the command in your Vim startup file.
   Edit the file, as mentioned at not-compatible . Or use this command to find out where it is:

```
	:scriptnames
```

Edit the file, for example with:

```
	:edit ~/.vimrc
```

Then add a line with the command to set the option, just like you typed it in Vim. Example:

```
	Go:set hlsearch<Esc>
```

"G" moves to the end of the file. "o" starts a new line, where you type the ":set" command. You end insert mode with <Esc>. Then write the file:

```
ZZ
```

If you now start Vim again, the 'hlsearch' option will already be set.

==

03.9 Simple search patterns

The Vim editor uses regular expressions to specify what to search for. Regular expressions are an extremely powerful and compact way to specify a search pattern. Unfortunately, this power comes at a price, because regular expressions are a bit tricky to specify.

In this section we mention only a few essential ones. More about search patterns and commands in chapter 27 usr_27.txt . You can find the full explanation here: pattern .

BEGINNING AND END OF A LINE

The ^ character matches the beginning of a line. On an English-US keyboard you find it above the 6. The pattern "include" matches the word include anywhere on the line. But the pattern "^include" matches the word include only if it is at the beginning of a line.

The $ character matches the end of a line. Therefore, "was$" matches the word was only if it is at the end of a line.

Let's mark the places where "/the" matches in this example line with "x"s:

```
        the solder holding one of the chips melted and the
        xxx                     xxx                 xxx
```

Using "/the$" we find this match:

```
        the solder holding one of the chips melted and the
                                                    xxx
```

And with "/^the" we find this one:

```
        the solder holding one of the chips melted and the
        xxx
```

You can try searching with "/^the$", it will only match a single line consisting of "the". White space does matter here, thus if a line contains a space after the word, like "the ", the pattern will not match.

MATCHING ANY SINGLE CHARACTER

The . (dot) character matches any existing character. For example, the pattern "c.m" matches a string whose first character is a c, whose second character is anything, and whose third character is m. Example:

```
        We use a computer that became the cummin winter.
```

```
                xxx             xxx      xxx
```

MATCHING SPECIAL CHARACTERS

If you really want to match a dot, you must avoid its special meaning by putting a backslash before it.
   If you search for "ter.", you will find these matches:

```
        We use a computer that became the cummin winter.
                     xxxx                          xxxx
```

Searching for "ter\." only finds the second match.

==
03.10 Using marks

When you make a jump to a position with the "G" command, Vim remembers the position from before this jump. This position is called a mark. To go back where you came from, use this command:

```
        ``
```

This ` is a backtick or open single-quote character.
   If you use the same command a second time you will jump back again. That's because the ` command is a jump itself, and the position from before this jump is remembered.

Generally, every time you do a command that can move the cursor further than within the same line, this is called a jump. This includes the search commands "/" and "n" (it doesn't matter how far away the match is). But not the character searches with "fx" and "tx" or the word movements "w" and "e".
   Also, "j" and "k" are not considered to be a jump. Even when you use a count to make them move the cursor quite a long way away.

The `` command jumps back and forth, between two points. The CTRL-O command jumps to older positions (Hint: O for older). CTRL-I then jumps back to newer positions (Hint: I is just next to O on the keyboard). Consider this sequence of commands:

```
        33G
        /^The
        CTRL-O
```

You first jump to line 33, then search for a line that starts with "The". Then with CTRL-O you jump back to line 33. Another CTRL-O takes you back to where you started. If you now use CTRL-I you jump to line 33 again. And to the match for "The" with another CTRL-I.

```
             |  example text   ^             |
        33G  |  example text   |  CTRL-O     | CTRL-I
             |  example text   |             |
             V  line 33 text   ^             V
```

```
        |  example text   |             |
   /^The |  example text   |  CTRL-O     | CTRL-I
        V  There you are   |             V
           example text
```

Note:
CTRL-I is the same as <Tab>.

The ":jumps" command gives a list of positions you jumped to. The entry which you used last is marked with a ">".

NAMED MARKS bookmark

Vim enables you to place your own marks in the text. The command "ma" marks the place under the cursor as mark a. You can place 26 marks (a through z) in your text. You can't see them, it's just a position that Vim remembers.
To go to a mark, use the command `{mark}, where {mark} is the mark letter. Thus to move to the a mark:

```
`a
```

The command 'mark (single quotation mark, or apostrophe) moves you to the beginning of the line containing the mark. This differs from the `mark command, which moves you to marked column.

The marks can be very useful when working on two related parts in a file. Suppose you have some text near the start of the file you need to look at, while working on some text near the end of the file.
Move to the text at the start and place the s (start) mark there:

```
ms
```

Then move to the text you want to work on and put the e (end) mark there:

```
me
```

Now you can move around, and when you want to look at the start of the file, you use this to jump there:

```
's
```

Then you can use '' to jump back to where you were, or 'e to jump to the text you were working on at the end.
There is nothing special about using s for start and e for end, they are just easy to remember.

You can use this command to get a list of marks:

```
:marks
```

You will notice a few special marks. These include:

```
'       The cursor position before doing a jump
```

```
        "       The cursor position when last editing the file
        [       Start of the last change
        ]       End of the last change
```

VIM USER MANUAL - by Bram Moolenaar

Making small changes

This chapter shows you several ways of making corrections and moving text around. It teaches you the three basic ways to change text: operator-motion, Visual mode and text objects.

Next chapter: usr_05.txt Set your settings
Previous chapter: usr_03.txt Moving around
Table of contents: usr_toc.txt

==========

04.1 Operators and motions

In chapter 2 you learned the "x" command to delete a single character. And using a count: "4x" deletes four characters.

The "dw" command deletes a word. You may recognize the "w" command as the move word command. In fact, the "d" command may be followed by any motion command, and it deletes from the current location to the place where the cursor winds up.

The "4w" command, for example, moves the cursor over four words. The d4w command deletes four words.

```
        To err is human. To really foul up you need a computer.
                         ------------------>
                                d4w

        To err is human. you need a computer.
```

Vim only deletes up to the position where the motion takes the cursor. That's because Vim knows that you probably don't want to delete the first character of a word. If you use the "e" command to move to the end of a word, Vim guesses that you do want to include that last character:

```
        To err is human. you need a computer.
                        -------->
                           d2e

        To err is human. a computer.
```

Whether the character under the cursor is included depends on the command you used to move to that character. The reference manual calls this "exclusive" when the character isn't included and "inclusive" when it is.

The "$" command moves to the end of a line. The "d$" command deletes from the cursor to the end of the line. This is an inclusive motion, thus the last character of the line is included in the delete operation:

```
        To err is human. a computer.
                       ------------>
                            d$

        To err is human
```

There is a pattern here: operator-motion. You first type an operator command. For example, "d" is the delete operator. Then you type a motion command like "4l" or "w". This way you can operate on any text you can move over.

04.2 Changing text

Another operator is "c", change. It acts just like the "d" operator, except it leaves you in Insert mode. For example, "cw" changes a word. Or more specifically, it deletes a word and then puts you in Insert mode.

```
        To err is human
           ------->
             c2wbe<Esc>

        To be human
```

This "c2wbe<Esc>" contains these bits:

```
        c       the change operator
        2w      move two words (they are deleted and Insert mode started)
        be      insert this text
        <Esc>   back to Normal mode
```

If you have paid attention, you will have noticed something strange: The space before "human" isn't deleted. There is a saying that for every problem there is an answer that is simple, clear, and wrong. That is the case with the example used here for the "cw" command. The c operator works just like the d operator, with one exception: "cw". It actually works like "ce", change to end of word. Thus the space after the word isn't included. This is an exception that dates back to the old Vi. Since many people are used to it now, the inconsistency has remained in Vim.

MORE CHANGES

Like "dd" deletes a whole line, "cc" changes a whole line. It keeps the existing indent (leading white space) though.

Just like "d$" deletes until the end of the line, "c$" changes until the end of the line. It's like doing "d$" to delete the text and then "a" to start Insert mode and append new text.

SHORTCUTS

Some operator-motion commands are used so often that they have been given a single letter command:

```
        x  stands for  dl  (delete character under the cursor)
        X  stands for  dh  (delete character left of the cursor)
        D  stands for  d$  (delete to end of the line)
        C  stands for  c$  (change to end of the line)
        s  stands for  cl  (change one character)
        S  stands for  cc  (change a whole line)
```

WHERE TO PUT THE COUNT

The commands "3dw" and "d3w" delete three words. If you want to get really picky about things, the first command, "3dw", deletes one word three times; the command "d3w" deletes three words once. This is a difference without a distinction. You can actually put in two counts, however. For example, "3d2w" deletes two words, repeated three times, for a total of six words.

REPLACING WITH ONE CHARACTER

The "r" command is not an operator. It waits for you to type a character, and will replace the character under the cursor with it. You could do the same with "cl" or with the "s" command, but with "r" you don't have to press <Esc>

```
        there is somerhing grong here
        rT           rt    rw

        There is something wrong here
```

Using a count with "r" causes that many characters to be replaced with the same character. Example:

```
        There is something wrong here
                           5rx

        There is something xxxxx here
```

To replace a character with a line break use "r<Enter>". This deletes one character and inserts a line break. Using a count here only applies to the number of characters deleted: "4r<Enter>" replaces four characters with one line break.

==
 04.3   Repeating a change

The "." command is one of the most simple yet powerful commands in Vim. It repeats the last change. For instance, suppose you are editing an HTML file and want to delete all the <B> tags. You position the cursor on the first < and delete the <B> with the command "df>". You then go to the < of the next </B> and kill it using the "." command. The "." command executes the last change command (in this case, "df>"). To delete another tag, position the cursor on the < and use the "." command.

```
                          To <B>generate</B> a table of <B>contents
        f<   find first <     --->
        df>  delete to >         -->
        f<   find next <           --------->
        .    repeat df>                  --->
        f<   find next <                    ------------->
        .    repeat df>                                 -->
```

The "." command works for all changes you make, except for the "u" (undo), CTRL-R (redo) and commands that start with a colon (:).

Another example: You want to change the word "four" to "five". It appears several times in your text. You can do this quickly with this sequence of commands:

```
        /four<Enter>    find the first string "four"
        cwfive<Esc>     change the word to "five"
        n               find the next "four"
        .               repeat the change to "five"
        n               find the next "four"
        .               repeat the change
                        etc.
```

04.4 Visual mode

To delete simple items the operator-motion changes work quite well. But often it's not so easy to decide which command will move over the text you want to change. Then you can use Visual mode.

You start Visual mode by pressing "v". You move the cursor over the text you want to work on. While you do this, the text is highlighted. Finally type the operator command.
   For example, to delete from halfway one word to halfway another word:

```
              This is an examination sample of visual mode
                             ---------->
                               velllld

              This is an example of visual mode
```

When doing this you don't really have to count how many times you have to press "l" to end up in the right position. You can immediately see what text will be deleted when you press "d".

If at any time you decide you don't want to do anything with the highlighted

text, just press <Esc> and Visual mode will stop without doing anything.

SELECTING LINES

If you want to work on whole lines, use "V" to start Visual mode. You will see right away that the whole line is highlighted, without moving around. When you move left or right nothing changes. When you move up or down the selection is extended whole lines at a time.
   For example, select three lines with "Vjj":

```
                        +-------------------------+
                        | text more text          |
                     >> | more text more text     | |
        selected lines >> | text text text          | | Vjj
                     >> | text more               | V
                        | more text more          |
                        +-------------------------+
```

SELECTING BLOCKS

If you want to work on a rectangular block of characters, use CTRL-V to start Visual mode. This is very useful when working on tables.

```
                name            Q1      Q2      Q3
                pierre          123     455     234
                john            0       90      39
                steve           392     63      334
```

To delete the middle "Q2" column, move the cursor to the "Q" of "Q2". Press CTRL-V to start blockwise Visual mode. Now move the cursor three lines down with "3j" and to the next word with "w". You can see the first character of the last column is included. To exclude it, use "h". Now press "d" and the middle column is gone.

GOING TO THE OTHER SIDE

If you have selected some text in Visual mode, and discover that you need to change the other end of the selection, use the "o" command (Hint: o for other end). The cursor will go to the other end, and you can move the cursor to change where the selection starts. Pressing "o" again brings you back to the other end.

When using blockwise selection, you have four corners. "o" only takes you to one of the other corners, diagonally. Use "O" to move to the other corner in the same line.

Note that "o" and "O" in Visual mode work very differently from Normal mode, where they open a new line below or above the cursor.

When you delete something with the "d", "x", or another command, the text is saved. You can paste it back by using the p command. (The Vim name for this is put).
Take a look at how this works. First you will delete an entire line, by putting the cursor on the line you want to delete and typing "dd". Now you move the cursor to where you want to put the line and use the "p" (put) command. The line is inserted on the line below the cursor.

```
a line          a line        a line
line 2    dd    line 3    p   line 3
line 3                        line 2
```

Because you deleted an entire line, the "p" command placed the text line below the cursor. If you delete part of a line (a word, for instance), the "p" command puts it just after the cursor.

```
Some more boring try text to out commands.
                 ---->
                  dw

Some more boring text to out commands.
                 ------->
                    welp

Some more boring text to try out commands.
```

MORE ON PUTTING

The "P" command puts text like "p", but before the cursor. When you deleted a whole line with "dd", "P" will put it back above the cursor. When you deleted a word with "dw", "P" will put it back just before the cursor.

You can repeat putting as many times as you like. The same text will be used.

You can use a count with "p" and "P". The text will be repeated as many times as specified with the count. Thus "dd" and then "3p" puts three copies of the same deleted line.

SWAPPING TWO CHARACTERS

Frequently when you are typing, your fingers get ahead of your brain (or the other way around?). The result is a typo such as "teh" for "the". Vim makes it easy to correct such problems. Just put the cursor on the e of "teh" and execute the command "xp". This works as follows: "x" deletes the character e and places it in a register. "p" puts the text after the cursor, which is after the h.

```
teh     th     the
 x       p
```

==

04.6 Copying text

To copy text from one place to another, you could delete it, use "u" to undo the deletion and then "p" to put it somewhere else. There is an easier way: yanking. The "y" operator copies text into a register. Then a "p" command can be used to put it.
Yanking is just a Vim name for copying. The "c" letter was already used for the change operator, and "y" was still available. Calling this operator "yank" made it easier to remember to use the "y" key.

Since "y" is an operator, you use "yw" to yank a word. A count is possible as usual. To yank two words use "y2w". Example:

```
        let sqr = LongVariable *
                  -------------->
                        y2w

        let sqr = LongVariable *
                               p

        let sqr = LongVariable * LongVariable
```

Notice that "yw" includes the white space after a word. If you don't want this, use "ye".

The "yy" command yanks a whole line, just like "dd" deletes a whole line. Unexpectedly, while "D" deletes from the cursor to the end of the line, "Y" works like "yy", it yanks the whole line. Watch out for this inconsistency! Use "y$" to yank to the end of the line.

```
        a text line   yy        a text line            a text line
        line 2                  line 2          p      line 2
        last line               last line              a text line
                                                       last line
```

==========

04.7 Using the clipboard

If you are using the GUI version of Vim (gvim), you can find the "Copy" item in the "Edit" menu. First select some text with Visual mode, then use the Edit/Copy menu. The selected text is now copied to the clipboard. You can paste the text in other programs. In Vim itself too.

If you have copied text to the clipboard in another application, you can paste it in Vim with the Edit/Paste menu. This works in Normal mode and Insert mode. In Visual mode the selected text is replaced with the pasted text.

The "Cut" menu item deletes the text before it's put on the clipboard. The "Copy", "Cut" and "Paste" items are also available in the popup menu (only when there is a popup menu, of course). If your Vim has a toolbar, you can also find these items there.

If you are not using the GUI, or if you don't like using a menu, you have to use another way. You use the normal "y" (yank) and "p" (put) commands, but

prepend "* (double-quote star) before it. To copy a line to the clipboard:

```
"*yy
```

To put text from the clipboard back into the text:

```
"*p
```

This only works on versions of Vim that include clipboard support. More about the clipboard in section 09.3 and here: clipboard .

==========

04.8 Text objects

If the cursor is in the middle of a word and you want to delete that word, you need to move back to its start before you can do "dw". There is a simpler way to do this: "daw".

```
this is some example text.
               daw

this is some text.
```

The "d" of "daw" is the delete operator. "aw" is a text object. Hint: "aw" stands for "A Word". Thus "daw" is "Delete A Word". To be precise, the white space after the word is also deleted (the white space before the word at the end of the line).

Using text objects is the third way to make changes in Vim. We already had operator-motion and Visual mode. Now we add operator-text object.
   It is very similar to operator-motion, but instead of operating on the text between the cursor position before and after a movement command, the text object is used as a whole. It doesn't matter where in the object the cursor was.

To change a whole sentence use "cis". Take this text:

```
Hello there.  This
is an example.  Just
some text.
```

Move to the start of the second line, on "is an". Now use "cis":

```
Hello there.    Just
some text.
```

The cursor is in between the blanks in the first line. Now you type the new sentence "Another line.":

```
Hello there.  Another line.  Just
some text.
```

"cis" consists of the "c" (change) operator and the "is" text object. This stands for "Inner Sentence". There is also the "as" (a sentence) object. The

difference is that "as" includes the white space after the sentence and "is" doesn't. If you would delete a sentence, you want to delete the white space at the same time, thus use "das". If you want to type new text the white space can remain, thus you use "cis".

You can also use text objects in Visual mode. It will include the text object in the Visual selection. Visual mode continues, thus you can do this several times. For example, start Visual mode with "v" and select a sentence with "as". Now you can repeat "as" to include more sentences. Finally you use an operator to do something with the selected sentences.

You can find a long list of text objects here: text-objects .

==
 04.9   Replace mode

The "R" command causes Vim to enter replace mode. In this mode, each character you type replaces the one under the cursor. This continues until you type <Esc>.
   In this example you start Replace mode on the first "t" of "text":

        This is text.
                Rinteresting.<Esc>

        This is interesting.

You may have noticed that this command replaced 5 characters in the line with twelve others. The "R" command automatically extends the line if it runs out of characters to replace. It will not continue on the next line.

You can switch between Insert mode and Replace mode with the <Insert> key.

When you use <BS> (backspace) to make correction, you will notice that the old text is put back. Thus it works like an undo command for the last typed character.

==
 04.10 Conclusion

The operators, movement commands and text objects give you the possibility to make lots of combinations. Now that you know how it works, you can use N operators with M movement commands to make N * M commands!

You can find a list of operators here: operator

For example, there are many other ways to delete pieces of text. Here are a few often used ones:

```
x       delete character under the cursor (short for "dl")
X       delete character before the cursor (short for "dh")
D       delete from cursor to end of line (short for "d$")
dw      delete from cursor to next start of word
db      delete from cursor to previous start of word
diw     delete word under the cursor (excluding white space)
```

```
daw     delete word under the cursor (including white space)
dG      delete until the end of the file
dgg     delete until the start of the file

If you use "c" instead of "d" they become change commands.  And with "y" you
yank the text.  And so forth.

There are a few often used commands to make changes that didn't fit somewhere
else:

        ~       change case of the character under the cursor, and move the
                cursor to the next character.  This is not an operator (unless
                'tildeop' is set), thus you can't use it with a motion
                command.  It does work in Visual mode and changes case for
                all the selected text then.

        I       Start Insert mode after moving the cursor to the first
                non-blank in the line.

        A       Start Insert mode after moving the cursor to the end of the
                line.

==========

05.1 The vimrc file vimrc-intro

You probably got tired of typing commands that you use very often. To start Vim with all your favorite option settings and mappings, you write them in what is called the vimrc file. Vim executes the commands in this file when it starts up.

If you already have a vimrc file (e.g., when your sysadmin has one setup for you), you can edit it this way:

```
:edit $MYVIMRC
```

If you don't have a vimrc file yet, see vimrc to find out where you can create a vimrc file. Also, the ":version" command mentions the name of the "user vimrc file" Vim looks for.

For Unix and Macintosh this file is always used and is recommended:

```
~/.vimrc
```

For MS-DOS and MS-Windows you can use one of these:

```
$HOME/_vimrc
$VIM/_vimrc
```

If you are creating the vimrc file for the first time, it is recommended to put this line at the top:

```
source $VIMRUNTIME/defaults.vim
```

This initializes Vim for new users (as opposed to traditional Vi users). See
 defaults.vim for the details.

The vimrc file can contain all the commands that you type after a colon. The
most simple ones are for setting options. For example, if you want Vim to
always start with the 'incsearch' option on, add this line your vimrc file:

```
	set incsearch
```

For this new line to take effect you need to exit Vim and start it again.
Later you will learn how to do this without exiting Vim.

This chapter only explains the most basic items. For more information on how
to write a Vim script file: usr_41.txt .

==
 05.2   The example vimrc file explained   vimrc_example.vim

In the first chapter was explained how the example vimrc (included in the
Vim distribution) file can be used to make Vim startup in not-compatible mode
(see not-compatible). The file can be found here:

```
	$VIMRUNTIME/vimrc_example.vim
```

In this section we will explain the various commands used in this file. This
will give you hints about how to set up your own preferences. Not everything
will be explained though. Use the ":help" command to find out more.

```
	set nocompatible
```

As mentioned in the first chapter, these manuals explain Vim working in an
improved way, thus not completely Vi compatible. Setting the 'compatible'
option off, thus 'nocompatible' takes care of this.

```
	set backspace=indent,eol,start
```

This specifies where in Insert mode the <BS> is allowed to delete the
character in front of the cursor. The three items, separated by commas, tell
Vim to delete the white space at the start of the line, a line break and the
character before where Insert mode started.

```
	set autoindent
```

This makes Vim use the indent of the previous line for a newly created line.
Thus there is the same amount of white space before the new line. For example
when pressing <Enter> in Insert mode, and when using the "o" command to open a
new line.

```
	if has("vms")
```

```
  set nobackup
else
  set backup
endif
```

This tells Vim to keep a backup copy of a file when overwriting it. But not on the VMS system, since it keeps old versions of files already. The backup file will have the same name as the original file with "~" added. See 07.4

```
set history=50
```

Keep 50 commands and 50 search patterns in the history. Use another number if you want to remember fewer or more lines.

```
set ruler
```

Always display the current cursor position in the lower right corner of the Vim window.

```
set showcmd
```

Display an incomplete command in the lower right corner of the Vim window, left of the ruler. For example, when you type "2f", Vim is waiting for you to type the character to find and "2f" is displayed. When you press "w" next, the "2fw" command is executed and the displayed "2f" is removed.

```
+-----------------------------------------------+
|text in the Vim window                         |
|~                                              |
|~                                              |
|-- VISUAL --                  2f     43,8   17% |
+-----------------------------------------------+
 ^^^^^^^^^^^                 ^^^^^^^^ ^^^^^^^^^^
  'showmode'                'showcmd'  'ruler'
```

```
set incsearch
```

Display the match for a search pattern when halfway typing it.

```
map Q gq
```

This defines a key mapping. More about that in the next section. This defines the "Q" command to do formatting with the "gq" operator. This is how it worked before Vim 5.0. Otherwise the "Q" command starts Ex mode, but you will not need it.

```
vnoremap _g y:exe "grep /" . escape(@", '\\/') . "/ *.c *.h"<CR>
```

This mapping yanks the visually selected text and searches for it in C files.
This is a complicated mapping. You can see that mappings can be used to do
quite complicated things. Still, it is just a sequence of commands that are
executed like you typed them.

```
if &t_Co > 2 || has("gui_running")
  syntax on
  set hlsearch
endif
```

This switches on syntax highlighting, but only if colors are available. And
the 'hlsearch' option tells Vim to highlight matches with the last used search
pattern. The "if" command is very useful to set options only when some
condition is met. More about that in usr_41.txt .

vimrc-filetype

```
filetype plugin indent on
```

This switches on three very clever mechanisms:
1. Filetype detection.
   Whenever you start editing a file, Vim will try to figure out what kind of
   file this is. When you edit "main.c", Vim will see the ".c" extension and
   recognize this as a "c" filetype. When you edit a file that starts with
   "#!/bin/sh", Vim will recognize it as a "sh" filetype.
   The filetype detection is used for syntax highlighting and the other two
   items below.
   See filetypes .

2. Using filetype plugin files
   Many different filetypes are edited with different options. For example,
   when you edit a "c" file, it's very useful to set the 'cindent' option to
   automatically indent the lines. These commonly useful option settings are
   included with Vim in filetype plugins. You can also add your own, see
    write-filetype-plugin .

3. Using indent files
   When editing programs, the indent of a line can often be computed
   automatically. Vim comes with these indent rules for a number of
   filetypes. See :filetype-indent-on and 'indentexpr'.

```
autocmd FileType text setlocal textwidth=78
```

This makes Vim break text to avoid lines getting longer than 78 characters.
But only for files that have been detected to be plain text. There are
actually two parts here. "autocmd FileType text" is an autocommand. This
defines that when the file type is set to "text" the following command is
automatically executed. "setlocal textwidth=78" sets the 'textwidth' option
to 78, but only locally in one file.

restore-cursor

```
autocmd BufReadPost *
    \ if line("'\"") > 1 && line("'\"") <= line("$") |
```

```
\   exe "normal! g`\"" |
\ endif
```

Another autocommand. This time it is used after reading any file. The complicated stuff after it checks if the '" mark is defined, and jumps to it if so. The backslash at the start of a line is used to continue the command from the previous line. That avoids a line getting very long.
See line-continuation . This only works in a Vim script file, not when typing commands at the command-line.

05.3 Simple mappings

A mapping enables you to bind a set of Vim commands to a single key. Suppose, for example, that you need to surround certain words with curly braces. In other words, you need to change a word such as "amount" into "{amount}". With the :map command, you can tell Vim that the F5 key does this job. The command is as follows:

```
:map <F5> i{<Esc>ea}<Esc>
```

Note:
When entering this command, you must enter <F5> by typing four characters. Similarly, <Esc> is not entered by pressing the <Esc> key, but by typing five characters. Watch out for this difference when reading the manual!

Let's break this down:

<F5>	The F5 function key. This is the trigger key that causes the command to be executed as the key is pressed.
i{<Esc>	Insert the { character. The <Esc> key ends Insert mode.
e	Move to the end of the word.
a}<Esc>	Append the } to the word.

After you execute the ":map" command, all you have to do to put {} around a word is to put the cursor on the first character and press F5.

In this example, the trigger is a single key; it can be any string. But when you use an existing Vim command, that command will no longer be available. You better avoid that.
One key that can be used with mappings is the backslash. Since you probably want to define more than one mapping, add another character. You could map "\p" to add parentheses around a word, and "\c" to add curly braces, for example:

```
:map \p i(<Esc>ea)<Esc>
:map \c i{<Esc>ea}<Esc>
```

You need to type the \ and the p quickly after another, so that Vim knows they belong together.

The ":map" command (with no arguments) lists your current mappings. At
least the ones for Normal mode. More about mappings in section 40.1 .

==
 05.4   Adding a package   add-package   matchit-install

A package is a set of files that you can add to Vim. There are two kinds of
packages: optional and automatically loaded on startup.

The Vim distribution comes with a few packages that you can optionally use.
For example, the matchit plugin. This plugin makes the "%" command jump to
matching HTML tags, if/else/endif in Vim scripts, etc. Very useful, although
it's not backwards compatible (that's why it is not enabled by default).

To start using the matchit plugin, add one line to your vimrc file:
        packadd! matchit

That's all! After restarting Vim you can find help about this plugin:
        :help matchit

This works, because when `:packadd` loaded the plugin it also added the
package directory in 'runtimepath', so that the help file can be found.

You can find packages on the Internet in various places. It usually comes as
an archive or as a repository. For an archive you can follow these steps:
        1. create the package directory:
                mkdir -p ~/.vim/pack/fancy
           "fancy" can be any name of your liking. Use one that describes the
           package.
        2. unpack the archive in that directory. This assumes the top
           directory in the archive is "start":
                cd ~/.vim/pack/fancy
                unzip /tmp/fancy.zip
           If the archive layout is different make sure that you end up with a
           path like this:
                ~/.vim/pack/fancy/start/fancytext/plugin/fancy.vim
           Here "fancytext" is the name of the package, it can be anything
           else.

More information about packages can be found here: packages .

==
 05.5   Adding a plugin   add-plugin   plugin

Vim's functionality can be extended by adding plugins. A plugin is nothing
more than a Vim script file that is loaded automatically when Vim starts. You
can add a plugin very easily by dropping it in your plugin directory.
{not available when Vim was compiled without the |+eval| feature}

There are two types of plugins:

    global plugin: Used for all kinds of files
  filetype plugin: Only used for a specific type of file

The global plugins will be discussed first, then the filetype ones
add-filetype-plugin .

GLOBAL PLUGINS standard-plugin

When you start Vim, it will automatically load a number of global plugins.
You don't have to do anything for this. They add functionality that most
people will want to use, but which was implemented as a Vim script instead of
being compiled into Vim. You can find them listed in the help index
standard-plugin-list . Also see load-plugins .

add-global-plugin

You can add a global plugin to add functionality that will always be present
when you use Vim. There are only two steps for adding a global plugin:
1. Get a copy of the plugin.
2. Drop it in the right directory.

GETTING A GLOBAL PLUGIN

Where can you find plugins?
- Some are always loaded, you can see them in the directory $VIMRUNTIME/plugin.
- Some come with Vim. You can find them in the directory $VIMRUNTIME/macros
  and its sub-directories and under $VIM/vimfiles/pack/dist/opt/.
- Download from the net. There is a large collection on http://www.vim.org.
- They are sometimes posted in a Vim maillist .
- You could write one yourself, see write-plugin .

Some plugins come as a vimball archive, see vimball .
Some plugins can be updated automatically, see getscript .

USING A GLOBAL PLUGIN

First read the text in the plugin itself to check for any special conditions.
Then copy the file to your plugin directory:

system	plugin directory
Unix	~/.vim/plugin/
PC and OS/2	$HOME/vimfiles/plugin or $VIM/vimfiles/plugin
Amiga	s:vimfiles/plugin
Macintosh	$VIM:vimfiles:plugin
Mac OS X	~/.vim/plugin/
RISC-OS	Choices:vimfiles.plugin

Example for Unix (assuming you didn't have a plugin directory yet):

```
mkdir ~/.vim
mkdir ~/.vim/plugin
cp /tmp/yourplugin.vim ~/.vim/plugin
```

That's all! Now you can use the commands defined in this plugin.

Instead of putting plugins directly into the plugin/ directory, you may
better organize them by putting them into subdirectories under plugin/.
As an example, consider using "~/.vim/plugin/perl/*.vim" for all your Perl
plugins.

FILETYPE PLUGINS add-filetype-plugin ftplugins

The Vim distribution comes with a set of plugins for different filetypes that
you can start using with this command:

```
:filetype plugin on
```

That's all! See vimrc-filetype .

If you are missing a plugin for a filetype you are using, or you found a
better one, you can add it. There are two steps for adding a filetype plugin:
1. Get a copy of the plugin.
2. Drop it in the right directory.

GETTING A FILETYPE PLUGIN

You can find them in the same places as the global plugins. Watch out if the
type of file is mentioned, then you know if the plugin is a global or a
filetype one. The scripts in $VIMRUNTIME/macros are global ones, the filetype
plugins are in $VIMRUNTIME/ftplugin.

USING A FILETYPE PLUGIN ftplugin-name

You can add a filetype plugin by dropping it in the right directory. The
name of this directory is in the same directory mentioned above for global
plugins, but the last part is "ftplugin". Suppose you have found a plugin for
the "stuff" filetype, and you are on Unix. Then you can move this file to the
ftplugin directory:

```
mv thefile ~/.vim/ftplugin/stuff.vim
```

If that file already exists you already have a plugin for "stuff". You might
want to check if the existing plugin doesn't conflict with the one you are
adding. If it's OK, you can give the new one another name:

```
mv thefile ~/.vim/ftplugin/stuff_too.vim
```

The underscore is used to separate the name of the filetype from the rest,
which can be anything. If you use "otherstuff.vim" it wouldn't work, it would
be loaded for the "otherstuff" filetype.

On MS-DOS you cannot use long filenames. You would run into trouble if you
add a second plugin and the filetype has more than six characters. You can
use an extra directory to get around this:

```
mkdir $VIM/vimfiles/ftplugin/fortran
```

```
        copy thefile $VIM/vimfiles/ftplugin/fortran/too.vim
```

The generic names for the filetype plugins are:

```
        ftplugin/<filetype>.vim
        ftplugin/<filetype>_<name>.vim
        ftplugin/<filetype>/<name>.vim
```

Here "<name>" can be any name that you prefer.
Examples for the "stuff" filetype on Unix:

```
        ~/.vim/ftplugin/stuff.vim
        ~/.vim/ftplugin/stuff_def.vim
        ~/.vim/ftplugin/stuff/header.vim
```

The <filetype> part is the name of the filetype the plugin is to be used for. Only files of this filetype will use the settings from the plugin. The <name> part of the plugin file doesn't matter, you can use it to have several plugins for the same filetype. Note that it must end in ".vim".

Further reading:

filetype-plugins	Documentation for the filetype plugins and information about how to avoid that mappings cause problems.
load-plugins	When the global plugins are loaded during startup.
ftplugin-overrule	Overruling the settings from a global plugin.
write-plugin	How to write a plugin script.
plugin-details	For more information about using plugins or when your plugin doesn't work.
new-filetype	How to detect a new file type.

==========

05.6 Adding a help file add-local-help

If you are lucky, the plugin you installed also comes with a help file. We will explain how to install the help file, so that you can easily find help for your new plugin.

Let us use the "doit.vim" plugin as an example. This plugin comes with documentation: "doit.txt". Let's first copy the plugin to the right directory. This time we will do it from inside Vim. (You may skip some of the "mkdir" commands if you already have the directory.)

```
        :!mkdir ~/.vim
        :!mkdir ~/.vim/plugin
        :!cp /tmp/doit.vim ~/.vim/plugin
```

The "cp" command is for Unix, on MS-DOS you can use "copy".

Now create a "doc" directory in one of the directories in 'runtimepath'.

```
        :!mkdir ~/.vim/doc
```

Copy the help file to the "doc" directory.

```
:!cp /tmp/doit.txt ~/.vim/doc
```

Now comes the trick, which allows you to jump to the subjects in the new help file: Generate the local tags file with the :helptags command.

```
:helptags ~/.vim/doc
```

Now you can use the

```
:help doit
```

command to find help for "doit" in the help file you just added. You can see an entry for the local help file when you do:

```
:help local-additions
```

The title lines from the local help files are automagically added to this section. There you can see which local help files have been added and jump to them through the tag.

For writing a local help file, see write-local-help .

==

05.7 The option window

If you are looking for an option that does what you want, you can search in the help files here: options . Another way is by using this command:

```
:options
```

This opens a new window, with a list of options with a one-line explanation. The options are grouped by subject. Move the cursor to a subject and press <Enter> to jump there. Press <Enter> again to jump back. Or use CTRL-O.

You can change the value of an option. For example, move to the "displaying text" subject. Then move the cursor down to this line:

```
set wrap        nowrap
```

When you hit <Enter>, the line will change to:

```
set nowrap      wrap
```

The option has now been switched off.

Just above this line is a short description of the 'wrap' option. Move the cursor one line up to place it in this line. Now hit <Enter> and you jump to the full help on the 'wrap' option.

For options that take a number or string argument you can edit the value. Then press <Enter> to apply the new value. For example, move the cursor a few lines up to this line:

```
set so=0
```

Position the cursor on the zero with "$". Change it into a five with "r5".
Then press <Enter> to apply the new value. When you now move the cursor
around you will notice that the text starts scrolling before you reach the
border. This is what the 'scrolloff' option does, it specifies an offset
from the window border where scrolling starts.

==
 05.8   Often used options

There are an awful lot of options. Most of them you will hardly ever use.
Some of the more useful ones will be mentioned here. Don't forget you can
find more help on these options with the ":help" command, with single quotes
before and after the option name. For example:

	:help 'wrap'

In case you have messed up an option value, you can set it back to the
default by putting an ampersand (&) after the option name. Example:

	:set iskeyword&

NOT WRAPPING LINES

Vim normally wraps long lines, so that you can see all of the text. Sometimes
it's better to let the text continue right of the window. Then you need to
scroll the text left-right to see all of a long line. Switch wrapping off
with this command:

	:set nowrap

Vim will automatically scroll the text when you move to text that is not
displayed. To see a context of ten characters, do this:

	:set sidescroll=10

This doesn't change the text in the file, only the way it is displayed.

WRAPPING MOVEMENT COMMANDS

Most commands for moving around will stop moving at the start and end of a
line. You can change that with the 'whichwrap' option. This sets it to the
default value:

	:set whichwrap=b,s

This allows the <BS> key, when used in the first position of a line, to move
the cursor to the end of the previous line. And the <Space> key moves from
the end of a line to the start of the next one.

To allow the cursor keys <Left> and <Right> to also wrap, use this command:

```
	:set whichwrap=b,s,<,>
```

This is still only for Normal mode. To let <Left> and <Right> do this in Insert mode as well:

```
	:set whichwrap=b,s,<,>,[,]
```

There are a few other flags that can be added, see 'whichwrap'.

VIEWING TABS

When there are tabs in a file, you cannot see where they are. To make them visible:

```
	:set list
```

Now every tab is displayed as ^I. And a $ is displayed at the end of each line, so that you can spot trailing spaces that would otherwise go unnoticed.
   A disadvantage is that this looks ugly when there are many Tabs in a file. If you have a color terminal, or are using the GUI, Vim can show the spaces and tabs as highlighted characters. Use the 'listchars' option:

```
	:set listchars=tab:>-,trail:-
```

Now every tab will be displayed as ">---" (with more or less "-") and trailing white space as "-". Looks a lot better, doesn't it?

KEYWORDS

The 'iskeyword' option specifies which characters can appear in a word:

```
	:set iskeyword
	 iskeyword=@,48-57,_,192-255
```

The "@" stands for all alphabetic letters. "48-57" stands for ASCII characters 48 to 57, which are the numbers 0 to 9. "192-255" are the printable latin characters.
   Sometimes you will want to include a dash in keywords, so that commands like "w" consider "upper-case" to be one word. You can do it like this:

```
	:set iskeyword+=-
	:set iskeyword
	 iskeyword=@,48-57,_,192-255,-
```

If you look at the new value, you will see that Vim has added a comma for you.
   To remove a character use "-=". For example, to remove the underscore:

```
	:set iskeyword-=_
	:set iskeyword
	 iskeyword=@,48-57,192-255,-
```

This time a comma is automatically deleted.

ROOM FOR MESSAGES

When Vim starts there is one line at the bottom that is used for messages.
When a message is long, it is either truncated, thus you can only see part of
it, or the text scrolls and you have to press <Enter> to continue.
   You can set the 'cmdheight' option to the number of lines used for
messages. Example:

```
:set cmdheight=3
```

This does mean there is less room to edit text, thus it's a compromise.

==

Next chapter: usr_06.txt   Using syntax highlighting

Copyright: see manual-copyright   vim:tw=78:ts=8:ft=help:norl:

VIM USER MANUAL - by Bram Moolenaar

Using syntax highlighting

Black and white text is boring. With colors your file comes to life. This not only looks nice, it also speeds up your work. Change the colors used for the different sorts of text. Print your text, with the colors you see on the screen.

Next chapter: usr_07.txt Editing more than one file
Previous chapter: usr_05.txt Set your settings
Table of contents: usr_toc.txt

06.1 Switching it on

It all starts with one simple command:

```
:syntax enable
```

That should work in most situations to get color in your files. Vim will automagically detect the type of file and load the right syntax highlighting. Suddenly comments are blue, keywords brown and strings red. This makes it easy to overview the file. After a while you will find that black&white text slows you down!

If you always want to use syntax highlighting, put the ":syntax enable" command in your vimrc file.

If you want syntax highlighting only when the terminal supports colors, you can put this in your vimrc file:

```
if &t_Co > 1
   syntax enable
endif
```

If you want syntax highlighting only in the GUI version, put the ":syntax enable" command in your gvimrc file.

06.2 No or wrong colors?

There can be a number of reasons why you don't see colors:

- Your terminal does not support colors.
	Vim will use bold, italic and underlined text, but this doesn't look
	very nice. You probably will want to try to get a terminal with
	colors. For Unix, I recommend the xterm from the XFree86 project:
	 xfree-xterm .

- Your terminal does support colors, but Vim doesn't know this.
	Make sure your $TERM setting is correct. For example, when using an
	xterm that supports colors:

		setenv TERM xterm-color

	or (depending on your shell):

		TERM=xterm-color; export TERM

	The terminal name must match the terminal you are using. If it
	still doesn't work, have a look at xterm-color , which shows a few
	ways to make Vim display colors (not only for an xterm).

- The file type is not recognized.
	Vim doesn't know all file types, and sometimes it's near to impossible
	to tell what language a file uses. Try this command:

		:set filetype

	If the result is "filetype=" then the problem is indeed that Vim
	doesn't know what type of file this is. You can set the type
	manually:

		:set filetype=fortran

	To see which types are available, look in the directory
	$VIMRUNTIME/syntax. For the GUI you can use the Syntax menu.
	Setting the filetype can also be done with a modeline , so that the
	file will be highlighted each time you edit it. For example, this
	line can be used in a Makefile (put it near the start or end of the
	file):

		# vim: syntax=make

	You might know how to detect the file type yourself. Often the file
	name extension (after the dot) can be used.
	See new-filetype for how to tell Vim to detect that file type.

- There is no highlighting for your file type.
	You could try using a similar file type by manually setting it as
	mentioned above. If that isn't good enough, you can write your own
	syntax file, see mysyntaxfile .

Or the colors could be wrong:

- The colored text is very hard to read.

Vim guesses the background color that you are using. If it is black (or another dark color) it will use light colors for text. If it is white (or another light color) it will use dark colors for text. If Vim guessed wrong the text will be hard to read. To solve this, set the 'background' option. For a dark background:

```
:set background=dark
```

And for a light background:

```
:set background=light
```

Make sure you put this _before_ the ":syntax enable" command, otherwise the colors will already have been set. You could do ":syntax reset" after setting 'background' to make Vim set the default colors again.

- The colors are wrong when scrolling bottom to top.
  Vim doesn't read the whole file to parse the text. It starts parsing wherever you are viewing the file. That saves a lot of time, but sometimes the colors are wrong. A simple fix is hitting CTRL-L. Or scroll back a bit and then forward again.
  For a real fix, see :syn-sync . Some syntax files have a way to make it look further back, see the help for the specific syntax file. For example, tex.vim for the TeX syntax.

==
06.3 Different colors :syn-default-override

If you don't like the default colors, you can select another color scheme. In the GUI use the Edit/Color Scheme menu. You can also type the command:

```
:colorscheme evening
```

"evening" is the name of the color scheme. There are several others you might want to try out. Look in the directory $VIMRUNTIME/colors.

When you found the color scheme that you like, add the ":colorscheme" command to your vimrc file.

You could also write your own color scheme. This is how you do it:

1. Select a color scheme that comes close. Copy this file to your own Vim directory. For Unix, this should work:

   ```
   !mkdir ~/.vim/colors
   !cp $VIMRUNTIME/colors/morning.vim ~/.vim/colors/mine.vim
   ```

   This is done from Vim, because it knows the value of $VIMRUNTIME.

2. Edit the color scheme file. These entries are useful:

   ```
   term            attributes in a B&W terminal
   cterm           attributes in a color terminal
   ```

```
        ctermfg         foreground color in a color terminal
        ctermbg         background color in a color terminal
        gui             attributes in the GUI
        guifg           foreground color in the GUI
        guibg           background color in the GUI
```

For example, to make comments green:

```
:highlight Comment ctermfg=green guifg=green
```

Attributes you can use for "cterm" and "gui" are "bold" and "underline". If you want both, use "bold,underline". For details see the :highlight command.

3. Tell Vim to always use your color scheme. Put this line in your vimrc :

```
colorscheme mine
```

If you want to see what the most often used color combinations look like, use this command:

```
:runtime syntax/colortest.vim
```

You will see text in various color combinations. You can check which ones are readable and look nice.

==========

06.4 With colors or without colors

Displaying text in color takes a lot of effort. If you find the displaying too slow, you might want to disable syntax highlighting for a moment:

```
:syntax clear
```

When editing another file (or the same one) the colors will come back.

:syn-off

If you want to stop highlighting completely use:

```
:syntax off
```

This will completely disable syntax highlighting and remove it immediately for all buffers.

:syn-manual

If you want syntax highlighting only for specific files, use this:

```
:syntax manual
```

This will enable the syntax highlighting, but not switch it on automatically when starting to edit a buffer. To switch highlighting on for the current buffer, set the 'syntax' option:

```
:set syntax=ON
```

==
06.5 Printing with colors syntax-printing

In the MS-Windows version you can print the current file with this command:

```
:hardcopy
```

You will get the usual printer dialog, where you can select the printer and a few settings. If you have a color printer, the paper output should look the same as what you see inside Vim. But when you use a dark background the colors will be adjusted to look good on white paper.

There are several options that change the way Vim prints:
'printdevice'
'printheader'
'printfont'
'printoptions'

To print only a range of lines, use Visual mode to select the lines and then type the command:

```
v100j:hardcopy
```

"v" starts Visual mode. "100j" moves a hundred lines down, they will be highlighted. Then ":hardcopy" will print those lines. You can use other commands to move in Visual mode, of course.

This also works on Unix, if you have a PostScript printer. Otherwise, you will have to do a bit more work. You need to convert the text to HTML first, and then print it from a web browser.

Convert the current file to HTML with this command:

```
:TOhtml
```

In case that doesn't work:

```
:source $VIMRUNTIME/syntax/2html.vim
```

You will see it crunching away, this can take quite a while for a large file. Some time later another window shows the HTML code. Now write this somewhere (doesn't matter where, you throw it away later):

```
:write main.c.html
```

Open this file in your favorite browser and print it from there. If all goes well, the output should look exactly as it does in Vim. See 2html.vim for details. Don't forget to delete the HTML file when you are done with it.

Instead of printing, you could also put the HTML file on a web server, and let others look at the colored text.

Next chapter: usr_07.txt Editing more than one file

Copyright: see manual-copyright vim:tw=78:ts=8:ft=help:norl:

VIM USER MANUAL - by Bram Moolenaar

Editing more than one file

No matter how many files you have, you can edit them without leaving Vim.
Define a list of files to work on and jump from one to the other. Copy text
from one file and put it in another one.

Next chapter: usr_08.txt Splitting windows
Previous chapter: usr_06.txt Using syntax highlighting
Table of contents: usr_toc.txt

==========

07.1 Edit another file

So far you had to start Vim for every file you wanted to edit. There is a
simpler way. To start editing another file, use this command:

```
:edit foo.txt
```

You can use any file name instead of "foo.txt". Vim will close the current
file and open the new one. If the current file has unsaved changes, however,
Vim displays an error message and does not open the new file:

```
E37: No write since last change (use ! to override)
```

Note:
Vim puts an error ID at the start of each error message. If you do
not understand the message or what caused it, look in the help system
for this ID. In this case:

```
:help E37
```

At this point, you have a number of alternatives. You can write the file
using this command:

```
:write
```

Or you can force Vim to discard your changes and edit the new file, using the
force (!) character:

```
:edit! foo.txt
```

If you want to edit another file, but not write the changes in the current file yet, you can make it hidden:

```
:hide edit foo.txt
```

The text with changes is still there, but you can't see it. This is further explained in section 22.4 : The buffer list.

==

07.2 A list of files

You can start Vim to edit a sequence of files. For example:

```
vim one.c two.c three.c
```

This command starts Vim and tells it that you will be editing three files. Vim displays just the first file. After you have done your thing in this file, to edit the next file you use this command:

```
:next
```

If you have unsaved changes in the current file, you will get an error message and the ":next" will not work. This is the same problem as with ":edit" mentioned in the previous section. To abandon the changes:

```
:next!
```

But mostly you want to save the changes and move on to the next file. There is a special command for this:

```
:wnext
```

This does the same as using two separate commands:

```
:write
:next
```

WHERE AM I?

To see which file in the argument list you are editing, look in the window title. It should show something like "(2 of 3)". This means you are editing the second file out of three files.
   If you want to see the list of files, use this command:

```
:args
```

This is short for "arguments". The output might look like this:

```
one.c [two.c] three.c
```

These are the files you started Vim with. The one you are currently editing, "two.c", is in square brackets.

MOVING TO OTHER ARGUMENTS

To go back one file:

```
:previous
```

This is just like the ":next" command, except that it moves in the other direction. Again, there is a shortcut command for when you want to write the file first:

```
:wprevious
```

To move to the very last file in the list:

```
:last
```

And to move back to the first one again:

```
:first
```

There is no ":wlast" or ":wfirst" command though!

You can use a count for ":next" and ":previous". To skip two files forward:

```
:2next
```

AUTOMATIC WRITING

When moving around the files and making changes, you have to remember to use ":write". Otherwise you will get an error message. If you are sure you always want to write modified files, you can tell Vim to automatically write them:

```
:set autowrite
```

When you are editing a file which you may not want to write, switch it off again:

```
:set noautowrite
```

EDITING ANOTHER LIST OF FILES

You can redefine the list of files without the need to exit Vim and start it again. Use this command to edit three other files:

```
:args five.c six.c seven.h
```

Or use a wildcard, like it's used in the shell:

```
:args *.txt
```

Vim will take you to the first file in the list. Again, if the current file has changes, you can either write the file first, or use ":args!" (with ! added) to abandon the changes.

DID YOU EDIT THE LAST FILE?

arglist-quit

When you use a list of files, Vim assumes you want to edit them all. To protect you from exiting too early, you will get this error when you didn't edit the last file in the list yet:

```
E173: 46 more files to edit
```

If you really want to exit, just do it again. Then it will work (but not when you did other commands in between).

==

07.3 Jumping from file to file

To quickly jump between two files, press CTRL-^ (on English-US keyboards the ^ is above the 6 key). Example:

```
:args one.c two.c three.c
```

You are now in one.c.

```
:next
```

Now you are in two.c. Now use CTRL-^ to go back to one.c. Another CTRL-^ and you are back in two.c. Another CTRL-^ and you are in one.c again. If you now do:

```
:next
```

You are in three.c. Notice that the CTRL-^ command does not change the idea of where you are in the list of files. Only commands like ":next" and ":previous" do that.

The file you were previously editing is called the "alternate" file. When you just started Vim CTRL-^ will not work, since there isn't a previous file.

PREDEFINED MARKS

After jumping to another file, you can use two predefined marks which are very useful:

```
`"
```

This takes you to the position where the cursor was when you left the file. Another mark that is remembered is the position where you made the last change:

```
`.
```

Suppose you are editing the file "one.txt". Somewhere halfway through the file you use "x" to delete a character. Then you go to the last line with "G" and write the file with ":w". You edit several other files, and then use ":edit one.txt" to come back to "one.txt". If you now use `" Vim jumps to the last line of the file. Using `. takes you to the position where you deleted the character. Even when you move around in the file `" and `. will take you to the remembered position. At least until you make another change or leave the file.

FILE MARKS

In chapter 4 was explained how you can place a mark in a file with "mx" and jump to that position with "`x". That works within one file. If you edit another file and place marks there, these are specific for that file. Thus each file has its own set of marks, they are local to the file.
So far we were using marks with a lowercase letter. There are also marks with an uppercase letter. These are global, they can be used from any file. For example suppose that we are editing the file "foo.txt". Go to halfway down the file ("50%") and place the F mark there (F for foo):

```
50%mF
```

Now edit the file "bar.txt" and place the B mark (B for bar) at its last line:

```
GmB
```

Now you can use the "'F" command to jump back to halfway foo.txt. Or edit yet another file, type "'B" and you are at the end of bar.txt again.

The file marks are remembered until they are placed somewhere else. Thus you can place the mark, do hours of editing and still be able to jump back to that mark.
It's often useful to think of a simple connection between the mark letter and where it is placed. For example, use the H mark in a header file, M in a Makefile and C in a C code file.

To see where a specific mark is, give an argument to the ":marks" command:

```
:marks M
```

You can also give several arguments:

```
:marks MCP
```

Don't forget that you can use CTRL-O and CTRL-I to jump to older and newer positions without placing marks there.

==
07.4 Backup files

Usually Vim does not produce a backup file. If you want to have one, all you need to do is execute the following command:

```
        :set backup
```

The name of the backup file is the original file with a ~ added to the end. If your file is named data.txt, for example, the backup file name is data.txt~.
   If you do not like the fact that the backup files end with ~, you can change the extension:

```
        :set backupext=.bak
```

This will use data.txt.bak instead of data.txt~.
   Another option that matters here is 'backupdir'. It specifies where the backup file is written. The default, to write the backup in the same directory as the original file, will mostly be the right thing.

        Note:
        When the 'backup' option isn't set but the 'writebackup' is, Vim will still create a backup file. However, it is deleted as soon as writing the file was completed successfully. This functions as a safety against losing your original file when writing fails in some way (disk full is the most common cause; being hit by lightning might be another, although less common).

KEEPING THE ORIGINAL FILE

If you are editing source files, you might want to keep the file before you make any changes. But the backup file will be overwritten each time you write the file. Thus it only contains the previous version, not the first one.
   To make Vim keep the original file, set the 'patchmode' option. This specifies the extension used for the first backup of a changed file. Usually you would do this:

```
        :set patchmode=.orig
```

When you now edit the file data.txt for the first time, make changes and write the file, Vim will keep a copy of the unchanged file under the name "data.txt.orig".
   If you make further changes to the file, Vim will notice that "data.txt.orig" already exists and leave it alone. Further backup files will then be called "data.txt~" (or whatever you specified with 'backupext').
   If you leave 'patchmode' empty (that is the default), the original file will not be kept.

==
07.5 Copy text between files

This explains how to copy text from one file to another. Let's start with a simple example. Edit the file that contains the text you want to copy. Move the cursor to the start of the text and press "v". This starts Visual mode. Now move the cursor to the end of the text and press "y". This yanks (copies) the selected text.
   To copy the above paragraph, you would do:

```
:edit thisfile
/This
vjjjj$y
```

Now edit the file you want to put the text in. Move the cursor to the character where you want the text to appear after. Use "p" to put the text there.

```
:edit otherfile
/There
p
```

Of course you can use many other commands to yank the text. For example, to select whole lines start Visual mode with "V". Or use CTRL-V to select a rectangular block. Or use "Y" to yank a single line, "yaw" to yank-a-word, etc.

The "p" command puts the text after the cursor. Use "P" to put the text before the cursor. Notice that Vim remembers if you yanked a whole line or a block, and puts it back that way.

USING REGISTERS

When you want to copy several pieces of text from one file to another, having to switch between the files and writing the target file takes a lot of time. To avoid this, copy each piece of text to its own register.

A register is a place where Vim stores text. Here we will use the registers named a to z (later you will find out there are others). Let's copy a sentence to the f register (f for First):

```
"fyas
```

The "yas" command yanks a sentence like before. It's the "f that tells Vim the text should be placed in the f register. This must come just before the yank command.

Now yank three whole lines to the l register (l for line):

```
"l3Y
```

The count could be before the "l just as well. To yank a block of text to the b (for block) register:

```
CTRL-Vjjww"by
```

Notice that the register specification "b is just before the "y" command. This is required. If you would have put it before the "w" command, it would not have worked.

Now you have three pieces of text in the f, l and b registers. Edit another file, move around and place the text where you want it:

```
"fp
```

Again, the register specification "f comes before the "p" command.

You can put the registers in any order. And the text stays in the register

until you yank something else into it. Thus you can put it as many times as you like.

When you delete text, you can also specify a register. Use this to move several pieces of text around. For example, to delete-a-word and write it in the w register:

```
"wdaw
```

Again, the register specification comes before the delete command "d".

APPENDING TO A FILE

When collecting lines of text into one file, you can use this command:

```
:write >> logfile
```

This will write the text of the current file to the end of "logfile". Thus it is appended. This avoids that you have to copy the lines, edit the log file and put them there. Thus you save two steps. But you can only append to the end of a file.
   To append only a few lines, select them in Visual mode before typing ":write". In chapter 10 you will learn other ways to select a range of lines.

==
07.6 Viewing a file

Sometimes you only want to see what a file contains, without the intention to ever write it back. There is the risk that you type ":w" without thinking and overwrite the original file anyway. To avoid this, edit the file read-only.
   To start Vim in readonly mode, use this command:

```
vim -R file
```

On Unix this command should do the same thing:

```
view file
```

You are now editing "file" in read-only mode. When you try using ":w" you will get an error message and the file won't be written.
   When you try to make a change to the file Vim will give you a warning:

```
W10: Warning: Changing a readonly file
```

The change will be done though. This allows for formatting the file, for example, to be able to read it easily.
   If you make changes to a file and forgot that it was read-only, you can still write it. Add the ! to the write command to force writing.

If you really want to forbid making changes in a file, do this:

```
vim -M file
```

Now every attempt to change the text will fail. The help files are like this, for example. If you try to make a change you get this error message:

```
E21: Cannot make changes, 'modifiable' is off
```

You could use the -M argument to setup Vim to work in a viewer mode. This is only voluntary though, since these commands will remove the protection:

```
:set modifiable
:set write
```

==

07.7 Changing the file name

A clever way to start editing a new file is by using an existing file that contains most of what you need. For example, you start writing a new program to move a file. You know that you already have a program that copies a file, thus you start with:

```
:edit copy.c
```

You can delete the stuff you don't need. Now you need to save the file under a new name. The ":saveas" command can be used for this:

```
:saveas move.c
```

Vim will write the file under the given name, and edit that file. Thus the next time you do ":write", it will write "move.c". "copy.c" remains unmodified.

When you want to change the name of the file you are editing, but don't want to write the file, you can use this command:

```
:file move.c
```

Vim will mark the file as "not edited". This means that Vim knows this is not the file you started editing. When you try to write the file, you might get this message:

```
E13: File exists (use ! to override)
```

This protects you from accidentally overwriting another file.

Next chapter: usr_08.txt Splitting windows

VIM USER MANUAL - by Bram Moolenaar

Splitting windows

Display two different files above each other. Or view two locations in the
file at the same time. See the difference between two files by putting them
side by side. All this is possible with split windows.

Next chapter: usr_09.txt Using the GUI
Previous chapter: usr_07.txt Editing more than one file
Table of contents: usr_toc.txt

==

08.1 Split a window

The easiest way to open a new window is to use the following command:

```
:split
```

This command splits the screen into two windows and leaves the cursor in the
top one:

```
+----------------------------------+
|/* file one.c */                  |
|~                                 |
|~                                 |
 one.c==============================
|/* file one.c */                  |
|~                                 |
 one.c==============================
|                                  |
+----------------------------------+
```

What you see here is two windows on the same file. The line with "====" is
the status line. It displays information about the window above it. (In
practice the status line will be in reverse video.)
   The two windows allow you to view two parts of the same file. For example,
you could make the top window show the variable declarations of a program, and
the bottom one the code that uses these variables.

The CTRL-W w command can be used to jump between the windows. If you are in

the top window, CTRL-W w jumps to the window below it. If you are in the bottom window it will jump to the first window. (CTRL-W CTRL-W does the same thing, in case you let go of the CTRL key a bit later.)

CLOSE THE WINDOW

To close a window, use the command:

```
:close
```

Actually, any command that quits editing a file works, like ":quit" and "ZZ". But ":close" prevents you from accidentally exiting Vim when you close the last window.

CLOSING ALL OTHER WINDOWS

If you have opened a whole bunch of windows, but now want to concentrate on one of them, this command will be useful:

```
:only
```

This closes all windows, except for the current one. If any of the other windows has changes, you will get an error message and that window won't be closed.

==========

08.2 Split a window on another file

The following command opens a second window and starts editing the given file:

```
:split two.c
```

If you were editing one.c, then the result looks like this:

```
+----------------------------------+
|/* file two.c */                  |
|~                                 |
|~                                 |
 two.c============================
|/* file one.c */                  |
|~                                 |
 one.c============================
|                                  |
+----------------------------------+
```

To open a window on a new, empty file, use this:

```
:new
```

You can repeat the ":split" and ":new" commands to create as many windows as you like.

08.3 Window size

The ":split" command can take a number argument. If specified, this will be the height of the new window. For example, the following opens a new window three lines high and starts editing the file alpha.c:

```
:3split alpha.c
```

For existing windows you can change the size in several ways. When you have a working mouse, it is easy: Move the mouse pointer to the status line that separates two windows, and drag it up or down.

To increase the size of a window:

```
CTRL-W +
```

To decrease it:

```
CTRL-W -
```

Both of these commands take a count and increase or decrease the window size by that many lines. Thus "4 CTRL-W +" make the window four lines higher.

To set the window height to a specified number of lines:

```
{height}CTRL-W _
```

That's: a number {height}, CTRL-W and then an underscore (the - key with Shift on English-US keyboards).
   To make a window as high as it can be, use the CTRL-W _ command without a count.

USING THE MOUSE

In Vim you can do many things very quickly from the keyboard. Unfortunately, the window resizing commands require quite a bit of typing. In this case, using the mouse is faster. Position the mouse pointer on a status line. Now press the left mouse button and drag. The status line will move, thus making the window on one side higher and the other smaller.

OPTIONS

The 'winheight' option can be set to a minimal desired height of a window and 'winminheight' to a hard minimum height.
   Likewise, there is 'winwidth' for the minimal desired width and 'winminwidth' for the hard minimum width.
   The 'equalalways' option, when set, makes Vim equalize the windows sizes when a window is closed or opened.

08.4 Vertical splits

The ":split" command creates the new window above the current one. To make the window appear at the left side, use:

```
:vsplit
```

or:

```
:vsplit two.c
```

The result looks something like this:

```
+--------------------------------------+
|/* file two.c */   |/* file one.c */  |
|~                  |~                 |
|~                  |~                 |
|~                  |~                 |
 two.c===============one.c=============
|                                      |
+--------------------------------------+
```

Actually, the | lines in the middle will be in reverse video. This is called the vertical separator. It separates the two windows left and right of it.

There is also the ":vnew" command, to open a vertically split window on a new, empty file. Another way to do this:

```
:vertical new
```

The ":vertical" command can be inserted before another command that splits a window. This will cause that command to split the window vertically instead of horizontally. (If the command doesn't split a window, it works unmodified.)

MOVING BETWEEN WINDOWS

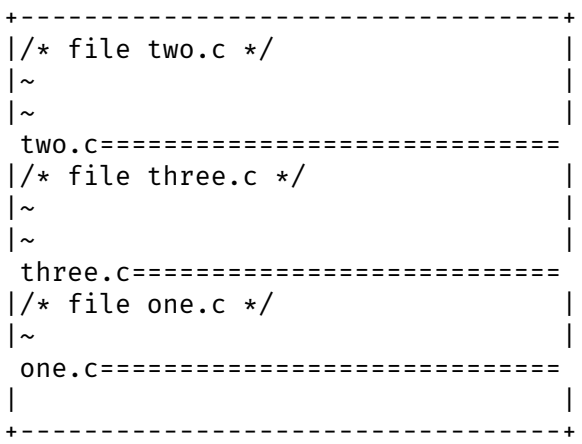
Since you can split windows horizontally and vertically as much as you like, you can create almost any layout of windows. Then you can use these commands to move between them:

```
CTRL-W h        move to the window on the left
CTRL-W j        move to the window below
CTRL-W k        move to the window above
CTRL-W l        move to the window on the right

CTRL-W t        move to the TOP window
CTRL-W b        move to the BOTTOM window
```

You will notice the same letters as used for moving the cursor. And the cursor keys can also be used, if you like.
   More commands to move to other windows: Q_wi .

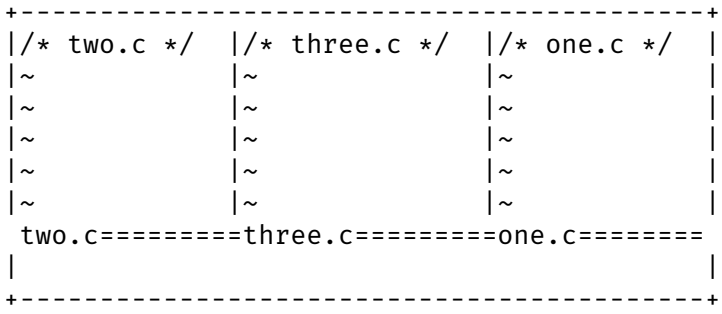
You have split a few windows, but now they are in the wrong place. Then you need a command to move the window somewhere else. For example, you have three windows like this:



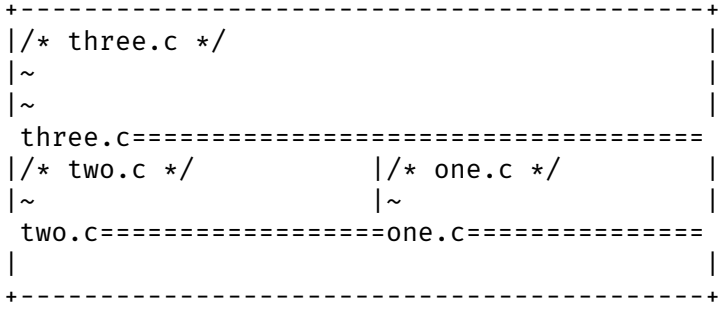
Clearly the last one should be at the top. Go to that window (using CTRL-W w) and the type this command:

	CTRL-W K

This uses the uppercase letter K. What happens is that the window is moved to the very top. You will notice that K is again used for moving upwards.
   When you have vertical splits, CTRL-W K will move the current window to the top and make it occupy the full width of the Vim window. If this is your layout:



Then using CTRL-W K in the middle window (three.c) will result in:



The other three similar commands (you can probably guess these now):

```
        CTRL-W H        move window to the far left
        CTRL-W J        move window to the bottom
        CTRL-W L        move window to the far right
```

==

08.6 Commands for all windows

When you have several windows open and you want to quit Vim, you can close each window separately. A quicker way is using this command:

```
        :qall
```

This stands for "quit all". If any of the windows contain changes, Vim will not exit. The cursor will automatically be positioned in a window with changes. You can then either use ":write" to save the changes, or ":quit!" to throw them away.

If you know there are windows with changes, and you want to save all these changes, use this command:

```
        :wall
```

This stands for "write all". But actually, it only writes files with changes. Vim knows it doesn't make sense to write files that were not changed.
   And then there is the combination of ":qall" and ":wall": the "write and quit all" command:

```
        :wqall
```

This writes all modified files and quits Vim.
   Finally, there is a command that quits Vim and throws away all changes:

```
        :qall!
```

Be careful, there is no way to undo this command!

OPENING A WINDOW FOR ALL ARGUMENTS

To make Vim open a window for each file, start it with the "-o" argument:

```
        vim -o one.txt two.txt three.txt
```

This results in:

```
        +--------------------------------+
        |file one.txt                    |
        |~                               |
         one.txt=======================
        |file two.txt                    |
```

```
        |~                              |
         two.txt=======================
        |file three.txt                 |
        |~                              |
         three.txt======================
        |                               |
        +-------------------------------+
```

The "-O" argument is used to get vertically split windows.
   When Vim is already running, the ":all" command opens a window for each file in the argument list. ":vertical all" does it with vertical splits.

==

08.7 Viewing differences with vimdiff

There is a special way to start Vim, which shows the differences between two files. Let's take a file "main.c" and insert a few characters in one line. Write this file with the 'backup' option set, so that the backup file "main.c~" will contain the previous version of the file.
   Type this command in a shell (not in Vim):

```
        vimdiff main.c~ main.c
```

Vim will start, with two windows side by side. You will only see the line in which you added characters, and a few lines above and below it.

```
         VV                   VV
        +----------------------------------------+
        |+ +--123 lines: /* a|+ +--123 lines: /* a|  <- fold
        |  text              |  text              |
        |  text              |  text              |
        |  text              |  text              |
        |  text              |  changed text      |  <- changed line
        |  text              |  text              |
        |  text              |  ------------------|  <- deleted line
        |  text              |  text              |
        |  text              |  text              |
        |  text              |  text              |
        |+ +--432 lines: text|+ +--432 lines: text|  <- fold
        |  ~                 |  ~                 |
        |  ~                 |  ~                 |
         main.c~==============main.c==============
        |                                        |
        +----------------------------------------+
```

(This picture doesn't show the highlighting, use the vimdiff command for a better look.)

The lines that were not modified have been collapsed into one line. This is called a closed fold. They are indicated in the picture with "<- fold". Thus the single fold line at the top stands for 123 text lines. These lines are equal in both files.
   The line marked with "<- changed line" is highlighted, and the inserted text is displayed with another color. This clearly shows what the difference

is between the two files.
   The line that was deleted is displayed with "---" in the main.c window. See the "<- deleted line" marker in the picture. These characters are not really there. They just fill up main.c, so that it displays the same number of lines as the other window.

THE FOLD COLUMN

Each window has a column on the left with a slightly different background. In the picture above these are indicated with "VV". You notice there is a plus character there, in front of each closed fold. Move the mouse pointer to that plus and click the left button. The fold will open, and you can see the text that it contains.
   The fold column contains a minus sign for an open fold. If you click on this -, the fold will close.
   Obviously, this only works when you have a working mouse. You can also use "zo" to open a fold and "zc" to close it.

DIFFING IN VIM

Another way to start in diff mode can be done from inside Vim. Edit the "main.c" file, then make a split and show the differences:

```
:edit main.c
:vertical diffsplit main.c~
```

The ":vertical" command is used to make the window split vertically. If you omit this, you will get a horizontal split.

If you have a patch or diff file, you can use the third way to start diff mode. First edit the file to which the patch applies. Then tell Vim the name of the patch file:

```
:edit main.c
:vertical diffpatch main.c.diff
```

WARNING: The patch file must contain only one patch, for the file you are editing. Otherwise you will get a lot of error messages, and some files might be patched unexpectedly.
   The patching will only be done to the copy of the file in Vim. The file on your harddisk will remain unmodified (until you decide to write the file).

SCROLL BINDING

When the files have more changes, you can scroll in the usual way. Vim will try to keep both the windows start at the same position, so you can easily see the differences side by side.
   When you don't want this for a moment, use this command:

```
:set noscrollbind
```

JUMPING TO CHANGES

When you have disabled folding in some way, it may be difficult to find the changes. Use this command to jump forward to the next change:

```
]c
```

To go the other way use:

```
[c
```

Prepended a count to jump further away.

REMOVING CHANGES

You can move text from one window to the other. This either removes differences or adds new ones. Vim doesn't keep the highlighting updated in all situations. To update it use this command:

```
:diffupdate
```

To remove a difference, you can move the text in a highlighted block from one window to another. Take the "main.c" and "main.c~" example above. Move the cursor to the left window, on the line that was deleted in the other window. Now type this command:

```
dp
```

The change will be removed by putting the text of the current window in the other window. "dp" stands for "diff put".
   You can also do it the other way around. Move the cursor to the right window, to the line where "changed" was inserted. Now type this command:

```
do
```

The change will now be removed by getting the text from the other window. Since there are no changes left now, Vim puts all text in a closed fold. "do" stands for "diff obtain". "dg" would have been better, but that already has a different meaning ("dgg" deletes from the cursor until the first line).

For details about diff mode, see vimdiff .

==
 08.8   Various

The 'laststatus' option can be used to specify when the last window has a statusline:

```
0       never
1       only when there are split windows (the default)
2       always
```

Many commands that edit another file have a variant that splits the window.
For Command-line commands this is done by prepending an "s". For example:
":tag" jumps to a tag, ":stag" splits the window and jumps to a
tag.
   For Normal mode commands a CTRL-W is prepended. CTRL-^ jumps to the
alternate file, CTRL-W CTRL-^ splits the window and edits the alternate file.

The 'splitbelow' option can be set to make a new window appear below the
current window. The 'splitright' option can be set to make a vertically split
window appear right of the current window.

When splitting a window you can prepend a modifier command to tell where the
window is to appear:

```
:leftabove {cmd}        left or above the current window
:aboveleft {cmd}        idem
:rightbelow {cmd}       right or below the current window
:belowright {cmd}       idem
:topleft {cmd}          at the top or left of the Vim window
:botright {cmd}         at the bottom or right of the Vim window
```

08.9 Tab pages

You will have noticed that windows never overlap. That means you quickly run
out of screen space. The solution for this is called Tab pages.

Assume you are editing "thisfile". To create a new tab page use this command:

```
:tabedit thatfile
```

This will edit the file "thatfile" in a window that occupies the whole Vim
window. And you will notice a bar at the top with the two file names:

```
+-----------------------------------+
| thisfile | /thatfile/ __________X|    (thatfile is bold)
|/* thatfile */                     |
|that                               |
|that                               |
|~                                  |
|~                                  |
|~                                  |
|                                   |
+-----------------------------------+
```

You now have two tab pages. The first one has a window for "thisfile" and the
second one a window for "thatfile". It's like two pages that are on top of
each other, with a tab sticking out of each page showing the file name.

Now use the mouse to click on "thisfile" in the top line. The result is

```
+-----------------------------------+
| /thisfile/ | thatfile __________X|    (thisfile is bold)
```

```
        |/* thisfile */                    |
        |this                              |
        |this                              |
        |~                                 |
        |~                                 |
        |~                                 |
        |                                  |
        +----------------------------------+
```

Thus you can switch between tab pages by clicking on the label in the top line. If you don't have a mouse or don't want to use it, you can use the "gt" command. Mnemonic: Goto Tab.

Now let's create another tab page with the command:

```
        :tab split
```

This makes a new tab page with one window that is editing the same buffer as the window we were in:

```
        +--------------------------------------+
        | thisfile | /thisfile/ | thatfile __X|   (thisfile is bold)
        |/* thisfile */                       |
        |this                                 |
        |this                                 |
        |~                                    |
        |~                                    |
        |~                                    |
        |                                     |
        +-------------------------------------+
```

You can put ":tab" before any Ex command that opens a window. The window will be opened in a new tab page. Another example:

```
        :tab help gt
```

Will show the help text for "gt" in a new tab page.

A few more things you can do with tab pages:

- click with the mouse in the space after the last label
  The next tab page will be selected, like with "gt".

- click with the mouse on the "X" in the top right corner
  The current tab page will be closed. Unless there are unsaved changes in the current tab page.

- double click with the mouse in the top line
  A new tab page will be created.

- the "tabonly" command
  Closes all tab pages except the current one. Unless there are unsaved changes in other tab pages.

For more information about tab pages see tab-page .

VIM USER MANUAL - by Bram Moolenaar

Using the GUI

Vim works in an ordinary terminal, while gVim has a Graphical User Interface (GUI). It can do the same things and a few more. The GUI offers menus, a toolbar, scrollbars and other items. This chapter is about these extra things that the GUI offers.

Next chapter: usr_10.txt Making big changes
Previous chapter: usr_08.txt Splitting windows
Table of contents: usr_toc.txt

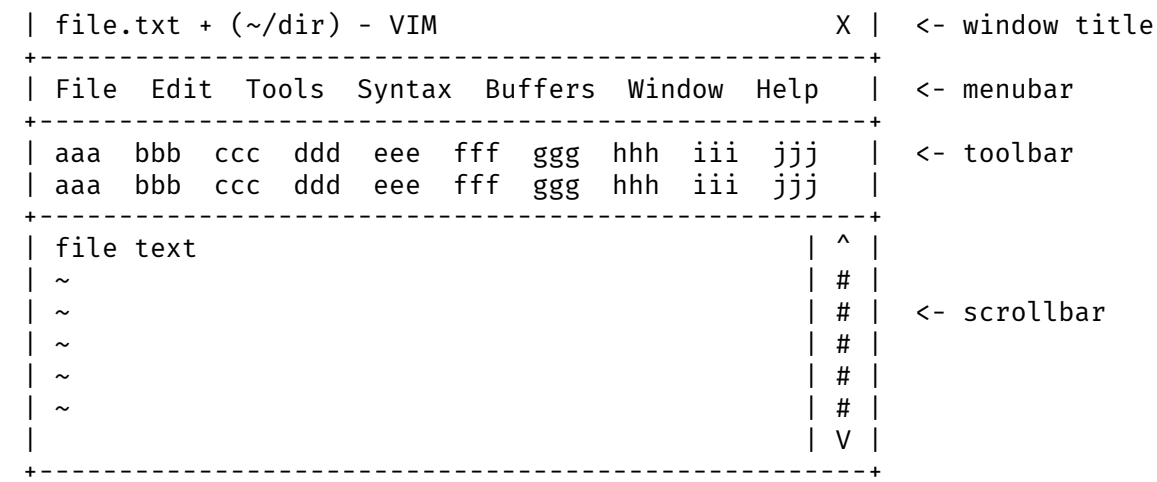
==========

09.1 Parts of the GUI

You might have an icon on your desktop that starts gvim. Otherwise, one of these commands should do it:

```
gvim file.txt
vim -g file.txt
```

If this doesn't work you don't have a version of Vim with GUI support. You will have to install one first.
Vim will open a window and display "file.txt" in it. What the window looks like depends on the version of Vim. It should resemble the following picture (for as far as this can be shown in ASCII!).



The largest space is occupied by the file text. This shows the file in the

same way as in a terminal. With some different colors and another font
perhaps.

THE WINDOW TITLE

At the very top is the window title. This is drawn by your window system.
Vim will set the title to show the name of the current file. First comes the
name of the file. Then some special characters and the directory of the file
in parens. These special characters can be present:

```
-       The file cannot be modified (e.g., a help file)
+       The file contains changes
=       The file is read-only
=+      The file is read-only, contains changes anyway
```

If nothing is shown you have an ordinary, unchanged file.

THE MENUBAR

You know how menus work, right? Vim has the usual items, plus a few more.
Browse them to get an idea of what you can use them for. A relevant submenu
is Edit/Global Settings. You will find these entries:

```
Toggle Toolbar          make the toolbar appear/disappear
Toggle Bottom Scrollbar make a scrollbar appear/disappear at the bottom
Toggle Left Scrollbar   make a scrollbar appear/disappear at the left
Toggle Right Scrollbar  make a scrollbar appear/disappear at the right
```

On most systems you can tear-off the menus. Select the top item of the menu,
the one that looks like a dashed line. You will get a separate window with
the items of the menu. It will hang around until you close the window.

THE TOOLBAR

This contains icons for the most often used actions. Hopefully the icons are
self-explanatory. There are tooltips to get an extra hint (move the mouse
pointer to the icon without clicking and don't move it for a second).

The "Edit/Global Settings/Toggle Toolbar" menu item can be used to make the
toolbar disappear. If you never want a toolbar, use this command in your
vimrc file:

```
:set guioptions-=T
```

This removes the 'T' flag from the 'guioptions' option. Other parts of the
GUI can also be enabled or disabled with this option. See the help for it.

THE SCROLLBARS

By default there is one scrollbar on the right. It does the obvious thing.

When you split the window, each window will get its own scrollbar.
   You can make a horizontal scrollbar appear with the menu item
Edit/Global Settings/Toggle Bottom Scrollbar. This is useful in diff mode, or
when the 'wrap' option has been reset (more about that later).

When there are vertically split windows, only the windows on the right side
will have a scrollbar. However, when you move the cursor to a window on the
left, it will be this one the that scrollbar controls. This takes a bit of
time to get used to.
   When you work with vertically split windows, consider adding a scrollbar on
the left. This can be done with a menu item, or with the 'guioptions' option:

```
:set guioptions+=l
```

This adds the 'l' flag to 'guioptions'.

==
09.2 Using the mouse

Standards are wonderful. In Microsoft Windows, you can use the mouse to
select text in a standard manner. The X Window system also has a standard
system for using the mouse. Unfortunately, these two standards are not the
same.
   Fortunately, you can customize Vim. You can make the behavior of the mouse
work like an X Window system mouse or a Microsoft Windows mouse. The following
command makes the mouse behave like an X Window mouse:

```
:behave xterm
```

The following command makes the mouse work like a Microsoft Windows mouse:

```
:behave mswin
```

The default behavior of the mouse on UNIX systems is xterm. The default
behavior on a Microsoft Windows system is selected during the installation
process. For details about what the two behaviors are, see :behave . Here
follows a summary.

XTERM MOUSE BEHAVIOR

Left mouse click	position the cursor
Left mouse drag	select text in Visual mode
Middle mouse click	paste text from the clipboard
Right mouse click	extend the selected text until the mouse pointer

MSWIN MOUSE BEHAVIOR

Left mouse click	position the cursor
Left mouse drag	select text in Select mode (see 09.4)
Left mouse click, with Shift	extend the selected text until the mouse pointer

Middle mouse click	paste text from the clipboard
Right mouse click	display a pop-up menu

The mouse can be further tuned. Check out these options if you want to change the way how the mouse works:

'mouse'	in which mode the mouse is used by Vim
'mousemodel'	what effect a mouse click has
'mousetime'	time between clicks for a double-click
'mousehide'	hide the mouse while typing
'selectmode'	whether the mouse starts Visual or Select mode

==========

09.3 The clipboard

In section 04.7 the basic use of the clipboard was explained. There is one essential thing to explain about X-windows: There are actually two places to exchange text between programs. MS-Windows doesn't have this.

In X-Windows there is the "current selection". This is the text that is currently highlighted. In Vim this is the Visual area (this assumes you are using the default option settings). You can paste this selection in another application without any further action.
   For example, in this text select a few words with the mouse. Vim will switch to Visual mode and highlight the text. Now start another gvim, without a file name argument, so that it displays an empty window. Click the middle mouse button. The selected text will be inserted.

The "current selection" will only remain valid until some other text is selected. After doing the paste in the other gvim, now select some characters in that window. You will notice that the words that were previously selected in the other gvim window are displayed differently. This means that it no longer is the current selection.

You don't need to select text with the mouse, using the keyboard commands for Visual mode works just as well.

THE REAL CLIPBOARD

Now for the other place with which text can be exchanged. We call this the "real clipboard", to avoid confusion. Often both the "current selection" and the "real clipboard" are called clipboard, you'll have to get used to that.
   To put text on the real clipboard, select a few different words in one of the gvims you have running. Then use the Edit/Copy menu entry. Now the text has been copied to the real clipboard. You can't see this, unless you have some application that shows the clipboard contents (e.g., KDE's Klipper).
   Now select the other gvim, position the cursor somewhere and use the Edit/Paste menu. You will see the text from the real clipboard is inserted.

USING BOTH

This use of both the "current selection" and the "real clipboard" might sound a bit confusing. But it is very useful. Let's show this with an example. Use one gvim with a text file and perform these actions:

- Select two words in Visual mode.
- Use the Edit/Copy menu to get these words onto the clipboard.
- Select one other word in Visual mode.
- Use the Edit/Paste menu item. What will happen is that the single selected word is replaced with the two words from the clipboard.
- Move the mouse pointer somewhere else and click the middle button. You will see that the word you just overwrote with the clipboard is inserted here.

If you use the "current selection" and the "real clipboard" with care, you can do a lot of useful editing with them.

USING THE KEYBOARD

If you don't like using the mouse, you can access the current selection and the real clipboard with two registers. The "* register is for the current selection.
   To make text become the current selection, use Visual mode. For example, to select a whole line just press "V".
   To insert the current selection before the cursor:

```
"*P
```

Notice the uppercase "P". The lowercase "p" puts the text after the cursor.

The "+ register is used for the real clipboard. For example, to copy the text from the cursor position until the end of the line to the clipboard:

```
"+y$
```

Remember, "y" is yank, which is Vim's copy command.
   To insert the contents of the real clipboard before the cursor:

```
"+P
```

It's the same as for the current selection, but uses the plus (+) register instead of the star (*) register.

==
09.4 Select mode

And now something that is used more often on MS-Windows than on X-Windows. But both can do it. You already know about Visual mode. Select mode is like Visual mode, because it is also used to select text. But there is an obvious difference: When typing text, the selected text is deleted and the typed text replaces it.

To start working with Select mode, you must first enable it (for MS-Windows it is probably already enabled, but you can do this anyway):

```
:set selectmode+=mouse
```

Now use the mouse to select some text. It is highlighted like in Visual mode.
Now press a letter. The selected text is deleted, and the single letter
replaces it. You are in Insert mode now, thus you can continue typing.

Since typing normal text causes the selected text to be deleted, you can not
use the normal movement commands "hjkl", "w", etc. Instead, use the shifted
function keys. <S-Left> (shifted cursor left key) moves the cursor left. The
selected text is changed like in Visual mode. The other shifted cursor keys
do what you expect. <S-End> and <S-Home> also work.

You can tune the way Select mode works with the 'selectmode' option.

VIM USER MANUAL - by Bram Moolenaar

Making big changes

In chapter 4 several ways to make small changes were explained. This chapter goes into making changes that are repeated or can affect a large amount of text. The Visual mode allows doing various things with blocks of text. Use an external program to do really complicated things.

Next chapter: usr_11.txt Recovering from a crash
Previous chapter: usr_09.txt Using the GUI
Table of contents: usr_toc.txt

10.1 Record and playback commands

The "." command repeats the preceding change. But what if you want to do something more complex than a single change? That's where command recording comes in. There are three steps:

1. The "q{register}" command starts recording keystrokes into the register named {register}. The register name must be between a and z.
2. Type your commands.
3. To finish recording, press q (without any extra character).

You can now execute the macro by typing the command "@{register}".

Take a look at how to use these commands in practice. You have a list of filenames that look like this:

```
stdio.h
fcntl.h
unistd.h
stdlib.h
```

And what you want is the following:

```
#include "stdio.h"
#include "fcntl.h"
#include "unistd.h"
#include "stdlib.h"
```

You start by moving to the first character of the first line. Next you execute the following commands:

```
qa                      Start recording a macro in register a.
^                       Move to the beginning of the line.
i#include "<Esc>        Insert the string #include " at the beginning
                        of the line.
$                       Move to the end of the line.
a"<Esc>                 Append the character double quotation mark (")
                        to the end of the line.
j                       Go to the next line.
q                       Stop recording the macro.
```

Now that you have done the work once, you can repeat the change by typing the command "@a" three times.

The "@a" command can be preceded by a count, which will cause the macro to be executed that number of times. In this case you would type:

```
3@a
```

MOVE AND EXECUTE

You might have the lines you want to change in various places. Just move the cursor to each location and use the "@a" command. If you have done that once, you can do it again with "@@". That's a bit easier to type. If you now execute register b with "@b", the next "@@" will use register b.

If you compare the playback method with using ".", there are several differences. First of all, "." can only repeat one change. As seen in the example above, "@a" can do several changes, and move around as well. Secondly, "." can only remember the last change. Executing a register allows you to make any changes and then still use "@a" to replay the recorded commands. Finally, you can use 26 different registers. Thus you can remember 26 different command sequences to execute.

USING REGISTERS

The registers used for recording are the same ones you used for yank and delete commands. This allows you to mix recording with other commands to manipulate the registers.

Suppose you have recorded a few commands in register n. When you execute this with "@n" you notice you did something wrong. You could try recording again, but perhaps you will make another mistake. Instead, use this trick:

```
G                       Go to the end of the file.
o<Esc>                  Create an empty line.
"np                     Put the text from the n register.  You now see
                        the commands you typed as text in the file.
{edits}                 Change the commands that were wrong.  This is
                        just like editing text.
0                       Go to the start of the line.
"ny$                    Yank the corrected commands into the n
```

```
                                register.
        dd                      Delete the scratch line.
```

Now you can execute the corrected commands with "@n". (If your recorded commands include line breaks, adjust the last two items in the example to include all the lines.)

APPENDING TO A REGISTER

So far we have used a lowercase letter for the register name. To append to a register, use an uppercase letter.

Suppose you have recorded a command to change a word to register c. It works properly, but you would like to add a search for the next word to change. This can be done with:

```
qC/word<Enter>q
```

You start with "qC", which records to the c register and appends. Thus writing to an uppercase register name means to append to the register with the same letter, but lowercase.

This works both with recording and with yank and delete commands. For example, you want to collect a sequence of lines into the a register. Yank the first line with:

```
"aY
```

Now move to the second line, and type:

```
"AY
```

Repeat this command for all lines. The a register now contains all those lines, in the order you yanked them.

==

10.2 Substitution find-replace

The ":substitute" command enables you to perform string replacements on a whole range of lines. The general form of this command is as follows:

```
:[range]substitute/from/to/[flags]
```

This command changes the "from" string to the "to" string in the lines specified with [range]. For example, you can change "Professor" to "Teacher" in all lines with the following command:

```
:%substitute/Professor/Teacher/
```

Note:
The ":substitute" command is almost never spelled out completely. Most of the time, people use the abbreviated version ":s". From here on the abbreviation will be used.

The "%" before the command specifies the command works on all lines. Without a range, ":s" only works on the current line. More about ranges in the next section 10.3 .

By default, the ":substitute" command changes only the first occurrence on each line. For example, the preceding command changes the line:

```
Professor Smith criticized Professor Johnson today.
```

to:

```
Teacher Smith criticized Professor Johnson today.
```

To change every occurrence on the line, you need to add the g (global) flag. The command:

```
:%s/Professor/Teacher/g
```

results in (starting with the original line):

```
Teacher Smith criticized Teacher Johnson today.
```

Other flags include p (print), which causes the ":substitute" command to print out the last line it changes. The c (confirm) flag tells ":substitute" to ask you for confirmation before it performs each substitution. Enter the following:

```
:%s/Professor/Teacher/c
```

Vim finds the first occurrence of "Professor" and displays the text it is about to change. You get the following prompt:

```
replace with Teacher (y/n/a/q/l/^E/^Y)?
```

At this point, you must enter one of the following answers:

```
y               Yes; make this change.
n               No; skip this match.
a               All; make this change and all remaining ones without
                further confirmation.
q               Quit; don't make any more changes.
l               Last; make this change and then quit.
CTRL-E          Scroll the text one line up.
CTRL-Y          Scroll the text one line down.
```

The "from" part of the substitute command is actually a pattern. The same kind as used for the search command. For example, this command only substitutes "the" when it appears at the start of a line:

```
:s/^the/these/
```

If you are substituting with a "from" or "to" part that includes a slash, you need to put a backslash before it. A simpler way is to use another character

instead of the slash. A plus, for example:

```
:s+one/two+one or two+
```

10.3 Command ranges

The ":substitute" command, and many other : commands, can be applied to a selection of lines. This is called a range.
   The simple form of a range is {number},{number}. For example:

```
:1,5s/this/that/g
```

Executes the substitute command on the lines 1 to 5. Line 5 is included. The range is always placed before the command.

A single number can be used to address one specific line:

```
:54s/President/Fool/
```

Some commands work on the whole file when you do not specify a range. To make them work on the current line the "." address is used. The ":write" command works like that. Without a range, it writes the whole file. To make it write only the current line into a file:

```
:.write otherfile
```

The first line always has number one. How about the last line? The "$" character is used for this. For example, to substitute in the lines from the cursor to the end:

```
:.,$s/yes/no/
```

The "%" range that we used before, is actually a short way to say "1,$", from the first to the last line.

USING A PATTERN IN A RANGE

Suppose you are editing a chapter in a book, and want to replace all occurrences of "grey" with "gray". But only in this chapter, not in the next one. You know that only chapter boundaries have the word "Chapter" in the first column. This command will work then:

```
:?^Chapter?,/^Chapter/s=grey=gray=g
```

You can see a search pattern is used twice. The first "?^Chapter?" finds the line above the current position that matches this pattern. Thus the ?pattern? range is used to search backwards. Similarly, "/^Chapter/" is used to search forward for the start of the next chapter.
   To avoid confusion with the slashes, the "=" character was used in the substitute command here. A slash or another character would have worked as well.

ADD AND SUBTRACT

There is a slight error in the above command: If the title of the next chapter had included "grey" it would be replaced as well. Maybe that's what you wanted, but what if you didn't? Then you can specify an offset.
   To search for a pattern and then use the line above it:

```
/Chapter/-1
```

You can use any number instead of the 1. To address the second line below the match:

```
/Chapter/+2
```

The offsets can also be used with the other items in a range. Look at this one:

```
:.+3,$-5
```

This specifies the range that starts three lines below the cursor and ends five lines before the last line in the file.

USING MARKS

Instead of figuring out the line numbers of certain positions, remembering them and typing them in a range, you can use marks.
   Place the marks as mentioned in chapter 3. For example, use "mt" to mark the top of an area and "mb" to mark the bottom. Then you can use this range to specify the lines between the marks (including the lines with the marks):

```
:'t,'b
```

VISUAL MODE AND RANGES

You can select text with Visual mode. If you then press ":" to start a colon command, you will see this:

```
:'<,'>
```

Now you can type the command and it will be applied to the range of lines that was visually selected.

> Note:
> When using Visual mode to select part of a line, or using CTRL-V to select a block of text, the colon commands will still apply to whole lines. This might change in a future version of Vim.

The '< and '> are actually marks, placed at the start and end of the Visual selection. The marks remain at their position until another Visual selection is made. Thus you can use the "'<" command to jump to position where the Visual area started. And you can mix the marks with other items:

```
:'>,$
```

This addresses the lines from the end of the Visual area to the end of the file.

A NUMBER OF LINES

When you know how many lines you want to change, you can type the number and then ":". For example, when you type "5:", you will get:

```
:.,.+4
```

Now you can type the command you want to use. It will use the range "." (current line) until ".+4" (four lines down). Thus it spans five lines.

==========

10.4 The global command

The ":global" command is one of the more powerful features of Vim. It allows you to find a match for a pattern and execute a command there. The general form is:

```
:[range]global/{pattern}/{command}
```

This is similar to the ":substitute" command. But, instead of replacing the matched text with other text, the command {command} is executed.

> Note:
> The command executed for ":global" must be one that starts with a colon. Normal mode commands can not be used directly. The :normal command can do this for you.

Suppose you want to change "foobar" to "barfoo", but only in C++ style comments. These comments start with "//". Use this command:

```
:g+//+s/foobar/barfoo/g
```

This starts with ":g". That is short for ":global", just like ":s" is short for ":substitute". Then the pattern, enclosed in plus characters. Since the pattern we are looking for contains a slash, this uses the plus character to separate the pattern. Next comes the substitute command that changes "foobar" into "barfoo".

The default range for the global command is the whole file. Thus no range was specified in this example. This is different from ":substitute", which works on one line without a range.

The command isn't perfect, since it also matches lines where "//" appears halfway a line, and the substitution will also take place before the "//".

Just like with ":substitute", any pattern can be used. When you learn more complicated patterns later, you can use them here.

==========

10.5 Visual block mode

With CTRL-V you can start selection of a rectangular area of text. There are a few commands that do something special with the text block.

There is something special about using the "$" command in Visual block mode. When the last motion command used was "$", all lines in the Visual selection will extend until the end of the line, also when the line with the cursor is shorter. This remains effective until you use a motion command that moves the cursor horizontally. Thus using "j" keeps it, "h" stops it.

INSERTING TEXT

The command "I{string}<Esc>" inserts the text {string} in each line, just left of the visual block. You start by pressing CTRL-V to enter visual block mode. Now you move the cursor to define your block. Next you type I to enter Insert mode, followed by the text to insert. As you type, the text appears on the first line only.

After you press <Esc> to end the insert, the text will magically be inserted in the rest of the lines contained in the visual selection. Example:

```
include one
include two
include three
include four
```

Move the cursor to the "o" of "one" and press CTRL-V. Move it down with "3j" to "four". You now have a block selection that spans four lines. Now type:

```
Imain.<Esc>
```

The result:

```
include main.one
include main.two
include main.three
include main.four
```

If the block spans short lines that do not extend into the block, the text is not inserted in that line. For example, make a Visual block selection that includes the word "long" in the first and last line of this text, and thus has no text selected in the second line:

```
This is a long line
short
Any other long line

          ^^^^ selected block
```

Now use the command "Ivery <Esc>". The result is:

```
This is a very long line
short
```

```
        Any other very long line
```

In the short line no text was inserted.

If the string you insert contains a newline, the "I" acts just like a Normal insert command and affects only the first line of the block.

The "A" command works the same way, except that it appends after the right side of the block. And it does insert text in a short line. Thus you can make a choice whether you do or don't want to append text to a short line.
   There is one special case for "A": Select a Visual block and then use "$" to make the block extend to the end of each line. Using "A" now will append the text to the end of each line.
   Using the same example from above, and then typing "$A XXX<Esc>, you get this result:

```
        This is a long line XXX
        short XXX
        Any other long line XXX
```

This really requires using the "$" command. Vim remembers that it was used. Making the same selection by moving the cursor to the end of the longest line with other movement commands will not have the same result.

CHANGING TEXT

The Visual block "c" command deletes the block and then throws you into Insert mode to enable you to type in a string. The string will be inserted in each line in the block.
   Starting with the same selection of the "long" words as above, then typing "c_LONG_<Esc>", you get this:

```
        This is a _LONG_ line
        short
        Any other _LONG_ line
```

Just like with "I" the short line is not changed. Also, you can't enter a newline in the new text.

The "C" command deletes text from the left edge of the block to the end of line. It then puts you in Insert mode so that you can type in a string, which is added to the end of each line.
   Starting with the same text again, and typing "Cnew text<Esc>" you get:

```
        This is a new text
        short
        Any other new text
```

Notice that, even though only the "long" word was selected, the text after it is deleted as well. Thus only the location of the left edge of the visual block really matters.
   Again, short lines that do not reach into the block are excluded.

Other commands that change the characters in the block:

```
        ~       swap case       (a -> A and A -> a)
        U       make uppercase  (a -> A and A -> A)
        u       make lowercase  (a -> a and A -> a)
```

FILLING WITH A CHARACTER

To fill the whole block with one character, use the "r" command. Again, starting with the same example text from above, and then typing "rx":

```
        This is a xxxx line
        short
        Any other xxxx line
```

Note:
If you want to include characters beyond the end of the line in the block, check out the 'virtualedit' feature in chapter 25.

SHIFTING

The command ">" shifts the selected text to the right one shift amount, inserting whitespace. The starting point for this shift is the left edge of the visual block.
With the same example again, ">" gives this result:

```
        This is a         long line
        short
        Any other         long line
```

The shift amount is specified with the 'shiftwidth' option. To change it to use 4 spaces:

```
        :set shiftwidth=4
```

The "<" command removes one shift amount of whitespace at the left edge of the block. This command is limited by the amount of text that is there; so if there is less than a shift amount of whitespace available, it removes what it can.

JOINING LINES

The "J" command joins all selected lines together into one line. Thus it removes the line breaks. Actually, the line break, leading white space and trailing white space is replaced by one space. Two spaces are used after a line ending (that can be changed with the 'joinspaces' option).
Let's use the example that we got so familiar with now. The result of using the "J" command:

```
        This is a long line short Any other long line
```

The "J" command doesn't require a blockwise selection. It works with "v" and "V" selection in exactly the same way.

If you don't want the white space to be changed, use the "gJ" command.

==
10.6 Reading and writing part of a file

When you are writing an e-mail message, you may want to include another file. This can be done with the ":read {filename}" command. The text of the file is put below the cursor line.
   Starting with this text:

```
Hi John,
Here is the diff that fixes the bug:
Bye, Pierre.
```

Move the cursor to the second line and type:

```
:read patch
```

The file named "patch" will be inserted, with this result:

```
Hi John,
Here is the diff that fixes the bug:
2c2
<       for (i = 0; i <= length; ++i)
---
>       for (i = 0; i < length; ++i)
Bye, Pierre.
```

The ":read" command accepts a range. The file will be put below the last line number of this range. Thus ":$r patch" appends the file "patch" at the end of the file.
   What if you want to read the file above the first line? This can be done with the line number zero. This line doesn't really exist, you will get an error message when using it with most commands. But this command is allowed:

```
:0read patch
```

The file "patch" will be put above the first line of the file.

WRITING A RANGE OF LINES

To write a range of lines to a file, the ":write" command can be used. Without a range it writes the whole file. With a range only the specified lines are written:

```
:.,$write tempo
```

This writes the lines from the cursor until the end of the file into the file "tempo". If this file already exists you will get an error message. Vim

protects you from accidentally overwriting an existing file. If you know what you are doing and want to overwrite the file, append !:

```
:.,$write! tempo
```

CAREFUL: The ! must follow the ":write" command immediately, without white space. Otherwise it becomes a filter command, which is explained later in this chapter.

APPENDING TO A FILE

In the first section of this chapter was explained how to collect a number of lines into a register. The same can be done to collect lines in a file. Write the first line with this command:

```
:.write collection
```

Now move the cursor to the second line you want to collect, and type this:

```
:.write >>collection
```

The ">>" tells Vim the "collection" file is not to be written as a new file, but the line must be appended at the end. You can repeat this as many times as you like.

==========

10.7 Formatting text

When you are typing plain text, it's nice if the length of each line is automatically trimmed to fit in the window. To make this happen while inserting text, set the 'textwidth' option:

```
:set textwidth=72
```

You might remember that in the example vimrc file this command was used for every text file. Thus if you are using that vimrc file, you were already using it. To check the current value of 'textwidth':

```
:set textwidth
```

Now lines will be broken to take only up to 72 characters. But when you insert text halfway a line, or when you delete a few words, the lines will get too long or too short. Vim doesn't automatically reformat the text.
   To tell Vim to format the current paragraph:

```
gqap
```

This starts with the "gq" command, which is an operator. Following is "ap", the text object that stands for "a paragraph". A paragraph is separated from the next paragraph by an empty line.

```
Note:
A blank line, which contains white space, does NOT separate
```

paragraphs. This is hard to notice!

Instead of "ap" you could use any motion or text object. If your paragraphs are properly separated, you can use this command to format the whole file:

```
gggqG
```

"gg" takes you to the first line, "gq" is the format operator and "G" the motion that jumps to the last line.

In case your paragraphs aren't clearly defined, you can format just the lines you manually select. Move the cursor to the first line you want to format. Start with the command "gqj". This formats the current line and the one below it. If the first line was short, words from the next line will be appended. If it was too long, words will be moved to the next line. The cursor moves to the second line. Now you can use "." to repeat the command. Keep doing this until you are at the end of the text you want to format.

==
10.8 Changing case

You have text with section headers in lowercase. You want to make the word "section" all uppercase. Do this with the "gU" operator. Start with the cursor in the first column:

```
                          gUw
      section header     ---->     SECTION header
```

The "gu" operator does exactly the opposite:

```
                          guw
      SECTION header     ---->     section header
```

You can also use "g~" to swap case. All these are operators, thus they work with any motion command, with text objects and in Visual mode.
   To make an operator work on lines you double it. The delete operator is "d", thus to delete a line you use "dd". Similarly, "gugu" makes a whole line lowercase. This can be shortened to "guu". "gUgU" is shortened to "gUU" and "g~g~" to "g~~". Example:

```
                            g~~
      Some GIRLS have Fun   ---->   sOME girls HAVE fUN
```

==
10.9 Using an external program

Vim has a very powerful set of commands, it can do anything. But there may still be something that an external command can do better or faster.
   The command "!{motion}{program}" takes a block of text and filters it through an external program. In other words, it runs the system command represented by {program}, giving it the block of text represented by {motion} as input. The output of this command then replaces the selected block.
   Because this summarizes badly if you are unfamiliar with UNIX filters, take a look at an example. The sort command sorts a file. If you execute the

following command, the unsorted file input.txt will be sorted and written to output.txt. (This works on both UNIX and Microsoft Windows.)

```
sort <input.txt >output.txt
```

Now do the same thing in Vim. You want to sort lines 1 through 5 of a file. You start by putting the cursor on line 1. Next you execute the following command:

```
!5G
```

The "!" tells Vim that you are performing a filter operation. The Vim editor expects a motion command to follow, indicating which part of the file to filter. The "5G" command tells Vim to go to line 5, so it now knows that it is to filter lines 1 (the current line) through 5.
In anticipation of the filtering, the cursor drops to the bottom of the screen and a ! prompt displays. You can now type in the name of the filter program, in this case "sort". Therefore, your full command is as follows:

```
!5Gsort<Enter>
```

The result is that the sort program is run on the first 5 lines. The output of the program replaces these lines.

```
line 55                      line 11
line 33                      line 22
line 11          -->         line 33
line 22                      line 44
line 44                      line 55
last line                    last line
```

The "!!" command filters the current line through a filter. In Unix the "date" command prints the current time and date. "!!date<Enter>" replaces the current line with the output of "date". This is useful to add a timestamp to a file.

WHEN IT DOESN'T WORK

Starting a shell, sending it text and capturing the output requires that Vim knows how the shell works exactly. When you have problems with filtering, check the values of these options:

'shell'	specifies the program that Vim uses to execute external programs.
'shellcmdflag'	argument to pass a command to the shell
'shellquote'	quote to be used around the command
'shellxquote'	quote to be used around the command and redirection
'shelltype'	kind of shell (only for the Amiga)
'shellslash'	use forward slashes in the command (only for MS-Windows and alikes)
'shellredir'	string used to write the command output into a file

On Unix this is hardly ever a problem, because there are two kinds of shells: "sh" like and "csh" like. Vim checks the 'shell' option and sets related

options automatically, depending on whether it sees "csh" somewhere in 'shell'.
   On MS-Windows, however, there are many different shells and you might have to tune the options to make filtering work. Check the help for the options for more information.

READING COMMAND OUTPUT

To read the contents of the current directory into the file, use this:

on Unix:
        :read !ls
on MS-Windows:
        :read !dir

The output of the "ls" or "dir" command is captured and inserted in the text, below the cursor. This is similar to reading a file, except that the "!" is used to tell Vim that a command follows.
   The command may have arguments. And a range can be used to tell where Vim should put the lines:

        :0read !date -u

This inserts the current time and date in UTC format at the top of the file. (Well, if you have a date command that accepts the "-u" argument.) Note the difference with using "!!date": that replaced a line, while ":read !date" will insert a line.

WRITING TEXT TO A COMMAND

The Unix command "wc" counts words. To count the words in the current file:

        :write !wc

This is the same write command as before, but instead of a file name the "!" character is used and the name of an external command. The written text will be passed to the specified command as its standard input. The output could look like this:

       4   47   249

The "wc" command isn't verbose. This means you have 4 lines, 47 words and 249 characters.

Watch out for this mistake:

        :write! wc

This will write the file "wc" in the current directory, with force. White space is important here!

REDRAWING THE SCREEN

If the external command produced an error message, the display may have been messed up. Vim is very efficient and only redraws those parts of the screen that it knows need redrawing. But it can't know about what another program has written. To tell Vim to redraw the screen:

CTRL-L

Next chapter: usr_11.txt Recovering from a crash

Copyright: see manual-copyright vim:tw=78:ts=8:ft=help:norl:

VIM USER MANUAL - by Bram Moolenaar

Recovering from a crash

Did your computer crash? And you just spent hours editing? Don't panic! Vim stores enough information to be able to restore most of your work. This chapter shows you how to get your work back and explains how the swap file is used.

Next chapter: usr_12.txt Clever tricks
Previous chapter: usr_10.txt Making big changes
Table of contents: usr_toc.txt

11.1 Basic recovery

In most cases recovering a file is quite simple, assuming you know which file you were editing (and the harddisk is still working). Start Vim on the file, with the "-r" argument added:

```
vim -r help.txt
```

Vim will read the swap file (used to store text you were editing) and may read bits and pieces of the original file. If Vim recovered your changes you will see these messages (with different file names, of course):

```
Using swap file ".help.txt.swp"
Original file "~/vim/runtime/doc/help.txt"
Recovery completed. You should check if everything is OK.
(You might want to write out this file under another name
and run diff with the original file to check for changes)
You may want to delete the .swp file now.
```

To be on the safe side, write this file under another name:

```
:write help.txt.recovered
```

Compare the file with the original file to check if you ended up with what you expected. Vimdiff is very useful for this 08.7 . For example:

```
:write help.txt.recovered
:edit #
:diffsp help.txt
```

Watch out for the original file to contain a more recent version (you saved the file just before the computer crashed). And check that no lines are

missing (something went wrong that Vim could not recover).
   If Vim produces warning messages when recovering, read them carefully.
This is rare though.

If the recovery resulted in text that is exactly the same as the file
contents, you will get this message:

```
Using swap file ".help.txt.swp"
Original file "~/vim/runtime/doc/help.txt"
Recovery completed. Buffer contents equals file contents.
You may want to delete the .swp file now.
```

This usually happens if you already recovered your changes, or you wrote the
file after making changes. It is safe to delete the swap file now.

It is normal that the last few changes can not be recovered. Vim flushes the
changes to disk when you don't type for about four seconds, or after typing
about two hundred characters. This is set with the 'updatetime' and
'updatecount' options. Thus when Vim didn't get a chance to save itself when
the system went down, the changes after the last flush will be lost.

If you were editing without a file name, give an empty string as argument:

```
vim -r ""
```

You must be in the right directory, otherwise Vim can't find the swap file.

==
11.2 Where is the swap file?

Vim can store the swap file in several places. Normally it is in the same
directory as the original file. To find it, change to the directory of the
file, and use:

```
vim -r
```

Vim will list the swap files that it can find. It will also look in other
directories where the swap file for files in the current directory may be
located. It will not find swap files in any other directories though, it
doesn't search the directory tree.
   The output could look like this:

```
Swap files found:
   In current directory:
1.    .main.c.swp
          owned by: mool   dated: Tue May 29 21:00:25 2001
        file name: ~mool/vim/vim6/src/main.c
         modified: YES
        user name: mool   host name: masaka.moolenaar.net
      process ID: 12525
   In directory ~/tmp:
      -- none --
   In directory /var/tmp:
      -- none --
```

```
           In directory /tmp:
              -- none --
```

If there are several swap files that look like they may be the one you want to use, a list is given of these swap files and you are requested to enter the number of the one you want to use. Carefully look at the dates to decide which one you want to use.
In case you don't know which one to use, just try them one by one and check the resulting files if they are what you expected.

USING A SPECIFIC SWAP FILE

If you know which swap file needs to be used, you can recover by giving the swap file name. Vim will then finds out the name of the original file from the swap file.

Example:
```
vim -r .help.txt.swo
```

This is also handy when the swap file is in another directory than expected. Vim recognizes files with the pattern *.s[uvw][a-z] as swap files.

If this still does not work, see what file names Vim reports and rename the files accordingly. Check the 'directory' option to see where Vim may have put the swap file.

Note:
Vim tries to find the swap file by searching the directories in the 'dir' option, looking for files that match "filename.sw?". If wildcard expansion doesn't work (e.g., when the 'shell' option is invalid), Vim does a desperate try to find the file "filename.swp". If that fails too, you will have to give the name of the swapfile itself to be able to recover the file.

==
11.3 Crashed or not? ATTENTION E325

Vim tries to protect you from doing stupid things. Suppose you innocently start editing a file, expecting the contents of the file to show up. Instead, Vim produces a very long message:

```
              E325: ATTENTION
       Found a swap file by the name ".main.c.swp"
                 owned by: mool   dated: Tue May 29 21:09:28 2001
                file name: ~mool/vim/vim6/src/main.c
                 modified: no
                user name: mool   host name: masaka.moolenaar.net
               process ID: 12559 (still running)
       While opening file "main.c"
                    dated: Tue May 29 19:46:12 2001

       (1) Another program may be editing the same file.
           If this is the case, be careful not to end up with two
```

```
            different instances of the same file when making changes.
            Quit, or continue with caution.

         (2) An edit session for this file crashed.
             If this is the case, use ":recover" or "vim -r main.c"
             to recover the changes (see ":help recovery").
             If you did this already, delete the swap file ".main.c.swp"
             to avoid this message.
```

You get this message, because, when starting to edit a file, Vim checks if a swap file already exists for that file. If there is one, there must be something wrong. It may be one of these two situations.

1. Another edit session is active on this file. Look in the message for the line with "process ID". It might look like this:

```
                process ID: 12559 (still running)
```

   The text "(still running)" indicates that the process editing this file runs on the same computer. When working on a non-Unix system you will not get this extra hint. When editing a file over a network, you may not see the hint, because the process might be running on another computer. In those two cases you must find out what the situation is yourself.
      If there is another Vim editing the same file, continuing to edit will result in two versions of the same file. The one that is written last will overwrite the other one, resulting in loss of changes. You better quit this Vim.

2. The swap file might be the result from a previous crash of Vim or the computer. Check the dates mentioned in the message. If the date of the swap file is newer than the file you were editing, and this line appears:

```
                modified: YES
```

   Then you very likely have a crashed edit session that is worth recovering.
      If the date of the file is newer than the date of the swap file, then either it was changed after the crash (perhaps you recovered it earlier, but didn't delete the swap file?), or else the file was saved before the crash but after the last write of the swap file (then you're lucky: you don't even need that old swap file). Vim will warn you for this with this extra line:

```
      NEWER than swap file!
```

UNREADABLE SWAP FILE

Sometimes the line

```
        [cannot be read]
```

will appear under the name of the swap file. This can be good or bad, depending on circumstances.

It is good if a previous editing session crashed without having made any changes to the file. Then a directory listing of the swap file will show that it has zero bytes. You may delete it and proceed.

It is slightly bad if you don't have read permission for the swap file. You may want to view the file read-only, or quit. On multi-user systems, if you yourself did the last changes under a different login name, a logout followed by a login under that other name might cure the "read error". Or else you might want to find out who last edited (or is editing) the file and have a talk with them.

It is very bad if it means there is a physical read error on the disk containing the swap file. Fortunately, this almost never happens.
You may want to view the file read-only at first (if you can), to see the extent of the changes that were "forgotten". If you are the one in charge of that file, be prepared to redo your last changes.

WHAT TO DO? swap-exists-choices

If dialogs are supported you will be asked to select one of six choices:

```
Swap file ".main.c.swp" already exists!
[O]pen Read-Only, (E)dit anyway, (R)ecover, (Q)uit, (A)bort, (D)elete it:
```

O Open the file readonly. Use this when you just want to view the file and don't need to recover it. You might want to use this when you know someone else is editing the file, but you just want to look in it and not make changes.

E Edit the file anyway. Use this with caution! If the file is being edited in another Vim, you might end up with two versions of the file. Vim will try to warn you when this happens, but better be safe then sorry.

R Recover the file from the swap file. Use this if you know that the swap file contains changes that you want to recover.

Q Quit. This avoids starting to edit the file. Use this if there is another Vim editing the same file.
   When you just started Vim, this will exit Vim. When starting Vim with files in several windows, Vim quits only if there is a swap file for the first one. When using an edit command, the file will not be loaded and you are taken back to the previously edited file.

A Abort. Like Quit, but also abort further commands. This is useful when loading a script that edits several files, such as a session with multiple windows.

D Delete the swap file. Use this when you are sure you no longer need it. For example, when it doesn't contain changes, or when the file itself is newer than the swap file.
   On Unix this choice is only offered when the process that created the swap file does not appear to be running.

If you do not get the dialog (you are running a version of Vim that does not support it), you will have to do it manually. To recover the file, use this command:

```
:recover
```

Vim cannot always detect that a swap file already exists for a file. This is the case when the other edit session puts the swap files in another directory or when the path name for the file is different when editing it on different machines. Therefore, don't rely on Vim always warning you.

If you really don't want to see this message, you can add the 'A' flag to the 'shortmess' option. But it's very unusual that you need this.

For remarks about encryption and the swap file, see :recover-crypt .

==

11.4 Further reading

swap-file	An explanation about where the swap file will be created and what its name is.
:preserve	Manually flushing the swap file to disk.
:swapname	See the name of the swap file for the current file.
'updatecount'	Number of key strokes after which the swap file is flushed to disk.
'updatetime'	Timeout after which the swap file is flushed to disk.
'swapsync'	Whether the disk is synced when the swap file is flushed.
'directory'	List of directory names where to store the swap file.
'maxmem'	Limit for memory usage before writing text to the swap file.
'maxmemtot'	Same, but for all files in total.

VIM USER MANUAL - by Bram Moolenaar

Clever tricks

By combining several commands you can make Vim do nearly everything. In this chapter a number of useful combinations will be presented. This uses the commands introduced in the previous chapters and a few more.

Next chapter: usr_20.txt Typing command-line commands quickly
Previous chapter: usr_11.txt Recovering from a crash
Table of contents: usr_toc.txt

==========

12.1 Replace a word

The substitute command can be used to replace all occurrences of a word with another word:

```
:%s/four/4/g
```

The "%" range means to replace in all lines. The "g" flag at the end causes all words in a line to be replaced.
This will not do the right thing if your file also contains "thirtyfour". It would be replaced with "thirty4". To avoid this, use the "\<" item to match the start of a word:

```
:%s/\<four/4/g
```

Obviously, this still goes wrong on "fourteen". Use "\>" to match the end of a word:

```
:%s/\<four\>/4/g
```

If you are programming, you might want to replace "four" in comments, but not in the code. Since this is difficult to specify, add the "c" flag to have the substitute command prompt you for each replacement:

```
:%s/\<four\>/4/gc
```

REPLACING IN SEVERAL FILES

Suppose you want to replace a word in more than one file. You could edit each file and type the command manually. It's a lot faster to use record and playback.
   Let's assume you have a directory with C++ files, all ending in ".cpp". There is a function called "GetResp" that you want to rename to "GetAnswer".

```
        vim *.cpp               Start Vim, defining the argument list to
                                contain all the C++ files.  You are now in the
                                first file.
        qq                      Start recording into the q register
        :%s/\<GetResp\>/GetAnswer/g
                                Do the replacements in the first file.
        :wnext                  Write this file and move to the next one.
        q                       Stop recording.
        @q                      Execute the q register.  This will replay the
                                substitution and ":wnext".  You can verify
                                that this doesn't produce an error message.
        999@q                   Execute the q register on the remaining files.
```

At the last file you will get an error message, because ":wnext" cannot move to the next file. This stops the execution, and everything is done.

        Note:
        When playing back a recorded sequence, an error stops the execution.
        Therefore, make sure you don't get an error message when recording.

There is one catch: If one of the .cpp files does not contain the word "GetResp", you will get an error and replacing will stop. To avoid this, add the "e" flag to the substitute command:

```
        :%s/\<GetResp\>/GetAnswer/ge
```

The "e" flag tells ":substitute" that not finding a match is not an error.

==

12.2 Change "Last, First" to "First Last"

You have a list of names in this form:

```
        Doe, John
        Smith, Peter
```

You want to change that to:

```
        John Doe
        Peter Smith
```

This can be done with just one command:

```
        :%s/\([^,]*\), \(.*\)/\2 \1/
```

Let's break this down in parts. Obviously it starts with a substitute command. The "%" is the line range, which stands for the whole file. Thus

the substitution is done in every line in the file.
   The arguments for the substitute command are "/from/to/". The slashes separate the "from" pattern and the "to" string. This is what the "from" pattern contains:

```
                                                    \([^,]*\), \(.*\)

        The first part between \( \) matches "Last"     \(     \)
            match anything but a comma                    [^,]
            any number of times                               *
        matches ", " literally                                   ,
        The second part between \( \) matches "First"                \(  \)
            any character                                              .
            any number of times                                         *
```

In the "to" part we have "\2" and "\1". These are called backreferences. They refer to the text matched by the "\(\)" parts in the pattern. "\2" refers to the text matched by the second "\(\)", which is the "First" name. "\1" refers to the first "\(\)", which is the "Last" name.
   You can use up to nine backreferences in the "to" part of a substitute command. "\0" stands for the whole matched pattern. There are a few more special items in a substitute command, see sub-replace-special .

==========

12.3 Sort a list

In a Makefile you often have a list of files. For example:

```
        OBJS = \
                version.o \
                pch.o \
                getopt.o \
                util.o \
                getopt1.o \
                inp.o \
                patch.o \
                backup.o
```

To sort this list, filter the text through the external sort command:

```
        /^OBJS
        j
        :.,/^$/-1!sort
```

This goes to the first line, where "OBJS" is the first thing in the line. Then it goes one line down and filters the lines until the next empty line. You could also select the lines in Visual mode and then use "!sort". That's easier to type, but more work when there are many lines.
   The result is this:

```
        OBJS = \
                backup.o
                getopt.o \
                getopt1.o \
                inp.o \
```

```
		patch.o \
		pch.o \
		util.o \
		version.o \
```

Notice that a backslash at the end of each line is used to indicate the line continues. After sorting, this is wrong! The "backup.o" line that was at the end didn't have a backslash. Now that it sorts to another place, it must have a backslash.

The simplest solution is to add the backslash with "A \<Esc>". You can keep the backslash in the last line, if you make sure an empty line comes after it. That way you don't have this problem again.

12.4 Reverse line order

The :global command can be combined with the :move command to move all the lines before the first line, resulting in a reversed file. The command is:

```
:global/^/m 0
```

Abbreviated:

```
:g/^/m 0
```

The "^" regular expression matches the beginning of the line (even if the line is blank). The :move command moves the matching line to after the mythical zeroth line, so the current matching line becomes the first line of the file. As the :global command is not confused by the changing line numbering, :global proceeds to match all remaining lines of the file and puts each as the first.

This also works on a range of lines. First move to above the first line and mark it with "mt". Then move the cursor to the last line in the range and type:

```
:'t+1,.g/^/m 't
```

12.5 Count words

Sometimes you have to write a text with a maximum number of words. Vim can count the words for you.

When the whole file is what you want to count the words in, use this command:

```
g CTRL-G
```

Do not type a space after the g, this is just used here to make the command easy to read.

The output looks like this:

```
Col 1 of 0; Line 141 of 157; Word 748 of 774; Byte 4489 of 4976
```

You can see on which word you are (748), and the total number of words in the file (774).

When the text is only part of a file, you could move to the start of the text, type "g CTRL-G", move to the end of the text, type "g CTRL-G" again, and then use your brain to compute the difference in the word position. That's a good exercise, but there is an easier way. With Visual mode, select the text you want to count words in. Then type g CTRL-G. The result:

```
Selected 5 of 293 Lines; 70 of 1884 Words; 359 of 10928 Bytes
```

For other ways to count words, lines and other items, see count-items .

==

12.6 Find a man page find-manpage

While editing a shell script or C program, you are using a command or function that you want to find the man page for (this is on Unix). Let's first use a simple way: Move the cursor to the word you want to find help on and press

```
K
```

Vim will run the external "man" program on the word. If the man page is found, it is displayed. This uses the normal pager to scroll through the text (mostly the "more" program). When you get to the end pressing <Enter> will get you back into Vim.

A disadvantage is that you can't see the man page and the text you are working on at the same time. There is a trick to make the man page appear in a Vim window. First, load the man filetype plugin:

```
:runtime! ftplugin/man.vim
```

Put this command in your vimrc file if you intend to do this often. Now you can use the ":Man" command to open a window on a man page:

```
:Man csh
```

You can scroll around and the text is highlighted. This allows you to find the help you were looking for. Use CTRL-W w to jump to the window with the text you were working on.

To find a man page in a specific section, put the section number first. For example, to look in section 3 for "echo":

```
:Man 3 echo
```

To jump to another man page, which is in the text with the typical form "word(1)", press CTRL-] on it. Further ":Man" commands will use the same window.

To display a man page for the word under the cursor, use this:

```
\K
```

(If you redefined the <Leader>, use it instead of the backslash).
For example, you want to know the return value of "strstr()" while editing
this line:

```
	if ( strstr (input, "aap") == )
```

Move the cursor to somewhere on "strstr" and type "\K". A window will open
to display the man page for strstr().

==
12.7 Trim blanks

Some people find spaces and tabs at the end of a line useless, wasteful, and
ugly. To remove whitespace at the end of every line, execute the following
command:

```
	:%s/\s\+$//
```

The line range "%" is used, thus this works on the whole file. The pattern
that the ":substitute" command matches with is "\s\+$". This finds white
space characters (\s), 1 or more of them (\+), before the end-of-line ($).
Later will be explained how you write patterns like this, see usr_27.txt .
   The "to" part of the substitute command is empty: "//". Thus it replaces
with nothing, effectively deleting the matched white space.

Another wasteful use of spaces is placing them before a tab. Often these can
be deleted without changing the amount of white space. But not always!
Therefore, you can best do this manually. Use this search command:

```
	/
```

You cannot see it, but there is a space before a tab in this command. Thus
it's "/<Space><Tab>".   Now use "x" to delete the space and check that the
amount of white space doesn't change. You might have to insert a tab if it
does change. Type "n" to find the next match. Repeat this until no more
matches can be found.

==
12.8 Find where a word is used

If you are a UNIX user, you can use a combination of Vim and the grep command
to edit all the files that contain a given word. This is extremely useful if
you are working on a program and want to view or edit all the files that
contain a specific variable.
   For example, suppose you want to edit all the C program files that contain
the word "frame_counter". To do this you use the command:

```
	vim `grep -l frame_counter *.c`
```

Let's look at this command in detail. The grep command searches through a set
of files for a given word. Because the -l argument is specified, the command
will only list the files containing the word and not print the matching lines.
The word it is searching for is "frame_counter". Actually, this can be any

regular expression. (Note: What grep uses for regular expressions is not exactly the same as what Vim uses.)
   The entire command is enclosed in backticks (`). This tells the UNIX shell to run this command and pretend that the results were typed on the command line. So what happens is that the grep command is run and produces a list of files, these files are put on the Vim command line. This results in Vim editing the file list that is the output of grep. You can then use commands like ":next" and ":first" to browse through the files.

FINDING EACH LINE

The above command only finds the files in which the word is found. You still have to find the word within the files.
   Vim has a built-in command that you can use to search a set of files for a given string. If you want to find all occurrences of "error_string" in all C program files, for example, enter the following command:

```
:grep error_string *.c
```

This causes Vim to search for the string "error_string" in all the specified files (*.c). The editor will now open the first file where a match is found and position the cursor on the first matching line. To go to the next matching line (no matter in what file it is), use the ":cnext" command. To go to the previous match, use the ":cprev" command. Use ":clist" to see all the matches and where they are.
   The ":grep" command uses the external commands grep (on Unix) or findstr (on Windows). You can change this by setting the option 'grepprg'.

   vim:tw=78:ts=8:ft=help:norl:

usr_20.txt For Vim version 8.1. Last change: 2006 Apr 24

VIM USER MANUAL - by Bram Moolenaar

Typing command-line commands quickly

Vim has a few generic features that makes it easier to enter commands. Colon commands can be abbreviated, edited and repeated. Completion is available for nearly everything.

Next chapter: usr_21.txt Go away and come back
Previous chapter: usr_12.txt Clever tricks
Table of contents: usr_toc.txt

==========

20.1 Command line editing

When you use a colon (:) command or search for a string with / or ?, Vim puts the cursor on the bottom of the screen. There you type the command or search pattern. This is called the Command line. Also when it's used for entering a search command.

The most obvious way to edit the command you type is by pressing the <BS> key. This erases the character before the cursor. To erase another character, typed earlier, first move the cursor with the cursor keys.
For example, you have typed this:

```
:s/col/pig/
```

Before you hit <Enter>, you notice that "col" should be "cow". To correct this, you type <Left> five times. The cursor is now just after "col". Type <BS> and "w" to correct:

```
:s/cow/pig/
```

Now you can press <Enter> directly. You don't have to move the cursor to the end of the line before executing the command.

The most often used keys to move around in the command line:

<Left>	one character left
<Right>	one character right
<S-Left> or <C-Left>	one word left
<S-Right> or <C-Right>	one word right
CTRL-B or <Home>	to begin of command line
CTRL-E or <End>	to end of command line

Note:
<S-Left> (cursor left key with Shift key pressed) and <C-Left> (cursor left key with Control pressed) will not work on all keyboards. Same for the other Shift and Control combinations.

You can also use the mouse to move the cursor.

DELETING

As mentioned, <BS> deletes the character before the cursor. To delete a whole word use CTRL-W.

```
/the fine pig
```

CTRL-W

```
/the fine
```

CTRL-U removes all text, thus allows you to start all over again.

OVERSTRIKE

The <Insert> key toggles between inserting characters and replacing the existing ones. Start with this text:

```
/the fine pig
```

Move the cursor to the start of "fine" with <S-Left> twice (or <Left> eight times, if <S-Left> doesn't work). Now press <Insert> to switch to overstrike and type "great":

```
/the greatpig
```

Oops, we lost the space. Now, don't use <BS>, because it would delete the "t" (this is different from Replace mode). Instead, press <Insert> to switch from overstrike to inserting, and type the space:

```
/the great pig
```

CANCELLING

You thought of executing a : or / command, but changed your mind. To get rid of what you already typed, without executing it, press CTRL-C or <Esc>.

Note:
<Esc> is the universal "get out" key. Unfortunately, in the good old Vi pressing <Esc> in a command line executed the command! Since that might be considered to be a bug, Vim uses <Esc> to cancel the command. But with the 'cpoptions' option it can be made Vi compatible. And when using a mapping (which might be written for Vi) <Esc> also works Vi compatible. Therefore, using CTRL-C is a method that always works.

If you are at the start of the command line, pressing <BS> will cancel the command. It's like deleting the ":" or "/" that the line starts with.

==
20.2 Command line abbreviations

Some of the ":" commands are really long. We already mentioned that ":substitute" can be abbreviated to ":s". This is a generic mechanism, all ":" commands can be abbreviated.

How short can a command get? There are 26 letters, and many more commands. For example, ":set" also starts with ":s", but ":s" doesn't start a ":set" command. Instead ":set" can be abbreviated to ":se".
   When the shorter form of a command could be used for two commands, it stands for only one of them. There is no logic behind which one, you have to learn them. In the help files the shortest form that works is mentioned. For example:

```
:s[ubstitute]
```

This means that the shortest form of ":substitute" is ":s". The following characters are optional. Thus ":su" and ":sub" also work.

In the user manual we will either use the full name of command, or a short version that is still readable. For example, ":function" can be abbreviated to ":fu". But since most people don't understand what that stands for, we will use ":fun". (Vim doesn't have a ":funny" command, otherwise ":fun" would be confusing too.)

It is recommended that in Vim scripts you write the full command name. That makes it easier to read back when you make later changes. Except for some often used commands like ":w" (":write") and ":r" (":read").
   A particularly confusing one is ":end", which could stand for ":endif", ":endwhile" or ":endfunction". Therefore, always use the full name.

SHORT OPTION NAMES

In the user manual the long version of the option names is used. Many options also have a short name. Unlike ":" commands, there is only one short name that works. For example, the short name of 'autoindent' is 'ai'. Thus these two commands do the same thing:

```
:set autoindent
:set ai
```

You can find the full list of long and short names here: option-list .

==
20.3 Command line completion

This is one of those Vim features that, by itself, is a reason to switch from Vi to Vim. Once you have used this, you can't do without.

Suppose you have a directory that contains these files:

```
	info.txt
	intro.txt
	bodyofthepaper.txt
```

To edit the last one, you use the command:

```
	:edit bodyofthepaper.txt
```

It's easy to type this wrong. A much quicker way is:

```
	:edit b<Tab>
```

Which will result in the same command. What happened? The <Tab> key does completion of the word before the cursor. In this case "b". Vim looks in the directory and finds only one file that starts with a "b". That must be the one you are looking for, thus Vim completes the file name for you.

Now type:

```
	:edit i<Tab>
```

Vim will beep, and give you:

```
	:edit info.txt
```

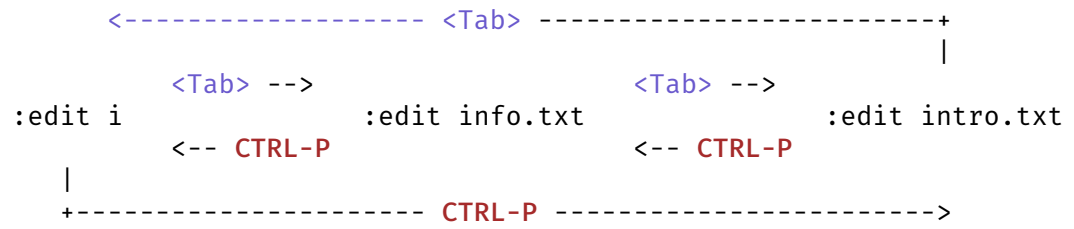
The beep means that Vim has found more than one match. It then uses the first match it found (alphabetically). If you press <Tab> again, you get:

```
	:edit intro.txt
```

Thus, if the first <Tab> doesn't give you the file you were looking for, press it again. If there are more matches, you will see them all, one at a time.
   If you press <Tab> on the last matching entry, you will go back to what you first typed:

```
	:edit i
```

Then it starts all over again. Thus Vim cycles through the list of matches.
Use CTRL-P to go through the list in the other direction:



CONTEXT

When you type ":set i" instead of ":edit i" and press <Tab> you get:

```
:set icon
```

Hey, why didn't you get ":set info.txt"? That's because Vim has context sensitive completion. The kind of words Vim will look for depends on the command before it. Vim knows that you cannot use a file name just after a ":set" command, but you can use an option name.
   Again, if you repeat typing the <Tab>, Vim will cycle through all matches. There are quite a few, it's better to type more characters first:

```
:set isk<Tab>
```

Gives:

```
:set iskeyword
```

Now type "=" and press <Tab>:

```
:set iskeyword=@,48-57,_,192-255
```

What happens here is that Vim inserts the old value of the option. Now you can edit it.
   What is completed with <Tab> is what Vim expects in that place. Just try it out to see how it works. In some situations you will not get what you want. That's either because Vim doesn't know what you want, or because completion was not implemented for that situation. In that case you will get a <Tab> inserted (displayed as ^I).

LIST MATCHES

When there are many matches, you would like to see an overview. Do this by pressing CTRL-D. For example, pressing CTRL-D after:

```
:set is
```

results in:

```
:set is
incsearch  isfname    isident    iskeyword  isprint
:set is
```

Vim lists the matches and then comes back with the text you typed. You can now check the list for the item you wanted. If it isn't there, you can use <BS> to correct the word. If there are many matches, type a few more characters before pressing <Tab> to complete the rest.
   If you have watched carefully, you will have noticed that "incsearch" doesn't start with "is". In this case "is" stands for the short name of "incsearch". (Many options have a short and a long name.) Vim is clever enough to know that you might have wanted to expand the short name of the option into the long name.

THERE IS MORE

The CTRL-L command completes the word to the longest unambiguous string. If you type ":edit i" and there are files "info.txt" and "info_backup.txt" you will get ":edit info".

The 'wildmode' option can be used to change the way completion works.
The 'wildmenu' option can be used to get a menu-like list of matches.
Use the 'suffixes' option to specify files that are less important and appear at the end of the list of files.
The 'wildignore' option specifies files that are not listed at all.

More about all of this here: cmdline-completion

==
20.4 Command line history

In chapter 3 we briefly mentioned the history. The basics are that you can use the <Up> key to recall an older command line. <Down> then takes you back to newer commands.

There are actually four histories. The ones we will mention here are for ":" commands and for "/" and "?" search commands. The "/" and "?" commands share the same history, because they are both search commands. The two other histories are for expressions and input lines for the input() function.
cmdline-history

Suppose you have done a ":set" command, typed ten more colon commands and then want to repeat that ":set" command again. You could press ":" and then ten times <Up>. There is a quicker way:

```
:se<Up>
```

Vim will now go back to the previous command that started with "se". You have a good chance that this is the ":set" command you were looking for. At least you should not have to press <Up> very often (unless ":set" commands is all you have done).

The <Up> key will use the text typed so far and compare it with the lines in the history. Only matching lines will be used.
If you do not find the line you were looking for, use <Down> to go back to what you typed and correct that. Or use CTRL-U to start all over again.

To see all the lines in the history:

```
:history
```

That's the history of ":" commands. The search history is displayed with this command:

```
:history /
```

CTRL-P will work like <Up>, except that it doesn't matter what you already typed. Similarly for CTRL-N and <Down>. CTRL-P stands for previous, CTRL-N

for next.

==
20.5 Command line window

Typing the text in the command line works different from typing text in Insert mode. It doesn't allow many commands to change the text. For most commands that's OK, but sometimes you have to type a complicated command. That's where the command line window is useful.

Open the command line window with this command:

```
q:
```

Vim now opens a (small) window at the bottom. It contains the command line history, and an empty line at the end:

```
+--------------------------------------+
|other window                          |
|~                                     |
 file.txt============================
|:e c                                  |
|:e config.h.in                        |
|:set path=.,/usr/include,,            |
|:set iskeyword=@,48-57,_,192-255      |
|:set is                               |
|:q                                    |
|:                                     |
 command-line========================
|                                      |
+--------------------------------------+
```

You are now in Normal mode. You can use the "hjkl" keys to move around. For example, move up with "5k" to the ":e config.h.in" line. Type "$h" to go to the "i" of "in" and type "cwout". Now you have changed the line to:

```
:e config.h.out
```

Now press <Enter> and this command will be executed. The command line window will close.

The <Enter> command will execute the line under the cursor. It doesn't matter whether Vim is in Insert mode or in Normal mode.

Changes in the command line window are lost. They do not result in the history to be changed. Except that the command you execute will be added to the end of the history, like with all executed commands.

The command line window is very useful when you want to have overview of the history, lookup a similar command, change it a bit and execute it. A search command can be used to find something.

In the previous example the "?config" search command could have been used to find the previous command that contains "config". It's a bit strange, because you are using a command line to search in the command line window. While typing that search command you can't open another command line window, there can be only one.

VIM USER MANUAL - by Bram Moolenaar

Go away and come back

This chapter goes into mixing the use of other programs with Vim. Either by executing program from inside Vim or by leaving Vim and coming back later. Furthermore, this is about the ways to remember the state of Vim and restore it later.

Next chapter: usr_22.txt Finding the file to edit
Previous chapter: usr_20.txt Typing command-line commands quickly
Table of contents: usr_toc.txt

21.1 Suspend and resume

Like most Unix programs Vim can be suspended by pressing CTRL-Z. This stops Vim and takes you back to the shell it was started in. You can then do any other commands until you are bored with them. Then bring back Vim with the "fg" command.

```
CTRL-Z
{any sequence of shell commands}
fg
```

You are right back where you left Vim, nothing has changed.
In case pressing CTRL-Z doesn't work, you can also use ":suspend". Don't forget to bring Vim back to the foreground, you would lose any changes that you made!

Only Unix has support for this. On other systems Vim will start a shell for you. This also has the functionality of being able to execute shell commands. But it's a new shell, not the one that you started Vim from.
When you are running the GUI you can't go back to the shell where Vim was started. CTRL-Z will minimize the Vim window instead.

21.2 Executing shell commands

To execute a single shell command from Vim use ":!{command}". For example, to see a directory listing:

```
:!ls
:!dir
```

The first one is for Unix, the second one for MS-Windows.
   Vim will execute the program. When it ends you will get a prompt to hit <Enter>. This allows you to have a look at the output from the command before returning to the text you were editing.
   The "!" is also used in other places where a program is run. Let's take a look at an overview:

```
:!{program}             execute {program}
:r !{program}           execute {program} and read its output
:w !{program}           execute {program} and send text to its input
:[range]!{program}      filter text through {program}
```

Notice that the presence of a range before "!{program}" makes a big difference. Without it executes the program normally, with the range a number of text lines is filtered through the program.

Executing a whole row of programs this way is possible. But a shell is much better at it. You can start a new shell this way:

```
:shell
```

This is similar to using CTRL-Z to suspend Vim. The difference is that a new shell is started.

When using the GUI the shell will be using the Vim window for its input and output. Since Vim is not a terminal emulator, this will not work perfectly. If you have trouble, try toggling the 'guipty' option. If this still doesn't work well enough, start a new terminal to run the shell in. For example with:

```
:!xterm&
```

21.3 Remembering information; viminfo

After editing for a while you will have text in registers, marks in various files, a command line history filled with carefully crafted commands. When you exit Vim all of this is lost. But you can get it back!

The viminfo file is designed to store status information:

```
Command-line and Search pattern history
Text in registers
Marks for various files
The buffer list
Global variables
```

Each time you exit Vim it will store this information in a file, the viminfo file. When Vim starts again, the viminfo file is read and the information restored.

The 'viminfo' option is set by default to restore a limited number of items. You might want to set it to remember more information. This is done through the following command:

```
:set viminfo=string
```

The string specifies what to save. The syntax of this string is an option character followed by an argument. The option/argument pairs are separated by commas.

Take a look at how you can build up your own viminfo string. First, the ' option is used to specify how many files for which you save marks (a-z). Pick a nice even number for this option (1000, for instance). Your command now looks like this:

```
:set viminfo='1000
```

The f option controls whether global marks (A-Z and 0-9) are stored. If this option is 0, none are stored. If it is 1 or you do not specify an f option, the marks are stored. You want this feature, so now you have this:

```
:set viminfo='1000,f1
```

The < option controls how many lines are saved for each of the registers. By default, all the lines are saved. If 0, nothing is saved. To avoid adding thousands of lines to your viminfo file (which might never get used and makes starting Vim slower) you use a maximum of 500 lines:

```
:set viminfo='1000,f1,<500
```

Other options you might want to use:

```
:       number of lines to save from the command line history
@       number of lines to save from the input line history
/       number of lines to save from the search history
r       removable media, for which no marks will be stored (can be
        used several times)
!       global variables that start with an uppercase letter and
        don't contain lowercase letters
h       disable 'hlsearch' highlighting when starting
%       the buffer list (only restored when starting Vim without file
        arguments)
c       convert the text using 'encoding'
n       name used for the viminfo file (must be the last option)
```

See the 'viminfo' option and viminfo-file for more information.

When you run Vim multiple times, the last one exiting will store its information. This may cause information that previously exiting Vims stored to be lost. Each item can be remembered only once.

GETTING BACK TO WHERE YOU STOPPED VIM

You are halfway editing a file and it's time to leave for holidays. You exit Vim and go enjoy yourselves, forgetting all about your work. After a couple of weeks you start Vim, and type:

```
'0
```

And you are right back where you left Vim. So you can get on with your work.
   Vim creates a mark each time you exit Vim. The last one is '0. The position that '0 pointed to is made '1. And '1 is made to '2, and so forth. Mark '9 is lost.
   The :marks command is useful to find out where '0 to '9 will take you.

GETTING BACK TO SOME FILE

If you want to go back to a file that you edited recently, but not when exiting Vim, there is a slightly more complicated way. You can see a list of files by typing the command:

```
:oldfiles
1: ~/.viminfo
2: ~/text/resume.txt
3: /tmp/draft
```

Now you would like to edit the second file, which is in the list preceded by "2:". You type:

```
:e #<2
```

Instead of ":e" you can use any command that has a file name argument, the "#<2" item works in the same place as "%" (current file name) and "#" (alternate file name). So you can also split the window to edit the third file:

```
:split #<3
```

That #<123 thing is a bit complicated when you just want to edit a file. Fortunately there is a simpler way:

```
:browse oldfiles
1: ~/.viminfo
2: ~/text/resume.txt
3: /tmp/draft
-- More --
```

You get the same list of files as with :oldfiles . If you want to edit "resume.txt" first press "q" to stop the listing. You will get a prompt:

```
Type number and <Enter> (empty cancels):
```

Type "2" and press <Enter> to edit the second file.

More info at :oldfiles , v:oldfiles and c_#< .

MOVE INFO FROM ONE VIM TO ANOTHER

You can use the ":wviminfo" and ":rviminfo" commands to save and restore the information while still running Vim. This is useful for exchanging register

contents between two instances of Vim, for example. In the first Vim do:

```
:wviminfo! ~/tmp/viminfo
```

And in the second Vim do:

```
:rviminfo! ~/tmp/viminfo
```

Obviously, the "w" stands for "write" and the "r" for "read".
   The ! character is used by ":wviminfo" to forcefully overwrite an existing file. When it is omitted, and the file exists, the information is merged into the file.
   The ! character used for ":rviminfo" means that all the information is used, this may overwrite existing information. Without the ! only information that wasn't set is used.
   These commands can also be used to store info and use it again later. You could make a directory full of viminfo files, each containing info for a different purpose.

==
21.4 Sessions

Suppose you are editing along, and it is the end of the day. You want to quit work and pick up where you left off the next day. You can do this by saving your editing session and restoring it the next day.
   A Vim session contains all the information about what you are editing. This includes things such as the file list, window layout, global variables, options and other information. (Exactly what is remembered is controlled by the 'sessionoptions' option, described below.)
   The following command creates a session file:

```
:mksession vimbook.vim
```

Later if you want to restore this session, you can use this command:

```
:source vimbook.vim
```

If you want to start Vim and restore a specific session, you can use the following command:

```
vim -S vimbook.vim
```

This tells Vim to read a specific file on startup. The 'S' stands for session (actually, you can source any Vim script with -S, thus it might as well stand for "source").

The windows that were open are restored, with the same position and size as before. Mappings and option values are like before.
   What exactly is restored depends on the 'sessionoptions' option. The default value is "blank,buffers,curdir,folds,help,options,winsize".

```
blank           keep empty windows
buffers         all buffers, not only the ones in a window
curdir          the current directory
```

```
        folds           folds, also manually created ones
        help            the help window
        options         all options and mappings
        winsize         window sizes
```

Change this to your liking. To also restore the size of the Vim window, for example, use:

```
        :set sessionoptions+=resize
```

SESSION HERE, SESSION THERE

The obvious way to use sessions is when working on different projects. Suppose you store your session files in the directory "~/.vim". You are currently working on the "secret" project and have to switch to the "boring" project:

```
        :wall
        :mksession! ~/.vim/secret.vim
        :source ~/.vim/boring.vim
```

This first uses ":wall" to write all modified files. Then the current session is saved, using ":mksession!". This overwrites the previous session. The next time you load the secret session you can continue where you were at this point. And finally you load the new "boring" session.

If you open help windows, split and close various windows, and generally mess up the window layout, you can go back to the last saved session:

```
        :source ~/.vim/boring.vim
```

Thus you have complete control over whether you want to continue next time where you are now, by saving the current setup in a session, or keep the session file as a starting point.

Another way of using sessions is to create a window layout that you like to use, and save this in a session. Then you can go back to this layout whenever you want.

For example, this is a nice layout to use:

```
        +----------------------------------------+
        |                  VIM - main help file  |
        |                                        |
        |Move around:  Use the cursor keys, or "h|
         help.txt================================
        |explorer   |                            |
        |dir        |~                           |
        |dir        |~                           |
        |file       |~                           |
        |file       |~                           |
        |file       |~                           |
        |file       |~                           |
         ~/========= [No File]==================|
        |                                        |
```

```
        +--------------------------------------+
```

This has a help window at the top, so that you can read this text. The narrow vertical window on the left contains a file explorer. This is a Vim plugin that lists the contents of a directory. You can select files to edit there. More about this in the next chapter.
Create this from a just started Vim with:

```
:help
CTRL-W w
:vertical split ~/
```

You can resize the windows a bit to your liking. Then save the session with:

```
:mksession ~/.vim/mine.vim
```

Now you can start Vim with this layout:

```
vim -S ~/.vim/mine.vim
```

Hint: To open a file you see listed in the explorer window in the empty window, move the cursor to the filename and press "O". Double clicking with the mouse will also do this.

UNIX AND MS-WINDOWS

Some people have to do work on MS-Windows systems one day and on Unix another day. If you are one of them, consider adding "slash" and "unix" to 'sessionoptions'. The session files will then be written in a format that can be used on both systems. This is the command to put in your vimrc file:

```
:set sessionoptions+=unix,slash
```

Vim will use the Unix format then, because the MS-Windows Vim can read and write Unix files, but Unix Vim can't read MS-Windows format session files. Similarly, MS-Windows Vim understands file names with / to separate names, but Unix Vim doesn't understand \.

SESSIONS AND VIMINFO

Sessions store many things, but not the position of marks, contents of registers and the command line history. You need to use the viminfo feature for these things.
In most situations you will want to use sessions separately from viminfo. This can be used to switch to another session, but keep the command line history. And yank text into registers in one session, and paste it back in another session.
You might prefer to keep the info with the session. You will have to do this yourself then. Example:

```
:mksession! ~/.vim/secret.vim
:wviminfo! ~/.vim/secret.viminfo
```

And to restore this again:

```
:source ~/.vim/secret.vim
:rviminfo! ~/.vim/secret.viminfo
```

==
21.5 Views

A session stores the looks of the whole of Vim. When you want to store the properties for one window only, use a view.

The use of a view is for when you want to edit a file in a specific way. For example, you have line numbers enabled with the 'number' option and defined a few folds. Just like with sessions, you can remember this view on the file and restore it later. Actually, when you store a session, it stores the view of each window.

There are two basic ways to use views. The first is to let Vim pick a name for the view file. You can restore the view when you later edit the same file. To store the view for the current window:

```
:mkview
```

Vim will decide where to store the view. When you later edit the same file you get the view back with this command:

```
:loadview
```

That's easy, isn't it?

Now you want to view the file without the 'number' option on, or with all folds open, you can set the options to make the window look that way. Then store this view with:

```
:mkview 1
```

Obviously, you can get this back with:

```
:loadview 1
```

Now you can switch between the two views on the file by using ":loadview" with and without the "1" argument.

You can store up to ten views for the same file this way, one unnumbered and nine numbered 1 to 9.

A VIEW WITH A NAME

The second basic way to use views is by storing the view in a file with a name you choose. This view can be loaded while editing another file. Vim will then switch to editing the file specified in the view. Thus you can use this to quickly switch to editing another file, with all its options set as you saved them.

For example, to save the view of the current file:

```
:mkview ~/.vim/main.vim
```

You can restore it with:

```
:source ~/.vim/main.vim
```

==

21.6 Modelines

When editing a specific file, you might set options specifically for that file. Typing these commands each time is boring. Using a session or view for editing a file doesn't work when sharing the file between several people.

The solution for this situation is adding a modeline to the file. This is a line of text that tells Vim the values of options, to be used in this file only.

A typical example is a C program where you make indents by a multiple of 4 spaces. This requires setting the 'shiftwidth' option to 4. This modeline will do that:

```
/* vim:set shiftwidth=4: */
```

Put this line as one of the first or last five lines in the file. When editing the file, you will notice that 'shiftwidth' will have been set to four. When editing another file, it's set back to the default value of eight.

For some files the modeline fits well in the header, thus it can be put at the top of the file. For text files and other files where the modeline gets in the way of the normal contents, put it at the end of the file.

The 'modelines' option specifies how many lines at the start and end of the file are inspected for containing a modeline. To inspect ten lines:

```
:set modelines=10
```

The 'modeline' option can be used to switch this off. Do this when you are working as root on Unix or Administrator on MS-Windows, or when you don't trust the files you are editing:

```
:set nomodeline
```

Use this format for the modeline:

```
any-text vim:set {option}={value} ... : any-text
```

The "any-text" indicates that you can put any text before and after the part that Vim will use. This allows making it look like a comment, like what was done above with /* and */.

The " vim:" part is what makes Vim recognize this line. There must be white space before "vim", or "vim" must be at the start of the line. Thus using something like "gvim:" will not work.

The part between the colons is a ":set" command. It works the same way as typing the ":set" command, except that you need to insert a backslash before a colon (otherwise it would be seen as the end of the modeline).

Another example:

```
        // vim:set textwidth=72 dir=c\:\tmp:  use c:\tmp here
```

There is an extra backslash before the first colon, so that it's included in the ":set" command. The text after the second colon is ignored, thus a remark can be placed there.

For more details see modeline .

==

Next chapter: usr_22.txt Finding the file to edit

Copyright: see manual-copyright vim:tw=78:ts=8:ft=help:norl:

VIM USER MANUAL - by Bram Moolenaar

Finding the file to edit

Files can be found everywhere. So how do you find them? Vim offers various ways to browse the directory tree. There are commands to jump to a file that is mentioned in another. And Vim remembers which files have been edited before.

Next chapter: usr_23.txt Editing other files
Previous chapter: usr_21.txt Go away and come back
Table of contents: usr_toc.txt

22.1 The file browser

Vim has a plugin that makes it possible to edit a directory. Try this:

```
:edit .
```

Through the magic of autocommands and Vim scripts, the window will be filled with the contents of the directory. It looks like this:

```
" ============================================================================
" Netrw Directory Listing                                        (netrw v109)
"   Sorted by      name
"   Sort sequence: [\/]$,\.h$,\.c$,\.cpp$,*,\.info$,\.swp$,\.o$\.obj$,\.bak$
"   Quick Help: <F1>:help  -:go up dir  D:delete  R:rename  s:sort-by  x:exec
" ============================================================================
../
./
check/
Makefile
autocmd.txt
change.txt
eval.txt~
filetype.txt~
help.txt.info
```

You can see these items:

1. The name of the browsing tool and its version number
2. The name of the browsing directory
3. The method of sorting (may be by name, time, or size)
4. How names are to be sorted (directories first, then *.h files, *.c files, etc)

5. How to get help (use the <F1> key), and an abbreviated listing
   of available commands
6. A listing of files, including "../", which allows one to list
   the parent directory.

If you have syntax highlighting enabled, the different parts are highlighted
so as to make it easier to spot them.

You can use Normal mode Vim commands to move around in the text. For example,
move the cursor atop a file and press <Enter>; you will then be editing that
file. To go back to the browser use ":edit ." again, or use ":Explore".
CTRL-O also works.

Try using <Enter> while the cursor is atop a directory name. The result is
that the file browser moves into that directory and displays the items found
there. Pressing <Enter> on the first directory "../" moves you one level
higher. Pressing "-" does the same thing, without the need to move to the
"../" item first.

You can press <F1> to get help on the things you can do in the netrw file
browser. This is what you get:

```
    9. Directory Browsing        netrw-browse   netrw-dir   netrw-list   netrw-help

    MAPS                                                                  netrw-maps
         <F1>.............Help.....................................|netrw-help|
         <cr>.............Browsing.................................|netrw-cr|
         <del>............Deleting Files or Directories............|netrw-delete|
         -................Going Up.................................|netrw--|
         a................Hiding Files or Directories..............|netrw-a|
         mb...............Bookmarking a Directory...................|netrw-mb|
         gb...............Changing to a Bookmarked Directory.........|netrw-gb|
         c................Make Browsing Directory The Current Dir....|netrw-c|
         d................Make A New Directory.....................|netrw-d|
         D................Deleting Files or Directories............|netrw-D|
         <c-h>............Edit File/Directory Hiding List...........|netrw-ctrl-h|
         i................Change Listing Style.....................|netrw-i|
         <c-l>............Refreshing the Listing....................|netrw-ctrl-l|
         o................Browsing with a Horizontal Split..........|netrw-o|
         p................Use Preview Window........................|netrw-p|
         P................Edit in Previous Window...................|netrw-p|
         q................Listing Bookmarks and History.............|netrw-qb|
         r................Reversing Sorting Order...................|netrw-r|
       (etc)
```

The <F1> key thus brings you to a netrw directory browsing contents help page.
It's a regular help page; use the usual CTRL-] to jump to tagged help items
and CTRL-O to jump back.

To select files for display and editing: (with the cursor is atop a filename)

```
        <enter>         Open the file in the current window.        netrw-cr
        o               Horizontally split window and display file  netrw-o
        v               Vertically split window and display file    netrw-v
```

```
        p               Use the  preview-window                    netrw-p
        P               Edit in the previous window                 netrw-P
        t               Open file in a new tab                      netrw-t
```

The following normal-mode commands may be used to control the browser display:

```
        i               Controls listing style (thin, long, wide, and tree).
                        The long listing includes size and date information.
        s               Repeatedly pressing s will change the way the files
                        are sorted; one may sort on name, modification time,
                        or size.
        r               Reverse the sorting order.
```

As a sampling of extra normal-mode commands:

```
        c               Change Vim's notion of the current directory to be
                        the same as the browser directory.  (see
                         g:netrw_keepdir  to control this, too)
        R               Rename the file or directory under the cursor; a
                        prompt will be issued for the new name.
        D               Delete the file or directory under the cursor; a
                        confirmation request will be issued.
        mb gb           Make bookmark/goto bookmark
```

One may also use command mode; again, just a sampling:

```
        :Explore [directory]    Browse specified/current directory
        :NetrwSettings          A comprehensive list of your current netrw
                                settings with help linkage.
```

The netrw browser is not limited to just your local machine; one may use urls such as: (that trailing / is important)

```
        :Explore ftp://somehost/path/to/dir/
        :e scp://somehost/path/to/dir/
```

See netrw-browse for more.

==========

22.2 The current directory

Just like the shell, Vim has the concept of a current directory. Suppose you are in your home directory and want to edit several files in a directory "VeryLongFileName". You could do:

```
        :edit VeryLongFileName/file1.txt
        :edit VeryLongFileName/file2.txt
        :edit VeryLongFileName/file3.txt
```

To avoid much of the typing, do this:

```
        :cd VeryLongFileName
        :edit file1.txt
```

```
:edit file2.txt
:edit file3.txt
```

The ":cd" command changes the current directory. You can see what the current directory is with the ":pwd" command:

```
:pwd
/home/Bram/VeryLongFileName
```

Vim remembers the last directory that you used. Use "cd -" to go back to it. Example:

```
:pwd
/home/Bram/VeryLongFileName
:cd /etc
:pwd
/etc
:cd -
:pwd
/home/Bram/VeryLongFileName
:cd -
:pwd
/etc
```

WINDOW LOCAL DIRECTORY

When you split a window, both windows use the same current directory. When you want to edit a number of files somewhere else in the new window, you can make it use a different directory, without changing the current directory in the other window. This is called a local directory.

```
:pwd
/home/Bram/VeryLongFileName
:split
:lcd /etc
:pwd
/etc
CTRL-W w
:pwd
/home/Bram/VeryLongFileName
```

So long as no ":lcd" command has been used, all windows share the same current directory. Doing a ":cd" command in one window will also change the current directory of the other window.
   For a window where ":lcd" has been used a different current directory is remembered. Using ":cd" or ":lcd" in other windows will not change it.
   When using a ":cd" command in a window that uses a different current directory, it will go back to using the shared directory.

==
22.3 Finding a file

You are editing a C program that contains this line:

```
	#include "inits.h"
```

You want to see what is in that "inits.h" file. Move the cursor on the name of the file and type:

```
	gf
```

Vim will find the file and edit it.
   What if the file is not in the current directory? Vim will use the 'path' option to find the file. This option is a list of directory names where to look for your file.
   Suppose you have your include files located in "c:/prog/include". This command will add it to the 'path' option:

```
	:set path+=c:/prog/include
```

This directory is an absolute path. No matter where you are, it will be the same place. What if you have located files in a subdirectory, below where the file is? Then you can specify a relative path name. This starts with a dot:

```
	:set path+=./proto
```

This tells Vim to look in the directory "proto", below the directory where the file in which you use "gf" is. Thus using "gf" on "inits.h" will make Vim look for "proto/inits.h", starting in the directory of the file.
   Without the "./", thus "proto", Vim would look in the "proto" directory below the current directory. And the current directory might not be where the file that you are editing is located.

The 'path' option allows specifying the directories where to search for files in many more ways. See the help on the 'path' option.
   The 'isfname' option is used to decide which characters are included in the file name, and which ones are not (e.g., the " character in the example above).

When you know the file name, but it's not to be found in the file, you can type it:

```
	:find inits.h
```

Vim will then use the 'path' option to try and locate the file. This is the same as the ":edit" command, except for the use of 'path'.

To open the found file in a new window use CTRL-W f instead of "gf", or use ":sfind" instead of ":find".

A nice way to directly start Vim to edit a file somewhere in the 'path':

```
	vim "+find stdio.h"
```

This finds the file "stdio.h" in your value of 'path'. The quotes are necessary to have one argument -+c .

==
22.4 The buffer list

The Vim editor uses the term buffer to describe a file being edited.
Actually, a buffer is a copy of the file that you edit. When you finish
changing the buffer, you write the contents of the buffer to the file.
Buffers not only contain file contents, but also all the marks, settings, and
other stuff that goes with it.

HIDDEN BUFFERS

Suppose you are editing the file one.txt and need to edit the file two.txt.
You could simply use ":edit two.txt", but since you made changes to one.txt
that won't work. You also don't want to write one.txt yet. Vim has a
solution for you:

```
:hide edit two.txt
```

The buffer "one.txt" disappears from the screen, but Vim still knows that you
are editing this buffer, so it keeps the modified text. This is called a
hidden buffer: The buffer contains text, but you can't see it.

The argument of ":hide" is another command. ":hide" makes that command
behave as if the 'hidden' option was set. You could also set this option
yourself. The effect is that when any buffer is abandoned, it becomes hidden.

Be careful! When you have hidden buffers with changes, don't exit Vim
without making sure you have saved all the buffers.

INACTIVE BUFFERS

When a buffer has been used once, Vim remembers some information about it.
When it is not displayed in a window and it is not hidden, it is still in the
buffer list. This is called an inactive buffer. Overview:

Active	Appears in a window, text loaded.
Hidden	Not in a window, text loaded.
Inactive	Not in a window, no text loaded.

The inactive buffers are remembered, because Vim keeps information about them,
like marks. And remembering the file name is useful too, so that you can see
which files you have edited. And edit them again.

LISTING BUFFERS

View the buffer list with this command:

```
:buffers
```

A command which does the same, is not so obvious to list buffers, but is much
shorter to type:

```
        :ls
```

The output could look like this:

```
  1 #h   "help.txt"                     line 62
  2 %a + "usr_21.txt"                   line 1
  3      "usr_toc.txt"                  line 1
```

The first column contains the buffer number. You can use this to edit the buffer without having to type the name, see below.
   After the buffer number come the flags. Then the name of the file and the line number where the cursor was the last time.
   The flags that can appear are these (from left to right):

```
        u       Buffer is unlisted  unlisted-buffer .
         %      Current buffer.
         #      Alternate buffer.
          a     Buffer is loaded and displayed.
          h     Buffer is loaded but hidden.
           =    Buffer is read-only.
           -    Buffer is not modifiable, the 'modifiable' option is off.
            +   Buffer has been modified.
```

EDITING A BUFFER

You can edit a buffer by its number. That avoids having to type the file name:

```
        :buffer 2
```

But the only way to know the number is by looking in the buffer list. You can use the name, or part of it, instead:

```
        :buffer help
```

Vim will find the best match for the name you type. If there is only one buffer that matches the name, it will be used. In this case "help.txt".
   To open a buffer in a new window:

```
        :sbuffer 3
```

This works with a name as well.

USING THE BUFFER LIST

You can move around in the buffer list with these commands:

```
        :bnext          go to next buffer
        :bprevious      go to previous buffer
        :bfirst         go to the first buffer
        :blast          go to the last buffer
```

To remove a buffer from the list, use this command:

```
:bdelete 3
```

Again, this also works with a name.
   If you delete a buffer that was active (visible in a window), that window will be closed. If you delete the current buffer, the current window will be closed. If it was the last window, Vim will find another buffer to edit. You can't be editing nothing!

> Note:
> Even after removing the buffer with ":bdelete" Vim still remembers it. It's actually made "unlisted", it no longer appears in the list from ":buffers". The ":buffers!" command will list unlisted buffers (yes, Vim can do the impossible). To really make Vim forget about a buffer, use ":bwipe". Also see the 'buflisted' option.

VIM USER MANUAL - by Bram Moolenaar

Editing other files

This chapter is about editing files that are not ordinary files. With Vim you can edit files that are compressed or encrypted. Some files need to be accessed over the internet. With some restrictions, binary files can be edited as well.

Next chapter: usr_24.txt Inserting quickly
Previous chapter: usr_22.txt Finding the file to edit
Table of contents: usr_toc.txt

==========

23.1 DOS, Mac and Unix files

Back in the early days, the old Teletype machines used two characters to start a new line. One to move the carriage back to the first position (carriage return, <CR>), another to move the paper up (line feed, <LF>).

When computers came out, storage was expensive. Some people decided that they did not need two characters for end-of-line. The UNIX people decided they could use <Line Feed> only for end-of-line. The Apple people standardized on <CR>. The MS-DOS (and Microsoft Windows) folks decided to keep the old <CR><LF>.

This means that if you try to move a file from one system to another, you have line-break problems. The Vim editor automatically recognizes the different file formats and handles things properly behind your back.

The option 'fileformats' contains the various formats that will be tried when a new file is edited. The following command, for example, tells Vim to try UNIX format first and MS-DOS format second:

```
:set fileformats=unix,dos
```

You will notice the format in the message you get when editing a file. You don't see anything if you edit a native file format. Thus editing a Unix file on Unix won't result in a remark. But when you edit a dos file, Vim will notify you of this:

```
"/tmp/test" [dos] 3L, 71C
```

For a Mac file you would see "[mac]".

The detected file format is stored in the 'fileformat' option. To see which format you have, execute the following command:

```
:set fileformat?
```

The three names that Vim uses are:

```
        unix            <LF>
        dos             <CR><LF>
        mac             <CR>
```

USING THE MAC FORMAT

On Unix, <LF> is used to break a line. It's not unusual to have a <CR> character halfway a line. Incidentally, this happens quite often in Vi (and Vim) scripts.
   On the Macintosh, where <CR> is the line break character, it's possible to have a <LF> character halfway a line.
   The result is that it's not possible to be 100% sure whether a file containing both <CR> and <LF> characters is a Mac or a Unix file. Therefore, Vim assumes that on Unix you probably won't edit a Mac file, and doesn't check for this type of file. To check for this format anyway, add "mac" to 'fileformats':

```
        :set fileformats+=mac
```

Then Vim will take a guess at the file format. Watch out for situations where Vim guesses wrong.

OVERRULING THE FORMAT

If you use the good old Vi and try to edit an MS-DOS format file, you will find that each line ends with a ^M character. (^M is <CR>). The automatic detection avoids this. Suppose you do want to edit the file that way? Then you need to overrule the format:

```
        :edit ++ff=unix file.txt
```

The "++" string is an item that tells Vim that an option name follows, which overrules the default for this single command. "++ff" is used for 'fileformat'. You could also use "++ff=mac" or "++ff=dos".
   This doesn't work for any option, only "++ff" and "++enc" are currently implemented. The full names "++fileformat" and "++encoding" also work.

CONVERSION

You can use the 'fileformat' option to convert from one file format to another. Suppose, for example, that you have an MS-DOS file named README.TXT that you want to convert to UNIX format. Start by editing the MS-DOS format file:

```
        vim README.TXT
```

Vim will recognize this as a dos format file. Now change the file format to UNIX:

```
:set fileformat=unix
:write
```

The file is written in Unix format.

23.2 Files on the internet

Someone sends you an e-mail message, which refers to a file by its URL. For example:

```
You can find the information here:
        ftp://ftp.vim.org/pub/vim/README
```

You could start a program to download the file, save it on your local disk and then start Vim to edit it.
   There is a much simpler way. Move the cursor to any character of the URL. Then use this command:

```
gf
```

With a bit of luck, Vim will figure out which program to use for downloading the file, download it and edit the copy. To open the file in a new window use CTRL-W f.
   If something goes wrong you will get an error message. It's possible that the URL is wrong, you don't have permission to read it, the network connection is down, etc. Unfortunately, it's hard to tell the cause of the error. You might want to try the manual way of downloading the file.

Accessing files over the internet works with the netrw plugin. Currently URLs with these formats are recognized:

```
ftp://          uses ftp
rcp://          uses rcp
scp://          uses scp
http://         uses wget (reading only)
```

Vim doesn't do the communication itself, it relies on the mentioned programs to be available on your computer. On most Unix systems "ftp" and "rcp" will be present. "scp" and "wget" might need to be installed.

Vim detects these URLs for each command that starts editing a new file, also with ":edit" and ":split", for example. Write commands also work, except for http://.

For more information, also about passwords, see netrw .

23.3 Encryption

Some information you prefer to keep to yourself. For example, when writing a test on a computer that students also use. You don't want clever students to figure out a way to read the questions before the exam starts. Vim can encrypt the file for you, which gives you some protection.

To start editing a new file with encryption, use the "-x" argument to start Vim. Example:

```
vim -x exam.txt
```

Vim prompts you for a key used for encrypting and decrypting the file:

```
Enter encryption key:
```

Carefully type the secret key now. You cannot see the characters you type, they will be replaced by stars. To avoid the situation that a typing mistake will cause trouble, Vim asks you to enter the key again:

```
Enter same key again:
```

You can now edit this file normally and put in all your secrets. When you finish editing the file and tell Vim to exit, the file is encrypted and written.

When you edit the file with Vim, it will ask you to enter the same key again. You don't need to use the "-x" argument. You can also use the normal ":edit" command. Vim adds a magic string to the file by which it recognizes that the file was encrypted.

If you try to view this file using another program, all you get is garbage. Also, if you edit the file with Vim and enter the wrong key, you get garbage. Vim does not have a mechanism to check if the key is the right one (this makes it much harder to break the key).

SWITCHING ENCRYPTION ON AND OFF

To disable the encryption of a file, set the 'key' option to an empty string:

```
:set key=
```

The next time you write the file this will be done without encryption.

Setting the 'key' option to enable encryption is not a good idea, because the password appears in the clear. Anyone shoulder-surfing can read your password.

To avoid this problem, the ":X" command was created. It asks you for an encryption key, just like the "-x" argument did:

```
:X
Enter encryption key: ******
Enter same key again: ******
```

LIMITS ON ENCRYPTION

The encryption algorithm used by Vim is weak. It is good enough to keep out the casual prowler, but not good enough to keep out a cryptology expert with lots of time on his hands. Also you should be aware that the swap file is not encrypted; so while you are editing, people with superuser privileges can read the unencrypted text from this file.

One way to avoid letting people read your swap file is to avoid using one.

If the -n argument is supplied on the command line, no swap file is used (instead, Vim puts everything in memory). For example, to edit the encrypted file "file.txt" without a swap file use the following command:

```
vim -x -n file.txt
```

When already editing a file, the swapfile can be disabled with:

```
:setlocal noswapfile
```

Since there is no swapfile, recovery will be impossible. Save the file a bit more often to avoid the risk of losing your changes.

While the file is in memory, it is in plain text. Anyone with privilege can look in the editor's memory and discover the contents of the file.
   If you use a viminfo file, be aware that the contents of text registers are written out in the clear as well.
   If you really want to secure the contents of a file, edit it only on a portable computer not connected to a network, use good encryption tools, and keep the computer locked up in a big safe when not in use.

==
23.4 Binary files

You can edit binary files with Vim. Vim wasn't really made for this, thus there are a few restrictions. But you can read a file, change a character and write it back, with the result that only that one character was changed and the file is identical otherwise.
   To make sure that Vim does not use its clever tricks in the wrong way, add the "-b" argument when starting Vim:

```
vim -b datafile
```

This sets the 'binary' option. The effect of this is that unexpected side effects are turned off. For example, 'textwidth' is set to zero, to avoid automatic formatting of lines. And files are always read in Unix file format.

Binary mode can be used to change a message in a program. Be careful not to insert or delete any characters, it would stop the program from working. Use "R" to enter replace mode.

Many characters in the file will be unprintable. To see them in Hex format:

```
:set display=uhex
```

Otherwise, the "ga" command can be used to see the value of the character under the cursor. The output, when the cursor is on an <Esc>, looks like this:

```
<^[>  27,  Hex 1b,  Octal 033
```

There might not be many line breaks in the file. To get some overview switch the 'wrap' option off:

```
:set nowrap
```

BYTE POSITION

To see on which byte you are in the file use this command:

```
g CTRL-G
```

The output is verbose:

```
Col 9-16 of 9-16; Line 277 of 330; Word 1806 of 2058; Byte 10580 of 12206
```

The last two numbers are the byte position in the file and the total number of bytes. This takes into account how 'fileformat' changes the number of bytes that a line break uses.
To move to a specific byte in the file, use the "go" command. For example, to move to byte 2345:

```
2345go
```

USING XXD

A real binary editor shows the text in two ways: as it is and in hex format. You can do this in Vim by first converting the file with the "xxd" program. This comes with Vim.
First edit the file in binary mode:

```
vim -b datafile
```

Now convert the file to a hex dump with xxd:

```
:%!xxd
```

The text will look like this:

```
0000000: 1f8b 0808 39d7 173b 0203 7474 002b 4e49  ....9..;..tt.+NI
0000010: 4b2c 8660 eb9c ecac c462 eb94 345e 2e30  K,.`.....b..4^.0
0000020: 373b 2731 0b22 0ca6 c1a2 d669 1035 39d9  7;'1."......i.59.
```

You can now view and edit the text as you like. Vim treats the information as ordinary text. Changing the hex does not cause the printable character to be changed, or the other way around.
Finally convert it back with:

```
:%!xxd -r
```

Only changes in the hex part are used. Changes in the printable text part on the right are ignored.

See the manual page of xxd for more information.

==

23.5 Compressed files

This is easy: You can edit a compressed file just like any other file. The "gzip" plugin takes care of decompressing the file when you edit it. And compressing it again when you write it.
These compression methods are currently supported:

```
.Z      compress
.gz     gzip
.bz2    bzip2
```

Vim uses the mentioned programs to do the actual compression and decompression. You might need to install the programs first.

==========

24.1 Making corrections

The <BS> key was already mentioned. It deletes the character just before the cursor. The <Del> key does the same for the character under (after) the cursor.

When you typed a whole word wrong, use CTRL-W:

```
The horse had fallen to the sky
                          CTRL-W
The horse had fallen to the
```

If you really messed up a line and want to start over, use CTRL-U to delete it. This keeps the text after the cursor and the indent. Only the text from the first non-blank to the cursor is deleted. With the cursor on the "f" of "fallen" in the next line pressing CTRL-U does this:

```
The horse had fallen to the
             CTRL-U
fallen to the
```

When you spot a mistake a few words back, you need to move the cursor there to correct it. For example, you typed this:

```
The horse had follen to the ground
```

You need to change "follen" to "fallen". With the cursor at the end, you

would type this to correct it:

```
                                      <Esc>4blraA

       get out of Insert mode          <Esc>
        four words back                      4b
        move on top of the "o"                 l
        replace with "a"                        ra
        restart Insert mode                       A
```

Another way to do this:

```
               <C-Left><C-Left><C-Left><C-Left><Right><Del>a<End>

       four words back             <C-Left><C-Left><C-Left><C-Left>
        move on top of the "o"                    <Right>
        delete the "o"                                  <Del>
        insert an "a"                                        a
        go to end of the line                                 <End>
```

This uses special keys to move around, while remaining in Insert mode. This resembles what you would do in a modeless editor. It's easier to remember, but takes more time (you have to move your hand from the letters to the cursor keys, and the <End> key is hard to press without looking at the keyboard).
   These special keys are most useful when writing a mapping that doesn't leave Insert mode. The extra typing doesn't matter then.
   An overview of the keys you can use in Insert mode:

```
        <C-Home>        to start of the file
        <PageUp>        a whole screenful up
        <Home>          to start of line
        <S-Left>        one word left
        <C-Left>        one word left
        <S-Right>       one word right
        <C-Right>       one word right
        <End>           to end of the line
        <PageDown>      a whole screenful down
        <C-End>         to end of the file
```

There are a few more, see ins-special-special .

==========

24.2 Showing matches

When you type a) it would be nice to see with which (it matches. To make Vim do that use this command:

```
        :set showmatch
```

When you now type a text like "(example)", as soon as you type the) Vim will briefly move the cursor to the matching (, keep it there for half a second, and move back to where you were typing.
   In case there is no matching (, Vim will beep. Then you know that you might have forgotten the (somewhere, or typed a) too many.

The match will also be shown for [] and {} pairs. You don't have to wait with typing the next character, as soon as Vim sees it the cursor will move back and inserting continues as before.

You can change the time Vim waits with the 'matchtime' option. For example, to make Vim wait one and a half second:

```
:set matchtime=15
```

The time is specified in tenths of a second.

24.3 Completion

Vim can automatically complete words on insertion. You type the first part of a word, press CTRL-P, and Vim guesses the rest.

Suppose, for example, that you are creating a C program and want to type in the following:

```
total = ch_array[0] + ch_array[1] + ch_array[2];
```

You start by entering the following:

```
total = ch_array[0] + ch_
```

At this point, you tell Vim to complete the word using the command CTRL-P. Vim searches for a word that starts with what's in front of the cursor. In this case, it is "ch_", which matches with the word ch_array. So typing CTRL-P gives you the following:

```
total = ch_array[0] + ch_array
```

After a little more typing, you get this (ending in a space):

```
total = ch_array[0] + ch_array[1] +
```

If you now type CTRL-P Vim will search again for a word that completes the word before the cursor. Since there is nothing in front of the cursor, it finds the first word backwards, which is "ch_array". Typing CTRL-P again gives you the next word that matches, in this case "total". A third CTRL-P searches further back. If there is nothing else, it causes the editor to run out of words, so it returns to the original text, which is nothing. A fourth CTRL-P causes the editor to start over again with "ch_array".

To search forward, use CTRL-N. Since the search wraps around the end of the file, CTRL-N and CTRL-P will find the same matches, but in a different sequence. Hint: CTRL-N is Next-match and CTRL-P is Previous-match.

The Vim editor goes through a lot of effort to find words to complete. By default, it searches the following places:

1. Current file
2. Files in other windows
3. Other loaded files (hidden buffers)
4. Files which are not loaded (inactive buffers)

5. Tag files
6. All files #included by the current file

OPTIONS

You can customize the search order with the 'complete' option.

The 'ignorecase' option is used. When it is set, case differences are ignored when searching for matches.

A special option for completion is 'infercase'. This is useful to find matches while ignoring case ('ignorecase' must be set) but still using the case of the word typed so far. Thus if you type "For" and Vim finds a match "fortunately", it will result in "Fortunately".

COMPLETING SPECIFIC ITEMS

If you know what you are looking for, you can use these commands to complete with a certain type of item:

CTRL-X CTRL-F	file names
CTRL-X CTRL-L	whole lines
CTRL-X CTRL-D	macro definitions (also in included files)
CTRL-X CTRL-I	current and included files
CTRL-X CTRL-K	words from a dictionary
CTRL-X CTRL-T	words from a thesaurus
CTRL-X CTRL-]	tags
CTRL-X CTRL-V	Vim command line

After each of them CTRL-N can be used to find the next match, CTRL-P to find the previous match.
More information for each of these commands here: ins-completion .

COMPLETING FILE NAMES

Let's take CTRL-X CTRL-F as an example. This will find file names. It scans the current directory for files and displays each one that matches the word in front of the cursor.
Suppose, for example, that you have the following files in the current directory:

```
main.c  sub_count.c  sub_done.c  sub_exit.c
```

Now enter Insert mode and start typing:

```
The exit code is in the file sub
```

At this point, you enter the command CTRL-X CTRL-F. Vim now completes the current word "sub" by looking at the files in the current directory. The first match is sub_count.c. This is not the one you want, so you match the next file by typing CTRL-N. This match is sub_done.c. Typing CTRL-N again

takes you to sub_exit.c. The results:

```
	The exit code is in the file sub_exit.c
```

If the file name starts with / (Unix) or C:\ (MS-Windows) you can find all files in the file system. For example, type "/u" and CTRL-X CTRL-F. This will match "/usr" (this is on Unix):

```
	the file is found in /usr/
```

If you now press CTRL-N you go back to "/u". Instead, to accept the "/usr/" and go one directory level deeper, use CTRL-X CTRL-F again:

```
	the file is found in /usr/X11R6/
```

The results depend on what is found in your file system, of course. The matches are sorted alphabetically.

COMPLETING IN SOURCE CODE

Source code files are well structured. That makes it possible to do completion in an intelligent way. In Vim this is called Omni completion. In some other editors it's called intellisense, but that is a trademark.

The key to Omni completion is CTRL-X CTRL-O. Obviously the O stands for Omni here, so that you can remember it easier. Let's use an example for editing C source:

```
	{
	    struct foo *p;
	    p->
```

The cursor is after "p->". Now type CTRL-X CTRL-O. Vim will offer you a list of alternatives, which are the items that "struct foo" contains. That is quite different from using CTRL-P, which would complete any word, while only members of "struct foo" are valid here.

For Omni completion to work you may need to do some setup. At least make sure filetype plugins are enabled. Your vimrc file should contain a line like this:

```
	filetype plugin on
```

Or:

```
	filetype plugin indent on
```

For C code you need to create a tags file and set the 'tags' option. That is explained ft-c-omni . For other filetypes you may need to do something similar, look below compl-omni-filetypes . It only works for specific filetypes. Check the value of the 'omnifunc' option to find out if it would work.

==

24.4 Repeating an insert

If you press CTRL-A, the editor inserts the text you typed the last time you were in Insert mode.
   Assume, for example, that you have a file that begins with the following:

```
"file.h"
/* Main program begins */
```

You edit this file by inserting "#include " at the beginning of the first line:

```
#include "file.h"
/* Main program begins */
```

You go down to the beginning of the next line using the commands "j^". You now start to insert a new "#include" line. So you type:

```
i CTRL-A
```

The result is as follows:

```
#include "file.h"
#include /* Main program begins */
```

The "#include " was inserted because CTRL-A inserts the text of the previous insert. Now you type "main.h"<Enter> to finish the line:

```
#include "file.h"
#include "main.h"
/* Main program begins */
```

The CTRL-@ command does a CTRL-A and then exits Insert mode. That's a quick way of doing exactly the same insertion again.

==========

24.5 Copying from another line

The CTRL-Y command inserts the character above the cursor. This is useful when you are duplicating a previous line. For example, you have this line of C code:

```
b_array[i]->s_next = a_array[i]->s_next;
```

Now you need to type the same line, but with "s_prev" instead of "s_next". Start the new line, and press CTRL-Y 14 times, until you are at the "n" of "next":

```
b_array[i]->s_next = a_array[i]->s_next;
b_array[i]->s_
```

Now you type "prev":

```
b_array[i]->s_next = a_array[i]->s_next;
b_array[i]->s_prev
```

Continue pressing CTRL-Y until the following "next":

```
        b_array[i]->s_next = a_array[i]->s_next;
        b_array[i]->s_prev = a_array[i]->s_
```

Now type "prev;" to finish it off.

The CTRL-E command acts like CTRL-Y except it inserts the character below the cursor.

==

24.6 Inserting a register

The command CTRL-R {register} inserts the contents of the register. This is useful to avoid having to type a long word. For example, you need to type this:

```
        r = VeryLongFunction(a) + VeryLongFunction(b) + VeryLongFunction(c)
```

The function name is defined in a different file. Edit that file and move the cursor on top of the function name there, and yank it into register v:

```
        "vyiw
```

"v is the register specification, "yiw" is yank-inner-word. Now edit the file where the new line is to be inserted, and type the first letters:

```
        r =
```

Now use CTRL-R v to insert the function name:

```
        r = VeryLongFunction
```

You continue to type the characters in between the function name, and use CTRL-R v two times more.

You could have done the same with completion. Using a register is useful when there are many words that start with the same characters.

If the register contains characters such as <BS> or other special characters, they are interpreted as if they had been typed from the keyboard. If you do not want this to happen (you really want the <BS> to be inserted in the text), use the command CTRL-R CTRL-R {register}.

==

24.7 Abbreviations

An abbreviation is a short word that takes the place of a long one. For example, "ad" stands for "advertisement". Vim enables you to type an abbreviation and then will automatically expand it for you.

To tell Vim to expand "ad" into "advertisement" every time you insert it, use the following command:

```
        :iabbrev ad advertisement
```

Now, when you type "ad", the whole word "advertisement" will be inserted into the text. This is triggered by typing a character that can't be part of a word, for example a space:

What Is Entered	What You See
I saw the a	I saw the a
I saw the ad	I saw the ad
I saw the ad<Space>	I saw the advertisement<Space>

The expansion doesn't happen when typing just "ad". That allows you to type a word like "add", which will not get expanded. Only whole words are checked for abbreviations.

ABBREVIATING SEVERAL WORDS

It is possible to define an abbreviation that results in multiple words. For example, to define "JB" as "Jack Benny", use the following command:

```
:iabbrev JB Jack Benny
```

As a programmer, I use two rather unusual abbreviations:

```
:iabbrev #b /*************************************
:iabbrev #e <Space>*************************************/
```

These are used for creating boxed comments. The comment starts with #b, which draws the top line. I then type the comment text and use #e to draw the bottom line.

Notice that the #e abbreviation begins with a space. In other words, the first two characters are space-star. Usually Vim ignores spaces between the abbreviation and the expansion. To avoid that problem, I spell space as seven characters: <, S, p, a, c, e, >.

```
Note:
":iabbrev" is a long word to type. ":iab" works just as well.
That's abbreviating the abbreviate command!
```

FIXING TYPING MISTAKES

It's very common to make the same typing mistake every time. For example, typing "teh" instead of "the". You can fix this with an abbreviation:

```
:abbreviate teh the
```

You can add a whole list of these. Add one each time you discover a common mistake.

LISTING ABBREVIATIONS

The ":abbreviate" command lists the abbreviations:

```
:abbreviate
i  #e             ************************************/
i  #b            /************************************
i  JB            Jack Benny
i  ad            advertisement
!  teh           the
```

The "i" in the first column indicates Insert mode. These abbreviations are only active in Insert mode. Other possible characters are:

```
c       Command-line mode                       :cabbrev
!       both Insert and Command-line mode       :abbreviate
```

Since abbreviations are not often useful in Command-line mode, you will mostly use the ":iabbrev" command. That avoids, for example, that "ad" gets expanded when typing a command like:

```
:edit ad
```

DELETING ABBREVIATIONS

To get rid of an abbreviation, use the ":unabbreviate" command. Suppose you have the following abbreviation:

```
:abbreviate @f fresh
```

You can remove it with this command:

```
:unabbreviate @f
```

While you type this, you will notice that @f is expanded to "fresh". Don't worry about this, Vim understands it anyway (except when you have an abbreviation for "fresh", but that's very unlikely).
   To remove all the abbreviations:

```
:abclear
```

":unabbreviate" and ":abclear" also come in the variants for Insert mode (":iunabbreviate and ":iabclear") and Command-line mode (":cunabbreviate" and ":cabclear").

REMAPPING ABBREVIATIONS

There is one thing to watch out for when defining an abbreviation: The resulting string should not be mapped. For example:

```
:abbreviate @a adder
:imap dd disk-door
```

When you now type @a, you will get "adisk-doorer". That's not what you want. To avoid this, use the ":noreabbrev" command. It does the same as

":abbreviate", but avoids that the resulting string is used for mappings:

```
:noreabbrev @a adder
```

Fortunately, it's unlikely that the result of an abbreviation is mapped.

==========

24.8 Entering special characters

The CTRL-V command is used to insert the next character literally. In other words, any special meaning the character has, it will be ignored. For example:

```
CTRL-V <Esc>
```

Inserts an escape character. Thus you don't leave Insert mode. (Don't type the space after CTRL-V, it's only to make this easier to read).

> Note:
> On MS-Windows CTRL-V is used to paste text. Use CTRL-Q instead of CTRL-V. On Unix, on the other hand, CTRL-Q does not work on some terminals, because it has a special meaning.

You can also use the command CTRL-V {digits} to insert a character with the decimal number {digits}. For example, the character number 127 is the <Del> character (but not necessarily the <Del> key!). To insert <Del> type:

```
CTRL-V 127
```

You can enter characters up to 255 this way. When you type fewer than two digits, a non-digit will terminate the command. To avoid the need of typing a non-digit, prepend one or two zeros to make three digits.
All the next commands insert a <Tab> and then a dot:

```
CTRL-V 9.
CTRL-V 09.
CTRL-V 009.
```

To enter a character in hexadecimal, use an "x" after the CTRL-V:

```
CTRL-V x7f
```

This also goes up to character 255 (CTRL-V xff). You can use "o" to type a character as an octal number and two more methods allow you to type up to a 16 bit and a 32 bit number (e.g., for a Unicode character):

```
CTRL-V o123
CTRL-V u1234
CTRL-V U12345678
```

==========

24.9 Digraphs

Some characters are not on the keyboard. For example, the copyright character

(©). To type these characters in Vim, you use digraphs, where two characters represent one. To enter a ©, for example, you press three keys:

```
CTRL-K Co
```

To find out what digraphs are available, use the following command:

```
:digraphs
```

Vim will display the digraph table. Here are three lines of it:

```
  AC ~_ 159  NS |  160  !I ¡  161  Ct ¢  162  Pd £  163  Cu ¤  164  Ye ¥  165
  BB ¦  166  SE §  167  ': ¨  168  Co ©  169  -a ª  170  << «  171  NO ¬  172
  --   173  Rg ®  174  'm ¯  175  DG °  176  +- ±  177  2S ²  178  3S ³  179
```

This shows, for example, that the digraph you get by typing CTRL-K Pd is the character (£). This is character number 163 (decimal).
Pd is short for Pound. Most digraphs are selected to give you a hint about the character they will produce. If you look through the list you will understand the logic.
You can exchange the first and second character, if there is no digraph for that combination. Thus CTRL-K dP also works. Since there is no digraph for "dP" Vim will also search for a "Pd" digraph.

> Note:
> The digraphs depend on the character set that Vim assumes you are using. On MS-DOS they are different from MS-Windows. Always use ":digraphs" to find out which digraphs are currently available.

You can define your own digraphs. Example:

```
:digraph a" ä
```

This defines that CTRL-K a" inserts an ä character. You can also specify the character with a decimal number. This defines the same digraph:

```
:digraph a" 228
```

More information about digraphs here: digraphs
Another way to insert special characters is with a keymap. More about that here: 45.5

==
24.10 Normal mode commands

Insert mode offers a limited number of commands. In Normal mode you have many more. When you want to use one, you usually leave Insert mode with <Esc>, execute the Normal mode command, and re-enter Insert mode with "i" or "a".
There is a quicker way. With **CTRL-O** {command} you can execute any Normal mode command from Insert mode. For example, to delete from the cursor to the end of the line:

```
CTRL-O D
```

You can execute only one Normal mode command this way. But you can specify a
register or a count. A more complicated example:

	CTRL-O "g3dw

This deletes up to the third word into register g.

VIM USER MANUAL - by Bram Moolenaar

Editing formatted text

Text hardly ever comes in one sentence per line. This chapter is about
breaking sentences to make them fit on a page and other formatting.
Vim also has useful features for editing single-line paragraphs and tables.

Next chapter: usr_26.txt Repeating
Previous chapter: usr_24.txt Inserting quickly
Table of contents: usr_toc.txt

==

25.1 Breaking lines

Vim has a number of functions that make dealing with text easier. By default,
the editor does not perform automatic line breaks. In other words, you have
to press <Enter> yourself. This is useful when you are writing programs where
you want to decide where the line ends. It is not so good when you are
creating documentation and want the text to be at most 70 character wide.
   If you set the 'textwidth' option, Vim automatically inserts line breaks.
Suppose, for example, that you want a very narrow column of only 30
characters. You need to execute the following command:

```
:set textwidth=30
```

Now you start typing (ruler added):

```
          1         2         3
12345678901234567890123456789012345
I taught programming for a whi
```

If you type "l" next, this makes the line longer than the 30-character limit.
When Vim sees this, it inserts a line break and you get the following:

```
          1         2         3
12345678901234567890123456789012345
I taught programming for a
whil
```

Continuing on, you can type in the rest of the paragraph:

```
          1         2         3
12345678901234567890123456789012345
I taught programming for a
```

```
while. One time, I was stopped
by the Fort Worth police,
because my homework was too
hard. True story.
```

You do not have to type newlines; Vim puts them in automatically.

Note:
The 'wrap' option makes Vim display lines with a line break, but this doesn't insert a line break in the file.

REFORMATTING

The Vim editor is not a word processor. In a word processor, if you delete something at the beginning of the paragraph, the line breaks are reworked. In Vim they are not; so if you delete the word "programming" from the first line, all you get is a short line:

```
          1         2         3
12345678901234567890123456789012345
I taught for a
while. One time, I was stopped
by the Fort Worth police,
because my homework was too
hard. True story.
```

This does not look good. To get the paragraph into shape you use the "gq" operator.

Let's first use this with a Visual selection. Starting from the first line, type:

```
v4jgq
```

"v" to start Visual mode, "4j" to move to the end of the paragraph and then the "gq" operator. The result is:

```
          1         2         3
12345678901234567890123456789012345
I taught for a while. One
time, I was stopped by the
Fort Worth police, because my
homework was too hard. True
story.
```

Note: there is a way to do automatic formatting for specific types of text layouts, see auto-format .

Since "gq" is an operator, you can use one of the three ways to select the text it works on: With Visual mode, with a movement and with a text object.

The example above could also be done with "gq4j". That's less typing, but you have to know the line count. A more useful motion command is "}". This moves to the end of a paragraph. Thus "gq}" formats from the cursor to the end of the current paragraph.

A very useful text object to use with "gq" is the paragraph. Try this:

```
gqap
```

"ap" stands for "a-paragraph". This formats the text of one paragraph (separated by empty lines). Also the part before the cursor.
If you have your paragraphs separated by empty lines, you can format the whole file by typing this:

```
gggqG
```

"gg" to move to the first line, "gqG" to format until the last line.
Warning: If your paragraphs are not properly separated, they will be joined together. A common mistake is to have a line with a space or tab. That's a blank line, but not an empty line.

Vim is able to format more than just plain text. See fo-table for how to change this. See the 'joinspaces' option to change the number of spaces used after a full stop.
It is possible to use an external program for formatting. This is useful if your text can't be properly formatted with Vim's builtin command. See the 'formatprg' option.

==
25.2 Aligning text

To center a range of lines, use the following command:

```
:{range}center [width]
```

{range} is the usual command-line range. [width] is an optional line width to use for centering. If [width] is not specified, it defaults to the value of 'textwidth'. (If 'textwidth' is 0, the default is 80.)
For example:

```
:1,5center 40
```

results in the following:

```
       I taught for a while. One
       time, I was stopped by the
     Fort Worth police, because my
      homework was too hard. True
                 story.
```

RIGHT ALIGNMENT

Similarly, the ":right" command right-justifies the text:

```
:1,5right 37
```

gives this result:

```
            I taught for a while. One
           time, I was stopped by the
        Fort Worth police, because my
          homework was too hard. True
                               story.
```

LEFT ALIGNMENT

Finally there is this command:

```
:{range}left [margin]
```

Unlike ":center" and ":right", however, the argument to ":left" is not the length of the line. Instead it is the left margin. If it is omitted, the text will be put against the left side of the screen (using a zero margin would do the same). If it is 5, the text will be indented 5 spaces. For example, use these commands:

```
:1left 5
:2,5left
```

This results in the following:

```
     I taught for a while. One
time, I was stopped by the
Fort Worth police, because my
homework was too hard. True
story.
```

JUSTIFYING TEXT

Vim has no built-in way of justifying text. However, there is a neat macro package that does the job. To use this package, execute the following command:

```
:packadd justify
```

Or put this line in your vimrc :

```
packadd! justify
```

This Vim script file defines a new visual command "_j". To justify a block of text, highlight the text in Visual mode and then execute "_j".
Look in the file for more explanations. To go there, do "gf" on this name: $VIMRUNTIME/pack/dist/opt/justify/plugin/justify.vim.

An alternative is to filter the text through an external program. Example:

```
:%!fmt
```

==
25.3 Indents and tabs

Indents can be used to make text stand out from the rest. The example texts in this manual, for example, are indented by eight spaces or a tab. You would normally enter this by typing a tab at the start of each line. Take this text:

```
	the first line
	the second line
```

This is entered by typing a tab, some text, <Enter>, tab and more text.
   The 'autoindent' option inserts indents automatically:

```
	:set autoindent
```

When a new line is started it gets the same indent as the previous line. In the above example, the tab after the <Enter> is not needed anymore.

INCREASING INDENT

To increase the amount of indent in a line, use the ">" operator. Often this is used as ">>", which adds indent to the current line.
   The amount of indent added is specified with the 'shiftwidth' option. The default value is 8. To make ">>" insert four spaces worth of indent, for example, type this:

```
	:set shiftwidth=4
```

When used on the second line of the example text, this is what you get:

```
	the first line
	    the second line
```

"4>>" will increase the indent of four lines.

TABSTOP

If you want to make indents a multiple of 4, you set 'shiftwidth' to 4. But when pressing a <Tab> you still get 8 spaces worth of indent. To change this, set the 'softtabstop' option:

```
	:set softtabstop=4
```

This will make the <Tab> key insert 4 spaces worth of indent. If there are already four spaces, a <Tab> character is used (saving seven characters in the file). (If you always want spaces and no tab characters, set the 'expandtab' option.)

```
	Note:
	You could set the 'tabstop' option to 4.  However, if you edit the
	file another time, with 'tabstop' set to the default value of 8, it
	will look wrong.  In other programs and when printing the indent will
	also be wrong.  Therefore it is recommended to keep 'tabstop' at eight
	all the time.  That's the standard value everywhere.
```

CHANGING TABS

You edit a file which was written with a tabstop of 3. In Vim it looks ugly, because it uses the normal tabstop value of 8. You can fix this by setting 'tabstop' to 3. But you have to do this every time you edit this file.
   Vim can change the use of tabstops in your file. First, set 'tabstop' to make the indents look good, then use the ":retab" command:

```
:set tabstop=3
:retab 8
```

The ":retab" command will change 'tabstop' to 8, while changing the text such that it looks the same. It changes spans of white space into tabs and spaces for this. You can now write the file. Next time you edit it the indents will be right without setting an option.
   Warning: When using ":retab" on a program, it may change white space inside a string constant. Therefore it's a good habit to use "\t" instead of a real tab.

==========

25.4 Dealing with long lines

Sometimes you will be editing a file that is wider than the number of columns in the window. When that occurs, Vim wraps the lines so that everything fits on the screen.
   If you switch the 'wrap' option off, each line in the file shows up as one line on the screen. Then the ends of the long lines disappear off the screen to the right.
   When you move the cursor to a character that can't be seen, Vim will scroll the text to show it. This is like moving a viewport over the text in the horizontal direction.
   By default, Vim does not display a horizontal scrollbar in the GUI. If you want to enable one, use the following command:

```
:set guioptions+=b
```

One horizontal scrollbar will appear at the bottom of the Vim window.

If you don't have a scrollbar or don't want to use it, use these commands to scroll the text. The cursor will stay in the same place, but it's moved back into the visible text if necessary.

```
zh              scroll right
4zh             scroll four characters right
zH              scroll half a window width right
ze              scroll right to put the cursor at the end
zl              scroll left
4zl             scroll four characters left
zL              scroll half a window width left
zs              scroll left to put the cursor at the start
```

Let's attempt to show this with one line of text. The cursor is on the "w" of "which". The "current window" above the line indicates the text that is

currently visible. The "window"s below the text indicate the text that is visible after the command left of it.

```
                            |<-- current window -->|
                 some long text, part of which is visible in the window
        ze         |<--     window     -->|
        zH          |<--     window     -->|
        4zh               |<--     window     -->|
        zh                   |<--     window     -->|
        zl                     |<--     window     -->|
        4zl                       |<--     window     -->|
        zL                              |<--     window     -->|
        zs                            |<--     window     -->|
```

MOVING WITH WRAP OFF

When 'wrap' is off and the text has scrolled horizontally, you can use the following commands to move the cursor to a character you can see. Thus text left and right of the window is ignored. These never cause the text to scroll:

```
        g0              to first visible character in this line
        g^              to first non-blank visible character in this line
        gm              to middle of this line
        g$              to last visible character in this line

                |<--     window    -->|
        some long    text, part of which is visible
                 g0  g^    gm        g$
```

BREAKING AT WORDS   edit-no-break

When preparing text for use by another program, you might have to make paragraphs without a line break. A disadvantage of using 'nowrap' is that you can't see the whole sentence you are working on. When 'wrap' is on, words are broken halfway, which makes them hard to read.

   A good solution for editing this kind of paragraph is setting the 'linebreak' option. Vim then breaks lines at an appropriate place when displaying the line. The text in the file remains unchanged.

   Without 'linebreak' text might look like this:

```
        +---------------------------------+
        |letter generation program for a b|
        |ank.  They wanted to send out a s|
        |pecial, personalized letter to th|
        |eir richest 1000 customers.  Unfo|
        |rtunately for the programmer, he |
        +---------------------------------+
```

After:

```
        :set linebreak
```

it looks like this:

```
        +---------------------------------+
        |letter generation program for a  |
        |bank.  They wanted to send out a |
        |special, personalized letter to  |
        |their richest 1000 customers.    |
        |Unfortunately for the programmer,|
        +---------------------------------+
```

Related options:
'breakat' specifies the characters where a break can be inserted.
'showbreak' specifies a string to show at the start of broken line.
Set 'textwidth' to zero to avoid a paragraph to be split.

MOVING BY VISIBLE LINES

The "j" and "k" commands move to the next and previous lines. When used on a long line, this means moving a lot of screen lines at once.
   To move only one screen line, use the "gj" and "gk" commands. When a line doesn't wrap they do the same as "j" and "k". When the line does wrap, they move to a character displayed one line below or above.
   You might like to use these mappings, which bind these movement commands to the cursor keys:

```
        :map <Up> gk
        :map <Down> gj
```

TURNING A PARAGRAPH INTO ONE LINE   edit-paragraph-join

If you want to import text into a program like MS-Word, each paragraph should be a single line. If your paragraphs are currently separated with empty lines, this is how you turn each paragraph into a single line:

```
        :g/./,/^$/join
```

That looks complicated. Let's break it up in pieces:

```
        :g/./          A ":global" command that finds all lines that contain
                       at least one character.
             ,/^$/     A range, starting from the current line (the non-empty
                       line) until an empty line.
                  join The ":join" command joins the range of lines together
                       into one line.
```

Starting with this text, containing eight lines broken at column 30:

```
        +---------------------------------+
        |A letter generation program      |
        |for a bank.  They wanted to      |
        |send out a special,              |
        |personalized letter.             |
```

```
        |                                   |
        |To their richest 1000              |
        |customers.  Unfortunately for      |
        |the programmer,                    |
        +-----------------------------------+
```

You end up with two lines:

```
        +-----------------------------------+
        |A letter generation program for a  |
        |bank.  They wanted to send out a s|
        |pecial, personalized letter.       |
        |To their richest 1000 customers.   |
        |Unfortunately for the programmer,  |
        +-----------------------------------+
```

Note that this doesn't work when the separating line is blank but not empty; when it contains spaces and/or tabs. This command does work with blank lines:

```
        :g/\S/,/^\s*$/join
```

This still requires a blank or empty line at the end of the file for the last paragraph to be joined.

==========

25.5 Editing tables

Suppose you are editing a table with four columns:

```
        nice table        test 1        test 2      test 3
        input A           0.534
        input B           0.913
```

You need to enter numbers in the third column. You could move to the second line, use "A", enter a lot of spaces and type the text.

For this kind of editing there is a special option:

```
        set virtualedit=all
```

Now you can move the cursor to positions where there isn't any text. This is called "virtual space". Editing a table is a lot easier this way.

Move the cursor by searching for the header of the last column:

```
        /test 3
```

Now press "j" and you are right where you can enter the value for "input A". Typing "0.693" results in:

```
        nice table        test 1     test 2      test 3
        input A           0.534                  0.693
        input B           0.913
```

Vim has automatically filled the gap in front of the new text for you. Now, to enter the next field in this column use "Bj". "B" moves back to the start

of a white space separated word. Then "j" moves to the place where the next field can be entered.

	Note:
	You can move the cursor anywhere in the display, also beyond the end of a line. But Vim will not insert spaces there, until you insert a character in that position.

COPYING A COLUMN

You want to add a column, which should be a copy of the third column and placed before the "test 1" column. Do this in seven steps:
1. Move the cursor to the left upper corner of this column, e.g., with "/test 3".
2. Press CTRL-V to start blockwise Visual mode.
3. Move the cursor down two lines with "2j". You are now in "virtual space": the "input B" line of the "test 3" column.
4. Move the cursor right, to include the whole column in the selection, plus the space that you want between the columns. "9l" should do it.
5. Yank the selected rectangle with "y".
6. Move the cursor to "test 1", where the new column must be placed.
7. Press "P".

The result should be:

```
	nice table        test 3    test 1     test 2      test 3
	input A           0.693     0.534                  0.693
	input B                     0.913
```

Notice that the whole "test 1" column was shifted right, also the line where the "test 3" column didn't have text.

Go back to non-virtual cursor movements with:

	:set virtualedit=

VIRTUAL REPLACE MODE

The disadvantage of using 'virtualedit' is that it "feels" different. You can't recognize tabs or spaces beyond the end of line when moving the cursor around. Another method can be used: Virtual Replace mode.
   Suppose you have a line in a table that contains both tabs and other characters. Use "rx" on the first tab:

```
	inp     0.693   0.534   0.693

	      |
	   rx |
	      V

	inpx0.693   0.534       0.693
```

The layout is messed up. To avoid that, use the "gr" command:

```
        inp     0.693   0.534   0.693

                |
          grx   |
                V

        inpx    0.693   0.534   0.693
```

What happens is that the "gr" command makes sure the new character takes the right amount of screen space. Extra spaces or tabs are inserted to fill the gap. Thus what actually happens is that a tab is replaced by "x" and then blanks added to make the text after it keep its place. In this case a tab is inserted.

When you need to replace more than one character, you use the "R" command to go to Replace mode (see 04.9). This messes up the layout and replaces the wrong characters:

```
        inp     0       0.534   0.693

                |
         R0.786 |
                V

        inp     0.78634 0.693
```

The "gR" command uses Virtual Replace mode. This preserves the layout:

```
        inp     0       0.534   0.693

                |
        gR0.786 |
                V

        inp     0.786   0.534   0.693
```

VIM USER MANUAL - by Bram Moolenaar

Repeating

An editing task is hardly ever unstructured. A change often needs to be made several times. In this chapter a number of useful ways to repeat a change will be explained.

Next chapter: usr_27.txt Search commands and patterns
Previous chapter: usr_25.txt Editing formatted text
Table of contents: usr_toc.txt

26.1 Repeating with Visual mode

Visual mode is very handy for making a change in any sequence of lines. You can see the highlighted text, thus you can check if the correct lines are changed. But making the selection takes some typing. The "gv" command selects the same area again. This allows you to do another operation on the same text.

Suppose you have some lines where you want to change "2001" to "2002" and "2000" to "2001":

```
The financial results for 2001 are better
than for 2000.  The income increased by 50%,
even though 2001 had more rain than 2000.
                2000           2001
income          45,403         66,234
```

First change "2001" to "2002". Select the lines in Visual mode, and use:

```
:s/2001/2002/g
```

Now use "gv" to reselect the same text. It doesn't matter where the cursor is. Then use ":s/2000/2001/g" to make the second change.

Obviously, you can repeat these changes several times.

26.2 Add and subtract

When repeating the change of one number into another, you often have a fixed offset. In the example above, one was added to each year. Instead of typing a substitute command for each year that appears, the CTRL-A command can be used.

Using the same text as above, search for a year:

```
/19[0-9][0-9]\|20[0-9][0-9]
```

Now press CTRL-A. The year will be increased by one:

```
The financial results for 2002 are better
than for 2000.  The income increased by 50%,
even though 2001 had more rain than 2000.
                2000          2001
income          45,403        66,234
```

Use "n" to find the next year, and press "." to repeat the CTRL-A ("." is a bit quicker to type). Repeat "n" and "." for all years that appear.
   Hint: set the 'hlsearch' option to see the matches you are going to change, then you can look ahead and do it faster.

Adding more than one can be done by prepending the number to CTRL-A. Suppose you have this list:

```
1.  item four
2.  item five
3.  item six
```

Move the cursor to "1." and type:

```
3 CTRL-A
```

The "1." will change to "4.". Again, you can use "." to repeat this on the other numbers.

Another example:

```
006     foo bar
007     foo bar
```

Using CTRL-A on these numbers results in:

```
007     foo bar
010     foo bar
```

7 plus one is 10? What happened here is that Vim recognized "007" as an octal number, because there is a leading zero. This notation is often used in C programs. If you do not want a number with leading zeros to be handled as octal, use this:

```
:set nrformats-=octal
```

The CTRL-X command does subtraction in a similar way.

==
26.3 Making a change in many files

Suppose you have a variable called "x_cnt" and you want to change it to "x_counter". This variable is used in several of your C files. You need to change it in all files. This is how you do it.

Put all the relevant files in the argument list:

```
:args *.c
```

This finds all C files and edits the first one. Now you can perform a substitution command on all these files:

```
:argdo %s/\<x_cnt\>/x_counter/ge | update
```

The ":argdo" command takes an argument that is another command. That command will be executed on all files in the argument list.

The "%s" substitute command that follows works on all lines. It finds the word "x_cnt" with "\<x_cnt\>". The "\<" and "\>" are used to match the whole word only, and not "px_cnt" or "x_cnt2".

The flags for the substitute command include "g" to replace all occurrences of "x_cnt" in the same line. The "e" flag is used to avoid an error message when "x_cnt" does not appear in the file. Otherwise ":argdo" would abort on the first file where "x_cnt" was not found.

The "|" separates two commands. The following "update" command writes the file only if it was changed. If no "x_cnt" was changed to "x_counter" nothing happens.

There is also the ":windo" command, which executes its argument in all windows. And ":bufdo" executes its argument on all buffers. Be careful with this, because you might have more files in the buffer list than you think. Check this with the ":buffers" command (or ":ls").

26.4 Using Vim from a shell script

Suppose you have a lot of files in which you need to change the string "-person-" to "Jones" and then print it. How do you do that? One way is to do a lot of typing. The other is to write a shell script to do the work.

The Vim editor does a superb job as a screen-oriented editor when using Normal mode commands. For batch processing, however, Normal mode commands do not result in clear, commented command files; so here you will use Ex mode instead. This mode gives you a nice command-line interface that makes it easy to put into a batch file. ("Ex command" is just another name for a command-line (:) command.)

The Ex mode commands you need are as follows:

```
%s/-person-/Jones/g
write tempfile
quit
```

You put these commands in the file "change.vim". Now to run the editor in batch mode, use this shell script:

```
for file in *.txt; do
  vim -e -s $file < change.vim
  lpr -r tempfile
done
```

The for-done loop is a shell construct to repeat the two lines in between,

while the $file variable is set to a different file name each time.
   The second line runs the Vim editor in Ex mode (-e argument) on the file $file and reads commands from the file "change.vim". The -s argument tells Vim to operate in silent mode. In other words, do not keep outputting the :prompt, or any other prompt for that matter.
   The "lpr -r tempfile" command prints the resulting "tempfile" and deletes it (that's what the -r argument does).

READING FROM STDIN

Vim can read text on standard input. Since the normal way is to read commands there, you must tell Vim to read text instead. This is done by passing the "-" argument in place of a file. Example:

```
ls | vim -
```

This allows you to edit the output of the "ls" command, without first saving the text in a file.
   If you use the standard input to read text from, you can use the "-S" argument to read a script:

```
producer | vim -S change.vim -
```

NORMAL MODE SCRIPTS

If you really want to use Normal mode commands in a script, you can use it like this:

```
vim -s script file.txt ...
```

Note:
"-s" has a different meaning when it is used without "-e". Here it means to source the "script" as Normal mode commands. When used with "-e" it means to be silent, and doesn't use the next argument as a file name.

The commands in "script" are executed like you typed them. Don't forget that a line break is interpreted as pressing <Enter>. In Normal mode that moves the cursor to the next line.
   To create the script you can edit the script file and type the commands. You need to imagine what the result would be, which can be a bit difficult. Another way is to record the commands while you perform them manually. This is how you do that:

```
vim -w script file.txt ...
```

All typed keys will be written to "script". If you make a small mistake you can just continue and remember to edit the script later.
   The "-w" argument appends to an existing script. That is good when you want to record the script bit by bit. If you want to start from scratch and start all over, use the "-W" argument. It overwrites any existing file.

usr_27.txt For Vim version 8.1. Last change: 2018 Jan 26

VIM USER MANUAL - by Bram Moolenaar

Search commands and patterns

In chapter 3 a few simple search patterns were mentioned 03.9 . Vim can do much more complex searches. This chapter explains the most often used ones. A detailed specification can be found here: pattern

Next chapter: usr_28.txt Folding
Previous chapter: usr_26.txt Repeating
Table of contents: usr_toc.txt

==========

27.1 Ignoring case

By default, Vim's searches are case sensitive. Therefore, "include", "INCLUDE", and "Include" are three different words and a search will match only one of them.

Now switch on the 'ignorecase' option:

```
:set ignorecase
```

Search for "include" again, and now it will match "Include", "INCLUDE" and "InClUDe". (Set the 'hlsearch' option to quickly see where a pattern matches.)

You can switch this off again with:

```
:set noignorecase
```

But let's keep it set, and search for "INCLUDE". It will match exactly the same text as "include" did. Now set the 'smartcase' option:

```
:set ignorecase smartcase
```

If you have a pattern with at least one uppercase character, the search becomes case sensitive. The idea is that you didn't have to type that uppercase character, so you must have done it because you wanted case to match. That's smart!

With these two options set you find the following matches:

```
pattern                 matches
```

```
        word                    word, Word, WORD, WoRd, etc.
        Word                    Word
        WORD                    WORD
        WoRd                    WoRd
```

CASE IN ONE PATTERN

If you want to ignore case for one specific pattern, you can do this by prepending the "\c" string. Using "\C" will make the pattern to match case. This overrules the 'ignorecase' and 'smartcase' options, when "\c" or "\C" is used their value doesn't matter.

```
        pattern                 matches
        \Cword                  word
        \CWord                  Word
        \cword                  word, Word, WORD, WoRd, etc.
        \cWord                  word, Word, WORD, WoRd, etc.
```

A big advantage of using "\c" and "\C" is that it sticks with the pattern. Thus if you repeat a pattern from the search history, the same will happen, no matter if 'ignorecase' or 'smartcase' was changed.

Note:
The use of "\" items in search patterns depends on the 'magic' option. In this chapter we will assume 'magic' is on, because that is the standard and recommended setting. If you would change 'magic', many search patterns would suddenly become invalid.

Note:
If your search takes much longer than you expected, you can interrupt it with CTRL-C on Unix and CTRL-Break on MS-DOS and MS-Windows.

27.2 Wrapping around the file end

By default, a forward search starts searching for the given string at the current cursor location. It then proceeds to the end of the file. If it has not found the string by that time, it starts from the beginning and searches from the start of the file to the cursor location.

Keep in mind that when repeating the "n" command to search for the next match, you eventually get back to the first match. If you don't notice this you keep searching forever! To give you a hint, Vim displays this message:

```
search hit BOTTOM, continuing at TOP
```

If you use the "?" command, to search in the other direction, you get this message:

```
search hit TOP, continuing at BOTTOM
```

Still, you don't know when you are back at the first match. One way to see this is by switching on the 'ruler' option:

```
:set ruler
```

Vim will display the cursor position in the lower righthand corner of the window (in the status line if there is one). It looks like this:

```
101,29        84%
```

The first number is the line number of the cursor. Remember the line number where you started, so that you can check if you passed this position again.

NOT WRAPPING

To turn off search wrapping, use the following command:

```
:set nowrapscan
```

Now when the search hits the end of the file, an error message displays:

```
E385: search hit BOTTOM without match for: forever
```

Thus you can find all matches by going to the start of the file with "gg" and keep searching until you see this message.
   If you search in the other direction, using "?", you get:

```
E384: search hit TOP without match for: forever
```

==========

27.3 Offsets

By default, the search command leaves the cursor positioned on the beginning of the pattern. You can tell Vim to leave it some other place by specifying an offset. For the forward search command "/", the offset is specified by appending a slash (/) and the offset:

```
/default/2
```

This command searches for the pattern "default" and then moves to the beginning of the second line past the pattern. Using this command on the paragraph above, Vim finds the word "default" in the first line. Then the cursor is moved two lines down and lands on "an offset".

If the offset is a simple number, the cursor will be placed at the beginning of the line that many lines from the match. The offset number can be positive or negative. If it is positive, the cursor moves down that many lines; if negative, it moves up.

CHARACTER OFFSETS

The "e" offset indicates an offset from the end of the match. It moves the cursor onto the last character of the match. The command:

```
/const/e
```

puts the cursor on the "t" of "const".
   From that position, adding a number moves forward that many characters.
This command moves to the character just after the match:

```
/const/e+1
```

A positive number moves the cursor to the right, a negative number moves it to the left. For example:

```
/const/e-1
```

moves the cursor to the "s" of "const".

If the offset begins with "b", the cursor moves to the beginning of the pattern. That's not very useful, since leaving out the "b" does the same thing. It does get useful when a number is added or subtracted. The cursor then goes forward or backward that many characters. For example:

```
/const/b+2
```

Moves the cursor to the beginning of the match and then two characters to the right. Thus it lands on the "n".

REPEATING

To repeat searching for the previously used search pattern, but with a different offset, leave out the pattern:

```
/that
//e
```

Is equal to:

```
/that/e
```

To repeat with the same offset:

```
/
```

"n" does the same thing. To repeat while removing a previously used offset:

```
//
```

SEARCHING BACKWARDS

The "?" command uses offsets in the same way, but you must use "?" to separate the offset from the pattern, instead of "/":

```
?const?e-2
```

The "b" and "e" keep their meaning, they don't change direction with the use

of "?".

START POSITION

When starting a search, it normally starts at the cursor position. When you specify a line offset, this can cause trouble. For example:

```
/const/-2
```

This finds the next word "const" and then moves two lines up. If you use "n" to search again, Vim could start at the current position and find the same "const" match. Then using the offset again, you would be back where you started. You would be stuck!
It could be worse: Suppose there is another match with "const" in the next line. Then repeating the forward search would find this match and move two lines up. Thus you would actually move the cursor back!

When you specify a character offset, Vim will compensate for this. Thus the search starts a few characters forward or backward, so that the same match isn't found again.

==========

27.4 Matching multiple times

The "*" item specifies that the item before it can match any number of times. Thus:

```
/a*
```

matches "a", "aa", "aaa", etc. But also "" (the empty string), because zero times is included.
The "*" only applies to the item directly before it. Thus "ab*" matches "a", "ab", "abb", "abbb", etc. To match a whole string multiple times, it must be grouped into one item. This is done by putting "\(" before it and "\)" after it. Thus this command:

```
/\(ab\)*
```

Matches: "ab", "abab", "ababab", etc. And also "".

To avoid matching the empty string, use "\+". This makes the previous item match one or more times.

```
/ab\+
```

Matches "ab", "abb", "abbb", etc. It does not match "a" when no "b" follows.

To match an optional item, use "\=". Example:

```
/folders\=
```

Matches "folder" and "folders".

SPECIFIC COUNTS

To match a specific number of items use the form "\{n,m}". "n" and "m" are numbers. The item before it will be matched "n" to "m" times inclusive . Example:

```
/ab\{3,5}
```

matches "abbb", "abbbb" and "abbbbb".
When "n" is omitted, it defaults to zero. When "m" is omitted it defaults to infinity. When ",m" is omitted, it matches exactly "n" times.
Examples:

pattern	match count
\{,4}	0, 1, 2, 3 or 4
\{3,}	3, 4, 5, etc.
\{0,1}	0 or 1, same as \=
\{0,}	0 or more, same as *
\{1,}	1 or more, same as \+
\{3}	3

MATCHING AS LITTLE AS POSSIBLE

The items so far match as many characters as they can find. To match as few as possible, use "\{-n,m}". It works the same as "\{n,m}", except that the minimal amount possible is used.
For example, use:

```
/ab\{-1,3}
```

Will match "ab" in "abbb". Actually, it will never match more than one b, because there is no reason to match more. It requires something else to force it to match more than the lower limit.
The same rules apply to removing "n" and "m". It's even possible to remove both of the numbers, resulting in "\{-}". This matches the item before it zero or more times, as few as possible. The item by itself always matches zero times. It is useful when combined with something else. Example:

```
/a.\{-}b
```

This matches "axb" in "axbxb". If this pattern would be used:

```
/a.*b
```

It would try to match as many characters as possible with ".*", thus it matches "axbxb" as a whole.

==========

27.5 Alternatives

The "or" operator in a pattern is "\|". Example:

```
        /foo\|bar
```

This matches "foo" or "bar". More alternatives can be concatenated:

```
        /one\|two\|three
```

Matches "one", "two" and "three".
   To match multiple times, the whole thing must be placed in "\(" and "\)":

```
        /\(foo\|bar\)\+
```

This matches "foo", "foobar", "foofoo", "barfoobar", etc.
   Another example:

```
        /end\(if\|while\|for\)
```

This matches "endif", "endwhile" and "endfor".

A related item is "\&". This requires that both alternatives match in the same place. The resulting match uses the last alternative. Example:

```
        /forever\&...
```

This matches "for" in "forever". It will not match "fortuin", for example.

==========

27.6 Character ranges

To match "a", "b" or "c" you could use "/a\|b\|c". When you want to match all letters from "a" to "z" this gets very long. There is a shorter method:

```
        /[a-z]
```

The [] construct matches a single character. Inside you specify which characters to match. You can include a list of characters, like this:

```
        /[0123456789abcdef]
```

This will match any of the characters included. For consecutive characters you can specify the range. "0-3" stands for "0123". "w-z" stands for "wxyz". Thus the same command as above can be shortened to:

```
        /[0-9a-f]
```

To match the "-" character itself make it the first or last one in the range. These special characters are accepted to make it easier to use them inside a [] range (they can actually be used anywhere in the search pattern):

```
        \e      <Esc>
        \t      <Tab>
        \r      <CR>
        \b      <BS>
```

There are a few more special cases for [] ranges, see /[] for the whole

story.

COMPLEMENTED RANGE

To avoid matching a specific character, use "^" at the start of the range.
The [] item then matches everything but the characters included. Example:

```
/"[^"]*"

 "        a double quote
  [^"]    any character that is not a double quote
      *   as many as possible
       "  a double quote again
```

This matches "foo" and "3!x", including the double quotes.

PREDEFINED RANGES

A number of ranges are used very often. Vim provides a shortcut for these.
For example:

```
/\a
```

Finds alphabetic characters. This is equal to using "/[a-zA-Z]". Here are a
few more of these:

item	matches	equivalent	
\d	digit	[0-9]	
\D	non-digit	[^0-9]	
\x	hex digit	[0-9a-fA-F]	
\X	non-hex digit	[^0-9a-fA-F]	
\s	white space	[ ]	(<Tab> and <Space>)
\S	non-white characters	[^]	(not <Tab> and <Space>)
\l	lowercase alpha	[a-z]	
\L	non-lowercase alpha	[^a-z]	
\u	uppercase alpha	[A-Z]	
\U	non-uppercase alpha	[^A-Z]	

Note:
Using these predefined ranges works a lot faster than the character
range it stands for.
These items can not be used inside []. Thus "[\d\l]" does NOT work to
match a digit or lowercase alpha. Use "\(\d\|\l\)" instead.

See /\s for the whole list of these ranges.

==
27.7 Character classes

The character range matches a fixed set of characters. A character class is
similar, but with an essential difference: The set of characters can be
redefined without changing the search pattern.

For example, search for this pattern:

```
/\f\+
```

The "\f" items stands for file name characters. Thus this matches a sequence of characters that can be a file name.

Which characters can be part of a file name depends on the system you are using. On MS-Windows, the backslash is included, on Unix it is not. This is specified with the 'isfname' option. The default value for Unix is:

```
:set isfname
isfname=@,48-57,/,.,-,_,+,,,#,$,%,~,=
```

For other systems the default value is different. Thus you can make a search pattern with "\f" to match a file name, and it will automatically adjust to the system you are using it on.

```
Note:
Actually, Unix allows using just about any character in a file name,
including white space. Including these characters in 'isfname' would
be theoretically correct. But it would make it impossible to find the
end of a file name in text. Thus the default value of 'isfname' is a
compromise.
```

The character classes are:

item	matches	option
\i	identifier characters	'isident'
\I	like \i, excluding digits	
\k	keyword characters	'iskeyword'
\K	like \k, excluding digits	
\p	printable characters	'isprint'
\P	like \p, excluding digits	
\f	file name characters	'isfname'
\F	like \f, excluding digits	

27.8 Matching a line break

Vim can find a pattern that includes a line break. You need to specify where the line break happens, because all items mentioned so far don't match a line break.

To check for a line break in a specific place, use the "\n" item:

```
/the\nword
```

This will match at a line that ends in "the" and the next line starts with "word". To match "the word" as well, you need to match a space or a line break. The item to use for it is "_s":

```
/the\_sword
```

To allow any amount of white space:

```
	/the\_s\+word
```

This also matches when "the " is at the end of a line and "   word" at the start of the next one.

"\s" matches white space, "_s" matches white space or a line break. Similarly, "\a" matches an alphabetic character, and "_a" matches an alphabetic character or a line break. The other character classes and ranges can be modified in the same way by inserting a "_".

Many other items can be made to match a line break by prepending "_". For example: "_." matches any character or a line break.

	Note:
	"_.*" matches everything until the end of the file. Be careful with this, it can make a search command very slow.

Another example is "_[]", a character range that includes a line break:

```
	/"\_[^"]*"
```

This finds a text in double quotes that may be split up in several lines.

==
27.9 Examples

Here are a few search patterns you might find useful. This shows how the items mentioned above can be combined.

FINDING A CALIFORNIA LICENSE PLATE

A sample license plate number is "1MGU103". It has one digit, three uppercase letters and three digits. Directly putting this into a search pattern:

```
	/\d\u\u\u\d\d\d
```

Another way is to specify that there are three digits and letters with a count:

```
	/\d\u\{3}\d\{3}
```

Using [] ranges instead:

```
	/[0-9][A-Z]\{3}[0-9]\{3}
```

Which one of these you should use? Whichever one you can remember. The simple way you can remember is much faster than the fancy way that you can't. If you can remember them all, then avoid the last one, because it's both more typing and slower to execute.

FINDING AN IDENTIFIER

In C programs (and many other computer languages) an identifier starts with a letter and further consists of letters and digits. Underscores can be used too. This can be found with:

```
/\<\h\w*\>
```

"\<" and "\>" are used to find only whole words. "\h" stands for "[A-Za-z_]" and "\w" for "[0-9A-Za-z_]".

Note:
"\<" and "\>" depend on the 'iskeyword' option. If it includes "-", for example, then "ident-" is not matched. In this situation use:

```
/\w\@<!\h\w*\w\@!
```

This checks if "\w" does not match before or after the identifier.
See /\@<! and /\@! .

Next chapter: usr_28.txt   Folding

VIM USER MANUAL - by Bram Moolenaar

Folding

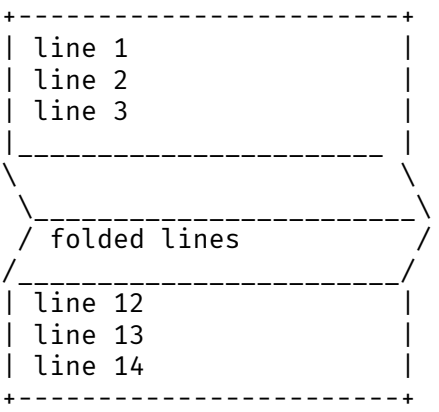
Structured text can be separated in sections. And sections in sub-sections.
Folding allows you to display a section as one line, providing an overview.
This chapter explains the different ways this can be done.

Next chapter: usr_29.txt Moving through programs
Previous chapter: usr_27.txt Search commands and patterns
Table of contents: usr_toc.txt

==

28.1 What is folding?

Folding is used to show a range of lines in the buffer as a single line on the
screen. Like a piece of paper which is folded to make it shorter:



The text is still in the buffer, unchanged. Only the way lines are displayed
is affected by folding.

The advantage of folding is that you can get a better overview of the
structure of text, by folding lines of a section and replacing it with a line
that indicates that there is a section.

==

28.2 Manual folding

Try it out: Position the cursor in a paragraph and type:

```
zfap
```

You will see that the paragraph is replaced by a highlighted line. You have created a fold. `zf` is an operator and `ap` a text object selection. You can use the `zf` operator with any movement command to create a fold for the text that it moved over. `zf` also works in Visual mode.

To view the text again, open the fold by typing:

```
zo
```

And you can close the fold again with:

```
zc
```

All the folding commands start with "z". With some fantasy, this looks like a folded piece of paper, seen from the side. The letter after the "z" has a mnemonic meaning to make it easier to remember the commands:

```
zf      F-old creation
zo      O-pen a fold
zc      C-lose a fold
```

Folds can be nested: A region of text that contains folds can be folded again. For example, you can fold each paragraph in this section, and then fold all the sections in this chapter. Try it out. You will notice that opening the fold for the whole chapter will restore the nested folds as they were, some may be open and some may be closed.

Suppose you have created several folds, and now want to view all the text. You could go to each fold and type "zo". To do this faster, use this command:

```
zr
```

This will R-educe the folding. The opposite is:

```
zm
```

This folds M-ore. You can repeat "zr" and "zm" to open and close nested folds of several levels.

If you have nested several levels deep, you can open all of them with:

```
zR
```

This R-educes folds until there are none left. And you can close all folds with:

```
zM
```

This folds M-ore and M-ore.

You can quickly disable the folding with the zn command. Then zN brings back the folding as it was. zi toggles between the two. This is a useful way of working:
- create folds to get overview on your file
- move around to where you want to do your work
- do zi to look at the text and edit it
- do zi again to go back to moving around

More about manual folding in the reference manual: fold-manual

==
28.3 Working with folds

When some folds are closed, movement commands like "j" and "k" move over a fold like it was a single, empty line. This allows you to quickly move around over folded text.

You can yank, delete and put folds as if it was a single line. This is very useful if you want to reorder functions in a program. First make sure that each fold contains a whole function (or a bit less) by selecting the right 'foldmethod'. Then delete the function with "dd", move the cursor and put it with "p". If some lines of the function are above or below the fold, you can use Visual selection:
- put the cursor on the first line to be moved
- hit "V" to start Visual mode
- put the cursor on the last line to be moved
- hit "d" to delete the selected lines.
- move the cursor to the new position and "p"ut the lines there.

It is sometimes difficult to see or remember where a fold is located, thus where a zo command would actually work. To see the defined folds:

```
:set foldcolumn=4
```

This will show a small column on the left of the window to indicate folds. A "+" is shown for a closed fold. A "-" is shown at the start of each open fold and "|" at following lines of the fold.

You can use the mouse to open a fold by clicking on the "+" in the foldcolumn. Clicking on the "-" or a "|" below it will close an open fold.

To open all folds at the cursor line use zO .
To close all folds at the cursor line use zC .
To delete a fold at the cursor line use zd .
To delete all folds at the cursor line use zD .

When in Insert mode, the fold at the cursor line is never closed. That allows you to see what you type!

Folds are opened automatically when jumping around or moving the cursor left or right. For example, the "0" command opens the fold under the cursor (if 'foldopen' contains "hor", which is the default). The 'foldopen' option

can be changed to open folds for specific commands. If you want the line
under the cursor always to be open, do this:

```
:set foldopen=all
```

Warning: You won't be able to move onto a closed fold then. You might want to
use this only temporarily and then set it back to the default:

```
:set foldopen&
```

You can make folds close automatically when you move out of it:

```
:set foldclose=all
```

This will re-apply 'foldlevel' to all folds that don't contain the cursor.
You have to try it out if you like how this feels. Use zm to fold more and
 zr to fold less (reduce folds).

The folding is local to the window. This allows you to open two windows on
the same buffer, one with folds and one without folds. Or one with all folds
closed and one with all folds open.

==
28.4 Saving and restoring folds

When you abandon a file (starting to edit another one), the state of the folds
is lost. If you come back to the same file later, all manually opened and
closed folds are back to their default. When folds have been created
manually, all folds are gone! To save the folds use the :mkview command:

```
:mkview
```

This will store the settings and other things that influence the view on the
file. You can change what is stored with the 'viewoptions' option.
When you come back to the same file later, you can load the view again:

```
:loadview
```

You can store up to ten views on one file. For example, to save the current
setup as the third view and load the second view:

```
:mkview 3
:loadview 2
```

Note that when you insert or delete lines the views might become invalid.
Also check out the 'viewdir' option, which specifies where the views are
stored. You might want to delete old views now and then.

==
28.5 Folding by indent

Defining folds with zf is a lot of work. If your text is structured by
giving lower level items a larger indent, you can use the indent folding
method. This will create folds for every sequence of lines with the same

indent. Lines with a larger indent will become nested folds. This works well with many programming languages.

Try this by setting the 'foldmethod' option:

```
:set foldmethod=indent
```

Then you can use the zm and zr commands to fold more and reduce folding. It's easy to see on this example text:

```
This line is not indented
        This line is indented once
                This line is indented twice
                This line is indented twice
        This line is indented once
This line is not indented
        This line is indented once
        This line is indented once
```

Note that the relation between the amount of indent and the fold depth depends on the 'shiftwidth' option. Each 'shiftwidth' worth of indent adds one to the depth of the fold. This is called a fold level.

When you use the zr and zm commands you actually increase or decrease the 'foldlevel' option. You could also set it directly:

```
:set foldlevel=3
```

This means that all folds with three times a 'shiftwidth' indent or more will be closed. The lower the foldlevel, the more folds will be closed. When 'foldlevel' is zero, all folds are closed. zM does set 'foldlevel' to zero. The opposite command zR sets 'foldlevel' to the deepest fold level that is present in the file.

Thus there are two ways to open and close the folds:
(A) By setting the fold level.
    This gives a very quick way of "zooming out" to view the structure of the text, move the cursor, and "zoom in" on the text again.

(B) By using zo and zc commands to open or close specific folds.
    This allows opening only those folds that you want to be open, while other folds remain closed.

This can be combined: You can first close most folds by using zm a few times and then open a specific fold with zo . Or open all folds with zR and then close specific folds with zc .

But you cannot manually define folds when 'foldmethod' is "indent", as that would conflict with the relation between the indent and the fold level.

More about folding by indent in the reference manual: fold-indent

==
28.6 Folding with markers

Markers in the text are used to specify the start and end of a fold region.
This gives precise control over which lines are included in a fold. The
disadvantage is that the text needs to be modified.

Try it:

```
:set foldmethod=marker
```

Example text, as it could appear in a C program:

```
/* foobar () {{{ */
int foobar()
{
        /* return a value {{{ */
        return 42;
        /* }}} */
}
/* }}} */
```

Notice that the folded line will display the text before the marker. This is
very useful to tell what the fold contains.

It's quite annoying when the markers don't pair up correctly after moving some
lines around. This can be avoided by using numbered markers. Example:

```
/* global variables {{{1 */
int varA, varB;

/* functions {{{1 */
/* funcA() {{{2 */
void funcA() {}

/* funcB() {{{2 */
void funcB() {}
/* }}}1 */
```

At every numbered marker a fold at the specified level begins. This will make
any fold at a higher level stop here. You can just use numbered start markers
to define all folds. Only when you want to explicitly stop a fold before
another starts you need to add an end marker.

More about folding with markers in the reference manual: fold-marker

==
28.7 Folding by syntax

For each language Vim uses a different syntax file. This defines the colors
for various items in the file. If you are reading this in Vim, in a terminal
that supports colors, the colors you see are made with the "help" syntax file.
   In the syntax files it is possible to add syntax items that have the "fold"
argument. These define a fold region. This requires writing a syntax file
and adding these items in it. That's not so easy to do. But once it's done,
all folding happens automatically.

Here we'll assume you are using an existing syntax file. Then there is nothing more to explain. You can open and close folds as explained above. The folds will be created and deleted automatically when you edit the file.

More about folding by syntax in the reference manual: fold-syntax

28.8 Folding by expression

This is similar to folding by indent, but instead of using the indent of a line a user function is called to compute the fold level of a line. You can use this for text where something in the text indicates which lines belong together. An example is an e-mail message where the quoted text is indicated by a ">" before the line. To fold these quotes use this:

```
:set foldmethod=expr
:set foldexpr=strlen(substitute(substitute(getline(v:lnum),'\\s','',\"g\"),'[^>].*
```

You can try it out on this text:

```
> quoted text he wrote
> quoted text he wrote
> > double quoted text I wrote
> > double quoted text I wrote
```

Explanation for the 'foldexpr' used in the example (inside out):

```
getline(v:lnum)                    gets the current line
substitute(...,'\\s','','g')       removes all white space from the line
substitute(...,'[^>].*','','')     removes everything after leading '>'s
strlen(...)                        counts the length of the string, which
                                   is the number of '>'s found
```

Note that a backslash must be inserted before every space, double quote and backslash for the ":set" command. If this confuses you, do

```
:set foldexpr
```

to check the actual resulting value. To correct a complicated expression, use the command-line completion:

```
:set foldexpr=<Tab>
```

Where <Tab> is a real Tab. Vim will fill in the previous value, which you can then edit.

When the expression gets more complicated you should put it in a function and set 'foldexpr' to call that function.

More about folding by expression in the reference manual: fold-expr

28.9 Folding unchanged lines

This is useful when you set the 'diff' option in the same window. The

vimdiff command does this for you. Example:

```
:setlocal diff foldmethod=diff scrollbind nowrap foldlevel=1
```

Do this in every window that shows a different version of the same file. You will clearly see the differences between the files, while the text that didn't change is folded.

For more details see fold-diff .

==

28.10 Which fold method to use?

All these possibilities make you wonder which method you should choose. Unfortunately, there is no golden rule. Here are some hints.

If there is a syntax file with folding for the language you are editing, that is probably the best choice. If there isn't one, you might try to write it. This requires a good knowledge of search patterns. It's not easy, but when it's working you will not have to define folds manually.

Typing commands to manually fold regions can be used for unstructured text. Then use the :mkview command to save and restore your folds.

The marker method requires you to change the file. If you are sharing the files with other people or you have to meet company standards, you might not be allowed to add them.
   The main advantage of markers is that you can put them exactly where you want them. That avoids that a few lines are missed when you cut and paste folds. And you can add a comment about what is contained in the fold.

Folding by indent is something that works in many files, but not always very well. Use it when you can't use one of the other methods. However, it is very useful for outlining. Then you specifically use one 'shiftwidth' for each nesting level.

Folding with expressions can make folds in almost any structured text. It is quite simple to specify, especially if the start and end of a fold can easily be recognized.
   If you use the "expr" method to define folds, but they are not exactly how you want them, you could switch to the "manual" method. This will not remove the defined folds. Then you can delete or add folds manually.

VIM USER MANUAL - by Bram Moolenaar

Moving through programs

The creator of Vim is a computer programmer. It's no surprise that Vim contains many features to aid in writing programs. Jump around to find where identifiers are defined and used. Preview declarations in a separate window. There is more in the next chapter.

Next chapter: usr_30.txt Editing programs
Previous chapter: usr_28.txt Folding
Table of contents: usr_toc.txt

==========

29.1 Using tags

What is a tag? It is a location where an identifier is defined. An example is a function definition in a C or C++ program. A list of tags is kept in a tags file. This can be used by Vim to directly jump from any place to the tag, the place where an identifier is defined.

To generate the tags file for all C files in the current directory, use the following command:

```
ctags *.c
```

"ctags" is a separate program. Most Unix systems already have it installed. If you do not have it yet, you can find Exuberant ctags here:

```
http://ctags.sf.net
```

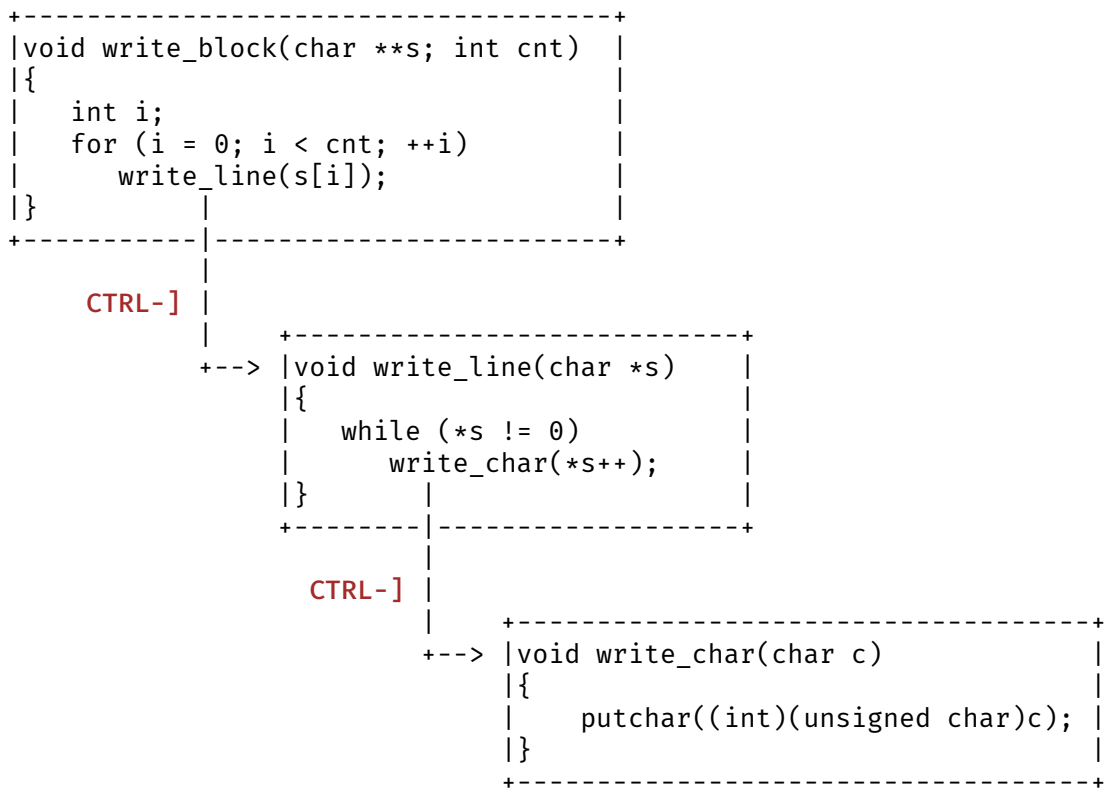
Now when you are in Vim and you want to go to a function definition, you can jump to it by using the following command:

```
:tag startlist
```

This command will find the function "startlist" even if it is in another file.

The CTRL-] command jumps to the tag of the word that is under the cursor. This makes it easy to explore a tangle of C code. Suppose, for example, that you are in the function "write_block". You can see that it calls "write_line". But what does "write_line" do? By placing the cursor on the call to "write_line" and pressing CTRL-], you jump to the definition of this function.

The "write_line" function calls "write_char". You need to figure out what it does. So you position the cursor over the call to "write_char" and press CTRL-]. Now you are at the definition of "write_char".



The ":tags" command shows the list of tags that you traversed through:

```
:tags
  # TO tag         FROM line  in file/text
  1  1 write_line          8  write_block.c
  2  1 write_char          7  write_line.c
>
```

Now to go back. The CTRL-T command goes to the preceding tag. In the example above you get back to the "write_line" function, in the call to "write_char".
   This command takes a count argument that indicates how many tags to jump back. You have gone forward, and now back. Let's go forward again. The following command goes to the tag on top of the list:

```
:tag
```

You can prefix it with a count and jump forward that many tags. For example: ":3tag". CTRL-T also can be preceded with a count.
   These commands thus allow you to go down a call tree with CTRL-] and back up again with CTRL-T. Use ":tags" to find out where you are.

SPLIT WINDOWS

The ":tag" command replaces the file in the current window with the one containing the new function. But suppose you want to see not only the old function but also the new one? You can split the window using the ":split"

command followed by the ":tag" command. Vim has a shorthand command that does both:

```
:stag tagname
```

To split the current window and jump to the tag under the cursor use this command:

```
CTRL-W ]
```

If a count is specified, the new window will be that many lines high.

MORE TAGS FILES

When you have files in many directories, you can create a tags file in each of them. Vim will then only be able to jump to tags within that directory.
   To find more tags files, set the 'tags' option to include all the relevant tags files. Example:

```
:set tags=./tags,./../tags,./*/tags
```

This finds a tags file in the same directory as the current file, one directory level higher and in all subdirectories.
   This is quite a number of tags files, but it may still not be enough. For example, when editing a file in "~/proj/src", you will not find the tags file "~/proj/sub/tags". For this situation Vim offers to search a whole directory tree for tags files. Example:

```
:set tags=~/proj/**/tags
```

ONE TAGS FILE

When Vim has to search many places for tags files, you can hear the disk rattling. It may get a bit slow. In that case it's better to spend this time while generating one big tags file. You might do this overnight.
   This requires the Exuberant ctags program, mentioned above. It offers an argument to search a whole directory tree:

```
cd ~/proj
ctags -R .
```

The nice thing about this is that Exuberant ctags recognizes various file types. Thus this doesn't work just for C and C++ programs, also for Eiffel and even Vim scripts. See the ctags documentation to tune this.
   Now you only need to tell Vim where your big tags file is:

```
:set tags=~/proj/tags
```

MULTIPLE MATCHES

When a function is defined multiple times (or a method in several classes), the ":tag" command will jump to the first one. If there is a match in the

current file, that one is used first.
   You can now jump to other matches for the same tag with:

```
:tnext
```

Repeat this to find further matches. If there are many, you can select which one to jump to:

```
:tselect tagname
```

Vim will present you with a list of choices:

```
  # pri kind tag               file
  1 F   f    mch_init          os_amiga.c
               mch_init()
  2 F   f    mch_init          os_mac.c
               mch_init()
  3 F   f    mch_init          os_msdos.c
               mch_init(void)
  4 F   f    mch_init          os_riscos.c
               mch_init()
Enter nr of choice (<CR> to abort):
```

You can now enter the number (in the first column) of the match that you would like to jump to. The information in the other columns give you a good idea of where the match is defined.

To move between the matching tags, these commands can be used:

```
:tfirst                 go to first match
:[count]tprevious       go to [count] previous match
:[count]tnext           go to [count] next match
:tlast                  go to last match
```

If [count] is omitted then one is used.

GUESSING TAG NAMES

Command line completion is a good way to avoid typing a long tag name. Just type the first bit and press <Tab>:

```
:tag write_<Tab>
```

You will get the first match. If it's not the one you want, press <Tab> until you find the right one.
   Sometimes you only know part of the name of a function. Or you have many tags that start with the same string, but end differently. Then you can tell Vim to use a pattern to find the tag.
   Suppose you want to jump to a tag that contains "block". First type this:

```
:tag /block
```

Now use command line completion: press <Tab>. Vim will find all tags that contain "block" and use the first match.
   The "/" before a tag name tells Vim that what follows is not a literal tag name, but a pattern. You can use all the items for search patterns here. For example, suppose you want to select a tag that starts with "write_":

```
:tselect /^write_
```

The "^" specifies that the tag starts with "write_". Otherwise it would also be found halfway a tag name. Similarly "$" at the end makes sure the pattern matches until the end of a tag.

A TAGS BROWSER

Since CTRL-] takes you to the definition of the identifier under the cursor, you can use a list of identifier names as a table of contents. Here is an example.
   First create a list of identifiers (this requires Exuberant ctags):

```
ctags --c-types=f -f functions *.c
```

Now start Vim without a file, and edit this file in Vim, in a vertically split window:

```
vim
:vsplit functions
```

The window contains a list of all the functions. There is some more stuff, but you can ignore that. Do ":setlocal ts=99" to clean it up a bit.
   In this window, define a mapping:

```
:nnoremap <buffer> <CR> 0ye<C-W>w:tag <C-R>"<CR>
```

Move the cursor to the line that contains the function you want to go to. Now press <Enter>. Vim will go to the other window and jump to the selected function.

RELATED ITEMS

To make case in tag names be ignored, you can set 'ignorecase' while leaving 'tagcase' as "followic", or set 'tagcase' to "ignore".

The 'tagbsearch' option tells if the tags file is sorted or not. The default is to assume a sorted tags file, which makes a tags search a lot faster, but doesn't work if the tags file isn't sorted.

The 'taglength' option can be used to tell Vim the number of significant characters in a tag.

Cscope is a free program. It does not only find places where an identifier is declared, but also where it is used. See cscope .

==
29.2 The preview window

When you edit code that contains a function call, you need to use the correct arguments. To know what values to pass you can look at how the function is defined. The tags mechanism works very well for this. Preferably the definition is displayed in another window. For this the preview window can be used.
   To open a preview window to display the function "write_char":

```
:ptag write_char
```

Vim will open a window, and jumps to the tag "write_char". Then it takes you back to the original position. Thus you can continue typing without the need to use a CTRL-W command.
   If the name of a function appears in the text, you can get its definition in the preview window with:

```
CTRL-W }
```

There is a script that automatically displays the text where the word under the cursor was defined. See CursorHold-example .

To close the preview window use this command:

```
:pclose
```

To edit a specific file in the preview window, use ":pedit". This can be useful to edit a header file, for example:

```
:pedit defs.h
```

Finally, ":psearch" can be used to find a word in the current file and any included files and display the match in the preview window. This is especially useful when using library functions, for which you do not have a tags file. Example:

```
:psearch popen
```

This will show the "stdio.h" file in the preview window, with the function prototype for popen():

```
FILE    *popen __P((const char *, const char *));
```

You can specify the height of the preview window, when it is opened, with the 'previewheight' option.

==
29.3 Moving through a program

Since a program is structured, Vim can recognize items in it. Specific commands can be used to move around.
   C programs often contain constructs like this:

```
#ifdef USE_POPEN
    fd = popen("ls", "r")
#else
    fd = fopen("tmp", "w")
#endif
```

But then much longer, and possibly nested. Position the cursor on the "#ifdef" and press %. Vim will jump to the "#else". Pressing % again takes you to the "#endif". Another % takes you to the "#ifdef" again.
   When the construct is nested, Vim will find the matching items. This is a good way to check if you didn't forget an "#endif".
   When you are somewhere inside a "#if" - "#endif", you can jump to the start of it with:

```
[#
```

If you are not after a "#if" or "#ifdef" Vim will beep. To jump forward to the next "#else" or "#endif" use:

```
]#
```

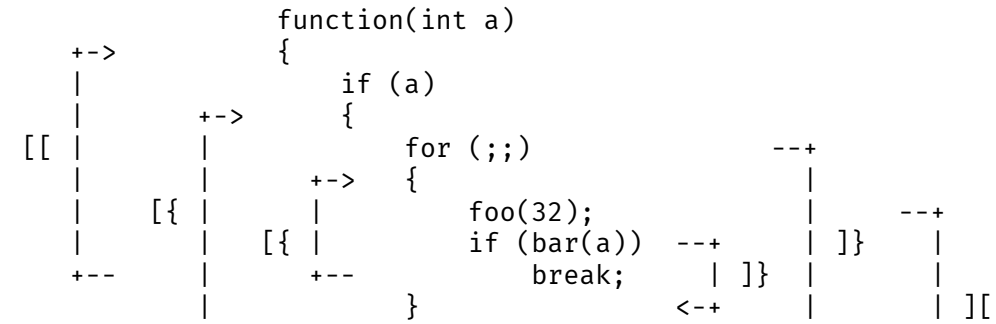
These two commands skip any "#if" - "#endif" blocks that they encounter. Example:

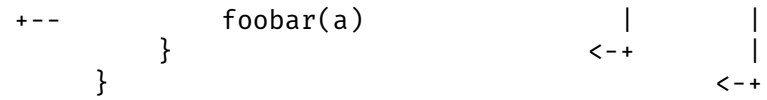
```
#if defined(HAS_INC_H)
    a = a + inc();
# ifdef USE_THEME
    a += 3;
# endif
    set_width(a);
```

With the cursor in the last line, "[#" moves to the first line. The "#ifdef" - "#endif" block in the middle is skipped.

MOVING IN CODE BLOCKS

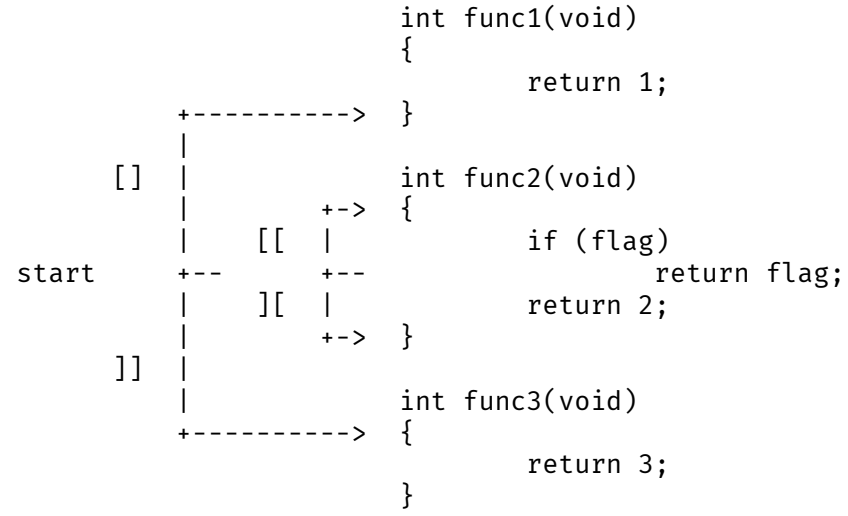
In C code blocks are enclosed in {}. These can get pretty long. To move to the start of the outer block use the "[[" command. Use "][" to find the end. This assumes that the "{" and "}" are in the first column.
   The "[{" command moves to the start of the current block. It skips over pairs of {} at the same level. "]}" jumps to the end.
   An overview:





When writing C++ or Java, the outer {} block is for the class. The next level of {} is for a method. When somewhere inside a class use "[m" to find the previous start of a method. "]m" finds the next start of a method.

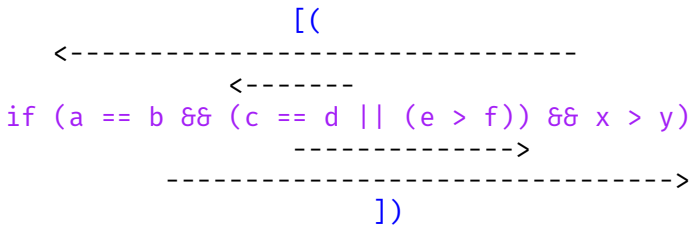
Additionally, "[]" moves backward to the end of a function and "]]" moves forward to the start of the next function. The end of a function is defined by a "}" in the first column.



Don't forget you can also use "%" to move between matching (), {} and []. That also works when they are many lines apart.

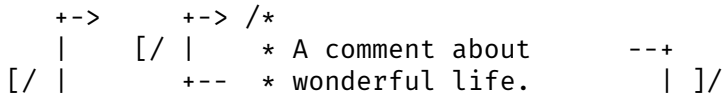
MOVING IN BRACES

The "[(" and "])" commands work similar to "[{" and "]}", except that they work on () pairs instead of {} pairs.



MOVING IN COMMENTS

To move back to the start of a comment use "[/". Move forward to the end of a comment with "]/". This only works for /* - */ comments.



```
          |            */                    <-+
          |
          +--          foo = bar * 3;         --+
                                                | ]/
                       /* a short comment */   <-+
```

==========

29.4 Finding global identifiers

You are editing a C program and wonder if a variable is declared as "int" or "unsigned". A quick way to find this is with the "[I" command.

Suppose the cursor is on the word "column". Type:

```
[I
```

Vim will list the matching lines it can find. Not only in the current file, but also in all included files (and files included in them, etc.). The result looks like this:

```
structs.h
 1:   29     unsigned     column;    /* column number */
```

The advantage over using tags or the preview window is that included files are searched. In most cases this results in the right declaration to be found. Also when the tags file is out of date. Also when you don't have tags for the included files.

However, a few things must be right for "[I" to do its work. First of all, the 'include' option must specify how a file is included. The default value works for C and C++. For other languages you will have to change it.

LOCATING INCLUDED FILES

Vim will find included files in the places specified with the 'path' option. If a directory is missing, some include files will not be found. You can discover this with this command:

```
:checkpath
```

It will list the include files that could not be found. Also files included by the files that could be found. An example of the output:

```
--- Included files not found in path ---
<io.h>
vim.h -->
  <functions.h>
  <clib/exec_protos.h>
```

The "io.h" file is included by the current file and can't be found. "vim.h" can be found, thus ":checkpath" goes into this file and checks what it includes. The "functions.h" and "clib/exec_protos.h" files, included by "vim.h" are not found.

```
Note:
```

Vim is not a compiler. It does not recognize "#ifdef" statements.
This means every "#include" statement is used, also when it comes
after "#if NEVER".

To fix the files that could not be found, add a directory to the 'path'
option. A good place to find out about this is the Makefile. Look out for
lines that contain "-I" items, like "-I/usr/local/X11". To add this directory
use:

```
:set path+=/usr/local/X11
```

When there are many subdirectories, you can use the "*" wildcard. Example:

```
:set path+=/usr/*/include
```

This would find files in "/usr/local/include" as well as "/usr/X11/include".

When working on a project with a whole nested tree of included files, the "**"
items is useful. This will search down in all subdirectories. Example:

```
:set path+=/projects/invent/**/include
```

This will find files in the directories:

```
/projects/invent/include
/projects/invent/main/include
/projects/invent/main/os/include
etc.
```

There are even more possibilities. Check out the 'path' option for info.
   If you want to see which included files are actually found, use this
command:

```
:checkpath!
```

You will get a (very long) list of included files, the files they include, and
so on. To shorten the list a bit, Vim shows "(Already listed)" for files that
were found before and doesn't list the included files in there again.

JUMPING TO A MATCH

"[I" produces a list with only one line of text. When you want to have a
closer look at the first item, you can jump to that line with the command:

```
[<Tab>
```

You can also use "[CTRL-I", since CTRL-I is the same as pressing <Tab>.

The list that "[I" produces has a number at the start of each line. When you
want to jump to another item than the first one, type the number first:

```
3[<Tab>
```

Will jump to the third item in the list. Remember that you can use CTRL-O to jump back to where you started from.

RELATED COMMANDS

```
        [i              only lists the first match
        ]I              only lists items below the cursor
        ]i              only lists the first item below the cursor
```

FINDING DEFINED IDENTIFIERS

The "[I" command finds any identifier. To find only macros, defined with "#define" use:

```
        [D
```

Again, this searches in included files. The 'define' option specifies what a line looks like that defines the items for "[D". You could change it to make it work with other languages than C or C++.
   The commands related to "[D" are:

```
        [d              only lists the first match
        ]D              only lists items below the cursor
        ]d              only lists the first item below the cursor
```

==========

29.5 Finding local identifiers

The "[I" command searches included files. To search in the current file only, and jump to the first place where the word under the cursor is used:

```
        gD
```

Hint: Goto Definition. This command is very useful to find a variable or function that was declared locally ("static", in C terms). Example (cursor on "counter"):

```
           +->   static int counter = 0;
           |
           |     int get_counter(void)
        gD |     {
           |         ++counter;
           +--       return counter;
                 }
```

To restrict the search even further, and look only in the current function, use this command:

```
        gd
```

This will go back to the start of the current function and find the first occurrence of the word under the cursor. Actually, it searches backwards to

an empty line above a "{" in the first column. From there it searches forward
for the identifier. Example (cursor on "idx"):

```
                int find_entry(char *name)
                {
           +->      int idx;
           |
        gd |        for (idx = 0; idx < table_len; ++idx)
           |            if (strcmp(table[idx].name, name) == 0)
           +--              return idx;
                }
```

==

30.1 Compiling

Vim has a set of so called "quickfix" commands. They enable you to compile a program from within Vim and then go through the errors generated and fix them (hopefully). You can then recompile and fix any new errors that are found until finally your program compiles without any error.

The following command runs the program "make" (supplying it with any argument you give) and captures the results:

```
:make {arguments}
```

If errors were generated, they are captured and the editor positions you where the first error occurred.
Take a look at an example ":make" session. (Typical :make sessions generate far more errors and fewer stupid ones.) After typing ":make" the screen looks like this:

```
:!make | &tee /tmp/vim215953.err
gcc -g -Wall -o prog main.c sub.c
main.c: In function 'main':
main.c:6: too many arguments to function 'do_sub'
main.c: At top level:
main.c:10: parse error before '}'
make: *** [prog] Error 1

2 returned
"main.c" 11L, 111C
(3 of 6): too many arguments to function 'do_sub'
Press ENTER or type command to continue
```

From this you can see that you have errors in the file "main.c". When you press <Enter>, Vim displays the file "main.c", with the cursor positioned on line 6, the first line with an error. You did not need to specify the file or the line number, Vim knew where to go by looking in the error messages.

```
                +-------------------------------------------------+
                |int main()                                       |
                |{                                                |
                |       int i=3;                                  |
      cursor -> |       do_sub("foo");                            |
                |       ++i;                                      |
                |       return (0);                               |
                |}                                                |
                |}                                                |
                | ~                                               |
                |(3 of 12): too many arguments to function 'do_sub' |
                +-------------------------------------------------+
```

The following command goes to where the next error occurs:

```
        :cnext
```

Vim jumps to line 10, the last line in the file, where there is an extra '}'.
   When there is not enough room, Vim will shorten the error message. To see the whole message use:

```
        :cc
```

You can get an overview of all the error messages with the ":clist" command. The output looks like this:

```
        :clist
       3 main.c: 6:too many arguments to function 'do_sub'
        5 main.c: 10:parse error before '}'
```

Only the lines where Vim recognized a file name and line number are listed here. It assumes those are the interesting lines and the rest is just boring messages. However, sometimes unrecognized lines do contain something you want to see. Output from the linker, for example, about an undefined function. To see all the messages add a "!" to the command:

```
        :clist!
       1 gcc -g -Wall -o prog main.c sub.c
        2 main.c: In function 'main':
        3 main.c:6: too many arguments to function 'do_sub'
        4 main.c: At top level:
        5 main.c:10: parse error before '}'
        6 make: *** [prog] Error 1
```

Vim will highlight the current error. To go back to the previous error, use:

```
        :cprevious
```

Other commands to move around in the error list:

```
        :cfirst         to first error
        :clast          to last error
        :cc 3           to error nr 3
```

USING ANOTHER COMPILER

The name of the program to run when the ":make" command is executed is defined by the 'makeprg' option. Usually this is set to "make", but Visual C++ users should set this to "nmake" by executing the following command:

```
        :set makeprg=nmake
```

You can also include arguments in this option. Special characters need to be escaped with a backslash. Example:

```
        :set makeprg=nmake\ -f\ project.mak
```

You can include special Vim keywords in the command specification. The % character expands to the name of the current file. So if you execute the command:

```
        :set makeprg=make\ %:S
```

When you are editing main.c, then ":make" executes the following command:

```
        make main.c
```

This is not too useful, so you will refine the command a little and use the :r (root) modifier:

```
        :set makeprg=make\ %:r:S.o
```

Now the command executed is as follows:

```
        make main.o
```

More about these modifiers here: filename-modifiers .

OLD ERROR LISTS

Suppose you ":make" a program. There is a warning message in one file and an error message in another. You fix the error and use ":make" again to check if it was really fixed. Now you want to look at the warning message. It doesn't show up in the last error list, since the file with the warning wasn't compiled again. You can go back to the previous error list with:

```
        :colder
```

Then use ":clist" and ":cc {nr}" to jump to the place with the warning.
   To go forward to the next error list:

```
        :cnewer
```

Vim remembers ten error lists.

SWITCHING COMPILERS

You have to tell Vim what format the error messages are that your compiler produces. This is done with the 'errorformat' option. The syntax of this option is quite complicated and it can be made to fit almost any compiler. You can find the explanation here: errorformat .

You might be using various different compilers. Setting the 'makeprg' option, and especially the 'errorformat' each time is not easy. Vim offers a simple method for this. For example, to switch to using the Microsoft Visual C++ compiler:

```
:compiler msvc
```

This will find the Vim script for the "msvc" compiler and set the appropriate options.
You can write your own compiler files. See write-compiler-plugin .

OUTPUT REDIRECTION

The ":make" command redirects the output of the executed program to an error file. How this works depends on various things, such as the 'shell'. If your ":make" command doesn't capture the output, check the 'makeef' and 'shellpipe' options. The 'shellquote' and 'shellxquote' options might also matter.

In case you can't get ":make" to redirect the file for you, an alternative is to compile the program in another window and redirect the output into a file. Then have Vim read this file with:

```
:cfile {filename}
```

Jumping to errors will work like with the ":make" command.

==
30.2 Indenting C style text

A program is much easier to understand when the lines have been properly indented. Vim offers various ways to make this less work. For C or C style programs like Java or C++, set the 'cindent' option. Vim knows a lot about C programs and will try very hard to automatically set the indent for you. Set the 'shiftwidth' option to the amount of spaces you want for a deeper level. Four spaces will work fine. One ":set" command will do it:

```
:set cindent shiftwidth=4
```

With this option enabled, when you type something such as "if (x)", the next line will automatically be indented an additional level.

```
                                if (flag)
Automatic indent   --->             do_the_work();
Automatic unindent <--          if (other_flag) {
Automatic indent   --->             do_file();
keep indent                         do_some_more();
Automatic unindent <--          }
```

When you type something in curly braces ({}), the text will be indented at the start and unindented at the end. The unindenting will happen after typing the '}', since Vim can't guess what you are going to type.

One side effect of automatic indentation is that it helps you catch errors in your code early. When you type a } to finish a function, only to find that the automatic indentation gives it more indent than what you expected, there is probably a } missing. Use the "%" command to find out which { matches the } you typed.
A missing) and ; also cause extra indent. Thus if you get more white space than you would expect, check the preceding lines.

When you have code that is badly formatted, or you inserted and deleted lines, you need to re-indent the lines. The "=" operator does this. The simplest form is:

```
==
```

This indents the current line. Like with all operators, there are three ways to use it. In Visual mode "=" indents the selected lines. A useful text object is "a{". This selects the current {} block. Thus, to re-indent the code block the cursor is in:

```
=a{
```

I you have really badly indented code, you can re-indent the whole file with:

```
gg=G
```

However, don't do this in files that have been carefully indented manually. The automatic indenting does a good job, but in some situations you might want to overrule it.

SETTING INDENT STYLE

Different people have different styles of indentation. By default Vim does a pretty good job of indenting in a way that 90% of programmers do. There are different styles, however; so if you want to, you can customize the indentation style with the 'cinoptions' option.
By default 'cinoptions' is empty and Vim uses the default style. You can add various items where you want something different. For example, to make curly braces be placed like this:

```
if (flag)
  {
    i = 8;
```

```
            j = 0;
          }
```

Use this command:

```
:set cinoptions+={2
```

There are many of these items. See cinoptions-values .

==========

30.3 Automatic indenting

You don't want to switch on the 'cindent' option manually every time you edit a C file. This is how you make it work automatically:

```
:filetype indent on
```

Actually, this does a lot more than switching on 'cindent' for C files. First of all, it enables detecting the type of a file. That's the same as what is used for syntax highlighting.
   When the filetype is known, Vim will search for an indent file for this type of file. The Vim distribution includes a number of these for various programming languages. This indent file will then prepare for automatic indenting specifically for this file.

If you don't like the automatic indenting, you can switch it off again:

```
:filetype indent off
```

If you don't like the indenting for one specific type of file, this is how you avoid it. Create a file with just this one line:

```
:let b:did_indent = 1
```

Now you need to write this in a file with a specific name:

```
{directory}/indent/{filetype}.vim
```

The {filetype} is the name of the file type, such as "cpp" or "java". You can see the exact name that Vim detected with this command:

```
:set filetype
```

In this file the output is:

```
filetype=help
```

Thus you would use "help" for {filetype}.
   For the {directory} part you need to use your runtime directory. Look at the output of this command:

```
set runtimepath
```

Now use the first item, the name before the first comma. Thus if the output

looks like this:

```
	runtimepath=~/.vim,/usr/local/share/vim/vim60/runtime,~/.vim/after
```

You use "~/.vim" for {directory}. Then the resulting file name is:

```
	~/.vim/indent/help.vim
```

Instead of switching the indenting off, you could write your own indent file.
How to do that is explained here: indent-expression .

==
30.4 Other indenting

The most simple form of automatic indenting is with the 'autoindent' option.
It uses the indent from the previous line. A bit smarter is the 'smartindent'
option. This is useful for languages where no indent file is available.
'smartindent' is not as smart as 'cindent', but smarter than 'autoindent'.
   With 'smartindent' set, an extra level of indentation is added for each {
and removed for each }. An extra level of indentation will also be added for
any of the words in the 'cinwords' option. Lines that begin with # are
treated specially: all indentation is removed. This is done so that
preprocessor directives will all start in column 1. The indentation is
restored for the next line.

CORRECTING INDENTS

When you are using 'autoindent' or 'smartindent' to get the indent of the
previous line, there will be many times when you need to add or remove one
'shiftwidth' worth of indent. A quick way to do this is using the CTRL-D and
CTRL-T commands in Insert mode.
   For example, you are typing a shell script that is supposed to look like
this:

```
	if test -n a; then
	   echo a
	   echo "-------"
	fi
```

Start off by setting these options:

```
	:set autoindent shiftwidth=3
```

You start by typing the first line, <Enter> and the start of the second line:

```
	if test -n a; then
	echo
```

Now you see that you need an extra indent. Type CTRL-T. The result:

```
	if test -n a; then
	   echo
```

The CTRL-T command, in Insert mode, adds one 'shiftwidth' to the indent, no matter where in the line you are.
   You continue typing the second line, <Enter> and the third line. This time the indent is OK. Then <Enter> and the last line. Now you have this:

```
if test -n a; then
   echo a
   echo "-------"
   fi
```

To remove the superfluous indent in the last line press CTRL-D. This deletes one 'shiftwidth' worth of indent, no matter where you are in the line.
   When you are in Normal mode, you can use the ">>" and "<<" commands to shift lines. ">" and "<" are operators, thus you have the usual three ways to specify the lines you want to indent. A useful combination is:

```
>i{
```

This adds one indent to the current block of lines, inside {}. The { and } lines themselves are left unmodified. ">a{" includes them. In this example the cursor is on "printf":

```
original text           after ">i{"             after ">a{"

if (flag)               if (flag)               if (flag)
{                       {                           {
printf("yes");              printf("yes");          printf("yes");
flag = 0;                   flag = 0;               flag = 0;
}                       }                           }
```

==========

30.5 Tabs and spaces

'tabstop' is set to eight by default. Although you can change it, you quickly run into trouble later. Other programs won't know what tabstop value you used. They probably use the default value of eight, and your text suddenly looks very different. Also, most printers use a fixed tabstop value of eight. Thus it's best to keep 'tabstop' alone. (If you edit a file which was written with a different tabstop setting, see 25.3 for how to fix that.)
   For indenting lines in a program, using a multiple of eight spaces makes you quickly run into the right border of the window. Using a single space doesn't provide enough visual difference. Many people prefer to use four spaces, a good compromise.
   Since a <Tab> is eight spaces and you want to use an indent of four spaces, you can't use a <Tab> character to make your indent. There are two ways to handle this:

1. Use a mix of <Tab> and space characters. Since a <Tab> takes the place of eight spaces, you have fewer characters in your file. Inserting a <Tab> is quicker than eight spaces. Backspacing works faster as well.

2. Use spaces only. This avoids the trouble with programs that use a different tabstop value.

Fortunately, Vim supports both methods quite well.

SPACES AND TABS

If you are using a combination of tabs and spaces, you just edit normally. The Vim defaults do a fine job of handling things.

You can make life a little easier by setting the 'softtabstop' option. This option tells Vim to make the <Tab> key look and feel as if tabs were set at the value of 'softtabstop', but actually use a combination of tabs and spaces.

After you execute the following command, every time you press the <Tab> key the cursor moves to the next 4-column boundary:

```
:set softtabstop=4
```

When you start in the first column and press <Tab>, you get 4 spaces inserted in your text. The second time, Vim takes out the 4 spaces and puts in a <Tab> (thus taking you to column 8). Thus Vim uses as many <Tab>s as possible, and then fills up with spaces.

When backspacing it works the other way around. A <BS> will always delete the amount specified with 'softtabstop'. Then <Tab>s are used as many as possible and spaces to fill the gap.

The following shows what happens pressing <Tab> a few times, and then using <BS>. A "." stands for a space and "------->" for a <Tab>.

```
type                    result
<Tab>                   ....
<Tab><Tab>              ------->
<Tab><Tab><Tab>         ------->....
<Tab><Tab><Tab><BS>     ------->
<Tab><Tab><Tab><BS><BS> ....
```

An alternative is to use the 'smarttab' option. When it's set, Vim uses 'shiftwidth' for a <Tab> typed in the indent of a line, and a real <Tab> when typed after the first non-blank character. However, <BS> doesn't work like with 'softtabstop'.

JUST SPACES

If you want absolutely no tabs in your file, you can set the 'expandtab' option:

```
:set expandtab
```

When this option is set, the <Tab> key inserts a series of spaces. Thus you get the same amount of white space as if a <Tab> character was inserted, but there isn't a real <Tab> character in your file.

The backspace key will delete each space by itself. Thus after typing one <Tab> you have to press the <BS> key up to eight times to undo it. If you are in the indent, pressing CTRL-D will be a lot quicker.

CHANGING TABS IN SPACES (AND BACK)

Setting 'expandtab' does not affect any existing tabs. In other words, any tabs in the document remain tabs. If you want to convert tabs to spaces, use the ":retab" command. Use these commands:

```
:set expandtab
:%retab
```

Now Vim will have changed all indents to use spaces instead of tabs. However, all tabs that come after a non-blank character are kept. If you want these to be converted as well, add a !:

```
:%retab!
```

This is a little bit dangerous, because it can also change tabs inside a string. To check if these exist, you could use this:

```
/"[^"\t]*\t[^"]*"
```

It's recommended not to use hard tabs inside a string. Replace them with "\t" to avoid trouble.

The other way around works just as well:

```
:set noexpandtab
:%retab!
```

==========

30.6 Formatting comments

One of the great things about Vim is that it understands comments. You can ask Vim to format a comment and it will do the right thing.

Suppose, for example, that you have the following comment:

```
/*
 * This is a test
 * of the text formatting.
 */
```

You then ask Vim to format it by positioning the cursor at the start of the comment and type:

```
gq]/
```

"gq" is the operator to format text. "]/" is the motion that takes you to the end of a comment. The result is:

```
/*
 * This is a test of the text formatting.
 */
```

Notice that Vim properly handled the beginning of each line.

An alternative is to select the text that is to be formatted in Visual mode

and type "gq".

To add a new line to the comment, position the cursor on the middle line and press "o". The result looks like this:

```
/*
 * This is a test of the text formatting.
 *
 */
```

Vim has automatically inserted a star and a space for you. Now you can type the comment text. When it gets longer than 'textwidth', Vim will break the line. Again, the star is inserted automatically:

```
/*
 * This is a test of the text formatting.
 * Typing a lot of text here will make Vim
 * break
 */
```

For this to work some flags must be present in 'formatoptions':

```
r       insert the star when typing <Enter> in Insert mode
o       insert the star when using "o" or "O" in Normal mode
c       break comment text according to 'textwidth'
```

See fo-table for more flags.

DEFINING A COMMENT

The 'comments' option defines what a comment looks like. Vim distinguishes between a single-line comment and a comment that has a different start, end and middle part.
   Many single-line comments start with a specific character. In C++ // is used, in Makefiles #, in Vim scripts ". For example, to make Vim understand C++ comments:

```
:set comments=://
```

The colon separates the flags of an item from the text by which the comment is recognized. The general form of an item in 'comments' is:

```
{flags}:{text}
```

The {flags} part can be empty, as in this case.
   Several of these items can be concatenated, separated by commas. This allows recognizing different types of comments at the same time. For example, let's edit an e-mail message. When replying, the text that others wrote is preceded with ">" and "!" characters. This command would work:

```
:set comments=n:>,n:!
```

There are two items, one for comments starting with ">" and one for comments

that start with "!". Both use the flag "n". This means that these comments nest. Thus a line starting with ">" may have another comment after the ">". This allows formatting a message like this:

```
> ! Did you see that site?
> ! It looks really great.
> I don't like it.  The
> colors are terrible.
What is the URL of that
site?
```

Try setting 'textwidth' to a different value, e.g., 80, and format the text by Visually selecting it and typing "gq". The result is:

```
> ! Did you see that site?  It looks really great.
> I don't like it.  The colors are terrible.
What is the URL of that site?
```

You will notice that Vim did not move text from one type of comment to another. The "I" in the second line would have fit at the end of the first line, but since that line starts with "> !" and the second line with ">", Vim knows that this is a different kind of comment.

A THREE PART COMMENT

A C comment starts with "/*", has "*" in the middle and "*/" at the end. The entry in 'comments' for this looks like this:

```
:set comments=s1:/*,mb:*,ex:*/
```

The start is defined with "s1:/*". The "s" indicates the start of a three-piece comment. The colon separates the flags from the text by which the comment is recognized: "/*". There is one flag: "1". This tells Vim that the middle part has an offset of one space.

The middle part "mb:*" starts with "m", which indicates it is a middle part. The "b" flag means that a blank must follow the text. Otherwise Vim would consider text like "*pointer" also to be the middle of a comment.

The end part "ex:*/" has the "e" for identification. The "x" flag has a special meaning. It means that after Vim automatically inserted a star, typing / will remove the extra space.

For more details see format-comments .

Next chapter: usr_31.txt Exploiting the GUI

VIM USER MANUAL - by Bram Moolenaar

Exploiting the GUI

Vim works well in a terminal, but the GUI has a few extra items. A file browser can be used for commands that use a file. A dialog to make a choice between alternatives. Use keyboard shortcuts to access menu items quickly.

Next chapter: usr_32.txt The undo tree
Previous chapter: usr_30.txt Editing programs
Table of contents: usr_toc.txt

==========

31.1 The file browser

When using the File/Open... menu you get a file browser. This makes it easier to find the file you want to edit. But what if you want to split a window to edit another file? There is no menu entry for this. You could first use Window/Split and then File/Open..., but that's more work.

Since you are typing most commands in Vim, opening the file browser with a typed command is possible as well. To make the split command use the file browser, prepend "browse":

```
:browse split
```

Select a file and then the ":split" command will be executed with it. If you cancel the file dialog nothing happens, the window isn't split.

You can also specify a file name argument. This is used to tell the file browser where to start. Example:

```
:browse split /etc
```

The file browser will pop up, starting in the directory "/etc".

The ":browse" command can be prepended to just about any command that opens a file.

If no directory is specified, Vim will decide where to start the file browser. By default it uses the same directory as the last time. Thus when you used ":browse split" and selected a file in "/usr/local/share", the next time you use a ":browse" it will start in "/usr/local/share" again.

This can be changed with the 'browsedir' option. It can have one of three values:

```
last            Use the last directory browsed (default)
buffer          Use the same directory as the current buffer
```

```
        current         use the current directory
```

For example, when you are in the directory "/usr", editing the file "/usr/local/share/readme", then the command:

```
        :set browsedir=buffer
        :browse edit
```

Will start the browser in "/usr/local/share". Alternatively:

```
        :set browsedir=current
        :browse edit
```

Will start the browser in "/usr".

        Note:
        To avoid using the mouse, most file browsers offer using key presses to navigate. Since this is different for every system, it is not explained here. Vim uses a standard browser when possible, your system documentation should contain an explanation on the keyboard shortcuts somewhere.

When you are not using the GUI version, you could use the file explorer window to select files like in a file browser. However, this doesn't work for the ":browse" command. See netrw-browse .

==

31.2 Confirmation

Vim protects you from accidentally overwriting a file and other ways to lose changes. If you do something that might be a bad thing to do, Vim produces an error message and suggests appending ! if you really want to do it.

To avoid retyping the command with the !, you can make Vim give you a dialog. You can then press "OK" or "Cancel" to tell Vim what you want.

For example, you are editing a file and made changes to it. You start editing another file with:

```
        :confirm edit foo.txt
```

Vim will pop up a dialog that looks something like this:

```
        +-------------------------------------+
        |                                     |
        |   ?   Save changes to "bar.txt"?    |
        |                                     |
        |   YES   NO             CANCEL       |
        +-------------------------------------+
```

Now make your choice. If you do want to save the changes, select "YES". If you want to lose the changes for ever: "NO". If you forgot what you were doing and want to check what really changed use "CANCEL". You will be back in the same file, with the changes still there.

Just like ":browse", the ":confirm" command can be prepended to most commands

that edit another file. They can also be combined:

```
:confirm browse edit
```

This will produce a dialog when the current buffer was changed. Then it will pop up a file browser to select the file to edit.

```
Note:
In the dialog you can use the keyboard to select the choice.
Typically the <Tab> key and the cursor keys change the choice.
Pressing <Enter> selects the choice.  This depends on the system
though.
```

When you are not using the GUI, the ":confirm" command works as well. Instead of popping up a dialog, Vim will print the message at the bottom of the Vim window and ask you to press a key to make a choice.

```
:confirm edit main.c
Save changes to "Untitled"?
[Y]es, (N)o, (C)ancel:
```

You can now press the single key for the choice. You don't have to press <Enter>, unlike other typing on the command line.

31.3 Menu shortcuts

The keyboard is used for all Vim commands. The menus provide a simple way to select commands, without knowing what they are called. But you have to move your hand from the keyboard and grab the mouse.

Menus can often be selected with keys as well. This depends on your system, but most often it works this way. Use the <Alt> key in combination with the underlined letter of a menu. For example, <A-w> (<Alt> and w) pops up the Window menu.

In the Window menu, the "split" item has the p underlined. To select it, let go of the <Alt> key and press p.

After the first selection of a menu with the <Alt> key, you can use the cursor keys to move through the menus. <Right> selects a submenu and <left> closes it. <Esc> also closes a menu. <Enter> selects a menu item.

There is a conflict between using the <Alt> key to select menu items, and using <Alt> key combinations for mappings. The 'winaltkeys' option tells Vim what it should do with the <Alt> key.

The default value "menu" is the smart choice: If the key combination is a menu shortcut it can't be mapped. All other keys are available for mapping.

The value "no" doesn't use any <Alt> keys for the menus. Thus you must use the mouse for the menus, and all <Alt> keys can be mapped.

The value "yes" means that Vim will use any <Alt> keys for the menus. Some <Alt> key combinations may also do other things than selecting a menu.

31.4 Vim window position and size

To see the current Vim window position on the screen use:

```
:winpos
```

This will only work in the GUI. The output may look like this:

```
Window position: X 272, Y 103
```

The position is given in screen pixels. Now you can use the numbers to move Vim somewhere else. For example, to move it to the left a hundred pixels:

```
:winpos 172 103
```

```
Note:
There may be a small offset between the reported position and where
the window moves.  This is because of the border around the window.
This is added by the window manager.
```

You can use this command in your startup script to position the window at a specific position.

The size of the Vim window is computed in characters. Thus this depends on the size of the font being used. You can see the current size with this command:

```
:set lines columns
```

To change the size set the 'lines' and/or 'columns' options to a new value:

```
:set lines=50
:set columns=80
```

Obtaining the size works in a terminal just like in the GUI. Setting the size is not possible in most terminals.

You can start the X-Windows version of gvim with an argument to specify the size and position of the window:

```
gvim -geometry {width}x{height}+{x_offset}+{y_offset}
```

{width} and {height} are in characters, {x_offset} and {y_offset} are in pixels. Example:

```
gvim -geometry 80x25+100+300
```

31.5 Various

You can use gvim to edit an e-mail message. In your e-mail program you must select gvim to be the editor for messages. When you try that, you will see that it doesn't work: The mail program thinks that editing is finished, while gvim is still running!

What happens is that gvim disconnects from the shell it was started in. That is fine when you start gvim in a terminal, so that you can do other work

in that terminal. But when you really want to wait for gvim to finish, you must prevent it from disconnecting. The "-f" argument does this:

```
gvim -f file.txt
```

The "-f" stands for foreground. Now Vim will block the shell it was started in until you finish editing and exit.

DELAYED START OF THE GUI

On Unix it's possible to first start Vim in a terminal. That's useful if you do various tasks in the same shell. If you are editing a file and decide you want to use the GUI after all, you can start it with:

```
:gui
```

Vim will open the GUI window and no longer use the terminal. You can continue using the terminal for something else. The "-f" argument is used here to run the GUI in the foreground. You can also use ":gui -f".

THE GVIM STARTUP FILE

When gvim starts, it reads the gvimrc file. That's similar to the vimrc file used when starting Vim. The gvimrc file can be used for settings and commands that are only to be used when the GUI is going to be started. For example, you can set the 'lines' option to set a different window size:

```
:set lines=55
```

You don't want to do this in a terminal, since its size is fixed (except for an xterm that supports resizing).

The gvimrc file is searched for in the same locations as the vimrc file. Normally its name is "~/.gvimrc" for Unix and "$VIM/_gvimrc" for MS-Windows. The $MYGVIMRC environment variable is set to it, thus you can use this command to edit the file, if you have one:

```
:edit $MYGVIMRC
```

If for some reason you don't want to use the normal gvimrc file, you can specify another one with the "-U" argument:

```
gvim -U thisrc ...
```

That allows starting gvim for different kinds of editing. You could set another font size, for example.

To completely skip reading a gvimrc file:

```
gvim -U NONE ...
```

VIM USER MANUAL - by Bram Moolenaar

The undo tree

Vim provides multi-level undo. If you undo a few changes and then make a new change you create a branch in the undo tree. This text is about moving through the branches.

Next chapter: usr_40.txt Make new commands
Previous chapter: usr_31.txt Exploiting the GUI
Table of contents: usr_toc.txt

32.1 Undo up to a file write

Sometimes you make several changes, and then discover you want to go back to when you have last written the file. You can do that with this command:

```
:earlier 1f
```

The "f" stands for "file" here.

You can repeat this command to go further back in the past. Or use a count different from 1 to go back faster.

If you go back too far, go forward again with:

```
:later 1f
```

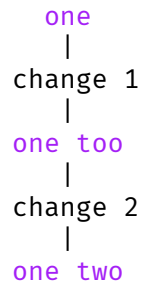
Note that these commands really work in time sequence. This matters if you made changes after undoing some changes. It's explained in the next section.

Also note that we are talking about text writes here. For writing the undo information in a file see undo-persistence .

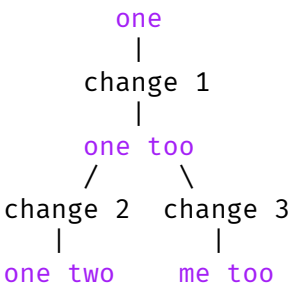
32.2 Numbering changes

In section 02.5 we only discussed one line of undo/redo. But it is also possible to branch off. This happens when you undo a few changes and then make a new change. The new changes become a branch in the undo tree.

Let's start with the text "one". The first change to make is to append " too". And then move to the first 'o' and change it into 'w'. We then have two changes, numbered 1 and 2, and three states of the text:



If we now undo one change, back to "one too", and change "one" to "me" we create a branch in the undo tree:



You can now use the `u` command to undo. If you do this twice you get to "one". Use `CTRL-R` to redo, and you will go to "one too". One more `CTRL-R` takes you to "me too". Thus undo and redo go up and down in the tree, using the branch that was last used.

What matters here is the order in which the changes are made. Undo and redo are not considered changes in this context. After each change you have a new state of the text.

Note that only the changes are numbered, the text shown in the tree above has no identifier. They are mostly referred to by the number of the change above it. But sometimes by the number of one of the changes below it, especially when moving up in the tree, so that you know which change was just undone.

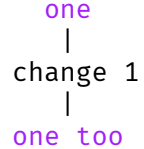
32.3 Jumping around the tree

So how do you get to "one two" now? You can use this command:

```
:undo 2
```

The text is now "one two", you are below change 2. You can use the `:undo` command to jump to below any change in the tree.

Now make another change: change "one" to "not":



```
          /     \
       change 2  change 3
          |         |
       one two    me too
          |
       change 4
          |
       not two
```

Now you change your mind and want to go back to "me too". Use the g- command. This moves back in time. Thus it doesn't walk the tree upwards or downwards, but goes to the change made before.

You can repeat g- and you will see the text change:

```
me too
one two
one too
one
```

Use g+ to move forward in time:

```
one
one too
one two
me too
not two
```

Using :undo is useful if you know what change you want to jump to. g- and g+ are useful if you don't know exactly what the change number is.

You can type a count before g- and g+ to repeat them.

32.4 Time travelling

When you have been working on text for a while the tree grows to become big. Then you may want to go to the text of some minutes ago.

To see what branches there are in the undo tree use this command:

```
:undolist
number changes  time
     3       2  16 seconds ago
     4       3  5 seconds ago
```

Here you can see the number of the leaves in each branch and when the change was made. Assuming we are below change 4, at "not two", you can go back ten seconds with this command:

```
:earlier 10s
```

Depending on how much time you took for the changes you end up at a certain position in the tree. The :earlier command argument can be "m" for minutes, "h" for hours and "d" for days. To go all the way back use a big number:

```
        :earlier 100d

To travel forward in time again use the  :later  command:

        :later 1m

The arguments are "s", "m" and "h", just like with  :earlier .

If you want even more details, or want to manipulate the information, you can
use the  undotree()  function.  To see what it returns:

        :echo undotree()

```

VIM USER MANUAL - by Bram Moolenaar

Make new commands

Vim is an extensible editor. You can take a sequence of commands you use
often and turn it into a new command. Or redefine an existing command.
Autocommands make it possible to execute commands automatically.

==========

40.1 Key mapping

A simple mapping was explained in section 05.3 . The principle is that one
sequence of key strokes is translated into another sequence of key strokes.
This is a simple, yet powerful mechanism.
   The simplest form is that one key is mapped to a sequence of keys. Since
the function keys, except <F1>, have no predefined meaning in Vim, these are
good choices to map. Example:

```
:map <F2> GoDate: <Esc>:read !date<CR>kJ
```

This shows how three modes are used. After going to the last line with "G",
the "o" command opens a new line and starts Insert mode. The text "Date: " is
inserted and <Esc> takes you out of insert mode.
   Notice the use of special keys inside <>. This is called angle bracket
notation. You type these as separate characters, not by pressing the key
itself. This makes the mappings better readable and you can copy and paste
the text without problems.
   The ":" character takes Vim to the command line. The ":read !date" command
reads the output from the "date" command and appends it below the current
line. The <CR> is required to execute the ":read" command.
   At this point of execution the text looks like this:

```
Date:
Fri Jun 15 12:54:34 CEST 2001
```

Now "kJ" moves the cursor up and joins the lines together.
   To decide which key or keys you use for mapping, see map-which-keys .

MAPPING AND MODES

The ":map" command defines remapping for keys in Normal mode. You can also
define mappings for other modes. For example, ":imap" applies to Insert mode.

You can use it to insert a date below the cursor:

```
:imap <F2> <CR>Date: <Esc>:read !date<CR>kJ
```

It looks a lot like the mapping for <F2> in Normal mode, only the start is different. The <F2> mapping for Normal mode is still there. Thus you can map the same key differently for each mode.
Notice that, although this mapping starts in Insert mode, it ends in Normal mode. If you want it to continue in Insert mode, append an "a" to the mapping.

Here is an overview of map commands and in which mode they work:

```
:map            Normal, Visual and Operator-pending
:vmap           Visual
:nmap           Normal
:omap           Operator-pending
:map!           Insert and Command-line
:imap           Insert
:cmap           Command-line
```

Operator-pending mode is when you typed an operator character, such as "d" or "y", and you are expected to type the motion command or a text object. Thus when you type "dw", the "w" is entered in operator-pending mode.

Suppose that you want to define <F7> so that the command d<F7> deletes a C program block (text enclosed in curly braces, {}). Similarly y<F7> would yank the program block into the unnamed register. Therefore, what you need to do is to define <F7> to select the current program block. You can do this with the following command:

```
:omap <F7> a{
```

This causes <F7> to perform a select block "a{" in operator-pending mode, just like you typed it. This mapping is useful if typing a { on your keyboard is a bit difficult.

LISTING MAPPINGS

To see the currently defined mappings, use ":map" without arguments. Or one of the variants that include the mode in which they work. The output could look like this:

```
   _g            :call MyGrep(1)<CR>
v  <F2>          :s/^/> /<CR>:noh<CR>``
n  <F2>          :.,$s/^/> /<CR>:noh<CR>``
   <xHome>       <Home>
   <xEnd>        <End>
```

The first column of the list shows in which mode the mapping is effective. This is "n" for Normal mode, "i" for Insert mode, etc. A blank is used for a mapping defined with ":map", thus effective in both Normal and Visual mode.

One useful purpose of listing the mapping is to check if special keys in <> form have been recognized (this only works when color is supported). For example, when <Esc> is displayed in color, it stands for the escape character. When it has the same color as the other text, it is five characters.

REMAPPING

The result of a mapping is inspected for other mappings in it. For example, the mappings for <F2> above could be shortened to:

```
:map <F2> G<F3>
:imap <F2> <Esc><F3>
:map <F3>  oDate: <Esc>:read !date<CR>kJ
```

For Normal mode <F2> is mapped to go to the last line, and then behave like <F3> was pressed. In Insert mode <F2> stops Insert mode with <Esc> and then also uses <F3>. Then <F3> is mapped to do the actual work.

Suppose you hardly ever use Ex mode, and want to use the "Q" command to format text (this was so in old versions of Vim). This mapping will do it:

```
:map Q gq
```

But, in rare cases you need to use Ex mode anyway. Let's map "gQ" to Q, so that you can still go to Ex mode:

```
:map gQ Q
```

What happens now is that when you type "gQ" it is mapped to "Q". So far so good. But then "Q" is mapped to "gq", thus typing "gQ" results in "gq", and you don't get to Ex mode at all.

To avoid keys to be mapped again, use the ":noremap" command:

```
:noremap gQ Q
```

Now Vim knows that the "Q" is not to be inspected for mappings that apply to it. There is a similar command for every mode:

```
:noremap        Normal, Visual and Operator-pending
:vnoremap       Visual
:nnoremap       Normal
:onoremap       Operator-pending
:noremap!       Insert and Command-line
:inoremap       Insert
:cnoremap       Command-line
```

RECURSIVE MAPPING

When a mapping triggers itself, it will run forever. This can be used to repeat an action an unlimited number of times.

For example, you have a list of files that contain a version number in the first line. You edit these files with "vim *.txt". You are now editing the

first file. Define this mapping:

```
:map ,, :s/5.1/5.2/<CR>:wnext<CR>,,
```

Now you type ",,". This triggers the mapping. It replaces "5.1" with "5.2" in the first line. Then it does a ":wnext" to write the file and edit the next one. The mapping ends in ",,". This triggers the same mapping again, thus doing the substitution, etc.
   This continues until there is an error. In this case it could be a file where the substitute command doesn't find a match for "5.1". You can then make a change to insert "5.1" and continue by typing ",," again. Or the ":wnext" fails, because you are in the last file in the list.
   When a mapping runs into an error halfway, the rest of the mapping is discarded. CTRL-C interrupts the mapping (CTRL-Break on MS-Windows).

DELETE A MAPPING

To remove a mapping use the ":unmap" command. Again, the mode the unmapping applies to depends on the command used:

```
:unmap          Normal, Visual and Operator-pending
:vunmap         Visual
:nunmap         Normal
:ounmap         Operator-pending
:unmap!         Insert and Command-line
:iunmap         Insert
:cunmap         Command-line
```

There is a trick to define a mapping that works in Normal and Operator-pending mode, but not in Visual mode. First define it for all three modes, then delete it for Visual mode:

```
:map <C-A> /---><CR>
:vunmap <C-A>
```

Notice that the five characters "<C-A>" stand for the single key CTRL-A.

To remove all mappings use the :mapclear command. You can guess the variations for different modes by now. Be careful with this command, it can't be undone.

SPECIAL CHARACTERS

The ":map" command can be followed by another command. A | character separates the two commands. This also means that a | character can't be used inside a map command. To include one, use <Bar> (five characters). Example:

```
:map <F8> :write <Bar> !checkin %:S<CR>
```

The same problem applies to the ":unmap" command, with the addition that you have to watch out for trailing white space. These two commands are different:

```
:unmap a | unmap b
:unmap a| unmap b
```

The first command tries to unmap "a ", with a trailing space.

When using a space inside a mapping, use <Space> (seven characters):

```
:map <Space> W
```

This makes the spacebar move a blank-separated word forward.

It is not possible to put a comment directly after a mapping, because the " character is considered to be part of the mapping. You can use |", this starts a new, empty command with a comment. Example:

```
:map <Space> W|     " Use spacebar to move forward a word
```

MAPPINGS AND ABBREVIATIONS

Abbreviations are a lot like Insert mode mappings. The arguments are handled in the same way. The main difference is the way they are triggered. An abbreviation is triggered by typing a non-word character after the word. A mapping is triggered when typing the last character.

Another difference is that the characters you type for an abbreviation are inserted in the text while you type them. When the abbreviation is triggered these characters are deleted and replaced by what the abbreviation produces. When typing the characters for a mapping, nothing is inserted until you type the last character that triggers it. If the 'showcmd' option is set, the typed characters are displayed in the last line of the Vim window.

An exception is when a mapping is ambiguous. Suppose you have done two mappings:

```
:imap aa foo
:imap aaa bar
```

Now, when you type "aa", Vim doesn't know if it should apply the first or the second mapping. It waits for another character to be typed. If it is an "a", the second mapping is applied and results in "bar". If it is a space, for example, the first mapping is applied, resulting in "foo", and then the space is inserted.

ADDITIONALLY...

The <script> keyword can be used to make a mapping local to a script. See :map-<script> .

The <buffer> keyword can be used to make a mapping local to a specific buffer. See :map-<buffer>

The <unique> keyword can be used to make defining a new mapping fail when it already exists. Otherwise a new mapping simply overwrites the old one. See :map-<unique> .

To make a key do nothing, map it to <Nop> (five characters). This will make the <F7> key do nothing at all:

```
:map <F7> <Nop>| map! <F7> <Nop>
```

There must be no space after <Nop>.

==========

40.2 Defining command-line commands

The Vim editor enables you to define your own commands. You execute these commands just like any other Command-line mode command.
To define a command, use the ":command" command, as follows:

```
:command DeleteFirst 1delete
```

Now when you execute the command ":DeleteFirst" Vim executes ":1delete", which deletes the first line.

> Note:
> User-defined commands must start with a capital letter. You cannot use ":X", ":Next" and ":Print". The underscore cannot be used! You can use digits, but this is discouraged.

To list the user-defined commands, execute the following command:

```
:command
```

Just like with the builtin commands, the user defined commands can be abbreviated. You need to type just enough to distinguish the command from another. Command line completion can be used to get the full name.

NUMBER OF ARGUMENTS

User-defined commands can take a series of arguments. The number of arguments must be specified by the -nargs option. For instance, the example :DeleteFirst command takes no arguments, so you could have defined it as follows:

```
:command -nargs=0 DeleteFirst 1delete
```

However, because zero arguments is the default, you do not need to add "-nargs=0". The other values of -nargs are as follows:

```
-nargs=0        No arguments
-nargs=1        One argument
-nargs=*        Any number of arguments
-nargs=?        Zero or one argument
-nargs=+        One or more arguments
```

USING THE ARGUMENTS

Inside the command definition, the arguments are represented by the
<args> keyword. For example:

```
:command -nargs=+ Say :echo "<args>"
```

Now when you type

```
:Say Hello World
```

Vim echoes "Hello World". However, if you add a double quote, it won't work.
For example:

```
:Say he said "hello"
```

To get special characters turned into a string, properly escaped to use as an
expression, use "<q-args>":

```
:command -nargs=+ Say :echo <q-args>
```

Now the above ":Say" command will result in this to be executed:

```
:echo "he said \"hello\""
```

The <f-args> keyword contains the same information as the <args> keyword,
except in a format suitable for use as function call arguments. For example:

```
:command -nargs=* DoIt :call AFunction(<f-args>)
:DoIt a b c
```

Executes the following command:

```
:call AFunction("a", "b", "c")
```

LINE RANGE

Some commands take a range as their argument. To tell Vim that you are
defining such a command, you need to specify a -range option. The values for
this option are as follows:

```
-range          Range is allowed; default is the current line.
-range=%        Range is allowed; default is the whole file.
-range={count}  Range is allowed; the last number in it is used as a
                single number whose default is {count}.
```

When a range is specified, the keywords <line1> and <line2> get the values of
the first and last line in the range. For example, the following command
defines the SaveIt command, which writes out the specified range to the file
"save_file":

```
:command -range=% SaveIt :<line1>,<line2>write! save_file
```

OTHER OPTIONS

Some of the other options and keywords are as follows:

-count={number}	The command can take a count whose default is {number}. The resulting count can be used through the <count> keyword.
-bang	You can use a !. If present, using <bang> will result in a !.
-register	You can specify a register. (The default is the unnamed register.) The register specification is available as <reg> (a.k.a. <register>).
-complete={type}	Type of command-line completion used. See :command-completion for the list of possible values.
-bar	The command can be followed by | and another command, or " and a comment.
-buffer	The command is only available for the current buffer.

Finally, you have the <lt> keyword. It stands for the character <. Use this to escape the special meaning of the <> items mentioned.

REDEFINING AND DELETING

To redefine the same command use the ! argument:

```
:command -nargs=+ Say :echo "<args>"
:command! -nargs=+ Say :echo <q-args>
```

To delete a user command use ":delcommand". It takes a single argument, which is the name of the command. Example:

```
:delcommand SaveIt
```

To delete all the user commands:

```
:comclear
```

Careful, this can't be undone!

More details about all this in the reference manual: user-commands .

==========

40.3 Autocommands

An autocommand is a command that is executed automatically in response to some event, such as a file being read or written or a buffer change. Through the use of autocommands you can train Vim to edit compressed files, for example. That is used in the gzip plugin.

Autocommands are very powerful. Use them with care and they will help you avoid typing many commands. Use them carelessly and they will cause a lot of

trouble.

Suppose you want to replace a datestamp on the end of a file every time it is written. First you define a function:

```
:function DateInsert()
:  $delete
:  read !date
:endfunction
```

You want this function to be called each time, just before a buffer is written to a file. This will make that happen:

```
:autocmd BufWritePre *  call DateInsert()
```

"BufWritePre" is the event for which this autocommand is triggered: Just before (pre) writing a buffer to a file. The "*" is a pattern to match with the file name. In this case it matches all files.
With this command enabled, when you do a ":write", Vim checks for any matching BufWritePre autocommands and executes them, and then it performs the ":write".
The general form of the :autocmd command is as follows:

```
:autocmd [group] {events} {file_pattern} [nested] {command}
```

The [group] name is optional. It is used in managing and calling the commands (more on this later). The {events} parameter is a list of events (comma separated) that trigger the command.
{file_pattern} is a filename, usually with wildcards. For example, using "*.txt" makes the autocommand be used for all files whose name end in ".txt". The optional [nested] flag allows for nesting of autocommands (see below), and finally, {command} is the command to be executed.

EVENTS

One of the most useful events is BufReadPost. It is triggered after a new file is being edited. It is commonly used to set option values. For example, you know that "*.gsm" files are GNU assembly language. To get the syntax file right, define this autocommand:

```
:autocmd BufReadPost *.gsm  set filetype=asm
```

If Vim is able to detect the type of file, it will set the 'filetype' option for you. This triggers the Filetype event. Use this to do something when a certain type of file is edited. For example, to load a list of abbreviations for text files:

```
:autocmd Filetype text  source ~/.vim/abbrevs.vim
```

When starting to edit a new file, you could make Vim insert a skeleton:

```
:autocmd BufNewFile *.[ch]  0read ~/skeletons/skel.c
```

See autocmd-events for a complete list of events.

PATTERNS

The {file_pattern} argument can actually be a comma-separated list of file patterns. For example: "*.c,*.h" matches files ending in ".c" and ".h".
   The usual file wildcards can be used. Here is a summary of the most often used ones:

```
*               Match any character any number of times
?               Match any character once
[abc]           Match the character a, b or c
.               Matches a dot
a{b,c}          Matches "ab" and "ac"
```

When the pattern includes a slash (/) Vim will compare directory names. Without the slash only the last part of a file name is used. For example, "*.txt" matches "/home/biep/readme.txt". The pattern "/home/biep/*" would also match it. But "home/foo/*.txt" wouldn't.
   When including a slash, Vim matches the pattern against both the full path of the file ("/home/biep/readme.txt") and the relative path (e.g., "biep/readme.txt").

> Note:
> When working on a system that uses a backslash as file separator, such as MS-Windows, you still use forward slashes in autocommands. This makes it easier to write the pattern, since a backslash has a special meaning. It also makes the autocommands portable.

DELETING

To delete an autocommand, use the same command as what it was defined with, but leave out the {command} at the end and use a !. Example:

```
:autocmd! FileWritePre *
```

This will delete all autocommands for the "FileWritePre" event that use the "*" pattern.

LISTING

To list all the currently defined autocommands, use this:

```
:autocmd
```

The list can be very long, especially when filetype detection is used. To list only part of the commands, specify the group, event and/or pattern. For example, to list all BufNewFile autocommands:

```
:autocmd BufNewFile
```

To list all autocommands for the pattern "*.c":

```
:autocmd * *.c
```

Using "*" for the event will list all the events. To list all autocommands for the cprograms group:

```
:autocmd cprograms
```

GROUPS

The {group} item, used when defining an autocommand, groups related autocommands together. This can be used to delete all the autocommands in a certain group, for example.
   When defining several autocommands for a certain group, use the ":augroup" command. For example, let's define autocommands for C programs:

```
:augroup cprograms
:  autocmd BufReadPost *.c,*.h :set sw=4 sts=4
:  autocmd BufReadPost *.cpp   :set sw=3 sts=3
:augroup END
```

This will do the same as:

```
:autocmd cprograms BufReadPost *.c,*.h :set sw=4 sts=4
:autocmd cprograms BufReadPost *.cpp   :set sw=3 sts=3
```

To delete all autocommands in the "cprograms" group:

```
:autocmd! cprograms
```

NESTING

Generally, commands executed as the result of an autocommand event will not trigger any new events. If you read a file in response to a FileChangedShell event, it will not trigger the autocommands that would set the syntax, for example. To make the events triggered, add the "nested" argument:

```
:autocmd FileChangedShell * nested  edit
```

EXECUTING AUTOCOMMANDS

It is possible to trigger an autocommand by pretending an event has occurred. This is useful to have one autocommand trigger another one. Example:

```
:autocmd BufReadPost *.new  execute "doautocmd BufReadPost " . expand("<afile>:r")
```

This defines an autocommand that is triggered when a new file has been edited. The file name must end in ".new". The ":execute" command uses expression evaluation to form a new command and execute it. When editing the file "tryout.c.new" the executed command will be:

```
:doautocmd BufReadPost tryout.c
```

The expand() function takes the "<afile>" argument, which stands for the file name the autocommand was executed for, and takes the root of the file name with ":r".

":doautocmd" executes on the current buffer. The ":doautoall" command works like "doautocmd" except it executes on all the buffers.

USING NORMAL MODE COMMANDS

The commands executed by an autocommand are Command-line commands. If you want to use a Normal mode command, the ":normal" command can be used. Example:

```
:autocmd BufReadPost *.log normal G
```

This will make the cursor jump to the last line of *.log files when you start to edit it.

Using the ":normal" command is a bit tricky. First of all, make sure its argument is a complete command, including all the arguments. When you use "i" to go to Insert mode, there must also be a <Esc> to leave Insert mode again. If you use a "/" to start a search pattern, there must be a <CR> to execute it.

The ":normal" command uses all the text after it as commands. Thus there can be no | and another command following. To work around this, put the ":normal" command inside an ":execute" command. This also makes it possible to pass unprintable characters in a convenient way. Example:

```
:autocmd BufReadPost *.chg execute "normal ONew entry:\<Esc>" |
        \ 1read !date
```

This also shows the use of a backslash to break a long command into more lines. This can be used in Vim scripts (not at the command line).

When you want the autocommand do something complicated, which involves jumping around in the file and then returning to the original position, you may want to restore the view on the file. See restore-position for an example.

IGNORING EVENTS

At times, you will not want to trigger an autocommand. The 'eventignore' option contains a list of events that will be totally ignored. For example, the following causes events for entering and leaving a window to be ignored:

```
:set eventignore=WinEnter,WinLeave
```

To ignore all events, use the following command:

```
:set eventignore=all
```

To set it back to the normal behavior, make 'eventignore' empty:

```
:set eventignore=
```

usr_41.txt For Vim version 8.1. Last change: 2018 Apr 11

VIM USER MANUAL - by Bram Moolenaar

Write a Vim script

The Vim script language is used for the startup vimrc file, syntax files, and many other things. This chapter explains the items that can be used in a Vim script. There are a lot of them, thus this is a long chapter.

Next chapter: usr_42.txt Add new menus

==

41.1 Introduction vim-script-intro script

Your first experience with Vim scripts is the vimrc file. Vim reads it when it starts up and executes the commands. You can set options to values you prefer. And you can use any colon command in it (commands that start with a ":"; these are sometimes referred to as Ex commands or command-line commands).
   Syntax files are also Vim scripts. As are files that set options for a specific file type. A complicated macro can be defined by a separate Vim script file. You can think of other uses yourself.

Let's start with a simple example:

```
:let i = 1
:while i < 5
:  echo "count is" i
:  let i += 1
:endwhile
```

Note:
The ":" characters are not really needed here. You only need to use them when you type a command. In a Vim script file they can be left

out. We will use them here anyway to make clear these are colon commands and make them stand out from Normal mode commands.
Note:
You can try out the examples by yanking the lines from the text here and executing them with :@"

The output of the example code is:

```
count is 1
count is 2
count is 3
count is 4
```

In the first line the ":let" command assigns a value to a variable. The generic form is:

```
:let {variable} = {expression}
```

In this case the variable name is "i" and the expression is a simple value, the number one.
The ":while" command starts a loop. The generic form is:

```
:while {condition}
:  {statements}
:endwhile
```

The statements until the matching ":endwhile" are executed for as long as the condition is true. The condition used here is the expression "i < 5". This is true when the variable i is smaller than five.
Note:
If you happen to write a while loop that keeps on running, you can interrupt it by pressing CTRL-C (CTRL-Break on MS-Windows).

The ":echo" command prints its arguments. In this case the string "count is" and the value of the variable i. Since i is one, this will print:

```
count is 1
```

Then there is the ":let i += 1" command. This does the same thing as ":let i = i + 1". This adds one to the variable i and assigns the new value to the same variable.

The example was given to explain the commands, but would you really want to make such a loop, it can be written much more compact:

```
:for i in range(1, 4)
:  echo "count is" i
:endfor
```

We won't explain how :for and range() work until later. Follow the links if you are impatient.

THREE KINDS OF NUMBERS

Numbers can be decimal, hexadecimal or octal. A hexadecimal number starts with "0x" or "0X". For example "0x1f" is decimal 31. An octal number starts with a zero. "017" is decimal 15. Careful: don't put a zero before a decimal number, it will be interpreted as an octal number!
   The ":echo" command always prints decimal numbers. Example:

```
:echo 0x7f 036
127 30
```

A number is made negative with a minus sign. This also works for hexadecimal and octal numbers. A minus sign is also used for subtraction. Compare this with the previous example:

```
:echo 0x7f -036
97
```

White space in an expression is ignored. However, it's recommended to use it for separating items, to make the expression easier to read. For example, to avoid the confusion with a negative number above, put a space between the minus sign and the following number:

```
:echo 0x7f - 036
```

==
41.2 Variables

A variable name consists of ASCII letters, digits and the underscore. It cannot start with a digit. Valid variable names are:

```
counter
_aap3
very_long_variable_name_with_underscores
FuncLength
LENGTH
```

Invalid names are "foo+bar" and "6var".
   These variables are global. To see a list of currently defined variables use this command:

```
:let
```

You can use global variables everywhere. This also means that when the variable "count" is used in one script file, it might also be used in another file. This leads to confusion at least, and real problems at worst. To avoid this, you can use a variable local to a script file by prepending "s:". For example, one script contains this code:

```
:let s:count = 1
:while s:count < 5
:  source other.vim
:  let s:count += 1
:endwhile
```

Since "s:count" is local to this script, you can be sure that sourcing the "other.vim" script will not change this variable. If "other.vim" also uses an "s:count" variable, it will be a different copy, local to that script. More about script-local variables here: script-variable .

There are more kinds of variables, see internal-variables . The most often used ones are:

b:name	variable local to a buffer
w:name	variable local to a window
g:name	global variable (also in a function)
v:name	variable predefined by Vim

DELETING VARIABLES

Variables take up memory and show up in the output of the ":let" command. To delete a variable use the ":unlet" command. Example:

```
:unlet s:count
```

This deletes the script-local variable "s:count" to free up the memory it uses. If you are not sure if the variable exists, and don't want an error message when it doesn't, append !:

```
:unlet! s:count
```

When a script finishes, the local variables used there will not be automatically freed. The next time the script executes, it can still use the old value. Example:

```
:if !exists("s:call_count")
:  let s:call_count = 0
:endif
:let s:call_count = s:call_count + 1
:echo "called" s:call_count "times"
```

The "exists()" function checks if a variable has already been defined. Its argument is the name of the variable you want to check. Not the variable itself! If you would do this:

```
:if !exists(s:call_count)
```

Then the value of s:call_count will be used as the name of the variable that exists() checks. That's not what you want.

The exclamation mark ! negates a value. When the value was true, it becomes false. When it was false, it becomes true. You can read it as "not". Thus "if !exists()" can be read as "if not exists()".

What Vim calls true is anything that is not zero. Zero is false.

Note:
Vim automatically converts a string to a number when it is looking for a number. When using a string that doesn't start with a digit the resulting number is zero. Thus look out for this:

```
:if "true"
```

The "true" will be interpreted as a zero, thus as false!

STRING VARIABLES AND CONSTANTS

So far only numbers were used for the variable value. Strings can be used as well. Numbers and strings are the basic types of variables that Vim supports. The type is dynamic, it is set each time when assigning a value to the variable with ":let". More about types in 41.8 .

To assign a string value to a variable, you need to use a string constant. There are two types of these. First the string in double quotes:

```
:let name = "peter"
:echo name
peter
```

If you want to include a double quote inside the string, put a backslash in front of it:

```
:let name = "\"peter\""
:echo name
"peter"
```

To avoid the need for a backslash, you can use a string in single quotes:

```
:let name = '"peter"'
:echo name
"peter"
```

Inside a single-quote string all the characters are as they are. Only the single quote itself is special: you need to use two to get one. A backslash is taken literally, thus you can't use it to change the meaning of the character after it.

In double-quote strings it is possible to use special characters. Here are a few useful ones:

```
\t              <Tab>
\n              <NL>, line break
\r              <CR>, <Enter>
\e              <Esc>
\b              <BS>, backspace
\"              "
\\              \, backslash
\<Esc>          <Esc>
\<C-W>          CTRL-W
```

The last two are just examples. The "\<name>" form can be used to include the special key "name".

See expr-quote for the full list of special items in a string.

==========

41.3 Expressions

Vim has a rich, yet simple way to handle expressions. You can read the

definition here: expression-syntax . Here we will show the most common items.
   The numbers, strings and variables mentioned above are expressions by themselves. Thus everywhere an expression is expected, you can use a number, string or variable. Other basic items in an expression are:

```
        $NAME           environment variable
        &name           option
        @r              register
```

Examples:

```
        :echo "The value of 'tabstop' is" &ts
        :echo "Your home directory is" $HOME
        :if @a > 5
```

The &name form can be used to save an option value, set it to a new value, do something and restore the old value. Example:

```
        :let save_ic = &ic
        :set noic
        :/The Start/,$delete
        :let &ic = save_ic
```

This makes sure the "The Start" pattern is used with the 'ignorecase' option off. Still, it keeps the value that the user had set. (Another way to do this would be to add "\C" to the pattern, see /\C .)

MATHEMATICS

It becomes more interesting if we combine these basic items. Let's start with mathematics on numbers:

```
        a + b           add
        a - b           subtract
        a * b           multiply
        a / b           divide
        a % b           modulo
```

The usual precedence is used. Example:

```
        :echo 10 + 5 * 2
       20
```

Grouping is done with parentheses. No surprises here. Example:

```
        :echo (10 + 5) * 2
       30
```

Strings can be concatenated with ".". Example:

```
        :echo "foo" . "bar"
       foobar
```

When the ":echo" command gets multiple arguments, it separates them with a space. In the example the argument is a single expression, thus no space is inserted.

Borrowed from the C language is the conditional expression:

```
a ? b : c
```

If "a" evaluates to true "b" is used, otherwise "c" is used. Example:

```
:let i = 4
:echo i > 5 ? "i is big" : "i is small"
i is small
```

The three parts of the constructs are always evaluated first, thus you could see it work as:

```
(a) ? (b) : (c)
```

41.4 Conditionals

The ":if" commands executes the following statements, until the matching ":endif", only when a condition is met. The generic form is:

```
:if {condition}
   {statements}
:endif
```

Only when the expression {condition} evaluates to true (non-zero) will the {statements} be executed. These must still be valid commands. If they contain garbage, Vim won't be able to find the ":endif".

You can also use ":else". The generic form for this is:

```
:if {condition}
   {statements}
:else
   {statements}
:endif
```

The second {statements} is only executed if the first one isn't.

Finally, there is ":elseif":

```
:if {condition}
   {statements}
:elseif {condition}
   {statements}
:endif
```

This works just like using ":else" and then "if", but without the need for an extra ":endif".

A useful example for your vimrc file is checking the 'term' option and doing something depending upon its value:

```
:if &term == "xterm"
:  " Do stuff for xterm
:elseif &term == "vt100"
:  " Do stuff for a vt100 terminal
:else
:  " Do something for other terminals
:endif
```

LOGIC OPERATIONS

We already used some of them in the examples. These are the most often used ones:

```
a == b          equal to
a != b          not equal to
a >  b          greater than
a >= b          greater than or equal to
a <  b          less than
a <= b          less than or equal to
```

The result is one if the condition is met and zero otherwise. An example:

```
:if v:version >= 700
:  echo "congratulations"
:else
:  echo "you are using an old version, upgrade!"
:endif
```

Here "v:version" is a variable defined by Vim, which has the value of the Vim version. 600 is for version 6.0. Version 6.1 has the value 601. This is very useful to write a script that works with multiple versions of Vim.
 v:version

The logic operators work both for numbers and strings. When comparing two strings, the mathematical difference is used. This compares byte values, which may not be right for some languages.
   When comparing a string with a number, the string is first converted to a number. This is a bit tricky, because when a string doesn't look like a number, the number zero is used. Example:

```
:if 0 == "one"
:  echo "yes"
:endif
```

This will echo "yes", because "one" doesn't look like a number, thus it is converted to the number zero.

For strings there are two more items:

```
a =~ b          matches with
a !~ b          does not match with
```

The left item "a" is used as a string. The right item "b" is used as a pattern, like what's used for searching. Example:

```
:if str =~ " "
:  echo "str contains a space"
:endif
:if str !~ '\.$'
:  echo "str does not end in a full stop"
:endif
```

Notice the use of a single-quote string for the pattern. This is useful, because backslashes would need to be doubled in a double-quote string and patterns tend to contain many backslashes.

The 'ignorecase' option is used when comparing strings. When you don't want that, append "#" to match case and "?" to ignore case. Thus "==?" compares two strings to be equal while ignoring case. And "!~#" checks if a pattern doesn't match, also checking the case of letters. For the full table see expr-== .

MORE LOOPING

The ":while" command was already mentioned. Two more statements can be used in between the ":while" and the ":endwhile":

:continue	Jump back to the start of the while loop; the loop continues.
:break	Jump forward to the ":endwhile"; the loop is discontinued.

Example:

```
:while counter < 40
:  call do_something()
:  if skip_flag
:    continue
:  endif
:  if finished_flag
:    break
:  endif
:  sleep 50m
:endwhile
```

The ":sleep" command makes Vim take a nap. The "50m" specifies fifty milliseconds. Another example is ":sleep 4", which sleeps for four seconds.

Even more looping can be done with the ":for" command, see below in 41.8 .

==========

41.5 Executing an expression

So far the commands in the script were executed by Vim directly. The ":execute" command allows executing the result of an expression. This is a

very powerful way to build commands and execute them.
   An example is to jump to a tag, which is contained in a variable:

```
:execute "tag " . tag_name
```

The "." is used to concatenate the string "tag " with the value of variable "tag_name". Suppose "tag_name" has the value "get_cmd", then the command that will be executed is:

```
:tag get_cmd
```

The ":execute" command can only execute colon commands. The ":normal" command executes Normal mode commands. However, its argument is not an expression but the literal command characters. Example:

```
:normal gg=G
```

This jumps to the first line and formats all lines with the "=" operator.
   To make ":normal" work with an expression, combine ":execute" with it. Example:

```
:execute "normal " . normal_commands
```

The variable "normal_commands" must contain the Normal mode commands.
   Make sure that the argument for ":normal" is a complete command. Otherwise Vim will run into the end of the argument and abort the command. For example, if you start Insert mode, you must leave Insert mode as well. This works:

```
:execute "normal Inew text \<Esc>"
```

This inserts "new text " in the current line. Notice the use of the special key "\<Esc>". This avoids having to enter a real <Esc> character in your script.

If you don't want to execute a string but evaluate it to get its expression value, you can use the eval() function:

```
:let optname = "path"
:let optval = eval('&' . optname)
```

A "&" character is prepended to "path", thus the argument to eval() is "&path". The result will then be the value of the 'path' option.
   The same thing can be done with:

```
:exe 'let optval = &' . optname
```

41.6 Using functions

Vim defines many functions and provides a large amount of functionality that way. A few examples will be given in this section. You can find the whole list here: functions .

A function is called with the ":call" command. The parameters are passed in between parentheses separated by commas. Example:

```
:call search("Date: ", "W")
```

This calls the search() function, with arguments "Date: " and "W". The search() function uses its first argument as a search pattern and the second one as flags. The "W" flag means the search doesn't wrap around the end of the file.

A function can be called in an expression. Example:

```
:let line = getline(".")
:let repl = substitute(line, '\a', "*", "g")
:call setline(".", repl)
```

The getline() function obtains a line from the current buffer. Its argument is a specification of the line number. In this case "." is used, which means the line where the cursor is.

The substitute() function does something similar to the ":substitute" command. The first argument is the string on which to perform the substitution. The second argument is the pattern, the third the replacement string. Finally, the last arguments are the flags.

The setline() function sets the line, specified by the first argument, to a new string, the second argument. In this example the line under the cursor is replaced with the result of the substitute(). Thus the effect of the three statements is equal to:

```
:substitute/\a/*/g
```

Using the functions becomes more interesting when you do more work before and after the substitute() call.

FUNCTIONS function-list

There are many functions. We will mention them here, grouped by what they are used for. You can find an alphabetical list here: functions . Use CTRL-] on the function name to jump to detailed help on it.

String manipulation: string-functions

nr2char()	get a character by its ASCII value
char2nr()	get ASCII value of a character
str2nr()	convert a string to a Number
str2float()	convert a string to a Float
printf()	format a string according to % items
escape()	escape characters in a string with a '\'
shellescape()	escape a string for use with a shell command
fnameescape()	escape a file name for use with a Vim command
tr()	translate characters from one set to another
strtrans()	translate a string to make it printable
tolower()	turn a string to lowercase
toupper()	turn a string to uppercase
match()	position where a pattern matches in a string
matchend()	position where a pattern match ends in a string
matchstr()	match of a pattern in a string

```
        matchstrpos()           match and positions of a pattern in a string
        matchlist()             like matchstr() and also return submatches
        stridx()                first index of a short string in a long string
        strridx()               last index of a short string in a long string
        strlen()                length of a string in bytes
        strchars()              length of a string in characters
        strwidth()              size of string when displayed
        strdisplaywidth()       size of string when displayed, deals with tabs
        substitute()            substitute a pattern match with a string
        submatch()              get a specific match in ":s" and substitute()
        strpart()               get part of a string using byte index
        strcharpart()           get part of a string using char index
        strgetchar()            get character from a string using char index
        expand()                expand special keywords
        iconv()                 convert text from one encoding to another
        byteidx()               byte index of a character in a string
        byteidxcomp()           like byteidx() but count composing characters
        repeat()                repeat a string multiple times
        eval()                  evaluate a string expression
        execute()               execute an Ex command and get the output

List manipulation:                                      list-functions
        get()                   get an item without error for wrong index
        len()                   number of items in a List
        empty()                 check if List is empty
        insert()                insert an item somewhere in a List
        add()                   append an item to a List
        extend()                append a List to a List
        remove()                remove one or more items from a List
        copy()                  make a shallow copy of a List
        deepcopy()              make a full copy of a List
        filter()                remove selected items from a List
        map()                   change each List item
        sort()                  sort a List
        reverse()               reverse the order of a List
        uniq()                  remove copies of repeated adjacent items
        split()                 split a String into a List
        join()                  join List items into a String
        range()                 return a List with a sequence of numbers
        string()                String representation of a List
        call()                  call a function with List as arguments
        index()                 index of a value in a List
        max()                   maximum value in a List
        min()                   minimum value in a List
        count()                 count number of times a value appears in a List
        repeat()                repeat a List multiple times

Dictionary manipulation:                                dict-functions
        get()                   get an entry without an error for a wrong key
        len()                   number of entries in a Dictionary
        has_key()               check whether a key appears in a Dictionary
        empty()                 check if Dictionary is empty
        remove()                remove an entry from a Dictionary
        extend()                add entries from one Dictionary to another
```

```
        filter()                remove selected entries from a Dictionary
        map()                   change each Dictionary entry
        keys()                  get List of Dictionary keys
        values()                get List of Dictionary values
        items()                 get List of Dictionary key-value pairs
        copy()                  make a shallow copy of a Dictionary
        deepcopy()              make a full copy of a Dictionary
        string()                String representation of a Dictionary
        max()                   maximum value in a Dictionary
        min()                   minimum value in a Dictionary
        count()                 count number of times a value appears

Floating point computation:                                 float-functions
        float2nr()              convert Float to Number
        abs()                   absolute value (also works for Number)
        round()                 round off
        ceil()                  round up
        floor()                 round down
        trunc()                 remove value after decimal point
        fmod()                  remainder of division
        exp()                   exponential
        log()                   natural logarithm (logarithm to base e)
        log10()                 logarithm to base 10
        pow()                   value of x to the exponent y
        sqrt()                  square root
        sin()                   sine
        cos()                   cosine
        tan()                   tangent
        asin()                  arc sine
        acos()                  arc cosine
        atan()                  arc tangent
        atan2()                 arc tangent
        sinh()                  hyperbolic sine
        cosh()                  hyperbolic cosine
        tanh()                  hyperbolic tangent
        isnan()                 check for not a number

Other computation:                                      bitwise-function
        and()                   bitwise AND
        invert()                bitwise invert
        or()                    bitwise OR
        xor()                   bitwise XOR
        sha256()                SHA-256 hash

Variables:                                                  var-functions
        type()                  type of a variable
        islocked()              check if a variable is locked
        funcref()               get a Funcref for a function reference
        function()              get a Funcref for a function name
        getbufvar()             get a variable value from a specific buffer
        setbufvar()             set a variable in a specific buffer
        getwinvar()             get a variable from specific window
        gettabvar()             get a variable from specific tab page
        gettabwinvar()          get a variable from specific window & tab page
```

```
        setwinvar()             set a variable in a specific window
        settabvar()             set a variable in a specific tab page
        settabwinvar()          set a variable in a specific window & tab page
        garbagecollect()        possibly free memory

Cursor and mark position:                   cursor-functions   mark-functions
        col()                   column number of the cursor or a mark
        virtcol()               screen column of the cursor or a mark
        line()                  line number of the cursor or mark
        wincol()                window column number of the cursor
        winline()               window line number of the cursor
        cursor()                position the cursor at a line/column
        screencol()             get screen column of the cursor
        screenrow()             get screen row of the cursor
        getcurpos()             get position of the cursor
        getpos()                get position of cursor, mark, etc.
        setpos()                set position of cursor, mark, etc.
        byte2line()             get line number at a specific byte count
        line2byte()             byte count at a specific line
        diff_filler()           get the number of filler lines above a line
        screenattr()            get attribute at a screen line/row
        screenchar()            get character code at a screen line/row

Working with text in the current buffer:                text-functions
        getline()               get a line or list of lines from the buffer
        setline()               replace a line in the buffer
        append()                append line or list of lines in the buffer
        indent()                indent of a specific line
        cindent()               indent according to C indenting
        lispindent()            indent according to Lisp indenting
        nextnonblank()          find next non-blank line
        prevnonblank()          find previous non-blank line
        search()                find a match for a pattern
        searchpos()             find a match for a pattern
        searchpair()            find the other end of a start/skip/end
        searchpairpos()         find the other end of a start/skip/end
        searchdecl()            search for the declaration of a name
        getcharsearch()         return character search information
        setcharsearch()         set character search information

                                    system-functions   file-functions
System functions and manipulation of files:
        glob()                  expand wildcards
        globpath()              expand wildcards in a number of directories
        glob2regpat()           convert a glob pattern into a search pattern
        findfile()              find a file in a list of directories
        finddir()               find a directory in a list of directories
        resolve()               find out where a shortcut points to
        fnamemodify()           modify a file name
        pathshorten()           shorten directory names in a path
        simplify()              simplify a path without changing its meaning
        executable()            check if an executable program exists
        exepath()               full path of an executable program
        filereadable()          check if a file can be read
```

```
        filewritable()          check if a file can be written to
        getfperm()              get the permissions of a file
        setfperm()              set the permissions of a file
        getftype()              get the kind of a file
        isdirectory()           check if a directory exists
        getfsize()              get the size of a file
        getcwd()                get the current working directory
        haslocaldir()           check if current window used  :lcd
        tempname()              get the name of a temporary file
        mkdir()                 create a new directory
        delete()                delete a file
        rename()                rename a file
        system()                get the result of a shell command as a string
        systemlist()            get the result of a shell command as a list
        hostname()              name of the system
        readfile()              read a file into a List of lines
        writefile()             write a List of lines into a file

Date and Time:                          date-functions   time-functions
        getftime()              get last modification time of a file
        localtime()             get current time in seconds
        strftime()              convert time to a string
        reltime()               get the current or elapsed time accurately
        reltimestr()            convert reltime() result to a string
        reltimefloat()          convert reltime() result to a Float

                        buffer-functions   window-functions   arg-functions
Buffers, windows and the argument list:
        argc()                  number of entries in the argument list
        argidx()                current position in the argument list
        arglistid()             get id of the argument list
        argv()                  get one entry from the argument list
        bufexists()             check if a buffer exists
        buflisted()             check if a buffer exists and is listed
        bufloaded()             check if a buffer exists and is loaded
        bufname()               get the name of a specific buffer
        bufnr()                 get the buffer number of a specific buffer
        tabpagebuflist()        return List of buffers in a tab page
        tabpagenr()             get the number of a tab page
        tabpagewinnr()          like winnr() for a specified tab page
        winnr()                 get the window number for the current window
        bufwinid()              get the window ID of a specific buffer
        bufwinnr()              get the window number of a specific buffer
        winbufnr()              get the buffer number of a specific window
        getbufline()            get a list of lines from the specified buffer
        win_findbuf()           find windows containing a buffer
        win_getid()             get window ID of a window
        win_gotoid()            go to window with ID
        win_id2tabwin()         get tab and window nr from window ID
        win_id2win()            get window nr from window ID
        getbufinfo()            get a list with buffer information
        gettabinfo()            get a list with tab page information
        getwininfo()            get a list with window information
        getchangelist()         get a list of change list entries
```

```
        getjumplist()           get a list of jump list entries

Command line:                                   command-line-functions
        getcmdline()            get the current command line
        getcmdpos()             get position of the cursor in the command line
        setcmdpos()             set position of the cursor in the command line
        getcmdtype()            return the current command-line type
        getcmdwintype()         return the current command-line window type
        getcompletion()         list of command-line completion matches

Quickfix and location lists:                    quickfix-functions
        getqflist()             list of quickfix errors
        setqflist()             modify a quickfix list
        getloclist()            list of location list items
        setloclist()            modify a location list

Insert mode completion:                         completion-functions
        complete()              set found matches
        complete_add()          add to found matches
        complete_check()        check if completion should be aborted
        pumvisible()            check if the popup menu is displayed

Folding:                                        folding-functions
        foldclosed()            check for a closed fold at a specific line
        foldclosedend()         like foldclosed() but return the last line
        foldlevel()             check for the fold level at a specific line
        foldtext()              generate the line displayed for a closed fold
        foldtextresult()        get the text displayed for a closed fold

Syntax and highlighting:          syntax-functions   highlighting-functions
        clearmatches()          clear all matches defined by  matchadd()  and
                                the  :match  commands
        getmatches()            get all matches defined by  matchadd()  and
                                the  :match  commands
        hlexists()              check if a highlight group exists
        hlID()                  get ID of a highlight group
        synID()                 get syntax ID at a specific position
        synIDattr()             get a specific attribute of a syntax ID
        synIDtrans()            get translated syntax ID
        synstack()              get list of syntax IDs at a specific position
        synconcealed()          get info about concealing
        diff_hlID()             get highlight ID for diff mode at a position
        matchadd()              define a pattern to highlight (a "match")
        matchaddpos()           define a list of positions to highlight
        matcharg()              get info about  :match  arguments
        matchdelete()           delete a match defined by  matchadd()  or a
                                 :match  command
        setmatches()            restore a list of matches saved by
                                 getmatches()

Spelling:                                       spell-functions
        spellbadword()          locate badly spelled word at or after cursor
        spellsuggest()          return suggested spelling corrections
        soundfold()             return the sound-a-like equivalent of a word
```

History: history-functions

histadd()	add an item to a history
histdel()	delete an item from a history
histget()	get an item from a history
histnr()	get highest index of a history list

Interactive: interactive-functions

browse()	put up a file requester
browsedir()	put up a directory requester
confirm()	let the user make a choice
getchar()	get a character from the user
getcharmod()	get modifiers for the last typed character
feedkeys()	put characters in the typeahead queue
input()	get a line from the user
inputlist()	let the user pick an entry from a list
inputsecret()	get a line from the user without showing it
inputdialog()	get a line from the user in a dialog
inputsave()	save and clear typeahead
inputrestore()	restore typeahead

GUI: gui-functions

getfontname()	get name of current font being used
getwinpos()	position of the Vim window
getwinposx()	X position of the Vim window
getwinposy()	Y position of the Vim window
balloon_show()	set the balloon content
balloon_split()	split a message for a balloon

Vim server: server-functions

serverlist()	return the list of server names
remote_startserver()	run a server
remote_send()	send command characters to a Vim server
remote_expr()	evaluate an expression in a Vim server
server2client()	send a reply to a client of a Vim server
remote_peek()	check if there is a reply from a Vim server
remote_read()	read a reply from a Vim server
foreground()	move the Vim window to the foreground
remote_foreground()	move the Vim server window to the foreground

Window size and position: window-size-functions

winheight()	get height of a specific window
winwidth()	get width of a specific window
win_screenpos()	get screen position of a window
winrestcmd()	return command to restore window sizes
winsaveview()	get view of current window
winrestview()	restore saved view of current window

Mappings: mapping-functions

hasmapto()	check if a mapping exists
mapcheck()	check if a matching mapping exists
maparg()	get rhs of a mapping
wildmenumode()	check if the wildmode is active

```
Testing:                                        test-functions
        assert_equal()          assert that two expressions values are equal
        assert_notequal()       assert that two expressions values are not equal
        assert_inrange()        assert that an expression is inside a range
        assert_match()          assert that a pattern matches the value
        assert_notmatch()       assert that a pattern does not match the value
        assert_false()          assert that an expression is false
        assert_true()           assert that an expression is true
        assert_exception()      assert that a command throws an exception
        assert_beeps()          assert that a command beeps
        assert_fails()          assert that a command fails
        assert_report()         report a test failure
        test_alloc_fail()       make memory allocation fail
        test_autochdir()        enable 'autochdir' during startup
        test_override()         test with Vim internal overrides
        test_garbagecollect_now()   free memory right now
        test_ignore_error()     ignore a specific error message
        test_null_channel()     return a null Channel
        test_null_dict()        return a null Dict
        test_null_job()         return a null Job
        test_null_list()        return a null List
        test_null_partial()     return a null Partial function
        test_null_string()      return a null String
        test_settime()          set the time Vim uses internally

Inter-process communication:                    channel-functions
        ch_canread()            check if there is something to read
        ch_open()               open a channel
        ch_close()              close a channel
        ch_close_in()           close the in part of a channel
        ch_read()               read a message from a channel
        ch_readraw()            read a raw message from a channel
        ch_sendexpr()           send a JSON message over a channel
        ch_sendraw()            send a raw message over a channel
        ch_evalexpr()           evaluates an expression over channel
        ch_evalraw()            evaluates a raw string over channel
        ch_status()             get status of a channel
        ch_getbufnr()           get the buffer number of a channel
        ch_getjob()             get the job associated with a channel
        ch_info()               get channel information
        ch_log()                write a message in the channel log file
        ch_logfile()            set the channel log file
        ch_setoptions()         set the options for a channel
        json_encode()           encode an expression to a JSON string
        json_decode()           decode a JSON string to Vim types
        js_encode()             encode an expression to a JSON string
        js_decode()             decode a JSON string to Vim types

Jobs:                                               job-functions
        job_start()             start a job
        job_stop()              stop a job
        job_status()            get the status of a job
        job_getchannel()        get the channel used by a job
        job_info()              get information about a job
```

```
        job_setoptions()        set options for a job

Terminal window:                                    terminal-functions
        term_start()            open a terminal window and run a job
        term_list()             get the list of terminal buffers
        term_sendkeys()         send keystrokes to a terminal
        term_wait()             wait for screen to be updated
        term_getjob()           get the job associated with a terminal
        term_scrape()           get row of a terminal screen
        term_getline()          get a line of text from a terminal
        term_getattr()          get the value of attribute {what}
        term_getcursor()        get the cursor position of a terminal
        term_getscrolled()      get the scroll count of a terminal
        term_getaltscreen()     get the alternate screen flag
        term_getsize()          get the size of a terminal
        term_getstatus()        get the status of a terminal
        term_gettitle()         get the title of a terminal
        term_gettty()           get the tty name of a terminal
        term_setansicolors()    set 16 ANSI colors, used for GUI
        term_getansicolors()    get 16 ANSI colors, used for GUI

Timers:                                             timer-functions
        timer_start()           create a timer
        timer_pause()           pause or unpause a timer
        timer_stop()            stop a timer
        timer_stopall()         stop all timers
        timer_info()            get information about timers

Various:                                            various-functions
        mode()                  get current editing mode
        visualmode()            last visual mode used
        exists()                check if a variable, function, etc. exists
        has()                   check if a feature is supported in Vim
        changenr()              return number of most recent change
        cscope_connection()     check if a cscope connection exists
        did_filetype()          check if a FileType autocommand was used
        eventhandler()          check if invoked by an event handler
        getpid()                get process ID of Vim

        libcall()               call a function in an external library
        libcallnr()             idem, returning a number

        undofile()              get the name of the undo file
        undotree()              return the state of the undo tree

        getreg()                get contents of a register
        getregtype()            get type of a register
        setreg()                set contents and type of a register
        reg_executing()         return the name of the register being executed
        reg_recording()         return the name of the register being recorded

        shiftwidth()            effective value of 'shiftwidth'

        wordcount()             get byte/word/char count of buffer
```

```
        taglist()               get list of matching tags
        tagfiles()              get a list of tags files

        luaeval()               evaluate Lua expression
        mzeval()                evaluate  MzScheme  expression
        perleval()              evaluate Perl expression ( +perl )
        py3eval()               evaluate Python expression ( +python3 )
        pyeval()                evaluate Python expression ( +python )
        pyxeval()               evaluate  python_x  expression
```

41.7 Defining a function

Vim enables you to define your own functions. The basic function declaration begins as follows:

```
        :function {name}({var1}, {var2}, ...)
        :  {body}
        :endfunction
```

Note:
Function names must begin with a capital letter.

Let's define a short function to return the smaller of two numbers. It starts with this line:

```
        :function Min(num1, num2)
```

This tells Vim that the function is named "Min" and it takes two arguments: "num1" and "num2".
The first thing you need to do is to check to see which number is smaller:

```
        :  if a:num1 < a:num2
```

The special prefix "a:" tells Vim that the variable is a function argument. Let's assign the variable "smaller" the value of the smallest number:

```
        :  if a:num1 < a:num2
        :    let smaller = a:num1
        :  else
        :    let smaller = a:num2
        :  endif
```

The variable "smaller" is a local variable. Variables used inside a function are local unless prefixed by something like "g:", "a:", or "s:".

Note:
To access a global variable from inside a function you must prepend "g:" to it. Thus "g:today" inside a function is used for the global variable "today", and "today" is another variable, local to the function.

You now use the ":return" statement to return the smallest number to the user.

Finally, you end the function:

```
:  return smaller
:endfunction
```

The complete function definition is as follows:

```
:function Min(num1, num2)
:  if a:num1 < a:num2
:    let smaller = a:num1
:  else
:    let smaller = a:num2
:  endif
:  return smaller
:endfunction
```

For people who like short functions, this does the same thing:

```
:function Min(num1, num2)
:  if a:num1 < a:num2
:    return a:num1
:  endif
:  return a:num2
:endfunction
```

A user defined function is called in exactly the same way as a built-in function. Only the name is different. The Min function can be used like this:

```
:echo Min(5, 8)
```

Only now will the function be executed and the lines be interpreted by Vim. If there are mistakes, like using an undefined variable or function, you will now get an error message. When defining the function these errors are not detected.

When a function reaches ":endfunction" or ":return" is used without an argument, the function returns zero.

To redefine a function that already exists, use the ! for the ":function" command:

```
:function!  Min(num1, num2, num3)
```

USING A RANGE

The ":call" command can be given a line range. This can have one of two meanings. When a function has been defined with the "range" keyword, it will take care of the line range itself.
  The function will be passed the variables "a:firstline" and "a:lastline". These will have the line numbers from the range the function was called with. Example:

```
:function Count_words() range
:  let lnum = a:firstline
:  let n = 0
:  while lnum <= a:lastline
:    let n = n + len(split(getline(lnum)))
:    let lnum = lnum + 1
:  endwhile
:  echo "found " . n . " words"
:endfunction
```

You can call this function with:

```
:10,30call Count_words()
```

It will be executed once and echo the number of words.
   The other way to use a line range is by defining a function without the "range" keyword. The function will be called once for every line in the range, with the cursor in that line. Example:

```
:function  Number()
:  echo "line " . line(".") . " contains: " . getline(".")
:endfunction
```

If you call this function with:

```
:10,15call Number()
```

The function will be called six times.

VARIABLE NUMBER OF ARGUMENTS

Vim enables you to define functions that have a variable number of arguments. The following command, for instance, defines a function that must have 1 argument (start) and can have up to 20 additional arguments:

```
:function Show(start, ...)
```

The variable "a:1" contains the first optional argument, "a:2" the second, and so on. The variable "a:0" contains the number of extra arguments.
   For example:

```
:function Show(start, ...)
:  echohl Title
:  echo "start is " . a:start
:  echohl None
:  let index = 1
:  while index <= a:0
:    echo "  Arg " . index . " is " . a:{index}
:    let index = index + 1
:  endwhile
:  echo ""
:endfunction
```

This uses the ":echohl" command to specify the highlighting used for the following ":echo" command. ":echohl None" stops it again. The ":echon" command works like ":echo", but doesn't output a line break.

You can also use the a:000 variable, it is a List of all the "..." arguments. See a:000 .

LISTING FUNCTIONS

The ":function" command lists the names and arguments of all user-defined functions:

```
:function
function Show(start, ...)
function GetVimIndent()
function SetSyn(name)
```

To see what a function does, use its name as an argument for ":function":

```
:function SetSyn
1     if &syntax == ''
2       let &syntax = a:name
3     endif
   endfunction
```

DEBUGGING

The line number is useful for when you get an error message or when debugging. See debug-scripts about debugging mode.
You can also set the 'verbose' option to 12 or higher to see all function calls. Set it to 15 or higher to see every executed line.

DELETING A FUNCTION

To delete the Show() function:

```
:delfunction Show
```

You get an error when the function doesn't exist.

FUNCTION REFERENCES

Sometimes it can be useful to have a variable point to one function or another. You can do it with the function() function. It turns the name of a function into a reference:

```
:let result = 0         " or 1
:function! Right()
:  return 'Right!'
:endfunc
```

```
:function! Wrong()
:  return 'Wrong!'
:endfunc
:
:if result == 1
:  let Afunc = function('Right')
:else
:  let Afunc = function('Wrong')
:endif
:echo call(Afunc, [])
Wrong!
```

Note that the name of a variable that holds a function reference must start with a capital. Otherwise it could be confused with the name of a builtin function.

The way to invoke a function that a variable refers to is with the call() function. Its first argument is the function reference, the second argument is a List with arguments.

Function references are most useful in combination with a Dictionary, as is explained in the next section.

==========

41.8 Lists and Dictionaries

So far we have used the basic types String and Number. Vim also supports two composite types: List and Dictionary.

A List is an ordered sequence of things. The things can be any kind of value, thus you can make a List of numbers, a List of Lists and even a List of mixed items. To create a List with three strings:

```
:let alist = ['aap', 'mies', 'noot']
```

The List items are enclosed in square brackets and separated by commas. To create an empty List:

```
:let alist = []
```

You can add items to a List with the add() function:

```
:let alist = []
:call add(alist, 'foo')
:call add(alist, 'bar')
:echo alist
['foo', 'bar']
```

List concatenation is done with +:

```
:echo alist + ['foo', 'bar']
['foo', 'bar', 'foo', 'bar']
```

Or, if you want to extend a List directly:

```
:let alist = ['one']
:call extend(alist, ['two', 'three'])
:echo alist
['one', 'two', 'three']
```

Notice that using add() will have a different effect:

```
:let alist = ['one']
:call add(alist, ['two', 'three'])
:echo alist
['one', ['two', 'three']]
```

The second argument of add() is added as a single item.

FOR LOOP

One of the nice things you can do with a List is iterate over it:

```
:let alist = ['one', 'two', 'three']
:for n in alist
:  echo n
:endfor
one
two
three
```

This will loop over each element in List "alist", assigning the value to variable "n". The generic form of a for loop is:

```
:for {varname} in {listexpression}
:  {commands}
:endfor
```

To loop a certain number of times you need a List of a specific length. The range() function creates one for you:

```
:for a in range(3)
:  echo a
:endfor
0
1
2
```

Notice that the first item of the List that range() produces is zero, thus the last item is one less than the length of the list.

You can also specify the maximum value, the stride and even go backwards:

```
:for a in range(8, 4, -2)
:  echo a
:endfor
8
6
4
```

A more useful example, looping over lines in the buffer:

```
:for line in getline(1, 20)
:  if line =~ "Date: "
:    echo matchstr(line, 'Date: \zs.*')
:  endif
:endfor
```

This looks into lines 1 to 20 (inclusive) and echoes any date found in there.

DICTIONARIES

A Dictionary stores key-value pairs. You can quickly lookup a value if you know the key. A Dictionary is created with curly braces:

```
:let uk2nl = {'one': 'een', 'two': 'twee', 'three': 'drie'}
```

Now you can lookup words by putting the key in square brackets:

```
:echo uk2nl['two']
twee
```

The generic form for defining a Dictionary is:

```
{<key> : <value>, ...}
```

An empty Dictionary is one without any keys:

```
{}
```

The possibilities with Dictionaries are numerous. There are various functions for them as well. For example, you can obtain a list of the keys and loop over them:

```
:for key in keys(uk2nl)
:  echo key
:endfor
three
one
two
```

You will notice the keys are not ordered. You can sort the list to get a specific order:

```
:for key in sort(keys(uk2nl))
:  echo key
:endfor
one
three
two
```

But you can never get back the order in which items are defined. For that you

need to use a List, it stores items in an ordered sequence.

DICTIONARY FUNCTIONS

The items in a Dictionary can normally be obtained with an index in square brackets:

```
:echo uk2nl['one']
een
```

A method that does the same, but without so many punctuation characters:

```
:echo uk2nl.one
een
```

This only works for a key that is made of ASCII letters, digits and the underscore. You can also assign a new value this way:

```
:let uk2nl.four = 'vier'
:echo uk2nl
{'three': 'drie', 'four': 'vier', 'one': 'een', 'two': 'twee'}
```

And now for something special: you can directly define a function and store a reference to it in the dictionary:

```
:function uk2nl.translate(line) dict
:  return join(map(split(a:line), 'get(self, v:val, "???")'))
:endfunction
```

Let's first try it out:

```
:echo uk2nl.translate('three two five one')
drie twee ??? een
```

The first special thing you notice is the "dict" at the end of the ":function" line. This marks the function as being used from a Dictionary. The "self" local variable will then refer to that Dictionary.

Now let's break up the complicated return command:

```
split(a:line)
```

The split() function takes a string, chops it into whitespace separated words and returns a list with these words. Thus in the example it returns:

```
:echo split('three two five one')
['three', 'two', 'five', 'one']
```

This list is the first argument to the map() function. This will go through the list, evaluating its second argument with "v:val" set to the value of each item. This is a shortcut to using a for loop. This command:

```
:let alist = map(split(a:line), 'get(self, v:val, "???")')
```

Is equivalent to:

```
:let alist = split(a:line)
:for idx in range(len(alist))
:  let alist[idx] = get(self, alist[idx], "???")
:endfor
```

The get() function checks if a key is present in a Dictionary. If it is, then the value is retrieved. If it isn't, then the default value is returned, in the example it's '???'. This is a convenient way to handle situations where a key may not be present and you don't want an error message.

The join() function does the opposite of split(): it joins together a list of words, putting a space in between.
This combination of split(), map() and join() is a nice way to filter a line of words in a very compact way.

OBJECT ORIENTED PROGRAMMING

Now that you can put both values and functions in a Dictionary, you can actually use a Dictionary like an object.
Above we used a Dictionary for translating Dutch to English. We might want to do the same for other languages. Let's first make an object (aka Dictionary) that has the translate function, but no words to translate:

```
:let transdict = {}
:function transdict.translate(line) dict
:  return join(map(split(a:line), 'get(self.words, v:val, "???")'))
:endfunction
```

It's slightly different from the function above, using 'self.words' to lookup word translations. But we don't have a self.words. Thus you could call this an abstract class.

Now we can instantiate a Dutch translation object:

```
:let uk2nl = copy(transdict)
:let uk2nl.words = {'one': 'een', 'two': 'twee', 'three': 'drie'}
:echo uk2nl.translate('three one')
drie een
```

And a German translator:

```
:let uk2de = copy(transdict)
:let uk2de.words = {'one': 'eins', 'two': 'zwei', 'three': 'drei'}
:echo uk2de.translate('three one')
drei eins
```

You see that the copy() function is used to make a copy of the "transdict" Dictionary and then the copy is changed to add the words. The original remains the same, of course.

Now you can go one step further, and use your preferred translator:

```
:if $LANG =~ "de"
:  let trans = uk2de
:else
:  let trans = uk2nl
:endif
:echo trans.translate('one two three')
een twee drie
```

Here "trans" refers to one of the two objects (Dictionaries). No copy is made. More about List and Dictionary identity can be found at list-identity and dict-identity .

Now you might use a language that isn't supported. You can overrule the translate() function to do nothing:

```
:let uk2uk = copy(transdict)
:function! uk2uk.translate(line)
:  return a:line
:endfunction
:echo uk2uk.translate('three one wladiwostok')
three one wladiwostok
```

Notice that a ! was used to overwrite the existing function reference. Now use "uk2uk" when no recognized language is found:

```
:if $LANG =~ "de"
:  let trans = uk2de
:elseif $LANG =~ "nl"
:  let trans = uk2nl
:else
:  let trans = uk2uk
:endif
:echo trans.translate('one two three')
one two three
```

For further reading see Lists and Dictionaries .

==========

41.9 Exceptions

Let's start with an example:

```
:try
:   read ~/templates/pascal.tmpl
:catch /E484:/
:   echo "Sorry, the Pascal template file cannot be found."
:endtry
```

The ":read" command will fail if the file does not exist. Instead of generating an error message, this code catches the error and gives the user a nice message.

For the commands in between ":try" and ":endtry" errors are turned into

exceptions. An exception is a string. In the case of an error the string contains the error message. And every error message has a number. In this case, the error we catch contains "E484:". This number is guaranteed to stay the same (the text may change, e.g., it may be translated).

When the ":read" command causes another error, the pattern "E484:" will not match in it. Thus this exception will not be caught and result in the usual error message.

You might be tempted to do this:

```
:try
:   read ~/templates/pascal.tmpl
:catch
:   echo "Sorry, the Pascal template file cannot be found."
:endtry
```

This means all errors are caught. But then you will not see errors that are useful, such as "E21: Cannot make changes, 'modifiable' is off".

Another useful mechanism is the ":finally" command:

```
:let tmp = tempname()
:try
:   exe ".,$write " . tmp
:   exe "!filter " . tmp
:   .,$delete
:   exe "$read " . tmp
:finally
:   call delete(tmp)
:endtry
```

This filters the lines from the cursor until the end of the file through the "filter" command, which takes a file name argument. No matter if the filtering works, something goes wrong in between ":try" and ":finally" or the user cancels the filtering by pressing CTRL-C, the "call delete(tmp)" is always executed. This makes sure you don't leave the temporary file behind.

More information about exception handling can be found in the reference manual: exception-handling .

==
41.10 Various remarks

Here is a summary of items that apply to Vim scripts. They are also mentioned elsewhere, but form a nice checklist.

The end-of-line character depends on the system. For Unix a single <NL> character is used. For MS-DOS, Windows, OS/2 and the like, <CR><LF> is used. This is important when using mappings that end in a <CR>. See :source_crnl .

WHITE SPACE

Blank lines are allowed and ignored.

Leading whitespace characters (blanks and TABs) are always ignored. The whitespaces between parameters (e.g. between the "set" and the "cpoptions" in the example below) are reduced to one blank character and plays the role of a separator, the whitespaces after the last (visible) character may or may not be ignored depending on the situation, see below.

For a ":set" command involving the "=" (equal) sign, such as in:

```
:set cpoptions    =aABceFst
```

the whitespace immediately before the "=" sign is ignored. But there can be no whitespace after the "=" sign!

To include a whitespace character in the value of an option, it must be escaped by a "\" (backslash) as in the following example:

```
:set tags=my\ nice\ file
```

The same example written as:

```
:set tags=my nice file
```

will issue an error, because it is interpreted as:

```
:set tags=my
:set nice
:set file
```

COMMENTS

The character " (the double quote mark) starts a comment. Everything after and including this character until the end-of-line is considered a comment and is ignored, except for commands that don't consider comments, as shown in examples below. A comment can start on any character position on the line.

There is a little "catch" with comments for some commands. Examples:

```
:abbrev dev development         " shorthand
:map <F3> o#include             " insert include
:execute cmd                    " do it
:!ls *.c                        " list C files
```

The abbreviation 'dev' will be expanded to 'development   " shorthand'. The mapping of <F3> will actually be the whole line after the 'o# ....' including the '" insert include'. The "execute" command will give an error. The "!" command will send everything after it to the shell, causing an error for an unmatched '"' character.

There can be no comment after ":map", ":abbreviate", ":execute" and "!" commands (there are a few more commands with this restriction). For the ":map", ":abbreviate" and ":execute" commands there is a trick:

```
:abbrev dev development|" shorthand
:map <F3> o#include|" insert include
:execute cmd                    |" do it
```

With the '|' character the command is separated from the next one. And that next command is only a comment. For the last command you need to do two things: :execute and use '|':

```
:exe '!ls *.c'                  |" list C files
```

Notice that there is no white space before the '|' in the abbreviation and mapping. For these commands, any character until the end-of-line or '|' is included. As a consequence of this behavior, you don't always see that trailing whitespace is included:

```
:map <F4> o#include
```

To spot these problems, you can set the 'list' option when editing vimrc files.

For Unix there is one special way to comment a line, that allows making a Vim script executable:

```
#!/usr/bin/env vim -S
echo "this is a Vim script"
quit
```

The "#" command by itself lists a line with the line number. Adding an exclamation mark changes it into doing nothing, so that you can add the shell command to execute the rest of the file. :#!   -S

PITFALLS

Even bigger problem arises in the following example:

```
:map ,ab o#include
:unmap ,ab
```

Here the unmap command will not work, because it tries to unmap ",ab ". This does not exist as a mapped sequence. An error will be issued, which is very hard to identify, because the ending whitespace character in ":unmap ,ab " is not visible.

And this is the same as what happens when one uses a comment after an 'unmap' command:

```
:unmap ,ab     " comment
```

Here the comment part will be ignored. However, Vim will try to unmap ',ab   ', which does not exist. Rewrite it as:

```
:unmap ,ab|    " comment
```

RESTORING THE VIEW

Sometimes you want to make a change and go back to where the cursor was.
Restoring the relative position would also be nice, so that the same line
appears at the top of the window.
   This example yanks the current line, puts it above the first line in the
file and then restores the view:

```
map ,p ma"aYHmbgg"aP`bzt`a
```

What this does:

```
ma"aYHmbgg"aP`bzt`a
ma                      set mark a at cursor position
   "aY                   yank current line into register a
      Hmb                go to top line in window and set mark b there
         gg              go to first line in file
           "aP           put the yanked line above it
              `b         go back to top line in display
                zt       position the text in the window as before
                   `a    go back to saved cursor position
```

PACKAGING

To avoid your function names to interfere with functions that you get from
others, use this scheme:
- Prepend a unique string before each function name. I often use an
  abbreviation. For example, "OW_" is used for the option window functions.
- Put the definition of your functions together in a file. Set a global
  variable to indicate that the functions have been loaded. When sourcing the
  file again, first unload the functions.
Example:

```
" This is the XXX package

if exists("XXX_loaded")
  delfun XXX_one
  delfun XXX_two
endif

function XXX_one(a)
        ... body of function ...
endfun

function XXX_two(b)
        ... body of function ...
endfun

let XXX_loaded = 1
```

==
41.11 Writing a plugin   write-plugin

You can write a Vim script in such a way that many people can use it. This is
called a plugin. Vim users can drop your script in their plugin directory and

use its features right away add-plugin .

There are actually two types of plugins:

  global plugins: For all types of files.
filetype plugins: Only for files of a specific type.

In this section the first type is explained. Most items are also relevant for writing filetype plugins. The specifics for filetype plugins are in the next section write-filetype-plugin .

NAME

First of all you must choose a name for your plugin. The features provided by the plugin should be clear from its name. And it should be unlikely that someone else writes a plugin with the same name but which does something different. And please limit the name to 8 characters, to avoid problems on old Windows systems.

A script that corrects typing mistakes could be called "typecorr.vim". We will use it here as an example.

For the plugin to work for everybody, it should follow a few guidelines. This will be explained step-by-step. The complete example plugin is at the end.

BODY

Let's start with the body of the plugin, the lines that do the actual work:

```
14     iabbrev teh the
15     iabbrev otehr other
16     iabbrev wnat want
17     iabbrev synchronisation
18             \ synchronization
19     let s:count = 4
```

The actual list should be much longer, of course.

The line numbers have only been added to explain a few things, don't put them in your plugin file!

HEADER

You will probably add new corrections to the plugin and soon have several versions lying around. And when distributing this file, people will want to know who wrote this wonderful plugin and where they can send remarks. Therefore, put a header at the top of your plugin:

```
1     " Vim global plugin for correcting typing mistakes
2     " Last Change:  2000 Oct 15
3     " Maintainer:   Bram Moolenaar <Bram@vim.org>
```

About copyright and licensing: Since plugins are very useful and it's hardly worth restricting their distribution, please consider making your plugin either public domain or use the Vim license. A short note about this near the top of the plugin should be sufficient. Example:

```
4     " License:      This file is placed in the public domain.
```

LINE CONTINUATION, AVOIDING SIDE EFFECTS use-cpo-save

In line 18 above, the line-continuation mechanism is used line-continuation. Users with 'compatible' set will run into trouble here, they will get an error message. We can't just reset 'compatible', because that has a lot of side effects. To avoid this, we will set the 'cpoptions' option to its Vim default value and restore it later. That will allow the use of line-continuation and make the script work for most people. It is done like this:

```
11     let s:save_cpo = &cpo
12     set cpo&vim
..
42     let &cpo = s:save_cpo
43     unlet s:save_cpo
```

We first store the old value of 'cpoptions' in the s:save_cpo variable. At the end of the plugin this value is restored.

Notice that a script-local variable is used s:var. A global variable could already be in use for something else. Always use script-local variables for things that are only used in the script.

NOT LOADING

It's possible that a user doesn't always want to load this plugin. Or the system administrator has dropped it in the system-wide plugin directory, but a user has his own plugin he wants to use. Then the user must have a chance to disable loading this specific plugin. This will make it possible:

```
6     if exists("g:loaded_typecorr")
7       finish
8     endif
9     let g:loaded_typecorr = 1
```

This also avoids that when the script is loaded twice it would cause error messages for redefining functions and cause trouble for autocommands that are added twice.

The name is recommended to start with "loaded_" and then the file name of the plugin, literally. The "g:" is prepended just to avoid mistakes when using the variable in a function (without "g:" it would be a variable local to the function).

Using "finish" stops Vim from reading the rest of the file, it's much quicker

than using if-endif around the whole file.

MAPPING

Now let's make the plugin more interesting: We will add a mapping that adds a correction for the word under the cursor. We could just pick a key sequence for this mapping, but the user might already use it for something else. To allow the user to define which keys a mapping in a plugin uses, the <Leader> item can be used:

```
 22       map <unique> <Leader>a  <Plug>TypecorrAdd
```

The "<Plug>TypecorrAdd" thing will do the work, more about that further on.

The user can set the "mapleader" variable to the key sequence that he wants this mapping to start with. Thus if the user has done:

```
        let mapleader = "_"
```

the mapping will define "_a". If the user didn't do this, the default value will be used, which is a backslash. Then a map for "\a" will be defined.

Note that <unique> is used, this will cause an error message if the mapping already happened to exist. :map-<unique>

But what if the user wants to define his own key sequence? We can allow that with this mechanism:

```
 21     if !hasmapto('<Plug>TypecorrAdd')
 22       map <unique> <Leader>a  <Plug>TypecorrAdd
 23     endif
```

This checks if a mapping to "<Plug>TypecorrAdd" already exists, and only defines the mapping from "<Leader>a" if it doesn't. The user then has a chance of putting this in his vimrc file:

```
        map ,c  <Plug>TypecorrAdd
```

Then the mapped key sequence will be ",c" instead of "_a" or "\a".

PIECES

If a script gets longer, you often want to break up the work in pieces. You can use functions or mappings for this. But you don't want these functions and mappings to interfere with the ones from other scripts. For example, you could define a function Add(), but another script could try to define the same function. To avoid this, we define the function local to the script by prepending it with "s:".

We will define a function that adds a new typing correction:

```
 30     function s:Add(from, correct)
```

```
 31       let to = input("type the correction for " . a:from . ": ")
 32       exe ":iabbrev " . a:from . " " . to
 ..
 36     endfunction
```

Now we can call the function s:Add() from within this script. If another script also defines s:Add(), it will be local to that script and can only be called from the script it was defined in. There can also be a global Add() function (without the "s:"), which is again another function.

<SID> can be used with mappings. It generates a script ID, which identifies the current script. In our typing correction plugin we use it like this:

```
 24     noremap <unique> <script> <Plug>TypecorrAdd  <SID>Add
 ..
 28     noremap <SID>Add  :call <SID>Add(expand("<cword>"), 1)<CR>
```

Thus when a user types "\a", this sequence is invoked:

```
        \a  ->  <Plug>TypecorrAdd  ->  <SID>Add  ->  :call <SID>Add()
```

If another script would also map <SID>Add, it would get another script ID and thus define another mapping.

Note that instead of s:Add() we use <SID>Add() here. That is because the mapping is typed by the user, thus outside of the script. The <SID> is translated to the script ID, so that Vim knows in which script to look for the Add() function.

This is a bit complicated, but it's required for the plugin to work together with other plugins. The basic rule is that you use <SID>Add() in mappings and s:Add() in other places (the script itself, autocommands, user commands).

We can also add a menu entry to do the same as the mapping:

```
 26     noremenu <script> Plugin.Add\ Correction      <SID>Add
```

The "Plugin" menu is recommended for adding menu items for plugins. In this case only one item is used. When adding more items, creating a submenu is recommended. For example, "Plugin.CVS" could be used for a plugin that offers CVS operations "Plugin.CVS.checkin", "Plugin.CVS.checkout", etc.

Note that in line 28 ":noremap" is used to avoid that any other mappings cause trouble. Someone may have remapped ":call", for example. In line 24 we also use ":noremap", but we do want "<SID>Add" to be remapped. This is why "<script>" is used here. This only allows mappings which are local to the script. :map-<script> The same is done in line 26 for ":noremenu". :menu-<script>

<SID> AND <Plug> using-<Plug>

Both <SID> and <Plug> are used to avoid that mappings of typed keys interfere with mappings that are only to be used from other mappings. Note the

difference between using <SID> and <Plug>:

<Plug> is visible outside of the script. It is used for mappings which the
        user might want to map a key sequence to. <Plug> is a special code
        that a typed key will never produce.
        To make it very unlikely that other plugins use the same sequence of
        characters, use this structure: <Plug> scriptname mapname
        In our example the scriptname is "Typecorr" and the mapname is "Add".
        This results in "<Plug>TypecorrAdd". Only the first character of
        scriptname and mapname is uppercase, so that we can see where mapname
        starts.

<SID>   is the script ID, a unique identifier for a script.
        Internally Vim translates <SID> to "<SNR>123_", where "123" can be any
        number. Thus a function "<SID>Add()" will have a name "<SNR>11_Add()"
        in one script, and "<SNR>22_Add()" in another. You can see this if
        you use the ":function" command to get a list of functions. The
        translation of <SID> in mappings is exactly the same, that's how you
        can call a script-local function from a mapping.

USER COMMAND

Now let's add a user command to add a correction:

```
 38     if !exists(":Correct")
 39       command -nargs=1  Correct  :call s:Add(<q-args>, 0)
 40     endif
```

The user command is defined only if no command with the same name already
exists. Otherwise we would get an error here. Overriding the existing user
command with ":command!" is not a good idea, this would probably make the user
wonder why the command he defined himself doesn't work. :command

SCRIPT VARIABLES

When a variable starts with "s:" it is a script variable. It can only be used
inside a script. Outside the script it's not visible. This avoids trouble
with using the same variable name in different scripts. The variables will be
kept as long as Vim is running. And the same variables are used when sourcing
the same script again. s:var

The fun is that these variables can also be used in functions, autocommands
and user commands that are defined in the script. In our example we can add
a few lines to count the number of corrections:

```
 19     let s:count = 4
 ..
 30     function s:Add(from, correct)
 ..
 34       let s:count = s:count + 1
 35       echo s:count . " corrections now"
 36     endfunction
```

First s:count is initialized to 4 in the script itself. When later the s:Add() function is called, it increments s:count. It doesn't matter from where the function was called, since it has been defined in the script, it will use the local variables from this script.

THE RESULT

Here is the resulting complete example:

```
 1     " Vim global plugin for correcting typing mistakes
 2     " Last Change:  2000 Oct 15
 3     " Maintainer:   Bram Moolenaar <Bram@vim.org>
 4     " License:      This file is placed in the public domain.
 5
 6     if exists("g:loaded_typecorr")
 7       finish
 8     endif
 9     let g:loaded_typecorr = 1
10
11     let s:save_cpo = &cpo
12     set cpo&vim
13
14     iabbrev teh the
15     iabbrev otehr other
16     iabbrev wnat want
17     iabbrev synchronisation
18             \ synchronization
19     let s:count = 4
20
21     if !hasmapto('<Plug>TypecorrAdd')
22       map <unique> <Leader>a  <Plug>TypecorrAdd
23     endif
24     noremap <unique> <script> <Plug>TypecorrAdd  <SID>Add
25
26     noremenu <script> Plugin.Add\ Correction      <SID>Add
27
28     noremap <SID>Add  :call <SID>Add(expand("<cword>"), 1)<CR>
29
30     function s:Add(from, correct)
31       let to = input("type the correction for " . a:from . ": ")
32       exe ":iabbrev " . a:from . " " . to
33       if a:correct | exe "normal viws\<C-R>\" \b\e" | endif
34       let s:count = s:count + 1
35       echo s:count . " corrections now"
36     endfunction
37
38     if !exists(":Correct")
39       command -nargs=1  Correct  :call s:Add(<q-args>, 0)
40     endif
41
42     let &cpo = s:save_cpo
43     unlet s:save_cpo
```

Line 33 wasn't explained yet. It applies the new correction to the word under the cursor. The :normal command is used to use the new abbreviation. Note that mappings and abbreviations are expanded here, even though the function was called from a mapping defined with ":noremap".

Using "unix" for the 'fileformat' option is recommended. The Vim scripts will then work everywhere. Scripts with 'fileformat' set to "dos" do not work on Unix. Also see :source_crnl . To be sure it is set right, do this before writing the file:

```
:set fileformat=unix
```

DOCUMENTATION write-local-help

It's a good idea to also write some documentation for your plugin. Especially when its behavior can be changed by the user. See add-local-help for how they are installed.

Here is a simple example for a plugin help file, called "typecorr.txt":

```
 1  *typecorr.txt*  Plugin for correcting typing mistakes
 2
 3  If you make typing mistakes, this plugin will have them corrected
 4  automatically.
 5
 6  There are currently only a few corrections.  Add your own if you like.
 7
 8  Mappings:
 9  <Leader>a   or   <Plug>TypecorrAdd
10          Add a correction for the word under the cursor.
11
12  Commands:
13  :Correct {word}
14          Add a correction for {word}.
15
16                                                  *typecorr-settings*
17  This plugin doesn't have any settings.
```

The first line is actually the only one for which the format matters. It will be extracted from the help file to be put in the "LOCAL ADDITIONS:" section of help.txt local-additions . The first "*" must be in the first column of the first line. After adding your help file do ":help" and check that the entries line up nicely.

You can add more tags inside ** in your help file. But be careful not to use existing help tags. You would probably use the name of your plugin in most of them, like "typecorr-settings" in the example.

Using references to other parts of the help in || is recommended. This makes it easy for the user to find associated help.

FILETYPE DETECTION plugin-filetype

If your filetype is not already detected by Vim, you should create a filetype detection snippet in a separate file. It is usually in the form of an autocommand that sets the filetype when the file name matches a pattern. Example:

```
au BufNewFile,BufRead *.foo set filetype=foofoo
```

Write this single-line file as "ftdetect/foofoo.vim" in the first directory that appears in 'runtimepath'. For Unix that would be "~/.vim/ftdetect/foofoo.vim". The convention is to use the name of the filetype for the script name.

You can make more complicated checks if you like, for example to inspect the contents of the file to recognize the language. Also see new-filetype .

SUMMARY plugin-special

Summary of special things to use in a plugin:

s:name	Variables local to the script.
<SID>	Script-ID, used for mappings and functions local to the script.
hasmapto()	Function to test if the user already defined a mapping for functionality the script offers.
<Leader>	Value of "mapleader", which the user defines as the keys that plugin mappings start with.
:map <unique>	Give a warning if a mapping already exists.
:noremap <script>	Use only mappings local to the script, not global mappings.
exists(":Cmd")	Check if a user command already exists.

==========

41.12 Writing a filetype plugin write-filetype-plugin ftplugin

A filetype plugin is like a global plugin, except that it sets options and defines mappings for the current buffer only. See add-filetype-plugin for how this type of plugin is used.

First read the section on global plugins above 41.11 . All that is said there also applies to filetype plugins. There are a few extras, which are explained here. The essential thing is that a filetype plugin should only have an effect on the current buffer.

DISABLING

If you are writing a filetype plugin to be used by many people, they need a chance to disable loading it. Put this at the top of the plugin:

```
" Only do this when not done yet for this buffer
if exists("b:did_ftplugin")
  finish
endif
let b:did_ftplugin = 1
```

This also needs to be used to avoid that the same plugin is executed twice for the same buffer (happens when using an ":edit" command without arguments).

Now users can disable loading the default plugin completely by making a filetype plugin with only this line:

```
let b:did_ftplugin = 1
```

This does require that the filetype plugin directory comes before $VIMRUNTIME in 'runtimepath'!

If you do want to use the default plugin, but overrule one of the settings, you can write the different setting in a script:

```
setlocal textwidth=70
```

Now write this in the "after" directory, so that it gets sourced after the distributed "vim.vim" ftplugin after-directory . For Unix this would be "~/.vim/after/ftplugin/vim.vim". Note that the default plugin will have set "b:did_ftplugin", but it is ignored here.

OPTIONS

To make sure the filetype plugin only affects the current buffer use the

```
:setlocal
```

command to set options. And only set options which are local to a buffer (see the help for the option to check that). When using :setlocal for global options or options local to a window, the value will change for many buffers, and that is not what a filetype plugin should do.

When an option has a value that is a list of flags or items, consider using "+=" and "-=" to keep the existing value. Be aware that the user may have changed an option value already. First resetting to the default value and then changing it is often a good idea. Example:

```
:setlocal formatoptions& formatoptions+=ro
```

MAPPINGS

To make sure mappings will only work in the current buffer use the

```
:map <buffer>
```

command. This needs to be combined with the two-step mapping explained above.
An example of how to define functionality in a filetype plugin:

```
if !hasmapto('<Plug>JavaImport')
  map <buffer> <unique> <LocalLeader>i <Plug>JavaImport
endif
noremap <buffer> <unique> <Plug>JavaImport oimport ""<Left><Esc>
```

 hasmapto() is used to check if the user has already defined a map to
<Plug>JavaImport. If not, then the filetype plugin defines the default
mapping. This starts with <LocalLeader> , which allows the user to select
the key(s) he wants filetype plugin mappings to start with. The default is a
backslash.
"<unique>" is used to give an error message if the mapping already exists or
overlaps with an existing mapping.
 :noremap is used to avoid that any other mappings that the user has defined
interferes. You might want to use ":noremap <script>" to allow remapping
mappings defined in this script that start with <SID>.

The user must have a chance to disable the mappings in a filetype plugin,
without disabling everything. Here is an example of how this is done for a
plugin for the mail filetype:

```
" Add mappings, unless the user didn't want this.
if !exists("no_plugin_maps") && !exists("no_mail_maps")
  " Quote text by inserting "> "
  if !hasmapto('<Plug>MailQuote')
    vmap <buffer> <LocalLeader>q <Plug>MailQuote
    nmap <buffer> <LocalLeader>q <Plug>MailQuote
  endif
  vnoremap <buffer> <Plug>MailQuote :s/^/> /<CR>
  nnoremap <buffer> <Plug>MailQuote :.,$s/^/> /<CR>
endif
```

Two global variables are used:
```
 no_plugin_maps         disables mappings for all filetype plugins
 no_mail_maps           disables mappings for the "mail" filetype
```

USER COMMANDS

To add a user command for a specific file type, so that it can only be used in
one buffer, use the "-buffer" argument to :command . Example:

```
:command -buffer  Make  make %:r.s
```

VARIABLES

A filetype plugin will be sourced for each buffer of the type it's for. Local
script variables s:var will be shared between all invocations. Use local

buffer variables b:var if you want a variable specifically for one buffer.

FUNCTIONS

When defining a function, this only needs to be done once. But the filetype plugin will be sourced every time a file with this filetype will be opened. This construct makes sure the function is only defined once:

```
:if !exists("*s:Func")
:  function s:Func(arg)
:    ...
:  endfunction
:endif
```

UNDO undo_indent undo_ftplugin

When the user does ":setfiletype xyz" the effect of the previous filetype should be undone. Set the b:undo_ftplugin variable to the commands that will undo the settings in your filetype plugin. Example:

```
let b:undo_ftplugin = "setlocal fo< com< tw< commentstring<"
        \ . "| unlet b:match_ignorecase b:match_words b:match_skip"
```

Using ":setlocal" with "<" after the option name resets the option to its global value. That is mostly the best way to reset the option value.

This does require removing the "C" flag from 'cpoptions' to allow line continuation, as mentioned above use-cpo-save .

For undoing the effect of an indent script, the b:undo_indent variable should be set accordingly.

FILE NAME

The filetype must be included in the file name ftplugin-name . Use one of these three forms:

```
.../ftplugin/stuff.vim
.../ftplugin/stuff_foo.vim
.../ftplugin/stuff/bar.vim
```

"stuff" is the filetype, "foo" and "bar" are arbitrary names.

SUMMARY ftplugin-special

Summary of special things to use in a filetype plugin:

<LocalLeader> Value of "maplocalleader", which the user defines as the keys that filetype plugin mappings start with.

:map <buffer>		Define a mapping local to the buffer.

:noremap <script>	Only remap mappings defined in this script that start
			with <SID>.

:setlocal		Set an option for the current buffer only.

:command -buffer	Define a user command local to the buffer.

exists("*s:Func")	Check if a function was already defined.

Also see plugin-special, the special things used for all plugins.

==
41.13 Writing a compiler plugin write-compiler-plugin

A compiler plugin sets options for use with a specific compiler. The user can load it with the :compiler command. The main use is to set the 'errorformat' and 'makeprg' options.

Easiest is to have a look at examples. This command will edit all the default compiler plugins:

```
:next $VIMRUNTIME/compiler/*.vim
```

Use :next to go to the next plugin file.

There are two special items about these files. First is a mechanism to allow a user to overrule or add to the default file. The default files start with:

```
:if exists("current_compiler")
:  finish
:endif
:let current_compiler = "mine"
```

When you write a compiler file and put it in your personal runtime directory (e.g., ~/.vim/compiler for Unix), you set the "current_compiler" variable to make the default file skip the settings.

:CompilerSet

The second mechanism is to use ":set" for ":compiler!" and ":setlocal" for ":compiler". Vim defines the ":CompilerSet" user command for this. However, older Vim versions don't, thus your plugin should define it then. This is an example:

```
if exists(":CompilerSet") != 2
  command -nargs=* CompilerSet setlocal <args>
endif
CompilerSet errorformat&		" use the default 'errorformat'
CompilerSet makeprg=nmake
```

When you write a compiler plugin for the Vim distribution or for a system-wide runtime directory, use the mechanism mentioned above. When "current_compiler" was already set by a user plugin nothing will be done.

When you write a compiler plugin to overrule settings from a default plugin, don't check "current_compiler". This plugin is supposed to be loaded last, thus it should be in a directory at the end of 'runtimepath'. For Unix that could be ~/.vim/after/compiler.

==

41.14 Writing a plugin that loads quickly write-plugin-quickload

A plugin may grow and become quite long. The startup delay may become noticeable, while you hardly ever use the plugin. Then it's time for a quickload plugin.

The basic idea is that the plugin is loaded twice. The first time user commands and mappings are defined that offer the functionality. The second time the functions that implement the functionality are defined.

It may sound surprising that quickload means loading a script twice. What we mean is that it loads quickly the first time, postponing the bulk of the script to the second time, which only happens when you actually use it. When you always use the functionality it actually gets slower!

Note that since Vim 7 there is an alternative: use the autoload functionality 41.15 .

The following example shows how it's done:

```
" Vim global plugin for demonstrating quick loading
" Last Change:  2005 Feb 25
" Maintainer:   Bram Moolenaar <Bram@vim.org>
" License:      This file is placed in the public domain.

if !exists("s:did_load")
        command -nargs=* BNRead  call BufNetRead(<f-args>)
        map <F19> :call BufNetWrite('something')<CR>

        let s:did_load = 1
        exe 'au FuncUndefined BufNet* source ' . expand('<sfile>')
        finish
endif

function BufNetRead(...)
        echo 'BufNetRead(' . string(a:000) . ')'
        " read functionality here
endfunction

function BufNetWrite(...)
        echo 'BufNetWrite(' . string(a:000) . ')'
        " write functionality here
endfunction
```

When the script is first loaded "s:did_load" is not set. The commands between the "if" and "endif" will be executed. This ends in a :finish command, thus the rest of the script is not executed.

The second time the script is loaded "s:did_load" exists and the commands after the "endif" are executed. This defines the (possible long) BufNetRead() and BufNetWrite() functions.

If you drop this script in your plugin directory Vim will execute it on startup. This is the sequence of events that happens:

1. The "BNRead" command is defined and the <F19> key is mapped when the script is sourced at startup. A FuncUndefined autocommand is defined. The ":finish" command causes the script to terminate early.

2. The user types the BNRead command or presses the <F19> key. The BufNetRead() or BufNetWrite() function will be called.

3. Vim can't find the function and triggers the FuncUndefined autocommand event. Since the pattern "BufNet*" matches the invoked function, the command "source fname" will be executed. "fname" will be equal to the name of the script, no matter where it is located, because it comes from expanding "<sfile>" (see expand()).

4. The script is sourced again, the "s:did_load" variable exists and the functions are defined.

Notice that the functions that are loaded afterwards match the pattern in the FuncUndefined autocommand. You must make sure that no other plugin defines functions that match this pattern.

==
41.15 Writing library scripts write-library-script

Some functionality will be required in several places. When this becomes more than a few lines you will want to put it in one script and use it from many scripts. We will call that one script a library script.

Manually loading a library script is possible, so long as you avoid loading it when it's already done. You can do this with the exists() function. Example:

```
if !exists('*MyLibFunction')
   runtime library/mylibscript.vim
endif
call MyLibFunction(arg)
```

Here you need to know that MyLibFunction() is defined in a script "library/mylibscript.vim" in one of the directories in 'runtimepath'.

To make this a bit simpler Vim offers the autoload mechanism. Then the example looks like this:

```
call mylib#myfunction(arg)
```

That's a lot simpler, isn't it? Vim will recognize the function name and when it's not defined search for the script "autoload/mylib.vim" in 'runtimepath'. That script must define the "mylib#myfunction()" function.

You can put many other functions in the mylib.vim script, you are free to
organize your functions in library scripts. But you must use function names
where the part before the '#' matches the script name. Otherwise Vim would
not know what script to load.

If you get really enthusiastic and write lots of library scripts, you may
want to use subdirectories. Example:

```
call netlib#ftp#read('somefile')
```

For Unix the library script used for this could be:

```
~/.vim/autoload/netlib/ftp.vim
```

Where the function is defined like this:

```
function netlib#ftp#read(fname)
        "  Read the file fname through ftp
endfunction
```

Notice that the name the function is defined with is exactly the same as the
name used for calling the function. And the part before the last '#'
exactly matches the subdirectory and script name.

You can use the same mechanism for variables:

```
let weekdays = dutch#weekdays
```

This will load the script "autoload/dutch.vim", which should contain something
like:

```
let dutch#weekdays = ['zondag', 'maandag', 'dinsdag', 'woensdag',
        \ 'donderdag', 'vrijdag', 'zaterdag']
```

Further reading: autoload .

==
41.16 Distributing Vim scripts distribute-script

Vim users will look for scripts on the Vim website: http://www.vim.org.
If you made something that is useful for others, share it!

Vim scripts can be used on any system. There might not be a tar or gzip
command. If you want to pack files together and/or compress them the "zip"
utility is recommended.

For utmost portability use Vim itself to pack scripts together. This can be
done with the Vimball utility. See vimball .

It's good if you add a line to allow automatic updating. See glvs-plugins .

Next chapter: usr_42.txt Add new menus

VIM USER MANUAL - by Bram Moolenaar

Add new menus

By now you know that Vim is very flexible. This includes the menus used in the GUI. You can define your own menu entries to make certain commands easily accessible. This is for mouse-happy users only.

Next chapter: usr_43.txt Using filetypes
Previous chapter: usr_41.txt Write a Vim script
Table of contents: usr_toc.txt

==========

42.1 Introduction

The menus that Vim uses are defined in the file "$VIMRUNTIME/menu.vim". If you want to write your own menus, you might first want to look through that file.

To define a menu item, use the ":menu" command. The basic form of this command is as follows:

```
:menu {menu-item} {keys}
```

The {menu-item} describes where on the menu to put the item. A typical {menu-item} is "File.Save", which represents the item "Save" under the "File" menu. A dot is used to separate the names. Example:

```
:menu File.Save  :update<CR>
```

The ":update" command writes the file when it was modified.

You can add another level: "Edit.Settings.Shiftwidth" defines a submenu "Settings" under the "Edit" menu, with an item "Shiftwidth". You could use even deeper levels. Don't use this too much, you need to move the mouse quite a bit to use such an item.

The ":menu" command is very similar to the ":map" command: the left side specifies how the item is triggered and the right hand side defines the characters that are executed. {keys} are characters, they are used just like you would have typed them. Thus in Insert mode, when {keys} is plain text, that text is inserted.

ACCELERATORS

The ampersand character (&) is used to indicate an accelerator. For instance, you can use Alt-F to select "File" and S to select "Save". (The 'winaltkeys' option may disable this though!). Therefore, the {menu-item} looks like

"&File.&Save". The accelerator characters will be underlined in the menu.
   You must take care that each key is used only once in each menu. Otherwise you will not know which of the two will actually be used. Vim doesn't warn you for this.

PRIORITIES

The actual definition of the File.Save menu item is as follows:

```
:menu 10.340 &File.&Save<Tab>:w  :confirm w<CR>
```

The number 10.340 is called the priority number. It is used by the editor to decide where it places the menu item. The first number (10) indicates the position on the menu bar. Lower numbered menus are positioned to the left, higher numbers to the right.
   These are the priorities used for the standard menus:

```
  10    20     40     50      60       70               9999

+-------------------------------------------------------------+
| File  Edit  Tools  Syntax  Buffers  Window            Help |
+-------------------------------------------------------------+
```

Notice that the Help menu is given a very high number, to make it appear on the far right.
   The second number (340) determines the location of the item within the pull-down menu. Lower numbers go on top, higher number on the bottom. These are the priorities in the File menu:

```
                +-----------------+
    10.310      |Open...          |
    10.320      |Split-Open...    |
    10.325      |New              |
    10.330      |Close            |
    10.335      |---------------- |
    10.340      |Save             |
    10.350      |Save As...       |
    10.400      |---------------- |
    10.410      |Split Diff with  |
    10.420      |Split Patched By |
    10.500      |---------------- |
    10.510      |Print            |
    10.600      |---------------- |
    10.610      |Save-Exit        |
    10.620      |Exit             |
                +-----------------+
```

Notice that there is room in between the numbers. This is where you can insert your own items, if you really want to (it's often better to leave the standard menus alone and add a new menu for your own items).
   When you create a submenu, you can add another ".number" to the priority. Thus each name in {menu-item} has its priority number.

SPECIAL CHARACTERS

The {menu-item} in this example is "&File.&Save<Tab>:w". This brings up an important point: {menu-item} must be one word. If you want to put a dot, space or tabs in the name, you either use the <> notation (<Space> and <Tab>, for instance) or use the backslash (\) escape.

```
:menu 10.305 &File.&Do\ It\.\.\. :exit<CR>
```

In this example, the name of the menu item "Do It..." contains a space and the command is ":exit<CR>".

The <Tab> character in a menu name is used to separate the part that defines the menu name from the part that gives a hint to the user. The part after the <Tab> is displayed right aligned in the menu. In the File.Save menu the name used is "&File.&Save<Tab>:w". Thus the menu name is "File.Save" and the hint is ":w".

SEPARATORS

The separator lines, used to group related menu items together, can be defined by using a name that starts and ends in a '-'. For example "-sep-". When using several separators the names must be different. Otherwise the names don't matter.

The command from a separator will never be executed, but you have to define one anyway. A single colon will do. Example:

```
:amenu 20.510 Edit.-sep3- :
```

==========

42.2 Menu commands

You can define menu items that exist for only certain modes. This works just like the variations on the ":map" command:

```
:menu           Normal, Visual and Operator-pending mode
:nmenu          Normal mode
:vmenu          Visual mode
:omenu          Operator-pending mode
:menu!          Insert and Command-line mode
:imenu          Insert mode
:cmenu          Command-line mode
:amenu          All modes
```

To avoid that the commands of a menu item are being mapped, use the command ":noremenu", ":nnoremenu", ":anoremenu", etc.

USING :AMENU

The ":amenu" command is a bit different. It assumes that the {keys} you give are to be executed in Normal mode. When Vim is in Visual or Insert mode

when the menu is used, Vim first has to go back to Normal mode. ":amenu" inserts a CTRL-C or CTRL-O for you. For example, if you use this command:

```
:amenu  90.100 Mine.Find\ Word  *
```

Then the resulting menu commands will be:

```
Normal mode:            *
Visual mode:            CTRL-C *
Operator-pending mode:  CTRL-C *
Insert mode:            CTRL-O *
Command-line mode:      CTRL-C *
```

When in Command-line mode the CTRL-C will abandon the command typed so far. In Visual and Operator-pending mode CTRL-C will stop the mode. The CTRL-O in Insert mode will execute the command and then return to Insert mode.

CTRL-O only works for one command. If you need to use two or more commands, put them in a function and call that function. Example:

```
:amenu  Mine.Next\ File  :call <SID>NextFile()<CR>
:function <SID>NextFile()
:  next
:  1/^Code
:endfunction
```

This menu entry goes to the next file in the argument list with ":next". Then it searches for the line that starts with "Code".

The <SID> before the function name is the script ID. This makes the function local to the current Vim script file. This avoids problems when a function with the same name is defined in another script file. See <SID> .

SILENT MENUS

The menu executes the {keys} as if you typed them. For a ":" command this means you will see the command being echoed on the command line. If it's a long command, the hit-Enter prompt will appear. That can be very annoying!

To avoid this, make the menu silent. This is done with the <silent> argument. For example, take the call to NextFile() in the previous example. When you use this menu, you will see this on the command line:

```
:call <SNR>34_NextFile()
```

To avoid this text on the command line, insert "<silent>" as the first argument:

```
:amenu <silent> Mine.Next\ File :call <SID>NextFile()<CR>
```

Don't use "<silent>" too often. It is not needed for short commands. If you make a menu for someone else, being able the see the executed command will give him a hint about what he could have typed, instead of using the mouse.

LISTING MENUS

When a menu command is used without a {keys} part, it lists the already defined menus. You can specify a {menu-item}, or part of it, to list specific menus. Example:

```
:amenu
```

This lists all menus. That's a long list! Better specify the name of a menu to get a shorter list:

```
:amenu Edit
```

This lists only the "Edit" menu items for all modes. To list only one specific menu item for Insert mode:

```
:imenu Edit.Undo
```

Take care that you type exactly the right name. Case matters here. But the '&' for accelerators can be omitted. The <Tab> and what comes after it can be left out as well.

DELETING MENUS

To delete a menu, the same command is used as for listing, but with "menu" changed to "unmenu". Thus ":menu" becomes, ":unmenu", ":nmenu" becomes ":nunmenu", etc. To delete the "Tools.Make" item for Insert mode:

```
:iunmenu Tools.Make
```

You can delete a whole menu, with all its items, by using the menu name. Example:

```
:aunmenu Syntax
```

This deletes the Syntax menu and all the items in it.

==========

42.3 Various

You can change the appearance of the menus with flags in 'guioptions'. In the default value they are all included, except "M". You can remove a flag with a command like:

```
:set guioptions-=m
```

m	When removed the menubar is not displayed.
M	When added the default menus are not loaded.
g	When removed the inactive menu items are not made grey but are completely removed. (Does not work on all systems.)

	t		When removed the tearoff feature is not enabled.

The dotted line at the top of a menu is not a separator line. When you select this item, the menu is "teared-off": It is displayed in a separate window. This is called a tearoff menu. This is useful when you use the same menu often.

For translating menu items, see :menutrans .

Since the mouse has to be used to select a menu item, it is a good idea to use the ":browse" command for selecting a file. And ":confirm" to get a dialog instead of an error message, e.g., when the current buffer contains changes. These two can be combined:

```
:amenu File.Open  :browse confirm edit<CR>
```

The ":browse" makes a file browser appear to select the file to edit. The ":confirm" will pop up a dialog when the current buffer has changes. You can then select to save the changes, throw them away or cancel the command.
For more complicated items, the confirm() and inputdialog() functions can be used. The default menus contain a few examples.

==========

42.4 Toolbar and popup menus

There are two special menus: ToolBar and PopUp. Items that start with these names do not appear in the normal menu bar.

TOOLBAR

The toolbar appears only when the "T" flag is included in the 'guioptions' option.
The toolbar uses icons rather than text to represent the command. For example, the {menu-item} named "ToolBar.New" causes the "New" icon to appear on the toolbar.
The Vim editor has 28 built-in icons. You can find a table here: builtin-tools . Most of them are used in the default toolbar. You can redefine what these items do (after the default menus are setup).
You can add another bitmap for a toolbar item. Or define a new toolbar item with a bitmap. For example, define a new toolbar item with:

```
:tmenu ToolBar.Compile  Compile the current file
:amenu ToolBar.Compile  :!cc %:S -o %:r:S<CR>
```

Now you need to create the icon. For MS-Windows it must be in bitmap format, with the name "Compile.bmp". For Unix XPM format is used, the file name is "Compile.xpm". The size must be 18 by 18 pixels. On MS-Windows other sizes can be used as well, but it will look ugly.
Put the bitmap in the directory "bitmaps" in one of the directories from 'runtimepath'. E.g., for Unix "~/.vim/bitmaps/Compile.xpm".

You can define tooltips for the items in the toolbar. A tooltip is a short text that explains what a toolbar item will do. For example "Open file". It

appears when the mouse pointer is on the item, without moving for a moment.
This is very useful if the meaning of the picture isn't that obvious.
Example:

```
:tmenu ToolBar.Make  Run make in the current directory

Note:
Pay attention to the case used.  "Toolbar" and "toolbar" are different
from "ToolBar"!
```

To remove a tooltip, use the :tunmenu command.

The 'toolbar' option can be used to display text instead of a bitmap, or both text and a bitmap. Most people use just the bitmap, since the text takes quite a bit of space.

POPUP MENU

The popup menu pops up where the mouse pointer is. On MS-Windows you activate it by clicking the right mouse button. Then you can select an item with the left mouse button. On Unix the popup menu is used by pressing and holding the right mouse button.

The popup menu only appears when the 'mousemodel' has been set to "popup" or "popup_setpos". The difference between the two is that "popup_setpos" moves the cursor to the mouse pointer position. When clicking inside a selection, the selection will be used unmodified. When there is a selection but you click outside of it, the selection is removed.

There is a separate popup menu for each mode. Thus there are never grey items like in the normal menus.

What is the meaning of life, the universe and everything? 42
Douglas Adams, the only person who knew what this question really was about is now dead, unfortunately. So now you might wonder what the meaning of death is...

Next chapter: usr_43.txt Using filetypes

VIM USER MANUAL - by Bram Moolenaar

Using filetypes

When you are editing a file of a certain type, for example a C program or a shell script, you often use the same option settings and mappings. You quickly get tired of manually setting these each time. This chapter explains how to do it automatically.

Next chapter: usr_44.txt Your own syntax highlighted
Previous chapter: usr_42.txt Add new menus
Table of contents: usr_toc.txt

==========

43.1 Plugins for a filetype filetype-plugin

How to start using filetype plugins has already been discussed here: add-filetype-plugin . But you probably are not satisfied with the default settings, because they have been kept minimal. Suppose that for C files you want to set the 'softtabstop' option to 4 and define a mapping to insert a three-line comment. You do this with only two steps:

your-runtime-dir

1. Create your own runtime directory. On Unix this usually is "~/.vim". In this directory create the "ftplugin" directory:

```
mkdir ~/.vim
mkdir ~/.vim/ftplugin
```

   When you are not on Unix, check the value of the 'runtimepath' option to see where Vim will look for the "ftplugin" directory:

```
set runtimepath
```

   You would normally use the first directory name (before the first comma). You might want to prepend a directory name to the 'runtimepath' option in your vimrc file if you don't like the default value.

2. Create the file "~/.vim/ftplugin/c.vim", with the contents:

```
setlocal softtabstop=4
noremap <buffer> <LocalLeader>c o/**************<CR><CR>/<Esc>
let b:undo_ftplugin = "setl softtabstop< | unmap <buffer> <LocalLeader>c"
```

Try editing a C file. You should notice that the 'softtabstop' option is set to 4. But when you edit another file it's reset to the default zero. That is because the ":setlocal" command was used. This sets the 'softtabstop' option only locally to the buffer. As soon as you edit another buffer, it will be

set to the value set for that buffer. For a new buffer it will get the
default value or the value from the last ":set" command.

Likewise, the mapping for "\c" will disappear when editing another buffer.
The ":map <buffer>" command creates a mapping that is local to the current
buffer. This works with any mapping command: ":map!", ":vmap", etc. The
 <LocalLeader> in the mapping is replaced with the value of the
"maplocalleader" variable.

The line to set b:undo_ftplugin is for when the filetype is set to another
value. In that case you will want to undo your preferences. The
b:undo_ftplugin variable is executed as a command. Watch out for characters
with a special meaning inside a string, such as a backslash.

You can find examples for filetype plugins in this directory:

```
$VIMRUNTIME/ftplugin/
```

More details about writing a filetype plugin can be found here:
 write-plugin .

==
 43.2   Adding a filetype

If you are using a type of file that is not recognized by Vim, this is how to
get it recognized. You need a runtime directory of your own. See
 your-runtime-dir above.

Create a file "filetype.vim" which contains an autocommand for your filetype.
(Autocommands were explained in section 40.3 .) Example:

```
augroup filetypedetect
au BufNewFile,BufRead *.xyz     setf xyz
augroup END
```

This will recognize all files that end in ".xyz" as the "xyz" filetype. The
":augroup" commands put this autocommand in the "filetypedetect" group. This
allows removing all autocommands for filetype detection when doing ":filetype
off". The "setf" command will set the 'filetype' option to its argument,
unless it was set already. This will make sure that 'filetype' isn't set
twice.

You can use many different patterns to match the name of your file. Directory
names can also be included. See autocmd-patterns . For example, the files
under "/usr/share/scripts/" are all "ruby" files, but don't have the expected
file name extension. Adding this to the example above:

```
augroup filetypedetect
au BufNewFile,BufRead *.xyz                     setf xyz
au BufNewFile,BufRead /usr/share/scripts/*      setf ruby
augroup END
```

However, if you now edit a file /usr/share/scripts/README.txt, this is not a
ruby file. The danger of a pattern ending in "*" is that it quickly matches

too many files. To avoid trouble with this, put the filetype.vim file in another directory, one that is at the end of 'runtimepath'. For Unix for example, you could use "~/.vim/after/filetype.vim".
   You now put the detection of text files in ~/.vim/filetype.vim:

```
augroup filetypedetect
au BufNewFile,BufRead *.txt                     setf text
augroup END
```

That file is found in 'runtimepath' first. Then use this in ~/.vim/after/filetype.vim, which is found last:

```
augroup filetypedetect
au BufNewFile,BufRead /usr/share/scripts/*      setf ruby
augroup END
```

What will happen now is that Vim searches for "filetype.vim" files in each directory in 'runtimepath'. First ~/.vim/filetype.vim is found. The autocommand to catch *.txt files is defined there. Then Vim finds the filetype.vim file in $VIMRUNTIME, which is halfway 'runtimepath'. Finally ~/.vim/after/filetype.vim is found and the autocommand for detecting ruby files in /usr/share/scripts is added.
   When you now edit /usr/share/scripts/README.txt, the autocommands are checked in the order in which they were defined. The *.txt pattern matches, thus "setf text" is executed to set the filetype to "text". The pattern for ruby matches too, and the "setf ruby" is executed. But since 'filetype' was already set to "text", nothing happens here.
   When you edit the file /usr/share/scripts/foobar the same autocommands are checked. Only the one for ruby matches and "setf ruby" sets 'filetype' to ruby.

RECOGNIZING BY CONTENTS

If your file cannot be recognized by its file name, you might be able to recognize it by its contents. For example, many script files start with a line like:

```
#!/bin/xyz
```

To recognize this script create a file "scripts.vim" in your runtime directory (same place where filetype.vim goes). It might look like this:

```
if did_filetype()
  finish
endif
if getline(1) =~ '^#!.*[/\\]xyz\>'
  setf xyz
endif
```

The first check with did_filetype() is to avoid that you will check the contents of files for which the filetype was already detected by the file name. That avoids wasting time on checking the file when the "setf" command won't do anything.

The scripts.vim file is sourced by an autocommand in the default filetype.vim file. Therefore, the order of checks is:

1. filetype.vim files before $VIMRUNTIME in 'runtimepath'
2. first part of $VIMRUNTIME/filetype.vim
3. all scripts.vim files in 'runtimepath'
4. remainder of $VIMRUNTIME/filetype.vim
5. filetype.vim files after $VIMRUNTIME in 'runtimepath'

If this is not sufficient for you, add an autocommand that matches all files and sources a script or executes a function to check the contents of the file.

Next chapter: usr_44.txt Your own syntax highlighted

usr_44.txt For Vim version 8.1. Last change: 2017 May 06

VIM USER MANUAL - by Bram Moolenaar

Your own syntax highlighted

Vim comes with highlighting for a couple of hundred different file types. If the file you are editing isn't included, read this chapter to find out how to get this type of file highlighted. Also see :syn-define in the reference manual.

Next chapter: usr_45.txt Select your language
Previous chapter: usr_43.txt Using filetypes
Table of contents: usr_toc.txt

==

44.1 Basic syntax commands

Using an existing syntax file to start with will save you a lot of time. Try finding a syntax file in $VIMRUNTIME/syntax for a language that is similar. These files will also show you the normal layout of a syntax file. To understand it, you need to read the following.

Let's start with the basic arguments. Before we start defining any new syntax, we need to clear out any old definitions:

```
:syntax clear
```

This isn't required in the final syntax file, but very useful when experimenting.

There are more simplifications in this chapter. If you are writing a syntax file to be used by others, read all the way through the end to find out the details.

LISTING DEFINED ITEMS

To check which syntax items are currently defined, use this command:

```
:syntax
```

You can use this to check which items have actually been defined. Quite useful when you are experimenting with a new syntax file. It also shows the colors used for each item, which helps to find out what is what.
To list the items in a specific syntax group use:

```
:syntax list {group-name}
```

This also can be used to list clusters (explained in 44.8). Just include the @ in the name.

MATCHING CASE

Some languages are not case sensitive, such as Pascal. Others, such as C, are case sensitive. You need to tell which type you have with the following commands:

```
:syntax case match
:syntax case ignore
```

The "match" argument means that Vim will match the case of syntax elements. Therefore, "int" differs from "Int" and "INT". If the "ignore" argument is used, the following are equivalent: "Procedure", "PROCEDURE" and "procedure".
The ":syntax case" commands can appear anywhere in a syntax file and affect the syntax definitions that follow. In most cases, you have only one ":syntax case" command in your syntax file; if you work with an unusual language that contains both case-sensitive and non-case-sensitive elements, however, you can scatter the ":syntax case" command throughout the file.

==========

44.2 Keywords

The most basic syntax elements are keywords. To define a keyword, use the following form:

```
:syntax keyword {group} {keyword} ...
```

The {group} is the name of a syntax group. With the ":highlight" command you can assign colors to a {group}. The {keyword} argument is an actual keyword. Here are a few examples:

```
:syntax keyword xType int long char
:syntax keyword xStatement if then else endif
```

This example uses the group names "xType" and "xStatement". By convention, each group name is prefixed by the filetype for the language being defined. This example defines syntax for the x language (eXample language without an interesting name). In a syntax file for "csh" scripts the name "cshType" would be used. Thus the prefix is equal to the value of 'filetype'.
These commands cause the words "int", "long" and "char" to be highlighted one way and the words "if", "then", "else" and "endif" to be highlighted another way. Now you need to connect the x group names to standard Vim names. You do this with the following commands:

```
        :highlight link xType Type
        :highlight link xStatement Statement
```

This tells Vim to highlight "xType" like "Type" and "xStatement" like "Statement". See group-name for the standard names.

UNUSUAL KEYWORDS

The characters used in a keyword must be in the 'iskeyword' option. If you use another character, the word will never match. Vim doesn't give a warning message for this.
The x language uses the '-' character in keywords. This is how it's done:

```
        :setlocal iskeyword+=-
        :syntax keyword xStatement when-not
```

The ":setlocal" command is used to change 'iskeyword' only for the current buffer. Still it does change the behavior of commands like "w" and "*". If that is not wanted, don't define a keyword but use a match (explained in the next section).

The x language allows for abbreviations. For example, "next" can be abbreviated to "n", "ne" or "nex". You can define them by using this command:

```
        :syntax keyword xStatement n[ext]
```

This doesn't match "nextone", keywords always match whole words only.

==========

44.3 Matches

Consider defining something a bit more complex. You want to match ordinary identifiers. To do this, you define a match syntax item. This one matches any word consisting of only lowercase letters:

```
        :syntax match xIdentifier /\<\l\+\>/
```

Note:
Keywords overrule any other syntax item. Thus the keywords "if", "then", etc., will be keywords, as defined with the ":syntax keyword" commands above, even though they also match the pattern for xIdentifier.

The part at the end is a pattern, like it's used for searching. The // is used to surround the pattern (like how it's done in a ":substitute" command). You can use any other character, like a plus or a quote.

Now define a match for a comment. In the x language it is anything from # to the end of a line:

```
        :syntax match xComment /#.*/
```

Since you can use any search pattern, you can highlight very complex things
with a match item. See pattern for help on search patterns.

==
44.4 Regions

In the example x language, strings are enclosed in double quotation marks (").
To highlight strings you define a region. You need a region start (double
quote) and a region end (double quote). The definition is as follows:

```
:syntax region xString start=/"/ end=/"/
```

The "start" and "end" directives define the patterns used to find the start
and end of the region. But what about strings that look like this?

```
"A string with a double quote (\") in it"
```

This creates a problem: The double quotation marks in the middle of the string
will end the region. You need to tell Vim to skip over any escaped double
quotes in the string. Do this with the skip keyword:

```
:syntax region xString start=/"/ skip=/\\"/ end=/"/
```

The double backslash matches a single backslash, since the backslash is a
special character in search patterns.

When to use a region instead of a match? The main difference is that a match
item is a single pattern, which must match as a whole. A region starts as
soon as the "start" pattern matches. Whether the "end" pattern is found or
not doesn't matter. Thus when the item depends on the "end" pattern to match,
you cannot use a region. Otherwise, regions are often simpler to define. And
it is easier to use nested items, as is explained in the next section.

==
44.5 Nested items

Take a look at this comment:

```
%Get input  TODO: Skip white space
```

You want to highlight TODO in big yellow letters, even though it is in a
comment that is highlighted blue. To let Vim know about this, you define the
following syntax groups:

```
:syntax keyword xTodo TODO contained
:syntax match xComment /%.*/ contains=xTodo
```

In the first line, the "contained" argument tells Vim that this keyword can
exist only inside another syntax item. The next line has "contains=xTodo".
This indicates that the xTodo syntax element is inside it. The result is that
the comment line as a whole is matched with "xComment" and made blue. The
word TODO inside it is matched by xTodo and highlighted yellow (highlighting
for xTodo was setup for this).

RECURSIVE NESTING

The x language defines code blocks in curly braces. And a code block may contain other code blocks. This can be defined this way:

```
:syntax region xBlock start=/{/ end=/}/ contains=xBlock
```

Suppose you have this text:

```
while i < b {
        if a {
                b = c;
        }
}
```

First a xBlock starts at the { in the first line. In the second line another { is found. Since we are inside a xBlock item, and it contains itself, a nested xBlock item will start here. Thus the "b = c" line is inside the second level xBlock region. Then a } is found in the next line, which matches with the end pattern of the region. This ends the nested xBlock. Because the } is included in the nested region, it is hidden from the first xBlock region. Then at the last } the first xBlock region ends.

KEEPING THE END

Consider the following two syntax items:

```
:syntax region xComment start=/%/ end=/$/ contained
:syntax region xPreProc start=/#/ end=/$/ contains=xComment
```

You define a comment as anything from % to the end of the line. A preprocessor directive is anything from # to the end of the line. Because you can have a comment on a preprocessor line, the preprocessor definition includes a "contains=xComment" argument. Now look what happens with this text:

```
#define X = Y  % Comment text
int foo = 1;
```

What you see is that the second line is also highlighted as xPreProc. The preprocessor directive should end at the end of the line. That is why you have used "end=/$/". So what is going wrong?

The problem is the contained comment. The comment starts with % and ends at the end of the line. After the comment ends, the preprocessor syntax continues. This is after the end of the line has been seen, so the next line is included as well.

To avoid this problem and to avoid a contained syntax item eating a needed end of line, use the "keepend" argument. This takes care of the double end-of-line matching:

```
:syntax region xComment start=/%/ end=/$/ contained
:syntax region xPreProc start=/#/ end=/$/ contains=xComment keepend
```

CONTAINING MANY ITEMS

You can use the contains argument to specify that everything can be contained.
For example:

```
:syntax region xList start=/\[/ end=/\]/ contains=ALL
```

All syntax items will be contained in this one. It also contains itself, but
not at the same position (that would cause an endless loop).
   You can specify that some groups are not contained. Thus contain all
groups but the ones that are listed:

```
:syntax region xList start=/\[/ end=/\]/ contains=ALLBUT,xString
```

With the "TOP" item you can include all items that don't have a "contained"
argument. "CONTAINED" is used to only include items with a "contained"
argument. See :syn-contains for the details.

==
44.6 Following groups

The x language has statements in this form:

```
if (condition) then
```

You want to highlight the three items differently. But "(condition)" and
"then" might also appear in other places, where they get different
highlighting. This is how you can do this:

```
:syntax match xIf /if/ nextgroup=xIfCondition skipwhite
:syntax match xIfCondition /([^)]*)/ contained nextgroup=xThen skipwhite
:syntax match xThen /then/ contained
```

The "nextgroup" argument specifies which item can come next. This is not
required. If none of the items that are specified are found, nothing happens.
For example, in this text:

```
if not (condition) then
```

The "if" is matched by xIf. "not" doesn't match the specified nextgroup
xIfCondition, thus only the "if" is highlighted.

The "skipwhite" argument tells Vim that white space (spaces and tabs) may
appear in between the items. Similar arguments are "skipnl", which allows a
line break in between the items, and "skipempty", which allows empty lines.
Notice that "skipnl" doesn't skip an empty line, something must match after
the line break.

==
44.7 Other arguments

MATCHGROUP

When you define a region, the entire region is highlighted according to the group name specified. To highlight the text enclosed in parentheses () with the group xInside, for example, use the following command:

```
:syntax region xInside start=/(/ end=/)/
```

Suppose, that you want to highlight the parentheses differently. You can do this with a lot of convoluted region statements, or you can use the "matchgroup" argument. This tells Vim to highlight the start and end of a region with a different highlight group (in this case, the xParen group):

```
:syntax region xInside matchgroup=xParen start=/(/ end=/)/
```

The "matchgroup" argument applies to the start or end match that comes after it. In the previous example both start and end are highlighted with xParen. To highlight the end with xParenEnd:

```
:syntax region xInside matchgroup=xParen start=/(/
        \ matchgroup=xParenEnd end=/)/
```

A side effect of using "matchgroup" is that contained items will not match in the start or end of the region. The example for "transparent" uses this.

TRANSPARENT

In a C language file you would like to highlight the () text after a "while" differently from the () text after a "for". In both of these there can be nested () items, which should be highlighted in the same way. You must make sure the () highlighting stops at the matching). This is one way to do this:

```
:syntax region cWhile matchgroup=cWhile start=/while\s*(/ end=/)/
        \ contains=cCondNest
:syntax region cFor matchgroup=cFor start=/for\s*(/ end=/)/
        \ contains=cCondNest
:syntax region cCondNest start=/(/ end=/)/ contained transparent
```

Now you can give cWhile and cFor different highlighting. The cCondNest item can appear in either of them, but take over the highlighting of the item it is contained in. The "transparent" argument causes this.
   Notice that the "matchgroup" argument has the same group as the item itself. Why define it then? Well, the side effect of using a matchgroup is that contained items are not found in the match with the start item then. This avoids that the cCondNest group matches the (just after the "while" or "for". If this would happen, it would span the whole text until the matching) and the region would continue after it. Now cCondNest only matches after the match with the start pattern, thus after the first (.

OFFSETS

Suppose you want to define a region for the text between (and) after an "if". But you don't want to include the "if" or the (and). You can do this

by specifying offsets for the patterns. Example:

```
:syntax region xCond start=/if\s*(/ms=e+1 end=/)/me=s-1
```

The offset for the start pattern is "ms=e+1". "ms" stands for Match Start.
This defines an offset for the start of the match. Normally the match starts
where the pattern matches. "e+1" means that the match now starts at the end
of the pattern match, and then one character further.
   The offset for the end pattern is "me=s-1". "me" stands for Match End.
"s-1" means the start of the pattern match and then one character back. The
result is that in this text:

```
if (foo == bar)
```

Only the text "foo == bar" will be highlighted as xCond.

More about offsets here: :syn-pattern-offset .

ONELINE

The "oneline" argument indicates that the region does not cross a line
boundary. For example:

```
:syntax region xIfThen start=/if/ end=/then/ oneline
```

This defines a region that starts at "if" and ends at "then". But if there is
no "then" after the "if", the region doesn't match.

```
Note:
When using "oneline" the region doesn't start if the end pattern
doesn't match in the same line.  Without "oneline" Vim does _not_
check if there is a match for the end pattern.  The region starts even
when the end pattern doesn't match in the rest of the file.
```

CONTINUATION LINES AND AVOIDING THEM

Things now become a little more complex. Let's define a preprocessor line.
This starts with a # in the first column and continues until the end of the
line. A line that ends with \ makes the next line a continuation line. The
way you handle this is to allow the syntax item to contain a continuation
pattern:

```
:syntax region xPreProc start=/^#/ end=/$/ contains=xLineContinue
:syntax match xLineContinue "\\$" contained
```

In this case, although xPreProc normally matches a single line, the group
contained in it (namely xLineContinue) lets it go on for more than one line.
For example, it would match both of these lines:

```
#define SPAM  spam spam spam \
                bacon and spam
```

In this case, this is what you want. If it is not what you want, you can call for the region to be on a single line by adding "excludenl" to the contained pattern. For example, you want to highlight "end" in xPreProc, but only at the end of the line. To avoid making the xPreProc continue on the next line, like xLineContinue does, use "excludenl" like this:

```
:syntax region xPreProc start=/^#/ end=/$/
        \ contains=xLineContinue,xPreProcEnd
:syntax match xPreProcEnd excludenl /end$/ contained
:syntax match xLineContinue "\\$" contained
```

"excludenl" must be placed before the pattern. Since "xLineContinue" doesn't have "excludenl", a match with it will extend xPreProc to the next line as before.

==

44.8 Clusters

One of the things you will notice as you start to write a syntax file is that you wind up generating a lot of syntax groups. Vim enables you to define a collection of syntax groups called a cluster.

Suppose you have a language that contains for loops, if statements, while loops, and functions. Each of them contains the same syntax elements: numbers and identifiers. You define them like this:

```
:syntax match xFor /^for.*/ contains=xNumber,xIdent
:syntax match xIf /^if.*/ contains=xNumber,xIdent
:syntax match xWhile /^while.*/ contains=xNumber,xIdent
```

You have to repeat the same "contains=" every time. If you want to add another contained item, you have to add it three times. Syntax clusters simplify these definitions by enabling you to have one cluster stand for several syntax groups.

To define a cluster for the two items that the three groups contain, use the following command:

```
:syntax cluster xState contains=xNumber,xIdent
```

Clusters are used inside other syntax items just like any syntax group. Their names start with @. Thus, you can define the three groups like this:

```
:syntax match xFor /^for.*/ contains=@xState
:syntax match xIf /^if.*/ contains=@xState
:syntax match xWhile /^while.*/ contains=@xState
```

You can add new group names to this cluster with the "add" argument:

```
:syntax cluster xState add=xString
```

You can remove syntax groups from this list as well:

```
:syntax cluster xState remove=xNumber
```

==

44.9 Including another syntax file

The C++ language syntax is a superset of the C language. Because you do not want to write two syntax files, you can have the C++ syntax file read in the one for C by using the following command:

```
:runtime! syntax/c.vim
```

The ":runtime!" command searches 'runtimepath' for all "syntax/c.vim" files. This makes the C parts of the C++ syntax be defined like for C files. If you have replaced the c.vim syntax file, or added items with an extra file, these will be loaded as well.

After loading the C syntax items the specific C++ items can be defined. For example, add keywords that are not used in C:

```
:syntax keyword cppStatement    new delete this friend using
```

This works just like in any other syntax file.

Now consider the Perl language. A Perl script consists of two distinct parts: a documentation section in POD format, and a program written in Perl itself. The POD section starts with "=head" and ends with "=cut".

You want to define the POD syntax in one file, and use it from the Perl syntax file. The ":syntax include" command reads in a syntax file and stores the elements it defined in a syntax cluster. For Perl, the statements are as follows:

```
:syntax include @Pod <sfile>:p:h/pod.vim
:syntax region perlPOD start=/^=head/ end=/^=cut/ contains=@Pod
```

When "=head" is found in a Perl file, the perlPOD region starts. In this region the @Pod cluster is contained. All the items defined as top-level items in the pod.vim syntax files will match here. When "=cut" is found, the region ends and we go back to the items defined in the Perl file.

The ":syntax include" command is clever enough to ignore a ":syntax clear" command in the included file. And an argument such as "contains=ALL" will only contain items defined in the included file, not in the file that includes it.

The "<sfile>:p:h/" part uses the name of the current file (<sfile>), expands it to a full path (:p) and then takes the head (:h). This results in the directory name of the file. This causes the pod.vim file in the same directory to be included.

==========

44.10 Synchronizing

Compilers have it easy. They start at the beginning of a file and parse it straight through. Vim does not have it so easy. It must start in the middle, where the editing is being done. So how does it tell where it is?

The secret is the ":syntax sync" command. This tells Vim how to figure out where it is. For example, the following command tells Vim to scan backward for the beginning or end of a C-style comment and begin syntax coloring from there:

```
:syntax sync ccomment
```

You can tune this processing with some arguments. The "minlines" argument tells Vim the minimum number of lines to look backward, and "maxlines" tells the editor the maximum number of lines to scan.

For example, the following command tells Vim to look at least 10 lines before the top of the screen:

```
:syntax sync ccomment minlines=10 maxlines=500
```

If it cannot figure out where it is in that space, it starts looking farther and farther back until it figures out what to do. But it looks no farther back than 500 lines. (A large "maxlines" slows down processing. A small one might cause synchronization to fail.)

To make synchronizing go a bit faster, tell Vim which syntax items can be skipped. Every match and region that only needs to be used when actually displaying text can be given the "display" argument.

By default, the comment to be found will be colored as part of the Comment syntax group. If you want to color things another way, you can specify a different syntax group:

```
:syntax sync ccomment xAltComment
```

If your programming language does not have C-style comments in it, you can try another method of synchronization. The simplest way is to tell Vim to space back a number of lines and try to figure out things from there. The following command tells Vim to go back 150 lines and start parsing from there:

```
:syntax sync minlines=150
```

A large "minlines" value can make Vim slower, especially when scrolling backwards in the file.

Finally, you can specify a syntax group to look for by using this command:

```
:syntax sync match {sync-group-name}
        \ grouphere {group-name} {pattern}
```

This tells Vim that when it sees {pattern} the syntax group named {group-name} begins just after the pattern given. The {sync-group-name} is used to give a name to this synchronization specification. For example, the sh scripting language begins an if statement with "if" and ends it with "fi":

```
if [ --f file.txt ] ; then
        echo "File exists"
fi
```

To define a "grouphere" directive for this syntax, you use the following command:

```
:syntax sync match shIfSync grouphere shIf "\<if\>"
```

The "groupthere" argument tells Vim that the pattern ends a group. For example, the end of the if/fi group is as follows:

```
:syntax sync match shIfSync groupthere NONE "\<fi\>"
```

In this example, the NONE tells Vim that you are not in any special syntax region. In particular, you are not inside an if block.

You also can define matches and regions that are with no "grouphere" or "groupthere" arguments. These groups are for syntax groups skipped during synchronization. For example, the following skips over anything inside {}, even if it would normally match another synchronization method:

```
:syntax sync match xSpecial /{.*}/
```

More about synchronizing in the reference manual: :syn-sync .

44.11 Installing a syntax file

When your new syntax file is ready to be used, drop it in a "syntax" directory in 'runtimepath'. For Unix that would be "~/.vim/syntax".
The name of the syntax file must be equal to the file type, with ".vim" added. Thus for the x language, the full path of the file would be:

```
~/.vim/syntax/x.vim
```

You must also make the file type be recognized. See 43.2 .

If your file works well, you might want to make it available to other Vim users. First read the next section to make sure your file works well for others. Then e-mail it to the Vim maintainer: <maintainer@vim.org>. Also explain how the filetype can be detected. With a bit of luck your file will be included in the next Vim version!

ADDING TO AN EXISTING SYNTAX FILE

We were assuming you were adding a completely new syntax file. When an existing syntax file works, but is missing some items, you can add items in a separate file. That avoids changing the distributed syntax file, which will be lost when installing a new version of Vim.
Write syntax commands in your file, possibly using group names from the existing syntax. For example, to add new variable types to the C syntax file:

```
:syntax keyword cType off_t uint
```

Write the file with the same name as the original syntax file. In this case "c.vim". Place it in a directory near the end of 'runtimepath'. This makes it loaded after the original syntax file. For Unix this would be:

```
~/.vim/after/syntax/c.vim
```

44.12 Portable syntax file layout

Wouldn't it be nice if all Vim users exchange syntax files? To make this

possible, the syntax file must follow a few guidelines.

Start with a header that explains what the syntax file is for, who maintains it and when it was last updated. Don't include too much information about changes history, not many people will read it. Example:

```
" Vim syntax file
" Language:     C
" Maintainer:   Bram Moolenaar <Bram@vim.org>
" Last Change:  2001 Jun 18
" Remark:       Included by the C++ syntax.
```

Use the same layout as the other syntax files. Using an existing syntax file as an example will save you a lot of time.

Choose a good, descriptive name for your syntax file. Use lowercase letters and digits. Don't make it too long, it is used in many places: The name of the syntax file "name.vim", 'filetype', b:current_syntax and the start of each syntax group (nameType, nameStatement, nameString, etc).

Start with a check for "b:current_syntax". If it is defined, some other syntax file, earlier in 'runtimepath' was already loaded:

```
if exists("b:current_syntax")
  finish
endif
```

To be compatible with Vim 5.8 use:

```
if version < 600
  syntax clear
elseif exists("b:current_syntax")
  finish
endif
```

Set "b:current_syntax" to the name of the syntax at the end. Don't forget that included files do this too, you might have to reset "b:current_syntax" if you include two files.

If you want your syntax file to work with Vim 5.x, add a check for v:version. Find an syntax file in the Vim 7.2 distribution for an example.

Do not include anything that is a user preference. Don't set 'tabstop', 'expandtab', etc. These belong in a filetype plugin.

Do not include mappings or abbreviations. Only include setting 'iskeyword' if it is really necessary for recognizing keywords.

To allow users select their own preferred colors, make a different group name for every kind of highlighted item. Then link each of them to one of the standard highlight groups. That will make it work with every color scheme. If you select specific colors it will look bad with some color schemes. And don't forget that some people use a different background color, or have only eight colors available.

For the linking use "hi def link", so that the user can select different
highlighting before your syntax file is loaded. Example:

```
hi def link nameString        String
hi def link nameNumber        Number
hi def link nameCommand       Statement
... etc ...
```

Add the "display" argument to items that are not used when syncing, to speed
up scrolling backwards and CTRL-L.

==

45.1 Language for Messages

When you start Vim, it checks the environment to find out what language you are using. Mostly this should work fine, and you get the messages in your language (if they are available). To see what the current language is, use this command:

```
:language
```

If it replies with "C", this means the default is being used, which is English.

> Note:
> Using different languages only works when Vim was compiled to handle it. To find out if it works, use the ":version" command and check the output for "+gettext" and "+multi_lang". If they are there, you are OK. If you see "-gettext" or "-multi_lang" you will have to find another Vim.

What if you would like your messages in a different language? There are several ways. Which one you should use depends on the capabilities of your system.

The first way is to set the environment to the desired language before starting Vim. Example for Unix:

```
env LANG=de_DE.ISO_8859-1  vim
```

This only works if the language is available on your system. The advantage is that all the GUI messages and things in libraries will use the right language as well. A disadvantage is that you must do this before starting Vim. If you want to change language while Vim is running, you can use the second method:

```
	:language fr_FR.ISO_8859-1
```

This way you can try out several names for your language. You will get an error message when it's not supported on your system. You don't get an error when translated messages are not available. Vim will silently fall back to using English.
   To find out which languages are supported on your system, find the directory where they are listed. On my system it is "/usr/share/locale". On some systems it's in "/usr/lib/locale". The manual page for "setlocale" should give you a hint where it is found on your system.
   Be careful to type the name exactly as it should be. Upper and lowercase matter, and the '-' and '_' characters are easily confused.

You can also set the language separately for messages, edited text and the time format. See :language .

DO-IT-YOURSELF MESSAGE TRANSLATION

If translated messages are not available for your language, you could write them yourself. To do this, get the source code for Vim and the GNU gettext package. After unpacking the sources, instructions can be found in the directory src/po/README.txt.
   It's not too difficult to do the translation. You don't need to be a programmer. You must know both English and the language you are translating to, of course.
   When you are satisfied with the translation, consider making it available to others. Upload it at vim-online (http://vim.sf.net) or e-mail it to the Vim maintainer <maintainer@vim.org>. Or both.

==
45.2 Language for Menus

The default menus are in English. To be able to use your local language, they must be translated. Normally this is automatically done for you if the environment is set for your language, just like with messages. You don't need to do anything extra for this. But it only works if translations for the language are available.
   Suppose you are in Germany, with the language set to German, but prefer to use "File" instead of "Datei". You can switch back to using the English menus this way:

```
	:set langmenu=none
```

It is also possible to specify a language:

```
	:set langmenu=nl_NL.ISO_8859-1
```

Like above, differences between "-" and "_" matter. However, upper/lowercase differences are ignored here.
   The 'langmenu' option must be set before the menus are loaded. Once the menus have been defined changing 'langmenu' has no direct effect. Therefore, put the command to set 'langmenu' in your vimrc file.
   If you really want to switch menu language while running Vim, you can do it

this way:

```
:source $VIMRUNTIME/delmenu.vim
:set langmenu=de_DE.ISO_8859-1
:source $VIMRUNTIME/menu.vim
```

There is one drawback: All menus that you defined yourself will be gone. You will need to redefine them as well.

DO-IT-YOURSELF MENU TRANSLATION

To see which menu translations are available, look in this directory:

```
$VIMRUNTIME/lang
```

The files are called menu_{language}.vim. If you don't see the language you want to use, you can do your own translations. The simplest way to do this is by copying one of the existing language files, and change it.
First find out the name of your language with the ":language" command. Use this name, but with all letters made lowercase. Then copy the file to your own runtime directory, as found early in 'runtimepath'. For example, for Unix you would do:

```
:!cp $VIMRUNTIME/lang/menu_ko_kr.euckr.vim ~/.vim/lang/menu_nl_be.iso_8859-1.vim
```

You will find hints for the translation in "$VIMRUNTIME/lang/README.txt".

45.3 Using another encoding

Vim guesses that the files you are going to edit are encoded for your language. For many European languages this is "latin1". Then each byte is one character. That means there are 256 different characters possible. For Asian languages this is not sufficient. These mostly use a double-byte encoding, providing for over ten thousand possible characters. This still isn't enough when a text is to contain several different languages. This is where Unicode comes in. It was designed to include all characters used in commonly used languages. This is the "Super encoding that replaces all others". But it isn't used that much yet.
Fortunately, Vim supports these three kinds of encodings. And, with some restrictions, you can use them even when your environment uses another language than the text.
Nevertheless, when you only edit files that are in the encoding of your language, the default should work fine and you don't need to do anything. The following is only relevant when you want to edit different languages.

```
Note:
Using different encodings only works when Vim was compiled to handle
it. To find out if it works, use the ":version" command and check the
output for "+multi_byte". If it's there, you are OK. If you see
"-multi_byte" you will have to find another Vim.
```

USING UNICODE IN THE GUI

The nice thing about Unicode is that other encodings can be converted to it and back without losing information. When you make Vim use Unicode internally, you will be able to edit files in any encoding.

Unfortunately, the number of systems supporting Unicode is still limited. Thus it's unlikely that your language uses it. You need to tell Vim you want to use Unicode, and how to handle interfacing with the rest of the system.

Let's start with the GUI version of Vim, which is able to display Unicode characters. This should work:

```
:set encoding=utf-8
:set guifont=-misc-fixed-medium-r-normal--18-120-100-100-c-90-iso10646-1
```

The 'encoding' option tells Vim the encoding of the characters that you use. This applies to the text in buffers (files you are editing), registers, Vim script files, etc. You can regard 'encoding' as the setting for the internals of Vim.

This example assumes you have this font on your system. The name in the example is for the X Window System. This font is in a package that is used to enhance xterm with Unicode support. If you don't have this font, you might find it here:

```
http://www.cl.cam.ac.uk/~mgk25/download/ucs-fonts.tar.gz
```

For MS-Windows, some fonts have a limited number of Unicode characters. Try using the "Courier New" font. You can use the Edit/Select Font... menu to select and try out the fonts available. Only fixed-width fonts can be used though. Example:

```
:set guifont=courier_new:h12
```

If it doesn't work well, try getting a fontpack. If Microsoft didn't move it, you can find it here:

```
http://www.microsoft.com/typography/fonts/default.aspx
```

Now you have told Vim to use Unicode internally and display text with a Unicode font. Typed characters still arrive in the encoding of your original language. This requires converting them to Unicode. Tell Vim the language from which to convert with the 'termencoding' option. You can do it like this:

```
:let &termencoding = &encoding
:set encoding=utf-8
```

This assigns the old value of 'encoding' to 'termencoding' before setting 'encoding' to utf-8. You will have to try out if this really works for your setup. It should work especially well when using an input method for an Asian language, and you want to edit Unicode text.

USING UNICODE IN A UNICODE TERMINAL

There are terminals that support Unicode directly. The standard xterm that comes with XFree86 is one of them. Let's use that as an example.
   First of all, the xterm must have been compiled with Unicode support. See UTF8-xterm how to check that and how to compile it when needed.
   Start the xterm with the "-u8" argument. You might also need so specify a font. Example:

```
xterm -u8 -fn -misc-fixed-medium-r-normal--18-120-100-100-c-90-iso10646-1
```

Now you can run Vim inside this terminal. Set 'encoding' to "utf-8" as before. That's all.

USING UNICODE IN AN ORDINARY TERMINAL

Suppose you want to work with Unicode files, but don't have a terminal with Unicode support. You can do this with Vim, although characters that are not supported by the terminal will not be displayed. The layout of the text will be preserved.

```
:let &termencoding = &encoding
:set encoding=utf-8
```

This is the same as what was used for the GUI. But it works differently: Vim will convert the displayed text before sending it to the terminal. That avoids that the display is messed up with strange characters.
   For this to work the conversion between 'termencoding' and 'encoding' must be possible. Vim will convert from latin1 to Unicode, thus that always works. For other conversions the +iconv feature is required.
   Try editing a file with Unicode characters in it. You will notice that Vim will put a question mark (or underscore or some other character) in places where a character should be that the terminal can't display. Move the cursor to a question mark and use this command:

```
ga
```

Vim will display a line with the code of the character. This gives you a hint about what character it is. You can look it up in a Unicode table. You could actually view a file that way, if you have lots of time at hand.

```
Note:
Since 'encoding' is used for all text inside Vim, changing it makes
all non-ASCII text invalid.  You will notice this when using registers
and the 'viminfo' file (e.g., a remembered search pattern).  It's
recommended to set 'encoding' in your vimrc file, and leave it alone.
```

==

45.4 Editing files with a different encoding

Suppose you have setup Vim to use Unicode, and you want to edit a file that is in 16-bit Unicode. Sounds simple, right? Well, Vim actually uses utf-8 encoding internally, thus the 16-bit encoding must be converted, since there is a difference between the character set (Unicode) and the encoding (utf-8 or 16-bit).

Vim will try to detect what kind of file you are editing. It uses the encoding names in the 'fileencodings' option. When using Unicode, the default value is: "ucs-bom,utf-8,latin1". This means that Vim checks the file to see if it's one of these encodings:

ucs-bom	File must start with a Byte Order Mark (BOM). This allows detection of 16-bit, 32-bit and utf-8 Unicode encodings.
utf-8	utf-8 Unicode. This is rejected when a sequence of bytes is illegal in utf-8.
latin1	The good old 8-bit encoding. Always works.

When you start editing that 16-bit Unicode file, and it has a BOM, Vim will detect this and convert the file to utf-8 when reading it. The 'fileencoding' option (without s at the end) is set to the detected value. In this case it is "utf-16le". That means it's Unicode, 16-bit and little-endian. This file format is common on MS-Windows (e.g., for registry files).

When writing the file, Vim will compare 'fileencoding' with 'encoding'. If they are different, the text will be converted.

An empty value for 'fileencoding' means that no conversion is to be done. Thus the text is assumed to be encoded with 'encoding'.

If the default 'fileencodings' value is not good for you, set it to the encodings you want Vim to try. Only when a value is found to be invalid will the next one be used. Putting "latin1" first doesn't work, because it is never illegal. An example, to fall back to Japanese when the file doesn't have a BOM and isn't utf-8:

```
:set fileencodings=ucs-bom,utf-8,sjis
```

See encoding-values for suggested values. Other values may work as well. This depends on the conversion available.

FORCING AN ENCODING

If the automatic detection doesn't work you must tell Vim what encoding the file is. Example:

```
:edit ++enc=koi8-r russian.txt
```

The "++enc" part specifies the name of the encoding to be used for this file only. Vim will convert the file from the specified encoding, Russian in this example, to 'encoding'. 'fileencoding' will also be set to the specified encoding, so that the reverse conversion can be done when writing the file.

The same argument can be used when writing the file. This way you can actually use Vim to convert a file. Example:

```
:write ++enc=utf-8 russian.txt
```

Note:
Conversion may result in lost characters. Conversion from an encoding to Unicode and back is mostly free of this problem, unless there are illegal characters. Conversion from Unicode to other encodings often

loses information when there was more than one language in the file.

==
45.5 Entering language text

Computer keyboards don't have much more than a hundred keys. Some languages have thousands of characters, Unicode has over hundred thousand. So how do you type these characters?

First of all, when you don't use too many of the special characters, you can use digraphs. This was already explained in 24.9 .

When you use a language that uses many more characters than keys on your keyboard, you will want to use an Input Method (IM). This requires learning the translation from typed keys to resulting character. When you need an IM you probably already have one on your system. It should work with Vim like with other programs. For details see mbyte-XIM for the X Window system and mbyte-IME for MS-Windows.

KEYMAPS

For some languages the character set is different from latin, but uses a similar number of characters. It's possible to map keys to characters. Vim uses keymaps for this.

Suppose you want to type Hebrew. You can load the keymap like this:

```
:set keymap=hebrew
```

Vim will try to find a keymap file for you. This depends on the value of 'encoding'. If no matching file was found, you will get an error message.

Now you can type Hebrew in Insert mode. In Normal mode, and when typing a ":" command, Vim automatically switches to English. You can use this command to switch between Hebrew and English:

```
CTRL-^
```

This only works in Insert mode and Command-line mode. In Normal mode it does something completely different (jumps to alternate file).

The usage of the keymap is indicated in the mode message, if you have the 'showmode' option set. In the GUI Vim will indicate the usage of keymaps with a different cursor color.

You can also change the usage of the keymap with the 'iminsert' and 'imsearch' options.

To see the list of mappings, use this command:

```
:lmap
```

To find out which keymap files are available, in the GUI you can use the Edit/Keymap menu. Otherwise you can use this command:

```
:echo globpath(&rtp, "keymap/*.vim")
```

DO-IT-YOURSELF KEYMAPS

You can create your own keymap file. It's not very difficult. Start with
a keymap file that is similar to the language you want to use. Copy it to the
"keymap" directory in your runtime directory. For example, for Unix, you
would use the directory "~/.vim/keymap".
   The name of the keymap file must look like this:

        keymap/{name}.vim
or
        keymap/{name}_{encoding}.vim

{name} is the name of the keymap. Chose a name that is obvious, but different
from existing keymaps (unless you want to replace an existing keymap file).
{name} cannot contain an underscore. Optionally, add the encoding used after
an underscore. Examples:

        keymap/hebrew.vim
        keymap/hebrew_utf-8.vim

The contents of the file should be self-explanatory. Look at a few of the
keymaps that are distributed with Vim. For the details, see mbyte-keymap .

LAST RESORT

If all other methods fail, you can enter any character with CTRL-V:

        encoding   type   range
        8-bit   CTRL-V 123   decimal 0-255
        8-bit   CTRL-V x a1   hexadecimal 00-ff
        16-bit   CTRL-V u 013b   hexadecimal 0000-ffff
        31-bit   CTRL-V U 001303a4   hexadecimal 00000000-7fffffff

Don't type the spaces. See i_CTRL-V_digit for the details.

Next chapter: usr_90.txt   Installing Vim

Copyright: see manual-copyright   vim:tw=78:ts=8:ft=help:norl:

VIM USER MANUAL - by Bram Moolenaar

Installing Vim

install

Before you can use Vim you have to install it. Depending on your system it's simple or easy. This chapter gives a few hints and also explains how upgrading to a new version is done.

Previous chapter: usr_45.txt Select your language
Table of contents: usr_toc.txt

==========

90.1 Unix

First you have to decide if you are going to install Vim system-wide or for a single user. The installation is almost the same, but the directory where Vim is installed in differs.

For a system-wide installation the base directory "/usr/local" is often used. But this may be different for your system. Try finding out where other packages are installed.

When installing for a single user, you can use your home directory as the base. The files will be placed in subdirectories like "bin" and "shared/vim".

FROM A PACKAGE

You can get precompiled binaries for many different UNIX systems. There is a long list with links on this page:

http://www.vim.org/binaries.html

Volunteers maintain the binaries, so they are often out of date. It is a good idea to compile your own UNIX version from the source. Also, creating the editor from the source allows you to control which features are compiled. This does require a compiler though.

If you have a Linux distribution, the "vi" program is probably a minimal version of Vim. It doesn't do syntax highlighting, for example. Try finding another Vim package in your distribution, or search on the web site.

FROM SOURCES

To compile and install Vim, you will need the following:

- A C compiler (GCC preferred)
- The GZIP program (you can get it from www.gnu.org)
- The Vim source and runtime archives

To get the Vim archives, look in this file for a mirror near you, this should provide the fastest download:

```
ftp://ftp.vim.org/pub/vim/MIRRORS
```

Or use the home site ftp.vim.org, if you think it's fast enough. Go to the "unix" directory and you'll find a list of files there. The version number is embedded in the file name. You will want to get the most recent version.
You can get the files for Unix in two ways: One big archive that contains everything, or four smaller ones that each fit on a floppy disk. For version 6.1 the single big one is called:

```
vim-6.1.tar.bz2
```

You need the bzip2 program to uncompress it. If you don't have it, get the four smaller files, which can be uncompressed with gzip. For Vim 6.1 they are called:

```
vim-6.1-src1.tar.gz
vim-6.1-src2.tar.gz
vim-6.1-rt1.tar.gz
vim-6.1-rt2.tar.gz
```

COMPILING

First create a top directory to work in, for example:

```
mkdir ~/vim
cd ~/vim
```

Then unpack the archives there. If you have the one big archive, you unpack it like this:

```
bzip2 -d -c path/vim-6.1.tar.bz2 | tar xf -
```

Change "path" to where you have downloaded the file.

```
gzip -d -c path/vim-6.1-src1.tar.gz | tar xf -
gzip -d -c path/vim-6.1-src2.tar.gz | tar xf -
gzip -d -c path/vim-6.1-rt1.tar.gz | tar xf -
gzip -d -c path/vim-6.1-rt2.tar.gz | tar xf -
```

If you are satisfied with getting the default features, and your environment is setup properly, you should be able to compile Vim with just this:

```
cd vim61/src
make
```

The make program will run configure and compile everything. Further on we

will explain how to compile with different features.
   If there are errors while compiling, carefully look at the error messages. There should be a hint about what went wrong. Hopefully you will be able to correct it. You might have to disable some features to make Vim compile. Look in the Makefile for specific hints for your system.

TESTING

Now you can check if compiling worked OK:

```
make test
```

This will run a sequence of test scripts to verify that Vim works as expected. Vim will be started many times and all kinds of text and messages flash by. If it is alright you will finally see:

```
test results:
ALL DONE
```

If you get "TEST FAILURE" some test failed. If there are one or two messages about failed tests, Vim might still work, but not perfectly. If you see a lot of error messages or Vim doesn't finish until the end, there must be something wrong. Either try to find out yourself, or find someone who can solve it. You could look in the maillist-archive for a solution. If everything else fails, you could ask in the vim maillist if someone can help you.

INSTALLING

install-home

If you want to install in your home directory, edit the Makefile and search for a line:

```
#prefix = $(HOME)
```

Remove the # at the start of the line.
   When installing for the whole system, Vim has most likely already selected a good installation directory for you. You can also specify one, see below. You need to become root for the following.

To install Vim do:

```
make install
```

That should move all the relevant files to the right place. Now you can try running vim to verify that it works. Use two simple tests to check if Vim can find its runtime files:

```
:help
:syntax enable
```

If this doesn't work, use this command to check where Vim is looking for the runtime files:

```
:echo $VIMRUNTIME
```

You can also start Vim with the "-V" argument to see what happens during startup:

```
vim -V
```

Don't forget that the user manual assumes you Vim in a certain way. After installing Vim, follow the instructions at not-compatible to make Vim work as assumed in this manual.

SELECTING FEATURES

Vim has many ways to select features. One of the simple ways is to edit the Makefile. There are many directions and examples. Often you can enable or disable a feature by uncommenting a line.

An alternative is to run "configure" separately. This allows you to specify configuration options manually. The disadvantage is that you have to figure out what exactly to type.

Some of the most interesting configure arguments follow. These can also be enabled from the Makefile.

--prefix={directory}	Top directory where to install Vim.
--with-features=tiny	Compile with many features disabled.
--with-features=small	Compile with some features disabled.
--with-features=big	Compile with more features enabled.
--with-features=huge	Compile with most features enabled. See +feature-list for which feature is enabled in which case.
--enable-perlinterp	Enable the Perl interface. There are similar arguments for ruby, python and tcl.
--disable-gui	Do not compile the GUI interface.
--without-x	Do not compile X-windows features. When both of these are used, Vim will not connect to the X server, which makes startup faster.

To see the whole list use:

```
./configure --help
```

You can find a bit of explanation for each feature, and links for more information here: feature-list .

For the adventurous, edit the file "feature.h". You can also change the source code yourself!

==

90.2 MS-Windows

There are two ways to install the Vim program for Microsoft Windows. You can uncompress several archives, or use a self-installing big archive. Most users with fairly recent computers will prefer the second method. For the first one, you will need:

	- An archive with binaries for Vim.
	- The Vim runtime archive.
	- A program to unpack the zip files.

To get the Vim archives, look in this file for a mirror near you, this should provide the fastest download:

	ftp://ftp.vim.org/pub/vim/MIRRORS

Or use the home site ftp.vim.org, if you think it's fast enough. Go to the "pc" directory and you'll find a list of files there. The version number is embedded in the file name. You will want to get the most recent version. We will use "61" here, which is version 6.1.

	gvim61.exe		The self-installing archive.

This is all you need for the second method. Just launch the executable, and follow the prompts.

For the first method you must chose one of the binary archives. These are available:

	gvim61.zip		The normal MS-Windows GUI version.
	gvim61ole.zip		The MS-Windows GUI version with OLE support.
				Uses more memory, supports interfacing with
				other OLE applications.
	vim61w32.zip		32 bit MS-Windows console version. For use in
				a Win NT/2000/XP console. Does not work well
				on Win 95/98.
	vim61d32.zip		32 bit MS-DOS version. For use in the
				Win 95/98 console window.
	vim61d16.zip		16 bit MS-DOS version. Only for old systems.
				Does not support long filenames.

You only need one of them. Although you could install both a GUI and a console version. You always need to get the archive with runtime files.

	vim61rt.zip		The runtime files.

Use your un-zip program to unpack the files. For example, using the "unzip" program:

```
cd c:\
unzip path\gvim61.zip
unzip path\vim61rt.zip
```

This will unpack the files in the directory "c:\vim\vim61". If you already have a "vim" directory somewhere, you will want to move to the directory just above it.

Now change to the "vim\vim61" directory and run the install program:

```
install
```

Carefully look through the messages and select the options you want to use.
If you finally select "do it" the install program will carry out the actions
you selected.
The install program doesn't move the runtime files. They remain where you
unpacked them.

In case you are not satisfied with the features included in the supplied
binaries, you could try compiling Vim yourself. Get the source archive from
the same location as where the binaries are. You need a compiler for which a
makefile exists. Microsoft Visual C works, but is expensive. The Free
Borland command-line compiler 5.5 can be used, as well as the free MingW and
Cygwin compilers. Check the file src/INSTALLpc.txt for hints.

==
90.3 Upgrading

If you are running one version of Vim and want to install another, here is
what to do.

UNIX

When you type "make install" the runtime files will be copied to a directory
which is specific for this version. Thus they will not overwrite a previous
version. This makes it possible to use two or more versions next to
each other.
The executable "vim" will overwrite an older version. If you don't care
about keeping the old version, running "make install" will work fine. You can
delete the old runtime files manually. Just delete the directory with the
version number in it and all files below it. Example:

```
rm -rf /usr/local/share/vim/vim58
```

There are normally no changed files below this directory. If you did change
the "filetype.vim" file, for example, you better merge the changes into the
new version before deleting it.

If you are careful and want to try out the new version for a while before
switching to it, install the new version under another name. You need to
specify a configure argument. For example:

```
./configure --with-vim-name=vim6
```

Before running "make install", you could use "make -n install" to check that
no valuable existing files are overwritten.
When you finally decide to switch to the new version, all you need to do is
to rename the binary to "vim". For example:

```
mv /usr/local/bin/vim6 /usr/local/bin/vim
```

MS-WINDOWS

Upgrading is mostly equal to installing a new version. Just unpack the files in the same place as the previous version. A new directory will be created, e.g., "vim61", for the files of the new version. Your runtime files, vimrc file, viminfo, etc. will be left alone.
   If you want to run the new version next to the old one, you will have to do some handwork. Don't run the install program, it will overwrite a few files of the old version. Execute the new binaries by specifying the full path. The program should be able to automatically find the runtime files for the right version. However, this won't work if you set the $VIMRUNTIME variable somewhere.
   If you are satisfied with the upgrade, you can delete the files of the previous version. See 90.5 .

==
90.4 Common installation issues

This section describes some of the common problems that occur when installing Vim and suggests some solutions. It also contains answers to many installation questions.

Q: I Do Not Have Root Privileges. How Do I Install Vim? (Unix)

Use the following configuration command to install Vim in a directory called $HOME/vim:

```
./configure --prefix=$HOME
```

This gives you a personal copy of Vim. You need to put $HOME/bin in your path to execute the editor. Also see install-home .

Q: The Colors Are Not Right on My Screen. (Unix)

Check your terminal settings by using the following command in a shell:

```
echo $TERM
```

If the terminal type listed is not correct, fix it. For more hints, see 06.2 . Another solution is to always use the GUI version of Vim, called gvim. This avoids the need for a correct terminal setup.

Q: My Backspace And Delete Keys Don't Work Right

The definition of what key sends what code is very unclear for backspace <BS> and Delete <Del> keys. First of all, check your $TERM setting. If there is nothing wrong with it, try this:

```
:set t_kb=^V<BS>
:set t_kD=^V<Del>
```

In the first line you need to press CTRL-V and then hit the backspace key.
In the second line you need to press CTRL-V and then hit the Delete key.
You can put these lines in your vimrc file, see 05.1 . A disadvantage is
that it won't work when you use another terminal some day. Look here for
alternate solutions: :fixdel .

Q: I Am Using RedHat Linux. Can I Use the Vim That Comes with the System?

By default RedHat installs a minimal version of Vim. Check your RPM packages
for something named "Vim-enhanced-version.rpm" and install that.

Q: How Do I Turn Syntax Coloring On? How do I make plugins work?

Use the example vimrc script. You can find an explanation on how to use it
here: not-compatible .

See chapter 6 for information about syntax highlighting: usr_06.txt .

Q: What Is a Good vimrc File to Use?

See the www.vim.org Web site for several good examples.

Q: Where Do I Find a Good Vim Plugin?

See the Vim-online site: http://vim.sf.net. Many users have uploaded useful
Vim scripts and plugins there.

Q: Where Do I Find More Tips?

See the Vim-online site: http://vim.sf.net. There is an archive with hints
from Vim users. You might also want to search in the maillist-archive .

==
90.5 Uninstalling Vim

In the unlikely event you want to uninstall Vim completely, this is how you do
it.

UNIX

When you installed Vim as a package, check your package manager to find out
how to remove the package again.
If you installed Vim from sources you can use this command:

```
make uninstall
```

However, if you have deleted the original files or you used an archive that

someone supplied, you can't do this. Do delete the files manually, here is an example for when "/usr/local" was used as the root:

```
rm -rf /usr/local/share/vim/vim61
rm /usr/local/bin/eview
rm /usr/local/bin/evim
rm /usr/local/bin/ex
rm /usr/local/bin/gview
rm /usr/local/bin/gvim
rm /usr/local/bin/gvim
rm /usr/local/bin/gvimdiff
rm /usr/local/bin/rgview
rm /usr/local/bin/rgvim
rm /usr/local/bin/rview
rm /usr/local/bin/rvim
rm /usr/local/bin/rvim
rm /usr/local/bin/view
rm /usr/local/bin/vim
rm /usr/local/bin/vimdiff
rm /usr/local/bin/vimtutor
rm /usr/local/bin/xxd
rm /usr/local/man/man1/eview.1
rm /usr/local/man/man1/evim.1
rm /usr/local/man/man1/ex.1
rm /usr/local/man/man1/gview.1
rm /usr/local/man/man1/gvim.1
rm /usr/local/man/man1/gvimdiff.1
rm /usr/local/man/man1/rgview.1
rm /usr/local/man/man1/rgvim.1
rm /usr/local/man/man1/rview.1
rm /usr/local/man/man1/rvim.1
rm /usr/local/man/man1/view.1
rm /usr/local/man/man1/vim.1
rm /usr/local/man/man1/vimdiff.1
rm /usr/local/man/man1/vimtutor.1
rm /usr/local/man/man1/xxd.1
```

MS-WINDOWS

If you installed Vim with the self-installing archive you can run the "uninstall-gui" program located in the same directory as the other Vim programs, e.g. "c:\vim\vim61". You can also launch it from the Start menu if installed the Vim entries there. This will remove most of the files, menu entries and desktop shortcuts. Some files may remain however, as they need a Windows restart before being deleted.
   You will be given the option to remove the whole "vim" directory. It probably contains your vimrc file and other runtime files that you created, so be careful.

Else, if you installed Vim with the zip archives, the preferred way is to use the "uninstal" program (note the missing l at the end). You can find it in the same directory as the "install" program, e.g., "c:\vim\vim61". This should also work from the usual "install/remove software" page.

However, this only removes the registry entries for Vim. You have to delete the files yourself. Simply select the directory "vim\vim61" and delete it recursively. There should be no files there that you changed, but you might want to check that first.
The "vim" directory probably contains your vimrc file and other runtime files that you created. You might want to keep that.

intro.txt For Vim version 8.1. Last change: 2018 Jan 24

VIM REFERENCE MANUAL by Bram Moolenaar

Introduction to Vim ref reference

==========

1. Introduction intro

Vim stands for Vi IMproved. It used to be Vi IMitation, but there are so many improvements that a name change was appropriate. Vim is a text editor which includes almost all the commands from the Unix program "Vi" and a lot of new ones. It is very useful for editing programs and other plain text.

All commands are given with the keyboard. This has the advantage that you can keep your fingers on the keyboard and your eyes on the screen. For those who want it, there is mouse support and a GUI version with scrollbars and menus (see gui.txt).

An overview of this manual can be found in the file "help.txt", help.txt . It can be accessed from within Vim with the <Help> or <F1> key and with the :help command (just type ":help", without the bars or quotes).

The 'helpfile' option can be set to the name of the help file, in case it is not located in the default place. You can jump to subjects like with tags: Use CTRL-] to jump to a subject under the cursor, use CTRL-T to jump back.

Throughout this manual the differences between Vi and Vim are mentioned in curly braces, like this: {Vi does not have on-line help}. See vi_diff.txt for a summary of the differences between Vim and Vi.

This manual refers to Vim on various machines. There may be small differences between different computers and terminals. Besides the remarks given in this document, there is a separate document for each supported system, see sys-file-list .

pronounce

Vim is pronounced as one word, like Jim, not vi-ai-em. It's written with a capital, since it's a name, again like Jim.

This manual is a reference for all the Vim commands and options. This is not an introduction to the use of Vi or Vim, it gets a bit complicated here and there. For beginners, there is a hands-on tutor . To learn using Vim, read the user manual usr_toc.txt .

book
There are many books on Vi that contain a section for beginners. There are two books I can recommend:

	"Vim - Vi Improved" by Steve Oualline

This is the very first book completely dedicated to Vim. It is very good for beginners. The most often used commands are explained with pictures and examples. The less often used commands are also explained, the more advanced features are summarized. There is a comprehensive index and a quick reference. Parts of this book have been included in the user manual frombook .
Published by New Riders Publishing. ISBN: 0735710015
For more information try one of these:
	http://iccf-holland.org/click5.html
	http://www.vim.org/iccf/click5.html

	"Learning the Vi editor" by Linda Lamb and Arnold Robbins

This is a book about Vi that includes a chapter on Vim (in the sixth edition). The first steps in Vi are explained very well. The commands that Vim adds are only briefly mentioned. There is also a German translation.
Published by O'Reilly. ISBN: 1-56592-426-6.

==
2. Vim on the internet   internet

www   WWW   faq   FAQ   distribution   download
The Vim pages contain the most recent information about Vim. They also contain links to the most recent version of Vim. The FAQ is a list of Frequently Asked Questions. Read this if you have problems.

	Vim home page:	http://www.vim.org/
	Vim FAQ:	http://vimdoc.sf.net/
	Downloading:	ftp://ftp.vim.org/pub/vim/MIRRORS

Usenet News group where Vim is discussed: news   usenet
	comp.editors
This group is also for other editors. If you write about Vim, don't forget to mention that.

mail-list   maillist
There are several mailing lists for Vim:
<vim@vim.org> vim-use   vim_use
	For discussions about using existing versions of Vim: Useful mappings, questions, answers, where to get a specific version, etc. There are quite a few people watching this list and answering questions, also for beginners. Don't hesitate to ask your question here.
<vim-dev@vim.org> vim-dev   vim_dev   vimdev
	For discussions about changing Vim: New features, porting, patches, beta-test versions, etc.
<vim-announce@vim.org> vim-announce   vim_announce
	Announcements about new versions of Vim; also for beta-test versions

and ports to different systems. This is a read-only list.
<vim-mac@vim.org>   vim-mac   vim_mac
For discussions about using and improving the Macintosh version of
Vim.

See http://www.vim.org/maillist.php for the latest information.

NOTE:
- You can only send messages to these lists if you have subscribed!
- You need to send the messages from the same location as where you subscribed
  from (to avoid spam mail).
- Maximum message size is 40000 characters.

                                                     subscribe-maillist
If you want to join, send a message to
        <vim-subscribe@vim.org>
Make sure that your "From:" address is correct. Then the list server will
give you help on how to subscribe.

                                                     maillist-archive
For more information and archives look on the Vim maillist page:
http://www.vim.org/maillist.php

Bug reports: bugs   bug-reports   bugreport.vim

There are two ways to report bugs, both work:
1. Send bug reports to: Vim Developers <vim-dev@vim.org>
   This is a maillist, you need to become a member first and many people will
   see the message. If you don't want that, e.g. because it is a security
   issue, send it to <bugs@vim.org>, this only goes to the Vim maintainer
   (that's Bram).
2. Open an issue on GitHub: https://github.com/vim/vim/issues
   The text will be forwarded to the vim-dev maillist.

Please be brief; all the time that is spent on answering mail is subtracted
from the time that is spent on improving Vim! Always give a reproducible
example and try to find out which settings or other things trigger the bug.

Preferably start Vim with:
        vim --clean -u reproduce.vim
Where reproduce.vim is a script that reproduces the problem. Try different
machines, if relevant (is this an MS-Windows specific bug perhaps?).

Send me patches if you can!

It will help to include information about the version of Vim you are using and
your setup. You can get the information with this command:
   :so $VIMRUNTIME/bugreport.vim
This will create a file "bugreport.txt" in the current directory, with a lot
of information of your environment. Before sending this out, check if it
doesn't contain any confidential information!

If Vim crashes, please try to find out where. You can find help on this here:

debug.txt .

In case of doubt or when you wonder if the problem has already been fixed but you can't find a fix for it, become a member of the vim-dev maillist and ask your question there. maillist

year-2000 Y2K

Since Vim internally doesn't use dates for editing, there is no year 2000 problem to worry about. Vim does use the time in the form of seconds since January 1st 1970. It is used for a time-stamp check of the edited file and the swap file, which is not critical and should only cause warning messages.

There might be a year 2038 problem, when the seconds don't fit in a 32 bit int anymore. This depends on the compiler, libraries and operating system. Specifically, time_t and the ctime() function are used. And the time_t is stored in four bytes in the swap file. But that's only used for printing a file date/time for recovery, it will never affect normal editing.

The Vim strftime() function directly uses the strftime() system function. localtime() uses the time() system function. getftime() uses the time returned by the stat() system function. If your system libraries are year 2000 compliant, Vim is too.

The user may create scripts for Vim that use external commands. These might introduce Y2K problems, but those are not really part of Vim itself.

==
3. Credits credits author Bram Moolenaar

Most of Vim was written by Bram Moolenaar <Bram@vim.org>.

Parts of the documentation come from several Vi manuals, written by:
        W.N. Joy
        Alan P.W. Hewett
        Mark Horton

The Vim editor is based on Stevie and includes (ideas from) other software, worked on by the people mentioned here. Other people helped by sending me patches, suggestions and giving feedback about what is good and bad in Vim.

Vim would never have become what it is now, without the help of these people!

Ron Aaron	Win32 GUI changes
Mohsin Ahmed	encryption
Zoltan Arpadffy	work on VMS port
Tony Andrews	Stevie
Gert van Antwerpen	changes for DJGPP on MS-DOS
Berkeley DB(3)	ideas for swap file implementation
Keith Bostic	Nvi
Walter Briscoe	Makefile updates, various patches
Ralf Brown	SPAWNO library for MS-DOS
Robert Colon	many useful remarks
Marcin Dalecki	GTK+ GUI port, toolbar icons, gettext()
Kayhan Demirel	sent me news in Uganda

Chris & John Downey	xvi (ideas for multi-windows version)
Henk Elbers	first VMS port
Daniel Elstner	GTK+ 2 port
Eric Fischer	Mac port, 'cindent', and other improvements
Benji Fisher	Answering lots of user questions
Bill Foster	Athena GUI port
Google	Lets me work on Vim one day a week
Loic Grenie	xvim (ideas for multi windows version)
Sven Guckes	Vim promoter and previous WWW page maintainer
Darren Hiebert	Exuberant ctags
Jason Hildebrand	GTK+ 2 port
Bruce Hunsaker	improvements for VMS port
Andy Kahn	Cscope support, GTK+ GUI port
Oezguer Kesim	Maintainer of Vim Mailing Lists
Axel Kielhorn	work on the Macintosh port
Steve Kirkendall	Elvis
Roger Knobbe	original port to Windows NT
Sergey Laskavy	Vim's help from Moscow
Felix von Leitner	Previous maintainer of Vim Mailing Lists
David Leonard	Port of Python extensions to Unix
Avner Lottem	Edit in right-to-left windows
Flemming Madsen	X11 client-server, various features and patches
Tony Mechelynck	answers many user questions
Paul Moore	Python interface extensions, many patches
Katsuhito Nagano	Work on multi-byte versions
Sung-Hyun Nam	Work on multi-byte versions
Vince Negri	Win32 GUI and generic console enhancements
Steve Oualline	Author of the first Vim book frombook
Dominique Pelle	valgrind reports and many fixes
A.Politz	Many bug reports and some fixes
George V. Reilly	Win32 port, Win32 GUI start-off
Stephen Riehm	bug collector
Stefan Roemer	various patches and help to users
Ralf Schandl	IBM OS/390 port
Olaf Seibert	DICE and BeBox version, regexp improvements
Mortaza Shiran	Farsi patches
Peter da Silva	termlib
Paul Slootman	OS/2 port
Henry Spencer	regular expressions
Dany St-Amant	Macintosh port
Tim Thompson	Stevie
G. R. (Fred) Walter	Stevie
Sven Verdoolaege	Perl interface
Robert Webb	Command-line completion, GUI versions, and lots of patches
Ingo Wilken	Tcl interface
Mike Williams	PostScript printing
Juergen Weigert	Lattice version, AUX improvements, UNIX and MS-DOS ports, autoconf
Stefan 'Sec' Zehl	Maintainer of vim.org
Yasuhiro Matsumoto	many MS-Windows improvements
Ken Takata	fixes and features
Kazunobu Kuriyama	GTK 3
Christian Brabandt	many fixes, features, user support, etc.

I wish to thank all the people that sent me bug reports and suggestions. The list is too long to mention them all here. Vim would not be the same without the ideas from all these people: They keep Vim alive!
love peace friendship gross-national-happiness

In this documentation there are several references to other versions of Vi:
Vi vi

Vi "the original". Without further remarks this is the version of Vi that appeared in Sun OS 4.x. ":version" returns "Version 3.7, 6/7/85". Sometimes other versions are referred to. Only runs under Unix. Source code only available with a license. More information on Vi can be found through:
http://vi-editor.org [doesn't currently work...]
Posix

Posix From the IEEE standard 1003.2, Part 2: Shell and utilities. Generally known as "Posix". This is a textual description of how Vi is supposed to work.
See posix-compliance .
Nvi

Nvi The "New" Vi. The version of Vi that comes with BSD 4.4 and FreeBSD. Very good compatibility with the original Vi, with a few extensions. The version used is 1.79. ":version" returns "Version 1.79 (10/23/96)". There has been no release the last few years, although there is a development version 1.81.
Source code is freely available.
Elvis

Elvis Another Vi clone, made by Steve Kirkendall. Very compact but isn't as flexible as Vim.
The version used is 2.1. It is still being developed. Source code is freely available.

==
4. Notation notation

When syntax highlighting is used to read this, text that is not typed literally is often highlighted with the Special group. These are items in [], {} and <>, and CTRL-X.

Note that Vim uses all possible characters in commands. Sometimes the [], {} and <> are part of what you type, the context should make this clear.

[] Characters in square brackets are optional.

count [count]

[count] An optional number that may precede the command to multiply or iterate the command. If no number is given, a count of one is used, unless otherwise noted. Note that in this manual the [count] is not mentioned in the description of the command, but only in the explanation. This was done to make the commands easier to look up. If the 'showcmd' option is on, the (partially) entered count is shown at the bottom of the

window. You can use <Del> to erase the last digit (N<Del>).

["x]		[quotex]
An optional register designation where text can be stored.
See registers . The x is a single character between 'a' and
'z' or 'A' and 'Z' or '"', and in some cases (with the put
command) between '0' and '9', '%', '#', or others. The
uppercase and lowercase letter designate the same register,
but the lowercase letter is used to overwrite the previous
register contents, while the uppercase letter is used to
append to the previous register contents. Without the ""x" or
with """" the stored text is put into the unnamed register.

{}		{}
Curly braces denote parts of the command which must appear,
but which can take a number of different values. The
differences between Vim and Vi are also given in curly braces
(this will be clear from the context).

{char1-char2}		{char1-char2}
A single character from the range char1 to char2. For
example: {a-z} is a lowercase letter. Multiple ranges may be
concatenated. For example, {a-zA-Z0-9} is any alphanumeric
character.

{motion}		{motion} movement
A command that moves the cursor. These are explained in
motion.txt . Examples:
	w		to start of next word
	b		to begin of current word
	4j		four lines down
	/The<CR>	to next occurrence of "The"
This is used after an operator command to move over the text
that is to be operated upon.
- If the motion includes a count and the operator also has a
  count, the two counts are multiplied. For example: "2d3w"
  deletes six words.
- The motion can be backwards, e.g. "db" to delete to the
  start of the word.
- The motion can also be a mouse click. The mouse is not
  supported in every terminal though.
- The ":omap" command can be used to map characters while an
  operator is pending.
- Ex commands can be used to move the cursor. This can be
  used to call a function that does some complicated motion.
  The motion is always characterwise exclusive, no matter
  what ":" command is used. This means it's impossible to
  include the last character of a line without the line break
  (unless 'virtualedit' is set).
  If the Ex command changes the text before where the operator
  starts or jumps to another buffer the result is
  unpredictable. It is possible to change the text further
  down. Jumping to another buffer is possible if the current
  buffer is not unloaded.

{Visual}

{Visual} A selected text area. It is started with the "v", "V", or CTRL-V command, then any cursor movement command can be used to change the end of the selected text.
This is used before an operator command to highlight the text that is to be operated upon.
See Visual-mode .

<character>

<character> A special character from the table below, optionally with modifiers, or a single ASCII character with modifiers.

'character'

'c' A single ASCII character.

CTRL-{char}

CTRL-{char} {char} typed as a control character; that is, typing {char} while holding the CTRL key down. The case of {char} does not matter; thus CTRL-A and CTRL-a are equivalent. But on some terminals, using the SHIFT key will produce another code, don't use it then.

'option'

'option' An option, or parameter, that can be set to a value, is enclosed in single quotes. See options .

quotecommandquote

"command" A reference to a command that you can type is enclosed in double quotes.
`command` New style command, this distinguishes it from other quoted text and strings.

key-notation key-codes keycodes

These names for keys are used in the documentation. They can also be used with the ":map" command (insert the key name by pressing CTRL-K and then the key you want the name for).

notation	meaning	equivalent	decimal value(s)	
<Nul>	zero	CTRL-@	0 (stored as 10)	<Nul>
<BS>	backspace	CTRL-H	8	backspace
<Tab>	tab	CTRL-I	9	tab Tab
				linefeed
<NL>	linefeed	CTRL-J	10 (used for <Nul>)	
<FF>	formfeed	CTRL-L	12	formfeed
<CR>	carriage return	CTRL-M	13	carriage-return
<Return>	same as <CR>			<Return>
<Enter>	same as <CR>			<Enter>
<Esc>	escape	CTRL-[	27	escape <Esc>
<Space>	space		32	space
<lt>	less-than	<	60	*<lt>*
<Bslash>	backslash	\	92	backslash <Bslash>
<Bar>	vertical bar	|	124	<Bar>

```
<Del>           delete                          127
<CSI>           command sequence intro  ALT-Esc 155     <CSI>
<xCSI>          CSI when typed in the GUI               <xCSI>

<EOL>           end-of-line (can be <CR>, <LF> or <CR><LF>,
                depends on system and 'fileformat')     <EOL>

<Up>            cursor-up                       cursor-up   cursor_up
<Down>          cursor-down                     cursor-down   cursor_down
<Left>          cursor-left                     cursor-left   cursor_left
<Right>         cursor-right                    cursor-right   cursor_right
<S-Up>          shift-cursor-up
<S-Down>        shift-cursor-down
<S-Left>        shift-cursor-left
<S-Right>       shift-cursor-right
<C-Left>        control-cursor-left
<C-Right>       control-cursor-right
<F1> - <F12>    function keys 1 to 12           function_key   function-key
<S-F1> - <S-F12> shift-function keys 1 to 12    <S-F1>
<Help>          help key
<Undo>          undo key
<Insert>        insert key
<Home>          home                            home
<End>           end                             end
<PageUp>        page-up                         page_up   page-up
<PageDown>      page-down                       page_down   page-down
<kHome>         keypad home (upper left)        keypad-home
<kEnd>          keypad end (lower left)         keypad-end
<kPageUp>       keypad page-up (upper right)    keypad-page-up
<kPageDown>     keypad page-down (lower right)  keypad-page-down
<kPlus>         keypad +                        keypad-plus
<kMinus>        keypad -                        keypad-minus
<kMultiply>     keypad *                        keypad-multiply
<kDivide>       keypad /                        keypad-divide
<kEnter>        keypad Enter                    keypad-enter
<kPoint>        keypad Decimal point            keypad-point
<k0> - <k9>     keypad 0 to 9                   keypad-0   keypad-9
<S-...>         shift-key                       shift   <S-
<C-...>         control-key                     control   ctrl   <C-
<M-...>         alt-key or meta-key             meta   alt   <M-
<A-...>         same as <M-...>                 <A-
<D-...>         command-key (Macintosh only)    <D-
<t_xx>          key with "xx" entry in termcap
-------------------------------------------------------------------------
```

Note: The shifted cursor keys, the help key, and the undo key are only available on a few terminals. On the Amiga, shifted function key 10 produces a code (CSI) that is also used by key sequences. It will be recognized only after typing another key.

Note: There are two codes for the delete key. 127 is the decimal ASCII value for the delete key, which is always recognized. Some delete keys send another value, in which case this value is obtained from the termcap entry "kD". Both values have the same effect. Also see :fixdel .

Note: The keypad keys are used in the same way as the corresponding "normal" keys. For example, <kHome> has the same effect as <Home>. If a keypad key sends the same raw key code as its non-keypad equivalent, it will be recognized as the non-keypad code. For example, when <kHome> sends the same code as <Home>, when pressing <kHome> Vim will think <Home> was pressed. Mapping <kHome> will not work then.

<>

Examples are often given in the <> notation. Sometimes this is just to make clear what you need to type, but often it can be typed literally, e.g., with the ":map" command. The rules are:

1. Any printable characters are typed directly, except backslash and '<'
2. A backslash is represented with "\\", double backslash, or "<Bslash>".
3. A real '<' is represented with "\<" or "<lt>". When there is no confusion possible, a '<' can be used directly.
4. "<key>" means the special key typed. This is the notation explained in the table above. A few examples:

<Esc>	Escape key
<C-G>	CTRL-G
<Up>	cursor up key
<C-LeftMouse>	Control- left mouse click
<S-F11>	Shifted function key 11
<M-a>	Meta- a ('a' with bit 8 set)
<M-A>	Meta- A ('A' with bit 8 set)
<t_kd>	"kd" termcap entry (cursor down key)

If you want to use the full <> notation in Vim, you have to make sure the '<' flag is excluded from 'cpoptions' (when 'compatible' is not set, it already is by default).

```
:set cpo-=<
```

The <> notation uses <lt> to escape the special meaning of key names. Using a backslash also works, but only when 'cpoptions' does not include the 'B' flag.

Examples for mapping CTRL-H to the six characters "<Home>":

```
:imap <C-H> \<Home>
:imap <C-H> <lt>Home>
```

The first one only works when the 'B' flag is not in 'cpoptions'. The second one always works.
To get a literal "<lt>" in a mapping:

```
:map <C-L> <lt>lt>
```

For mapping, abbreviation and menu commands you can then copy-paste the examples and use them directly. Or type them literally, including the '<' and '>' characters. This does NOT work for other commands, like ":set" and ":autocmd"!

==========

5. Modes, introduction vim-modes-intro vim-modes

Vim has seven BASIC modes:

Normal Normal-mode command-mode

Normal mode In Normal mode you can enter all the normal editor

commands. If you start the editor you are in this mode (unless you have set the 'insertmode' option, see below). This is also known as command mode.

Visual mode — This is like Normal mode, but the movement commands extend a highlighted area. When a non-movement command is used, it is executed for the highlighted area. See Visual-mode .
If the 'showmode' option is on "-- VISUAL --" is shown at the bottom of the window.

Select mode — This looks most like the MS-Windows selection mode. Typing a printable character deletes the selection and starts Insert mode. See Select-mode .
If the 'showmode' option is on "-- SELECT --" is shown at the bottom of the window.

Insert mode — In Insert mode the text you type is inserted into the buffer. See Insert-mode .
If the 'showmode' option is on "-- INSERT --" is shown at the bottom of the window.

Command-line mode
Cmdline mode — In Command-line mode (also called Cmdline mode) you can enter one line of text at the bottom of the window. This is for the Ex commands, ":", the pattern search commands, "?" and "/", and the filter command, "!". Cmdline-mode

Ex mode — Like Command-line mode, but after entering a command you remain in Ex mode. Very limited editing of the command line. Ex-mode

Terminal-Job mode — Interacting with a job in a terminal window. Typed keys go to the job and the job output is displayed in the terminal window. See terminal about how to switch to other modes.

There are seven ADDITIONAL modes. These are variants of the BASIC modes:

Operator-pending Operator-pending-mode

Operator-pending mode — This is like Normal mode, but after an operator command has started, and Vim is waiting for a {motion} to specify the text that the operator will work on.

Replace mode — Replace mode is a special case of Insert mode. You can do the same things as in Insert mode, but for each character you enter, one character of the existing text is deleted. See Replace-mode .
If the 'showmode' option is on "-- REPLACE --" is shown at the bottom of the window.

Virtual Replace mode — Virtual Replace mode is similar to Replace mode, but instead of file characters you are replacing screen real estate. See Virtual-Replace-mode .

If the 'showmode' option is on "-- VREPLACE --" is
shown at the bottom of the window.

Insert Normal mode	Entered when CTRL-O given in Insert mode. This is like Normal mode, but after executing one command Vim returns to Insert mode.
If the 'showmode' option is on "-- (insert) --" is shown at the bottom of the window.

Terminal-Normal mode	Using Normal mode in a terminal window. Making changes is impossible. Use an insert command, such as "a" or "i", to return to Terminal-Job mode.

Insert Visual mode	Entered when starting a Visual selection from Insert mode, e.g., by using CTRL-O and then "v", "V" or CTRL-V. When the Visual selection ends, Vim returns to Insert mode.
If the 'showmode' option is on "-- (insert) VISUAL --" is shown at the bottom of the window.

Insert Select mode	Entered when starting Select mode from Insert mode. E.g., by dragging the mouse or <S-Right>.
When the Select mode ends, Vim returns to Insert mode.
If the 'showmode' option is on "-- (insert) SELECT --" is shown at the bottom of the window.

==========

6. Switching from mode to mode mode-switching

If for any reason you do not know which mode you are in, you can always get back to Normal mode by typing <Esc> twice. This doesn't work for Ex mode though, use ":visual".
You will know you are back in Normal mode when you see the screen flash or hear the bell after you type <Esc>. However, when pressing <Esc> after using CTRL-O in Insert mode you get a beep but you are still in Insert mode, type <Esc> again.

i_esc

FROM mode \ TO mode	Normal	Visual	Select	Insert	Replace	Cmd-line	Ex
Normal		v V ^V	*4	*1	R gR	: / ? !	Q
Visual	*2		^G	c C	--	:	--
Select	*5	^O ^G		*6	--	--	--
Insert	<Esc>	--	--		<Insert>	--	--
Replace	<Esc>	--	--	<Insert>		--	--
Command-line	*3	--	--	:start	--		--
Ex	:vi	--	--	--	--	--	

-- not possible

*1 Go from Normal mode to Insert mode by giving the command "i", "I", "a", "A", "o", "O", "c", "C", "s" or S".
*2 Go from Visual mode to Normal mode by giving a non-movement command, which

causes the command to be executed, or by hitting <Esc> "v", "V" or "CTRL-V" (see v_v), which just stops Visual mode without side effects.
*3 Go from Command-line mode to Normal mode by:
- Hitting <CR> or <NL>, which causes the entered command to be executed.
- Deleting the complete line (e.g., with CTRL-U) and giving a final <BS>.
- Hitting CTRL-C or <Esc>, which quits the command-line without executing the command.
In the last case <Esc> may be the character defined with the 'wildchar' option, in which case it will start command-line completion. You can ignore that and type <Esc> again. {Vi: when hitting <Esc> the command-line is executed. This is unexpected for most people; therefore it was changed in Vim. But when the <Esc> is part of a mapping, the command-line is executed. If you want the Vi behaviour also when typing <Esc>, use ":cmap ^V<Esc> ^V^M"}
*4 Go from Normal to Select mode by:
- use the mouse to select text while 'selectmode' contains "mouse"
- use a non-printable command to move the cursor while keeping the Shift key pressed, and the 'selectmode' option contains "key"
- use "v", "V" or "CTRL-V" while 'selectmode' contains "cmd"
- use "gh", "gH" or "g CTRL-H" g_CTRL-H
*5 Go from Select mode to Normal mode by using a non-printable command to move the cursor, without keeping the Shift key pressed.
*6 Go from Select mode to Insert mode by typing a printable character. The selection is deleted and the character is inserted.

If the 'insertmode' option is on, editing a file will start in Insert mode.

CTRL-_CTRL-N i_CTRL-_CTRL-N c_CTRL-_CTRL-N v_CTRL-_CTRL-N
Additionally the command CTRL-\ CTRL-N or <C-\><C-N> can be used to go to Normal mode from any other mode. This can be used to make sure Vim is in Normal mode, without causing a beep like <Esc> would. However, this does not work in Ex mode. When used after a command that takes an argument, such as f or m , the timeout set with 'ttimeoutlen' applies.
When focus is in a terminal window, CTRL-\ CTRL-N goes to Normal mode for only one command, see t_CTRL-_CTRL-N .

CTRL-_CTRL-G i_CTRL-_CTRL-G c_CTRL-_CTRL-G v_CTRL-_CTRL-G
The command CTRL-\ CTRL-G or <C-\><C-G> can be used to go to Insert mode when 'insertmode' is set. Otherwise it goes to Normal mode. This can be used to make sure Vim is in the mode indicated by 'insertmode', without knowing in what mode Vim currently is.

Q mode-Ex Ex-mode Ex EX E501
Q Switch to "Ex" mode. This is a bit like typing ":" commands one after another, except:
- You don't have to keep pressing ":".
- The screen doesn't get updated after each command.
- There is no normal command-line editing.
- Mappings and abbreviations are not used.
In fact, you are editing the lines with the "standard" line-input editing commands (<Del> or <BS> to erase, CTRL-U to kill the whole line).
Vim will enter this mode by default if it's invoked as "ex" on the command-line.

Use the ":vi" command :visual to exit "Ex" mode.
Note: In older versions of Vim "Q" formatted text,
that is now done with gq . But if you use the
 vimrc_example.vim script "Q" works like "gq".

gQ

gQ Switch to "Ex" mode like with "Q", but really behave
like typing ":" commands after another. All command
line editing, completion etc. is available.
Use the ":vi" command :visual to exit "Ex" mode.
{not in Vi}

==
7. The window contents window-contents

In Normal mode and Insert/Replace mode the screen window will show the current
contents of the buffer: What You See Is What You Get. There are two
exceptions:
- When the 'cpoptions' option contains '$', and the change is within one line,
  the text is not directly deleted, but a '$' is put at the last deleted
  character.
- When inserting text in one window, other windows on the same text are not
  updated until the insert is finished.
{Vi: The screen is not always updated on slow terminals}

Lines longer than the window width will wrap, unless the 'wrap' option is off
(see below). The 'linebreak' option can be set to wrap at a blank character.

If the window has room after the last line of the buffer, Vim will show '~' in
the first column of the last lines in the window, like this:

```
+-----------------------+
|some line              |
|last line              |
|~                      |
|~                      |
+-----------------------+
```

Thus the '~' lines indicate that the end of the buffer was reached.

If the last line in a window doesn't fit, Vim will indicate this with a '@' in
the first column of the last lines in the window, like this:

```
+-----------------------+
|first line             |
|second line            |
|@                      |
|@                      |
+-----------------------+
```

Thus the '@' lines indicate that there is a line that doesn't fit in the
window.

When the "lastline" flag is present in the 'display' option, you will not see

'@' characters at the left side of window. If the last line doesn't fit completely, only the part that fits is shown, and the last three characters of the last line are replaced with "@@@", like this:

```
        +----------------------+
        |first line            |
        |second line           |
        |a very long line that d|
        |oesn't fit in the wi@@@|
        +----------------------+
```

If there is a single line that is too long to fit in the window, this is a special situation. Vim will show only part of the line, around where the cursor is. There are no special characters shown, so that you can edit all parts of this line.
{Vi: gives an "internal error" on lines that do not fit in the window}

The '@' occasion in the 'highlight' option can be used to set special highlighting for the '@' and '~' characters. This makes it possible to distinguish them from real characters in the buffer.

The 'showbreak' option contains the string to put in front of wrapped lines.

wrap-off
If the 'wrap' option is off, long lines will not wrap. Only the part that fits on the screen is shown. If the cursor is moved to a part of the line that is not shown, the screen is scrolled horizontally. The advantage of this method is that columns are shown as they are and lines that cannot fit on the screen can be edited. The disadvantage is that you cannot see all the characters of a line at once. The 'sidescroll' option can be set to the minimal number of columns to scroll. {Vi: has no 'wrap' option}

All normal ASCII characters are displayed directly on the screen. The <Tab> is replaced with the number of spaces that it represents. Other non-printing characters are replaced with "^{char}", where {char} is the non-printing character with 64 added. Thus character 7 (bell) will be shown as "^G". Characters between 127 and 160 are replaced with "~{char}", where {char} is the character with 64 subtracted. These characters occupy more than one position on the screen. The cursor can only be positioned on the first one.

If you set the 'number' option, all lines will be preceded with their number. Tip: If you don't like wrapping lines to mix with the line numbers, set the 'showbreak' option to eight spaces:
        ":set showbreak=\ \ \ \ \ \ \ \ "

If you set the 'list' option, <Tab> characters will not be shown as several spaces, but as "^I". A '$' will be placed at the end of the line, so you can find trailing blanks.

In Command-line mode only the command-line itself is shown correctly. The display of the buffer contents is updated as soon as you go back to Command mode.

The last line of the window is used for status and other messages. The

status messages will only be used if an option is on:

status message	option	default	Unix default
current mode	'showmode'	on	on
command characters	'showcmd'	on	off
cursor position	'ruler'	off	off

The current mode is "-- INSERT --" or "-- REPLACE --", see 'showmode' . The command characters are those that you typed but were not used yet. {Vi: does not show the characters you typed or the cursor position}

If you have a slow terminal you can switch off the status messages to speed up editing:

```
:set nosc noru nosm
```

If there is an error, an error message will be shown for at least one second (in reverse video). {Vi: error messages may be overwritten with other messages before you have a chance to read them}

Some commands show how many lines were affected. Above which threshold this happens can be controlled with the 'report' option (default 2).

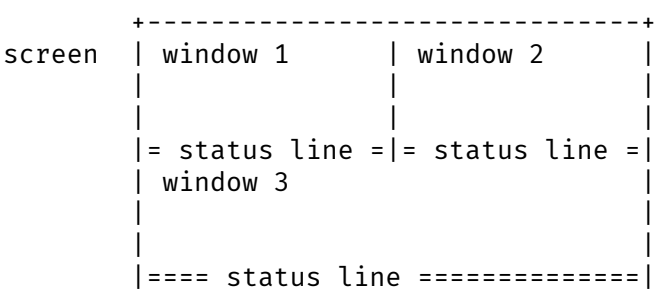
On the Amiga Vim will run in a CLI window. The name Vim and the full name of the current file name will be shown in the title bar. When the window is resized, Vim will automatically redraw the window. You may make the window as small as you like, but if it gets too small not a single line will fit in it. Make it at least 40 characters wide to be able to read most messages on the last line.

On most Unix systems, resizing the window is recognized and handled correctly by Vim. {Vi: not ok}

==
8. Definitions definitions

buffer	Contains lines of text, usually read from a file.
screen	The whole area that Vim uses to work in. This can be a terminal emulator window. Also called "the Vim window".
window	A view on a buffer. There can be multiple windows for one buffer.

A screen contains one or more windows, separated by status lines and with the command line at the bottom.



```
        |command line                   |
        +-------------------------------+
```

The command line is also used for messages. It scrolls up the screen when there is not enough room in the command line.

A difference is made between four types of lines:

buffer lines	The lines in the buffer. This is the same as the lines as they are read from/written to a file. They can be thousands of characters long.
logical lines	The buffer lines with folding applied. Buffer lines in a closed fold are changed to a single logical line: "+-- 99 lines folded". They can be thousands of characters long.
window lines	The lines displayed in a window: A range of logical lines with wrapping, line breaks, etc. applied. They can only be as long as the width of the window allows, longer lines are wrapped or truncated.
screen lines	The lines of the screen that Vim uses. Consists of the window lines of all windows, with status lines and the command line added. They can only be as long as the width of the screen allows. When the command line gets longer it wraps and lines are scrolled to make room.

```
buffer lines    logical lines   window lines    screen lines

1. one          1. one          1. +-- folded   1.  +-- folded
2. two          2. +-- folded   2. five         2.  five
3. three        3. five         3. six          3.  six
4. four         4. six          4. seven        4.  seven
5. five         5. seven                        5.  === status line ===
6. six                                          6.  aaa
7. seven                                        7.  bbb
                                                8.  ccc ccc c
1. aaa          1. aaa          1. aaa          9.  cc
2. bbb          2. bbb          2. bbb          10. ddd
3. ccc ccc ccc  3. ccc ccc ccc  3. ccc ccc c    11. ~
4. ddd          4. ddd          4. cc           12. === status line ===
                                5. ddd          13. (command line)
                                6. ~
```

helphelp.txt For Vim version 8.1. Last change: 2017 Mar 19

VIM REFERENCE MANUAL by Bram Moolenaar

Help on help files helphelp

==
1. Help commands online-help

help <Help> :h :help <F1> i_<F1> i_<Help>
<Help> or
:h[elp] Open a window and display the help file in read-only mode. If there is a help window open already, use that one. Otherwise, if the current window uses the full width of the screen or is at least 80 characters wide, the help window will appear just above the current window. Otherwise the new window is put at the very top.
The 'helplang' option is used to select a language, if the main help file is available in several languages.
{not in Vi}

{subject} E149 E661
:h[elp] {subject} Like ":help", additionally jump to the tag {subject}.
For example:
```
:help options
```

{subject} can include wildcards such as "*", "?" and "[a-z]":
```
:help z?     jump to help for any "z" command
:help z.     jump to the help for "z."
```
But when a tag exists it is taken literally:
```
:help :?     jump to help for ":?"
```

If there is no full match for the pattern, or there are several matches, the "best" match will be used. A sophisticated algorithm is used to decide which match is better than another one. These items are considered in the computation:
- A match with same case is much better than a match with different case.
- A match that starts after a non-alphanumeric character is better than a match in the middle of a word.
- A match at or near the beginning of the tag is better than a match further on.
- The more alphanumeric characters match, the better.
- The shorter the length of the match, the better.

The 'helplang' option is used to select a language, if
the {subject} is available in several languages.
To find a tag in a specific language, append "@ab",
where "ab" is the two-letter language code. See
help-translated .

Note that the longer the {subject} you give, the less
matches will be found. You can get an idea how this
all works by using commandline completion (type CTRL-D
after ":help subject" c_CTRL-D).
If there are several matches, you can have them listed
by hitting CTRL-D. Example:
	:help cont<Ctrl-D>

Instead of typing ":help CTRL-V" to search for help
for CTRL-V you can type:
	:help ^V
This also works together with other characters, for
example to find help for CTRL-V in Insert mode:
	:help i^V

It is also possible to first do ":help" and then
use ":tag {pattern}" in the help window. The
":tnext" command can then be used to jump to other
matches, "tselect" to list matches and choose one.
	:help index
	:tselect /.*mode

When there is no argument you will see matches for
"help", to avoid listing all possible matches (that
would be very slow).
The number of matches displayed is limited to 300.

The `:help` command can be followed by '|' and another
command, but you don't need to escape the '|' inside a
help command. So these both work:
	:help |
	:help k| only
Note that a space before the '|' is seen as part of
the ":help" argument.
You can also use <LF> or <CR> to separate the help
command from a following command. You need to type
CTRL-V first to insert the <LF> or <CR>. Example:
	:help so<C-V><CR>only
{not in Vi}

:h[elp]! [subject]	Like ":help", but in non-English help files prefer to
find a tag in a file with the same language as the
current file. See help-translated .

:helpc :helpclose

:helpc[lose]	Close one help window, if there is one.

:helpg :helpgrep

:helpg[rep] {pattern}[@xx]
Search all help text files and make a list of lines in which {pattern} matches. Jumps to the first match. The optional [@xx] specifies that only matches in the "xx" language are to be found.
You can navigate through the matches with the quickfix commands, e.g., :cnext to jump to the next one. Or use :cwindow to get the list of matches in the quickfix window.
{pattern} is used as a Vim regexp pattern. 'ignorecase' is not used, add "\c" to ignore case.
Example for case sensitive search:
:helpgrep Uganda
Example for case ignoring search:
:helpgrep uganda\c
Example for searching in French help:
:helpgrep backspace@fr
The pattern does not support line breaks, it must match within one line. You can use :grep instead, but then you need to get the list of help files in a complicated way.
Cannot be followed by another command, everything is used as part of the pattern. But you can use :execute when needed.
Compressed help files will not be searched (Fedora compresses the help files).
{not in Vi}

:lh :lhelpgrep

:lh[elpgrep] {pattern}[@xx]
Same as ":helpgrep", except the location list is used instead of the quickfix list. If the help window is already opened, then the location list for that window is used. Otherwise, a new help window is opened and the location list for that window is set. The location list for the current window is not changed then.

:exu :exusage

:exu[sage]
Show help on Ex commands. Added to simulate the Nvi command. {not in Vi}

:viu :viusage

:viu[sage]
Show help on Normal mode commands. Added to simulate the Nvi command. {not in Vi}

When no argument is given to :help the file given with the 'helpfile' option will be opened. Otherwise the specified tag is searched for in all "doc/tags" files in the directories specified in the 'runtimepath' option.

The initial height of the help window can be set with the 'helpheight' option (default 20).

Jump to specific subjects by using tags. This can be done in two ways:
- Use the "CTRL-]" command while standing on the name of a command or option.
  This only works when the tag is a keyword. "<C-Leftmouse>" and
  "g<LeftMouse>" work just like "CTRL-]".
- use the ":ta {subject}" command. This also works with non-keyword
  characters.

Use CTRL-T or CTRL-O to jump back.
Use ":q" to close the help window.

If there are several matches for an item you are looking for, this is how you
can jump to each one of them:
1. Open a help window
2. Use the ":tag" command with a slash prepended to the tag. E.g.:
        :tag /min
3. Use ":tnext" to jump to the next matching tag.

It is possible to add help files for plugins and other items. You don't need
to change the distributed help files for that. See add-local-help .

To write a local help file, see write-local-help .

Note that the title lines from the local help files are automagically added to
the "LOCAL ADDITIONS" section in the "help.txt" help file local-additions .
This is done when viewing the file in Vim, the file itself is not changed. It
is done by going through all help files and obtaining the first line of each
file. The files in $VIMRUNTIME/doc are skipped.

                                                        help-xterm-window
If you want to have the help in another xterm window, you could use this
command:
        :!xterm -e vim +help &

                        :helpfind   :helpf
:helpf[ind]   Like :help , but use a dialog to enter the argument.
                        Only for backwards compatibility. It now executes the
                        ToolBar.FindHelp menu entry instead of using a builtin
                        dialog. {only when compiled with |+GUI_GTK|}
                        {not in Vi}

                                    :helpt   :helptags
                              E154   E150   E151   E152   E153   E670
:helpt[ags] [++t] {dir}
                        Generate the help tags file(s) for directory {dir}.
                        When {dir} is ALL then all "doc" directories in
                        'runtimepath' will be used.

                        All "*.txt" and "*.??x" files in the directory and
                        sub-directories are scanned for a help tag definition
                        in between stars. The "*.??x" files are for
                        translated docs, they generate the "tags-??" file, see
                         help-translated . The generated tags files are
                        sorted.

When there are duplicates an error message is given.
An existing tags file is silently overwritten.

The optional "++t" argument forces adding the
"help-tags" tag. This is also done when the {dir} is
equal to $VIMRUNTIME/doc.

To rebuild the help tags in the runtime directory
(requires write permission there):
	:helptags $VIMRUNTIME/doc
{not in Vi}

==
2. Translated help files   help-translated

It is possible to add translated help files, next to the original English help
files. Vim will search for all help in "doc" directories in 'runtimepath'.
This is only available when compiled with the +multi_lang feature.

At this moment translations are available for:
	Chinese - multiple authors
	French - translated by David Blanchet
	Italian - translated by Antonio Colombo
	Japanese - multiple authors
	Polish - translated by Mikolaj Machowski
	Russian - translated by Vassily Ragosin
See the Vim website to find them: http://www.vim.org/translations.php

A set of translated help files consists of these files:

	help.abx
	howto.abx
	...
	tags-ab

"ab" is the two-letter language code. Thus for Italian the names are:

	help.itx
	howto.itx
	...
	tags-it

The 'helplang' option can be set to the preferred language(s). The default is
set according to the environment. Vim will first try to find a matching tag
in the preferred language(s). English is used when it cannot be found.

To find a tag in a specific language, append "@ab" to a tag, where "ab" is the
two-letter language code. Example:
	:he user-manual@it
	:he user-manual@en
The first one finds the Italian user manual, even when 'helplang' is empty.
The second one finds the English user manual, even when 'helplang' is set to
"it".

When using command-line completion for the ":help" command, the "@en"
extension is only shown when a tag exists for multiple languages. When the
tag only exists for English "@en" is omitted. When the first candidate has an
"@ab" extension and it matches the first language in 'helplang' "@ab" is also
omitted.

When using CTRL-] or ":help!" in a non-English help file Vim will try to
find the tag in the same language. If not found then 'helplang' will be used
to select a language.

Help files must use latin1 or utf-8 encoding. Vim assumes the encoding is
utf-8 when finding non-ASCII characters in the first line. Thus you must
translate the header with "For Vim version".

The same encoding must be used for the help files of one language in one
directory. You can use a different encoding for different languages and use
a different encoding for help files of the same language but in a different
directory.

Hints for translators:
- Do not translate the tags. This makes it possible to use 'helplang' to
  specify the preferred language. You may add new tags in your language.
- When you do not translate a part of a file, add tags to the English version,
  using the "tag@en" notation.
- Make a package with all the files and the tags file available for download.
  Users can drop it in one of the "doc" directories and start use it.
  Report this to Bram, so that he can add a link on www.vim.org.
- Use the :helptags command to generate the tags files. It will find all
  languages in the specified directory.

==
3. Writing help files   help-writing

For ease of use, a Vim help file for a plugin should follow the format of the
standard Vim help files. If you are writing a new help file it's best to copy
one of the existing files and use it as a template.

The first line in a help file should have the following format:

 helpfile_name.txt   For Vim version 7.3   Last change: 2010 June 4

The first field is a link to the help file name. The second field describes
the applicable Vim version. The last field specifies the last modification
date of the file. Each field is separated by a tab.

At the bottom of the help file, place a Vim modeline to set the 'textwidth'
and 'tabstop' options and the 'filetype' to "help". Never set a global option
in such a modeline, that can have consequences undesired by whoever reads that
help.

TAGS

To define a help tag, place the name between asterisks (*tag-name*). The
tag-name should be different from all the Vim help tag names and ideally
should begin with the name of the Vim plugin. The tag name is usually right
aligned on a line.

When referring to an existing help tag and to create a hot-link, place the
name between two bars (|) eg. help-writing .

When referring to a Vim command and to create a hot-link, place the
name between two backticks, eg. inside `:filetype`. You will see this is
highlighted as a command, like a code block (see below).

When referring to a Vim option in the help file, place the option name between
two single quotes, eg. 'statusline'

HIGHLIGHTING

To define a column heading, use a tilde character at the end of the line.
This will highlight the column heading in a different color. E.g.

Column heading

To separate sections in a help file, place a series of '=' characters in a
line starting from the first column. The section separator line is highlighted
differently.

To quote a block of ex-commands verbatim, place a greater than (>) character
at the end of the line before the block and a less than (<) character as the
first non-blank on a line following the block. Any line starting in column 1
also implicitly stops the block of ex-commands before it. E.g.

```
    function Example_Func()
        echo "Example"
    endfunction
```

The following are highlighted differently in a Vim help file:
  - a special key name expressed either in <> notation as in <PageDown>, or
    as a Ctrl character as in CTRL-X
  - anything between {braces}, e.g. {lhs} and {rhs}

The word "Note", "Notes" and similar automagically receive distinctive
highlighting. So do these:

```
        *Todo   something to do
        *Error  something wrong
```

You can find the details in $VIMRUNTIME/syntax/help.vim

index.txt For Vim version 8.1. Last change: 2018 Apr 19

VIM REFERENCE MANUAL by Bram Moolenaar

index

This file contains a list of all commands for each mode, with a tag and a short description. The lists are sorted on ASCII value.

Tip: When looking for certain functionality, use a search command. E.g., to look for deleting something, use: "/delete".

For an overview of options see help.txt option-list .
For an overview of built-in functions see functions .
For a list of Vim variables see vim-variable .
For a complete listing of all help items see help-tags .

==========

1. Insert mode insert-index

tag	char	action in Insert mode
i_CTRL-@	CTRL-@	insert previously inserted text and stop insert
i_CTRL-A	CTRL-A	insert previously inserted text
	CTRL-B	not used i_CTRL-B-gone
i_CTRL-C	CTRL-C	quit insert mode, without checking for abbreviation, unless 'insertmode' set.
i_CTRL-D	CTRL-D	delete one shiftwidth of indent in the current line
i_CTRL-E	CTRL-E	insert the character which is below the cursor
	CTRL-F	not used (but by default it's in 'cinkeys' to re-indent the current line)
i_CTRL-G_j	CTRL-G CTRL-J	line down, to column where inserting started
i_CTRL-G_j	CTRL-G j	line down, to column where inserting started
i_CTRL-G_j	CTRL-G <Down>	line down, to column where inserting started
i_CTRL-G_k	CTRL-G CTRL-K	line up, to column where inserting started
i_CTRL-G_k	CTRL-G k	line up, to column where inserting started
i_CTRL-G_k	CTRL-G <Up>	line up, to column where inserting started
i_CTRL-G_u	CTRL-G u	start new undoable edit
i_CTRL-G_U	CTRL-G U	don't break undo with next cursor movement
i_<BS>	<BS>	delete character before the cursor
i_digraph	{char1}<BS>{char2}	

```
                                enter digraph (only when 'digraph' option set)
i_CTRL-H        CTRL-H          same as <BS>
i_<Tab>         <Tab>           insert a <Tab> character
i_CTRL-I        CTRL-I          same as <Tab>
i_<NL>          <NL>            same as <CR>
i_CTRL-J        CTRL-J          same as <CR>
i_CTRL-K        CTRL-K {char1} {char2}
                                enter digraph
i_CTRL-L        CTRL-L          when 'insertmode' set: Leave Insert mode
i_<CR>          <CR>            begin new line
i_CTRL-M        CTRL-M          same as <CR>
i_CTRL-N        CTRL-N          find next match for keyword in front of the
                                cursor
i_CTRL-O        CTRL-O          execute a single command and return to insert
                                mode
i_CTRL-P        CTRL-P          find previous match for keyword in front of
                                the cursor
i_CTRL-Q        CTRL-Q          same as CTRL-V, unless used for terminal
                                control flow
i_CTRL-R        CTRL-R {0-9a-z"%#*:=}
                                insert the contents of a register
i_CTRL-R_CTRL-R  CTRL-R CTRL-R {0-9a-z"%#*:=}
                                insert the contents of a register literally
i_CTRL-R_CTRL-O  CTRL-R CTRL-O {0-9a-z"%#*:=}
                                insert the contents of a register literally
                                and don't auto-indent
i_CTRL-R_CTRL-P  CTRL-R CTRL-P {0-9a-z"%#*:=}
                                insert the contents of a register literally
                                and fix indent.
                CTRL-S          (used for terminal control flow)
i_CTRL-T        CTRL-T          insert one shiftwidth of indent in current
                                line
i_CTRL-U        CTRL-U          delete all entered characters in the current
                                line
i_CTRL-V        CTRL-V {char}   insert next non-digit literally
i_CTRL-V_digit   CTRL-V {number} insert three digit decimal number as a single
                                byte.
i_CTRL-W        CTRL-W          delete word before the cursor
i_CTRL-X        CTRL-X {mode}   enter CTRL-X sub mode, see  i_CTRL-X_index
i_CTRL-Y        CTRL-Y          insert the character which is above the cursor
i_CTRL-Z        CTRL-Z          when 'insertmode' set: suspend Vim
i_<Esc>         <Esc>           end insert mode (unless 'insertmode' set)
i_CTRL-[        CTRL-[          same as <Esc>
i_CTRL-\_CTRL-N  CTRL-\ CTRL-N  go to Normal mode
i_CTRL-\_CTRL-G  CTRL-\ CTRL-G  go to mode specified with 'insertmode'
                CTRL-\ a - z    reserved for extensions
                CTRL-\ others   not used
i_CTRL-]        CTRL-]          trigger abbreviation
i_CTRL-^        CTRL-^          toggle use of  :lmap  mappings
i_CTRL-_        CTRL-_          When 'allowrevins' set: change language
                                (Hebrew, Farsi) {only when compiled with
                                the  +rightleft  feature}

                <Space> to '~'  not used, except '0' and '^' followed by
```

CTRL-D

i_0_CTRL-D	0 CTRL-D	delete all indent in the current line
i_^_CTRL-D	^ CTRL-D	delete all indent in the current line, restore it in the next line
i_<Del>	<Del>	delete character under the cursor
	Meta characters (0x80 to 0xff, 128 to 255)	not used
i_<Left>	<Left>	cursor one character left
i_<S-Left>	<S-Left>	cursor one word left
i_<C-Left>	<C-Left>	cursor one word left
i_<Right>	<Right>	cursor one character right
i_<S-Right>	<S-Right>	cursor one word right
i_<C-Right>	<C-Right>	cursor one word right
i_<Up>	<Up>	cursor one line up
i_<S-Up>	<S-Up>	same as <PageUp>
i_<Down>	<Down>	cursor one line down
i_<S-Down>	<S-Down>	same as <PageDown>
i_<Home>	<Home>	cursor to start of line
i_<C-Home>	<C-Home>	cursor to start of file
i_<End>	<End>	cursor past end of line
i_<C-End>	<C-End>	cursor past end of file
i_<PageUp>	<PageUp>	one screenful backward
i_<PageDown>	<PageDown>	one screenful forward
i_<F1>	<F1>	same as <Help>
i_<Help>	<Help>	stop insert mode and display help window
i_<Insert>	<Insert>	toggle Insert/Replace mode
i_<LeftMouse>	<LeftMouse>	cursor at mouse click
i_<ScrollWheelDown>	<ScrollWheelDown>	move window three lines down
i_<S-ScrollWheelDown>	<S-ScrollWheelDown>	move window one page down
i_<ScrollWheelUp>	<ScrollWheelUp>	move window three lines up
i_<S-ScrollWheelUp>	<S-ScrollWheelUp>	move window one page up
i_<ScrollWheelLeft>	<ScrollWheelLeft>	move window six columns left
i_<S-ScrollWheelLeft>	<S-ScrollWheelLeft>	move window one page left
i_<ScrollWheelRight>	<ScrollWheelRight>	move window six columns right
i_<S-ScrollWheelRight>	<S-ScrollWheelRight>	move window one page right

commands in CTRL-X submode i_CTRL-X_index

i_CTRL-X_CTRL-D	CTRL-X CTRL-D	complete defined identifiers
i_CTRL-X_CTRL-E	CTRL-X CTRL-E	scroll up
i_CTRL-X_CTRL-F	CTRL-X CTRL-F	complete file names
i_CTRL-X_CTRL-I	CTRL-X CTRL-I	complete identifiers
i_CTRL-X_CTRL-K	CTRL-X CTRL-K	complete identifiers from dictionary
i_CTRL-X_CTRL-L	CTRL-X CTRL-L	complete whole lines
i_CTRL-X_CTRL-N	CTRL-X CTRL-N	next completion
i_CTRL-X_CTRL-O	CTRL-X CTRL-O	omni completion
i_CTRL-X_CTRL-P	CTRL-X CTRL-P	previous completion
i_CTRL-X_CTRL-S	CTRL-X CTRL-S	spelling suggestions
i_CTRL-X_CTRL-T	CTRL-X CTRL-T	complete identifiers from thesaurus
i_CTRL-X_CTRL-Y	CTRL-X CTRL-Y	scroll down

```
 i_CTRL-X_CTRL-U        CTRL-X CTRL-U   complete with 'completefunc'
 i_CTRL-X_CTRL-V        CTRL-X CTRL-V   complete like in : command line
 i_CTRL-X_CTRL-]        CTRL-X CTRL-]   complete tags
 i_CTRL-X_s             CTRL-X s        spelling suggestions
{not available when compiled without the |+insert_expand| feature}

==============================================================================
2. Normal mode                                                  normal-index

CHAR     any non-blank character
WORD     a sequence of non-blank characters
N        a number entered before the command
{motion} a cursor movement command
Nmove    the text that is moved over with a {motion}
SECTION  a section that possibly starts with '}' instead of '{'

note: 1 = cursor movement command; 2 = can be undone/redone

tag             char          note action in Normal mode
------------------------------------------------------------------------------
                CTRL-@                  not used
 CTRL-A         CTRL-A          2       add N to number at/after cursor
 CTRL-B         CTRL-B          1       scroll N screens Backwards
 CTRL-C         CTRL-C                  interrupt current (search) command
 CTRL-D         CTRL-D                  scroll Down N lines (default: half a screen)
 CTRL-E         CTRL-E                  scroll N lines upwards (N lines Extra)
 CTRL-F         CTRL-F          1       scroll N screens Forward
 CTRL-G         CTRL-G                  display current file name and position
 <BS>           <BS>            1       same as "h"
 CTRL-H         CTRL-H          1       same as "h"
 <Tab>          <Tab>           1       go to N newer entry in jump list
 CTRL-I         CTRL-I          1       same as <Tab>
 <NL>           <NL>            1       same as "j"
 CTRL-J         CTRL-J          1       same as "j"
                CTRL-K                  not used
 CTRL-L         CTRL-L                  redraw screen
 <CR>           <CR>            1       cursor to the first CHAR N lines lower
 CTRL-M         CTRL-M          1       same as <CR>
 CTRL-N         CTRL-N          1       same as "j"
 CTRL-O         CTRL-O          1       go to N older entry in jump list
 CTRL-P         CTRL-P          1       same as "k"
                CTRL-Q                  (used for terminal control flow)
 CTRL-R         CTRL-R          2       redo changes which were undone with 'u'
                CTRL-S                  (used for terminal control flow)
 CTRL-T         CTRL-T                  jump to N older Tag in tag list
 CTRL-U         CTRL-U                  scroll N lines Upwards (default: half a
                                        screen)
 CTRL-V         CTRL-V                  start blockwise Visual mode
 CTRL-W         CTRL-W {char}           window commands, see  CTRL-W
 CTRL-X         CTRL-X          2       subtract N from number at/after cursor
 CTRL-Y         CTRL-Y                  scroll N lines downwards
 CTRL-Z         CTRL-Z                  suspend program (or start new shell)
                CTRL-[ <Esc>            not used
 CTRL-\_CTRL-N  CTRL-\ CTRL-N           go to Normal mode (no-op)
```

```
CTRL-\_CTRL-G  CTRL-\ CTRL-G      go to mode specified with 'insertmode'
               CTRL-\ a - z       reserved for extensions
               CTRL-\ others      not used
CTRL-]         CTRL-]             :ta to ident under cursor
CTRL-^         CTRL-^             edit Nth alternate file (equivalent to
                                  ":e #N")
               CTRL-_             not used

<Space>        <Space>         1  same as "l"
!              !{motion}{filter}
                               2  filter Nmove text through the {filter}
                                  command
!!             !!{filter}      2  filter N lines through the {filter} command
quote          "{a-zA-Z0-9.%#:-"}  use register {a-zA-Z0-9.%#:-"} for next
                                  delete, yank or put (uppercase to append)
                                  ({.%#:} only work with put)
#              #               1  search backward for the Nth occurrence of
                                  the ident under the cursor
$              $               1  cursor to the end of Nth next line
%              %               1  find the next (curly/square) bracket on
                                  this line and go to its match, or go to
                                  matching comment bracket, or go to matching
                                  preprocessor directive.
N%             {count}%        1  go to N percentage in the file
&              &               2  repeat last :s
'              '{a-zA-Z0-9}    1  cursor to the first CHAR on the line with
                                  mark {a-zA-Z0-9}
''             ''              1  cursor to the first CHAR of the line where
                                  the cursor was before the latest jump.
'(             '(              1  cursor to the first CHAR on the line of the
                                  start of the current sentence
')             ')              1  cursor to the first CHAR on the line of the
                                  end of the current sentence
'<             '<              1  cursor to the first CHAR of the line where
                                  highlighted area starts/started in the
                                  current buffer.
'>             '>              1  cursor to the first CHAR of the line where
                                  highlighted area ends/ended in the current
                                  buffer.
'[             '[              1  cursor to the first CHAR on the line of the
                                  start of last operated text or start of put
                                  text
']             ']              1  cursor to the first CHAR on the line of the
                                  end of last operated text or end of put
                                  text
'{             '{              1  cursor to the first CHAR on the line of the
                                  start of the current paragraph
'}             '}              1  cursor to the first CHAR on the line of the
                                  end of the current paragraph
(              (               1  cursor N sentences backward
)              )               1  cursor N sentences forward
star           *               1  search forward for the Nth occurrence of
                                  the ident under the cursor
+              +               1  same as <CR>
```

,	,	1	repeat latest f, t, F or T in opposite direction N times
-	-	1	cursor to the first CHAR N lines higher
.	.	2	repeat last change with count replaced with N
/	/{pattern}<CR>	1	search forward for the Nth occurrence of {pattern}
/<CR>	/<CR>	1	search forward for {pattern} of last search
count	0	1	cursor to the first char of the line
count	1		prepend to command to give a count
count	2		"
count	3		"
count	4		"
count	5		"
count	6		"
count	7		"
count	8		"
count	9		"
:	:	1	start entering an Ex command
N:	{count}:		start entering an Ex command with range from current line to N-1 lines down
;	;	1	repeat latest f, t, F or T N times
<	<{motion}	2	shift Nmove lines one 'shiftwidth' leftwards
<<	<<	2	shift N lines one 'shiftwidth' leftwards
=	={motion}	2	filter Nmove lines through "indent"
==	==	2	filter N lines through "indent"
>	>{motion}	2	shift Nmove lines one 'shiftwidth' rightwards
>>	>>	2	shift N lines one 'shiftwidth' rightwards
?	?{pattern}<CR>	1	search backward for the Nth previous occurrence of {pattern}
?<CR>	?<CR>	1	search backward for {pattern} of last search
@	@{a-z}	2	execute the contents of register {a-z} N times
@:	@:		repeat the previous ":" command N times
@@	@@	2	repeat the previous @{a-z} N times
A	A	2	append text after the end of the line N times
B	B	1	cursor N WORDS backward
C	["x]C	2	change from the cursor position to the end of the line, and N-1 more lines [into register x]; synonym for "c$"
D	["x]D	2	delete the characters under the cursor until the end of the line and N-1 more lines [into register x]; synonym for "d$"
E	E	1	cursor forward to the end of WORD N
F	F{char}	1	cursor to the Nth occurrence of {char} to the left
G	G	1	cursor to line N, default last line
H	H	1	cursor to line N from top of screen
I	I	2	insert text before the first CHAR on the line N times
J	J	2	Join N lines; default is 2
K	K		lookup Keyword under the cursor with

			'keywordprg'
L	L	1	cursor to line N from bottom of screen
M	M	1	cursor to middle line of screen
N	N	1	repeat the latest '/' or '?' N times in opposite direction
O	O	2	begin a new line above the cursor and insert text, repeat N times
P	["x]P	2	put the text [from register x] before the cursor N times
Q	Q		switch to "Ex" mode
R	R	2	enter replace mode: overtype existing characters, repeat the entered text N-1 times
S	["x]S	2	delete N lines [into register x] and start insert; synonym for "cc".
T	T{char}	1	cursor till after Nth occurrence of {char} to the left
U	U	2	undo all latest changes on one line
V	V		start linewise Visual mode
W	W	1	cursor N WORDS forward
X	["x]X	2	delete N characters before the cursor [into register x]
Y	["x]Y		yank N lines [into register x]; synonym for "yy"
ZZ	ZZ		store current file if modified, and exit
ZQ	ZQ		exit current file always
[	[{char}		square bracket command (see [below)
\			not used
]	]{char}		square bracket command (see] below)
^	^	1	cursor to the first CHAR of the line
_	_	1	cursor to the first CHAR N - 1 lines lower
`	`{a-zA-Z0-9}	1	cursor to the mark {a-zA-Z0-9}
`(	`(	1	cursor to the start of the current sentence
`)	`)	1	cursor to the end of the current sentence
`<	`<	1	cursor to the start of the highlighted area
`>	`>	1	cursor to the end of the highlighted area
`[	`[	1	cursor to the start of last operated text or start of putted text
`]	`]	1	cursor to the end of last operated text or end of putted text
``	``	1	cursor to the position before latest jump
`{	`{	1	cursor to the start of the current paragraph
`}	`}	1	cursor to the end of the current paragraph
a	a	2	append text after the cursor N times
b	b	1	cursor N words backward
c	["x]c{motion}	2	delete Nmove text [into register x] and start insert
cc	["x]cc	2	delete N lines [into register x] and start insert
d	["x]d{motion}	2	delete Nmove text [into register x]
dd	["x]dd	2	delete N lines [into register x]
do	do	2	same as ":diffget"
dp	dp	2	same as ":diffput"
e	e	1	cursor forward to the end of word N

f	f{char}	1	cursor to Nth occurrence of {char} to the right
g	g{char}		extended commands, see g below
h	h	1	cursor N chars to the left
i	i	2	insert text before the cursor N times
j	j	1	cursor N lines downward
k	k	1	cursor N lines upward
l	l	1	cursor N chars to the right
m	m{A-Za-z}		set mark {A-Za-z} at cursor position
n	n	1	repeat the latest '/' or '?' N times
o	o	2	begin a new line below the cursor and insert text, repeat N times
p	["x]p	2	put the text [from register x] after the cursor N times
q	q{0-9a-zA-Z"}		record typed characters into named register {0-9a-zA-Z"} (uppercase to append)
q	q		(while recording) stops recording
q:	q:		edit : command-line in command-line window
q/	q/		edit / command-line in command-line window
q?	q?		edit ? command-line in command-line window
r	r{char}	2	replace N chars with {char}
s	["x]s	2	(substitute) delete N characters [into register x] and start insert
t	t{char}	1	cursor till before Nth occurrence of {char} to the right
u	u	2	undo changes
v	v		start characterwise Visual mode
w	w	1	cursor N words forward
x	["x]x	2	delete N characters under and after the cursor [into register x]
y	["x]y{motion}		yank Nmove text [into register x]
yy	["x]yy		yank N lines [into register x]
z	z{char}		commands starting with 'z', see z below
{	{	1	cursor N paragraphs backward
bar	|	1	cursor to column N
}	}	1	cursor N paragraphs forward
~	~	2	'tildeop' off: switch case of N characters under cursor and move the cursor N characters to the right
~	~{motion}		'tildeop' on: switch case of Nmove text
<C-End>	<C-End>	1	same as "G"
<C-Home>	<C-Home>	1	same as "gg"
<C-Left>	<C-Left>	1	same as "b"
<C-LeftMouse>	<C-LeftMouse>		":ta" to the keyword at the mouse click
<C-Right>	<C-Right>	1	same as "w"
<C-RightMouse>	<C-RightMouse>		same as "CTRL-T"
<Del>	["x]<Del>	2	same as "x"
N<Del>	{count}<Del>		remove the last digit from {count}
<Down>	<Down>	1	same as "j"
<End>	<End>	1	same as "$"
<F1>	<F1>		same as <Help>
<Help>	<Help>		open a help window
<Home>	<Home>	1	same as "0"
<Insert>	<Insert>	2	same as "i"

<Left>	<Left>	1	same as "h"
<LeftMouse>	<LeftMouse>	1	move cursor to the mouse click position
<MiddleMouse>	<MiddleMouse>	2	same as "gP" at the mouse click position
<PageDown>	<PageDown>		same as CTRL-F
<PageUp>	<PageUp>		same as CTRL-B
<Right>	<Right>	1	same as "l"
<RightMouse>	<RightMouse>		start Visual mode, move cursor to the mouse click position
<S-Down>	<S-Down>	1	same as CTRL-F
<S-Left>	<S-Left>	1	same as "b"
<S-LeftMouse>	<S-LeftMouse>		same as "*" at the mouse click position
<S-Right>	<S-Right>	1	same as "w"
<S-RightMouse>	<S-RightMouse>		same as "#" at the mouse click position
<S-Up>	<S-Up>	1	same as CTRL-B
<Undo>	<Undo>	2	same as "u"
<Up>	<Up>	1	same as "k"
<ScrollWheelDown>	<ScrollWheelDown>		move window three lines down
<S-ScrollWheelDown>	<S-ScrollWheelDown>		move window one page down
<ScrollWheelUp>	<ScrollWheelUp>		move window three lines up
<S-ScrollWheelUp>	<S-ScrollWheelUp>		move window one page up
<ScrollWheelLeft>	<ScrollWheelLeft>		move window six columns left
<S-ScrollWheelLeft>	<S-ScrollWheelLeft>		move window one page left
<ScrollWheelRight>	<ScrollWheelRight>		move window six columns right
<S-ScrollWheelRight>	<S-ScrollWheelRight>		move window one page right

==========

2.1 Text objects objects

These can be used after an operator or in Visual mode to select an object.

tag	command	action in op-pending and Visual mode
v_aquote	a"	double quoted string
v_a'	a'	single quoted string
v_a(	a(	same as ab
v_a)	a)	same as ab
v_a<	a<	"a <>" from '<' to the matching '>'
v_a>	a>	same as a<
v_aB	aB	"a Block" from "[{" to "]}" (with brackets)
v_aW	aW	"a WORD" (with white space)
v_a[	a[	"a []" from '[' to the matching ']'
v_a]	a]	same as a[
v_a`	a`	string in backticks
v_ab	ab	"a block" from "[(" to "])" (with braces)
v_ap	ap	"a paragraph" (with white space)
v_as	as	"a sentence" (with white space)
v_at	at	"a tag block" (with white space)
v_aw	aw	"a word" (with white space)
v_a{	a{	same as aB
v_a}	a}	same as aB
v_iquote	i"	double quoted string without the quotes
v_i'	i'	single quoted string without the quotes
v_i(	i(	same as ib
v_i)	i)	same as ib

v_i<	i<	"inner <>" from '<' to the matching '>'
v_i>	i>	same as i<
v_iB	iB	"inner Block" from "[{" and "]}"
v_iW	iW	"inner WORD"
v_i[	i[	"inner []" from '[' to the matching ']'
v_i]	i]	same as i[
v_i`	i`	string in backticks without the backticks
v_ib	ib	"inner block" from "[(" to "])"
v_ip	ip	"inner paragraph"
v_is	is	"inner sentence"
v_it	it	"inner tag block"
v_iw	iw	"inner word"
v_i{	i{	same as iB
v_i}	i}	same as iB

==========

2.2 Window commands CTRL-W

tag	command	action in Normal mode
CTRL-W_CTRL-B	CTRL-W CTRL-B	same as "CTRL-W b"
CTRL-W_CTRL-C	CTRL-W CTRL-C	same as "CTRL-W c"
CTRL-W_CTRL-D	CTRL-W CTRL-D	same as "CTRL-W d"
CTRL-W_CTRL-F	CTRL-W CTRL-F	same as "CTRL-W f"
	CTRL-W CTRL-G	same as "CTRL-W g .."
CTRL-W_CTRL-H	CTRL-W CTRL-H	same as "CTRL-W h"
CTRL-W_CTRL-I	CTRL-W CTRL-I	same as "CTRL-W i"
CTRL-W_CTRL-J	CTRL-W CTRL-J	same as "CTRL-W j"
CTRL-W_CTRL-K	CTRL-W CTRL-K	same as "CTRL-W k"
CTRL-W_CTRL-L	CTRL-W CTRL-L	same as "CTRL-W l"
CTRL-W_CTRL-N	CTRL-W CTRL-N	same as "CTRL-W n"
CTRL-W_CTRL-O	CTRL-W CTRL-O	same as "CTRL-W o"
CTRL-W_CTRL-P	CTRL-W CTRL-P	same as "CTRL-W p"
CTRL-W_CTRL-Q	CTRL-W CTRL-Q	same as "CTRL-W q"
CTRL-W_CTRL-R	CTRL-W CTRL-R	same as "CTRL-W r"
CTRL-W_CTRL-S	CTRL-W CTRL-S	same as "CTRL-W s"
CTRL-W_CTRL-T	CTRL-W CTRL-T	same as "CTRL-W t"
CTRL-W_CTRL-V	CTRL-W CTRL-V	same as "CTRL-W v"
CTRL-W_CTRL-W	CTRL-W CTRL-W	same as "CTRL-W w"
CTRL-W_CTRL-X	CTRL-W CTRL-X	same as "CTRL-W x"
CTRL-W_CTRL-Z	CTRL-W CTRL-Z	same as "CTRL-W z"
CTRL-W_CTRL-]	CTRL-W CTRL-]	same as "CTRL-W]"
CTRL-W_CTRL-^	CTRL-W CTRL-^	same as "CTRL-W ^"
CTRL-W_CTRL-_	CTRL-W CTRL-_	same as "CTRL-W _"
CTRL-W_quote	CTRL-W "	terminal window: paste register
CTRL-W_+	CTRL-W +	increase current window height N lines
CTRL-W_-	CTRL-W -	decrease current window height N lines
CTRL-W_.	CTRL-W .	terminal window: type CTRL-W
CTRL-W_:	CTRL-W :	same as : , edit a command line
CTRL-W_<	CTRL-W <	decrease current window width N columns
CTRL-W_=	CTRL-W =	make all windows the same height & width
CTRL-W_>	CTRL-W >	increase current window width N columns
CTRL-W_H	CTRL-W H	move current window to the far left
CTRL-W_J	CTRL-W J	move current window to the very bottom

CTRL-W_K	CTRL-W K	move current window to the very top
CTRL-W_L	CTRL-W L	move current window to the far right
CTRL-W_N	CTRL-W N	terminal window: go to Terminal Normal mode
CTRL-W_P	CTRL-W P	go to preview window
CTRL-W_R	CTRL-W R	rotate windows upwards N times
CTRL-W_S	CTRL-W S	same as "CTRL-W s"
CTRL-W_T	CTRL-W T	move current window to a new tab page
CTRL-W_W	CTRL-W W	go to N previous window (wrap around)
CTRL-W_]	CTRL-W]	split window and jump to tag under cursor
CTRL-W_^	CTRL-W ^	split current window and edit alternate file N
CTRL-W__	CTRL-W _	set current window height to N (default: very high)
CTRL-W_b	CTRL-W b	go to bottom window
CTRL-W_c	CTRL-W c	close current window (like :close)
CTRL-W_d	CTRL-W d	split window and jump to definition under the cursor
CTRL-W_f	CTRL-W f	split window and edit file name under the cursor
CTRL-W_F	CTRL-W F	split window and edit file name under the cursor and jump to the line number following the file name.
CTRL-W_g_CTRL-]	CTRL-W g CTRL-]	split window and do :tjump to tag under cursor
CTRL-W_g]	CTRL-W g]	split window and do :tselect for tag under cursor
CTRL-W_g}	CTRL-W g }	do a :ptjump to the tag under the cursor
CTRL-W_gf	CTRL-W g f	edit file name under the cursor in a new tab page
CTRL-W_gF	CTRL-W g F	edit file name under the cursor in a new tab page and jump to the line number following the file name.
CTRL-W_h	CTRL-W h	go to Nth left window (stop at first window)
CTRL-W_i	CTRL-W i	split window and jump to declaration of identifier under the cursor
CTRL-W_j	CTRL-W j	go N windows down (stop at last window)
CTRL-W_k	CTRL-W k	go N windows up (stop at first window)
CTRL-W_l	CTRL-W l	go to Nth right window (stop at last window)
CTRL-W_n	CTRL-W n	open new window, N lines high
CTRL-W_o	CTRL-W o	close all but current window (like :only)
CTRL-W_p	CTRL-W p	go to previous (last accessed) window
CTRL-W_q	CTRL-W q	quit current window (like :quit)
CTRL-W_r	CTRL-W r	rotate windows downwards N times
CTRL-W_s	CTRL-W s	split current window in two parts, new window N lines high
CTRL-W_t	CTRL-W t	go to top window
CTRL-W_v	CTRL-W v	split current window vertically, new window N columns wide
CTRL-W_w	CTRL-W w	go to N next window (wrap around)
CTRL-W_x	CTRL-W x	exchange current window with window N (default: next window)
CTRL-W_z	CTRL-W z	close preview window
CTRL-W_bar	CTRL-W |	set window width to N columns
CTRL-W_}	CTRL-W }	show tag under cursor in preview window

CTRL-W_<Down>	CTRL-W <Down>	same as "CTRL-W j"
CTRL-W_<Up>	CTRL-W <Up>	same as "CTRL-W k"
CTRL-W_<Left>	CTRL-W <Left>	same as "CTRL-W h"
CTRL-W_<Right>	CTRL-W <Right>	same as "CTRL-W l"

2.3 Square bracket commands [ ]

tag	char	note	action in Normal mode
[_CTRL-D	[CTRL-D		jump to first #define found in current and included files matching the word under the cursor, start searching at beginning of current file
[_CTRL-I	[CTRL-I		jump to first line in current and included files that contains the word under the cursor, start searching at beginning of current file
[#	[#	1	cursor to N previous unmatched #if, #else or #ifdef
['	['	1	cursor to previous lowercase mark, on first non-blank
[(	[(	1	cursor N times back to unmatched '('
[star	[*	1	same as "[/"
[`	[`	1	cursor to previous lowercase mark
[/	[/	1	cursor to N previous start of a C comment
[D	[D		list all defines found in current and included files matching the word under the cursor, start searching at beginning of current file
[I	[I		list all lines found in current and included files that contain the word under the cursor, start searching at beginning of current file
[P	[P	2	same as "[p"
[[	[[	1	cursor N sections backward
[]	[]	1	cursor N SECTIONS backward
[c	[c	1	cursor N times backwards to start of change
[d	[d		show first #define found in current and included files matching the word under the cursor, start searching at beginning of current file
[f	[f		same as "gf"
[i	[i		show first line found in current and included files that contains the word under the cursor, start searching at beginning of current file
[m	[m	1	cursor N times back to start of member function
[p	[p	2	like "P", but adjust indent to current line
[s	[s	1	move to the previous misspelled word
[z	[z	1	move to start of open fold
[{	[{	1	cursor N times back to unmatched '{'
[<MiddleMouse>	[<MiddleMouse>	2	same as "[p"

]_CTRL-D	] CTRL-D		jump to first #define found in current and included files matching the word under the cursor, start searching at cursor position
]_CTRL-I	] CTRL-I		jump to first line in current and included files that contains the word under the cursor, start searching at cursor position
]#	]#	1	cursor to N next unmatched #endif or #else
]'	]'	1	cursor to next lowercase mark, on first non-blank
])	])	1	cursor N times forward to unmatched ')'
]star	]*	1	same as "]/"
]`	]`	1	cursor to next lowercase mark
]/	]/	1	cursor to N next end of a C comment
]D	]D		list all #defines found in current and included files matching the word under the cursor, start searching at cursor position
]I	]I		list all lines found in current and included files that contain the word under the cursor, start searching at cursor position
]P	]P	2	same as "[p"
][	][	1	cursor N SECTIONS forward
]]	]]	1	cursor N sections forward
]c	]c	1	cursor N times forward to start of change
]d	]d		show first #define found in current and included files matching the word under the cursor, start searching at cursor position
]f	]f		same as "gf"
]i	]i		show first line found in current and included files that contains the word under the cursor, start searching at cursor position
]m	]m	1	cursor N times forward to end of member function
]p	]p	2	like "p", but adjust indent to current line
]s	]s	1	move to next misspelled word
]z	]z	1	move to end of open fold
]}	]}	1	cursor N times forward to unmatched '}'
]<MiddleMouse>	]<MiddleMouse>	2	same as "]p"

==========

2.4 Commands starting with 'g' g

tag	char	note	action in Normal mode
g_CTRL-A	g CTRL-A		only when compiled with MEM_PROFILE defined: dump a memory profile
g_CTRL-G	g CTRL-G		show information about current cursor position
g_CTRL-H	g CTRL-H		start Select block mode
g_CTRL-]	g CTRL-]		:tjump to the tag under the cursor
g#	g#	1	like "#", but without using "\<" and "\>"
g$	g$	1	when 'wrap' off go to rightmost character of

			the current line that is on the screen; when 'wrap' on go to the rightmost character of the current screen line
g&	g&	2	repeat last ":s" on all lines
g'	g'{mark}	1	like ' but without changing the jumplist
g`	g`{mark}	1	like ` but without changing the jumplist
gstar	g*	1	like "*", but without using "\<" and "\>"
g+	g+		go to newer text state N times
g,	g,	1	go to N newer position in change list
g-	g-		go to older text state N times
g0	g0	1	when 'wrap' off go to leftmost character of the current line that is on the screen; when 'wrap' on go to the leftmost character of the current screen line
g8	g8		print hex value of bytes used in UTF-8 character under the cursor
g;	g;	1	go to N older position in change list
g<	g<		display previous command output
g?	g?	2	Rot13 encoding operator
g?g?	g??	2	Rot13 encode current line
g?g?	g?g?	2	Rot13 encode current line
gD	gD	1	go to definition of word under the cursor in current file
gE	gE	1	go backwards to the end of the previous WORD
gH	gH		start Select line mode
gI	gI	2	like "I", but always start in column 1
gJ	gJ	2	join lines without inserting space
gN	gN	1,2	find the previous match with the last used search pattern and Visually select it
gP	["x]gP	2	put the text [from register x] before the cursor N times, leave the cursor after it
gQ	gQ		switch to "Ex" mode with Vim editing
gR	gR	2	enter Virtual Replace mode
gT	gT		go to the previous tab page
gU	gU{motion}	2	make Nmove text uppercase
gV	gV		don't reselect the previous Visual area when executing a mapping or menu in Select mode
g]	g]		:tselect on the tag under the cursor
g^	g^	1	when 'wrap' off go to leftmost non-white character of the current line that is on the screen; when 'wrap' on go to the leftmost non-white character of the current screen line
g_	g_	1	cursor to the last CHAR N - 1 lines lower
ga	ga		print ascii value of character under the cursor
gd	gd	1	go to definition of word under the cursor in current function
ge	ge	1	go backwards to the end of the previous word
gf	gf		start editing the file whose name is under the cursor

gF	gF		start editing the file whose name is under the cursor and jump to the line number following the filename.
gg	gg	1	cursor to line N, default first line
gh	gh		start Select mode
gi	gi	2	like "i", but first move to the '^ mark
gj	gj	1	like "j", but when 'wrap' on go N screen lines down
gk	gk	1	like "k", but when 'wrap' on go N screen lines up
gn	gn	1,2	find the next match with the last used search pattern and Visually select it
gm	gm	1	go to character at middle of the screenline
go	go	1	cursor to byte N in the buffer
gp	["x]gp	2	put the text [from register x] after the cursor N times, leave the cursor after it
gq	gq{motion}	2	format Nmove text
gr	gr{char}	2	virtual replace N chars with {char}
gs	gs		go to sleep for N seconds (default 1)
gt	gt		go to the next tab page
gu	gu{motion}	2	make Nmove text lowercase
gv	gv		reselect the previous Visual area
gw	gw{motion}	2	format Nmove text and keep cursor
netrw-gx	gx		execute application for file name under the cursor (only with netrw plugin)
g@	g@{motion}		call 'operatorfunc'
g~	g~{motion}	2	swap case for Nmove text
g<Down>	g<Down>	1	same as "gj"
g<End>	g<End>	1	same as "g$"
g<Home>	g<Home>	1	same as "g0"
g<LeftMouse>	g<LeftMouse>		same as <C-LeftMouse>
	g<MiddleMouse>		same as <C-MiddleMouse>
g<RightMouse>	g<RightMouse>		same as <C-RightMouse>
g<Up>	g<Up>	1	same as "gk"

==========

2.5 Commands starting with 'z' z

tag	char	note	action in Normal mode
z<CR>	z<CR>		redraw, cursor line to top of window, cursor on first non-blank
zN<CR>	z{height}<CR>		redraw, make window {height} lines high
z+	z+		cursor on line N (default line below window), otherwise like "z<CR>"
z-	z-		redraw, cursor line at bottom of window, cursor on first non-blank
z.	z.		redraw, cursor line to center of window, cursor on first non-blank
z=	z=		give spelling suggestions
zA	zA		open a closed fold or close an open fold recursively
zC	zC		close folds recursively
zD	zD		delete folds recursively

zE	zE		eliminate all folds
zF	zF		create a fold for N lines
zG	zG		mark word as good spelled word
zH	zH		when 'wrap' off scroll half a screenwidth to the right
zL	zL		when 'wrap' off scroll half a screenwidth to the left
zM	zM		set 'foldlevel' to zero
zN	zN		set 'foldenable'
zO	zO		open folds recursively
zR	zR		set 'foldlevel' to the deepest fold
zW	zW		mark word as wrong (bad) spelled word
zX	zX		re-apply 'foldlevel'
z^	z^		cursor on line N (default line above window), otherwise like "z-"
za	za		open a closed fold, close an open fold
zb	zb		redraw, cursor line at bottom of window
zc	zc		close a fold
zd	zd		delete a fold
ze	ze		when 'wrap' off scroll horizontally to position the cursor at the end (right side) of the screen
zf	zf{motion}		create a fold for Nmove text
zg	zg		mark word as good spelled word
zh	zh		when 'wrap' off scroll screen N characters to the right
zi	zi		toggle 'foldenable'
zj	zj	1	move to the start of the next fold
zk	zk	1	move to the end of the previous fold
zl	zl		when 'wrap' off scroll screen N characters to the left
zm	zm		subtract one from 'foldlevel'
zn	zn		reset 'foldenable'
zo	zo		open fold
zr	zr		add one to 'foldlevel'
zs	zs		when 'wrap' off scroll horizontally to position the cursor at the start (left side) of the screen
zt	zt		redraw, cursor line at top of window
zv	zv		open enough folds to view the cursor line
zw	zw		mark word as wrong (bad) spelled word
zx	zx		re-apply 'foldlevel' and do "zv"
zz	zz		redraw, cursor line at center of window
z<Left>	z<Left>		same as "zh"
z<Right>	z<Right>		same as "zl"

==========

3. Visual mode visual-index

Most commands in Visual mode are the same as in Normal mode. The ones listed here are those that are different.

tag	command	note	action in Visual mode

```
v_CTRL-\_CTRL-N  CTRL-\ CTRL-N    stop Visual mode
v_CTRL-\_CTRL-G  CTRL-\ CTRL-G    go to mode specified with 'insertmode'
v_CTRL-A        CTRL-A          2 add N to number in highlighted text
v_CTRL-C        CTRL-C            stop Visual mode
v_CTRL-G        CTRL-G            toggle between Visual mode and Select mode
v_<BS>          <BS>            2 Select mode: delete highlighted area
v_CTRL-H        CTRL-H          2 same as <BS>
v_CTRL-O        CTRL-O            switch from Select to Visual mode for one
                                  command
v_CTRL-V        CTRL-V            make Visual mode blockwise or stop Visual
                                  mode
v_CTRL-X        CTRL-X          2 subtract N from number in highlighted text
v_<Esc>         <Esc>             stop Visual mode
v_CTRL-]        CTRL-]            jump to highlighted tag
v_!             !{filter}       2 filter the highlighted lines through the
                                  external command {filter}
v_:             :                 start a command-line with the highlighted
                                  lines as a range
v_<             <               2 shift the highlighted lines one
                                  'shiftwidth' left
v_=             =               2 filter the highlighted lines through the
                                  external program given with the 'equalprg'
                                  option
v_>             >               2 shift the highlighted lines one
                                  'shiftwidth' right
v_b_A           A               2 block mode: append same text in all lines,
                                  after the highlighted area
v_C             C               2 delete the highlighted lines and start
                                  insert
v_D             D               2 delete the highlighted lines
v_b_I           I               2 block mode: insert same text in all lines,
                                  before the highlighted area
v_J             J               2 join the highlighted lines
v_K             K                 run 'keywordprg' on the highlighted area
v_O             O                 Move horizontally to other corner of area.
                Q                 does not start Ex mode
v_R             R               2 delete the highlighted lines and start
                                  insert
v_S             S               2 delete the highlighted lines and start
                                  insert
v_U             U               2 make highlighted area uppercase
v_V             V                 make Visual mode linewise or stop Visual
                                  mode
v_X             X               2 delete the highlighted lines
v_Y             Y                 yank the highlighted lines
v_aquote        a"                extend highlighted area with a double
                                  quoted string
v_a'            a'                extend highlighted area with a single
                                  quoted string
v_a(            a(                same as ab
v_a)            a)                same as ab
v_a<            a<                extend highlighted area with a <> block
v_a>            a>                same as a<
v_aB            aB                extend highlighted area with a {} block
```

v_aW	aW		extend highlighted area with "a WORD"
v_a[	a[		extend highlighted area with a [] block
v_a]	a]		same as a[
v_a`	a`		extend highlighted area with a backtick quoted string
v_ab	ab		extend highlighted area with a () block
v_ap	ap		extend highlighted area with a paragraph
v_as	as		extend highlighted area with a sentence
v_at	at		extend highlighted area with a tag block
v_aw	aw		extend highlighted area with "a word"
v_a{	a{		same as aB
v_a}	a}		same as aB
v_c	c	2	delete highlighted area and start insert
v_d	d	2	delete highlighted area
v_g_CTRL-A	g CTRL-A	2	add N to number in highlighted text
v_g_CTRL-X	g CTRL-X	2	subtract N from number in highlighted text
v_gJ	gJ	2	join the highlighted lines without inserting spaces
v_gq	gq	2	format the highlighted lines
v_gv	gv		exchange current and previous highlighted area
v_iquote	i"		extend highlighted area with a double quoted string (without quotes)
v_i'	i'		extend highlighted area with a single quoted string (without quotes)
v_i(	i(		same as ib
v_i)	i)		same as ib
v_i<	i<		extend highlighted area with inner <> block
v_i>	i>		same as i<
v_iB	iB		extend highlighted area with inner {} block
v_iW	iW		extend highlighted area with "inner WORD"
v_i[	i[		extend highlighted area with inner [] block
v_i]	i]		same as i[
v_i`	i`		extend highlighted area with a backtick quoted string (without the backticks)
v_ib	ib		extend highlighted area with inner () block
v_ip	ip		extend highlighted area with inner paragraph
v_is	is		extend highlighted area with inner sentence
v_it	it		extend highlighted area with inner tag block
v_iw	iw		extend highlighted area with "inner word"
v_i{	i{		same as iB
v_i}	i}		same as iB
v_o	o		move cursor to other corner of area
v_r	r	2	replace highlighted area with a character
v_s	s	2	delete highlighted area and start insert
v_u	u	2	make highlighted area lowercase
v_v	v		make Visual mode characterwise or stop Visual mode
v_x	x	2	delete the highlighted area
v_y	y		yank the highlighted area
v_~	~	2	swap case for the highlighted area

==========

4. Command-line editing ex-edit-index

Get to the command-line with the ':', '!', '/' or '?' commands.
Normal characters are inserted at the current cursor position.
"Completion" below refers to context-sensitive completion. It will complete
file names, tags, commands etc. as appropriate.

tag	command	action in Command-line editing mode
	CTRL-@	not used
c_CTRL-A	CTRL-A	do completion on the pattern in front of the cursor and insert all matches
c_CTRL-B	CTRL-B	cursor to begin of command-line
c_CTRL-C	CTRL-C	same as <Esc>
c_CTRL-D	CTRL-D	list completions that match the pattern in front of the cursor
c_CTRL-E	CTRL-E	cursor to end of command-line
'cedit'	CTRL-F	default value for 'cedit': opens the command-line window; otherwise not used
c_CTRL-G	CTRL-G	next match when 'incsearch' is active
c_<BS>	<BS>	delete the character in front of the cursor
c_digraph	{char1} <BS> {char2}	enter digraph when 'digraph' is on
c_CTRL-H	CTRL-H	same as <BS>
c_<Tab>	<Tab>	if 'wildchar' is <Tab>: Do completion on the pattern in front of the cursor
c_<S-Tab>	<S-Tab>	same as CTRL-P
c_wildchar	'wildchar'	Do completion on the pattern in front of the cursor (default: <Tab>)
c_CTRL-I	CTRL-I	same as <Tab>
c_<NL>	<NL>	same as <CR>
c_CTRL-J	CTRL-J	same as <CR>
c_CTRL-K	CTRL-K {char1} {char2}	enter digraph
c_CTRL-L	CTRL-L	do completion on the pattern in front of the cursor and insert the longest common part
c_<CR>	<CR>	execute entered command
c_CTRL-M	CTRL-M	same as <CR>
c_CTRL-N	CTRL-N	after using 'wildchar' with multiple matches: go to next match, otherwise: recall older command-line from history.
	CTRL-O	not used
c_CTRL-P	CTRL-P	after using 'wildchar' with multiple matches: go to previous match, otherwise: recall older command-line from history.
c_CTRL-Q	CTRL-Q	same as CTRL-V, unless it's used for terminal control flow
c_CTRL-R	CTRL-R {0-9a-z"%#*:= CTRL-F CTRL-P CTRL-W CTRL-A}	insert the contents of a register or object under the cursor as if typed
c_CTRL-R_CTRL-R	CTRL-R CTRL-R {0-9a-z"%#*:= CTRL-F CTRL-P CTRL-W CTRL-A}	insert the contents of a register or object under the cursor literally
	CTRL-S	(used for terminal control flow)
c_CTRL-T	CTRL-T	previous match when 'incsearch' is active

```
 c_CTRL-U       CTRL-U          remove all characters
 c_CTRL-V       CTRL-V          insert next non-digit literally, insert three
                                digit decimal number as a single byte.
 c_CTRL-W       CTRL-W          delete the word in front of the cursor
                CTRL-X          not used (reserved for completion)
                CTRL-Y          copy (yank) modeless selection
                CTRL-Z          not used (reserved for suspend)
 c_<Esc>        <Esc>           abandon command-line without executing it
 c_CTRL-[       CTRL-[          same as <Esc>
 c_CTRL-\_CTRL-N  CTRL-\ CTRL-N go to Normal mode, abandon command-line
 c_CTRL-\_CTRL-G  CTRL-\ CTRL-G go to mode specified with 'insertmode',
                                abandon command-line
                CTRL-\ a - d    reserved for extensions
 c_CTRL-\_e     CTRL-\ e {expr} replace the command line with the result of
                                {expr}
                CTRL-\ f - z    reserved for extensions
                CTRL-\ others   not used
 c_CTRL-]       CTRL-]          trigger abbreviation
 c_CTRL-^       CTRL-^          toggle use of  :lmap  mappings
 c_CTRL-_       CTRL-_          when 'allowrevins' set: change language
                                (Hebrew, Farsi)
 c_<Del>        <Del>           delete the character under the cursor

 c_<Left>       <Left>          cursor left
 c_<S-Left>     <S-Left>        cursor one word left
 c_<C-Left>     <C-Left>        cursor one word left
 c_<Right>      <Right>         cursor right
 c_<S-Right>    <S-Right>       cursor one word right
 c_<C-Right>    <C-Right>       cursor one word right
 c_<Up>         <Up>            recall previous command-line from history that
                                matches pattern in front of the cursor
 c_<S-Up>       <S-Up>          recall previous command-line from history
 c_<Down>       <Down>          recall next command-line from history that
                                matches pattern in front of the cursor
 c_<S-Down>     <S-Down>        recall next command-line from history
 c_<Home>       <Home>          cursor to start of command-line
 c_<End>        <End>           cursor to end of command-line
 c_<PageDown>   <PageDown>      same as <S-Down>
 c_<PageUp>     <PageUp>        same as <S-Up>
 c_<Insert>     <Insert>        toggle insert/overstrike mode
 c_<LeftMouse>  <LeftMouse>     cursor at mouse click

You found it, Arthur!                                holy-grail   :smile

==============================================================================
5. EX commands                                       ex-cmd-index   :index

This is a brief but complete listing of all the ":" commands, without
mentioning any arguments.  The optional part of the command name is inside [].
The commands are sorted on the non-optional part of their name.

tag           command         action
------------------------------------------------------------------------------
 :!             :!              filter lines or execute an external command
```

:!!	:!!	repeat last ":!" command
:#	:#	same as ":number"
:&	:&	repeat last ":substitute"
:star	:*	execute contents of a register
:<	:<	shift lines one 'shiftwidth' left
:=	:=	print the cursor line number
:>	:>	shift lines one 'shiftwidth' right
:@	:@	execute contents of a register
:@@	:@@	repeat the previous ":@"
:Next	:N[ext]	go to previous file in the argument list
:Print	:P[rint]	print lines
:X	:X	ask for encryption key
:append	:a[ppend]	append text
:abbreviate	:ab[breviate]	enter abbreviation
:abclear	:abc[lear]	remove all abbreviations
:aboveleft	:abo[veleft]	make split window appear left or above
:all	:al[l]	open a window for each file in the argument list
:amenu	:am[enu]	enter new menu item for all modes
:anoremenu	:an[oremenu]	enter a new menu for all modes that will not be remapped
:args	:ar[gs]	print the argument list
:argadd	:arga[dd]	add items to the argument list
:argdelete	:argd[elete]	delete items from the argument list
:argedit	:arge[dit]	add item to the argument list and edit it
:argdo	:argdo	do a command on all items in the argument list
:argglobal	:argg[lobal]	define the global argument list
:arglocal	:argl[ocal]	define a local argument list
:argument	:argu[ment]	go to specific file in the argument list
:ascii	:as[cii]	print ascii value of character under the cursor
:autocmd	:au[tocmd]	enter or show autocommands
:augroup	:aug[roup]	select the autocommand group to use
:aunmenu	:aun[menu]	remove menu for all modes
:buffer	:b[uffer]	go to specific buffer in the buffer list
:bNext	:bN[ext]	go to previous buffer in the buffer list
:ball	:ba[ll]	open a window for each buffer in the buffer list
:badd	:bad[d]	add buffer to the buffer list
:bdelete	:bd[elete]	remove a buffer from the buffer list
:behave	:be[have]	set mouse and selection behavior
:belowright	:bel[owright]	make split window appear right or below
:bfirst	:bf[irst]	go to first buffer in the buffer list
:blast	:bl[ast]	go to last buffer in the buffer list
:bmodified	:bm[odified]	go to next buffer in the buffer list that has been modified
:bnext	:bn[ext]	go to next buffer in the buffer list
:botright	:bo[tright]	make split window appear at bottom or far right
:bprevious	:bp[revious]	go to previous buffer in the buffer list
:brewind	:br[ewind]	go to first buffer in the buffer list
:break	:brea[k]	break out of while loop
:breakadd	:breaka[dd]	add a debugger breakpoint
:breakdel	:breakd[el]	delete a debugger breakpoint
:breaklist	:breakl[ist]	list debugger breakpoints
:browse	:bro[wse]	use file selection dialog
:bufdo	:bufdo	execute command in each listed buffer

:buffers	:buffers	list all files in the buffer list
:bunload	:bun[load]	unload a specific buffer
:bwipeout	:bw[ipeout]	really delete a buffer
:change	:c[hange]	replace a line or series of lines
:cNext	:cN[ext]	go to previous error
:cNfile	:cNf[ile]	go to last error in previous file
:cabbrev	:ca[bbrev]	like ":abbreviate" but for Command-line mode
:cabclear	:cabc[lear]	clear all abbreviations for Command-line mode
:caddbuffer	:cad[dbuffer]	add errors from buffer
:caddexpr	:cadde[xpr]	add errors from expr
:caddfile	:caddf[ile]	add error message to current quickfix list
:call	:cal[l]	call a function
:catch	:cat[ch]	part of a :try command
:cbottom	:cbo[ttom]	scroll to the bottom of the quickfix window
:cbuffer	:cb[uffer]	parse error messages and jump to first error
:cc	:cc	go to specific error
:cclose	:ccl[ose]	close quickfix window
:cd	:cd	change directory
:cdo	:cdo	execute command in each valid error list entry
:cfdo	:cfd[o]	execute command in each file in error list
:center	:ce[nter]	format lines at the center
:cexpr	:cex[pr]	read errors from expr and jump to first
:cfile	:cf[ile]	read file with error messages and jump to first
:cfirst	:cfir[st]	go to the specified error, default first one
:cgetbuffer	:cgetb[uffer]	get errors from buffer
:cgetexpr	:cgete[xpr]	get errors from expr
:cgetfile	:cg[etfile]	read file with error messages
:changes	:changes	print the change list
:chdir	:chd[ir]	change directory
:checkpath	:che[ckpath]	list included files
:checktime	:checkt[ime]	check timestamp of loaded buffers
:chistory	:chi[story]	list the error lists
:clast	:cla[st]	go to the specified error, default last one
:clearjumps	:cle[arjumps]	clear the jump list
:clist	:cl[ist]	list all errors
:close	:clo[se]	close current window
:cmap	:cm[ap]	like ":map" but for Command-line mode
:cmapclear	:cmapc[lear]	clear all mappings for Command-line mode
:cmenu	:cme[nu]	add menu for Command-line mode
:cnext	:cn[ext]	go to next error
:cnewer	:cnew[er]	go to newer error list
:cnfile	:cnf[ile]	go to first error in next file
:cnoremap	:cno[remap]	like ":noremap" but for Command-line mode
:cnoreabbrev	:cnorea[bbrev]	like ":noreabbrev" but for Command-line mode
:cnoremenu	:cnoreme[nu]	like ":noremenu" but for Command-line mode
:copy	:co[py]	copy lines
:colder	:col[der]	go to older error list
:colorscheme	:colo[rscheme]	load a specific color scheme
:command	:com[mand]	create user-defined command
:comclear	:comc[lear]	clear all user-defined commands
:compiler	:comp[iler]	do settings for a specific compiler
:continue	:con[tinue]	go back to :while
:confirm	:conf[irm]	prompt user when confirmation required
:copen	:cope[n]	open quickfix window

```
:cprevious      :cp[revious]    go to previous error
:cpfile         :cpf[ile]       go to last error in previous file
:cquit          :cq[uit]        quit Vim with an error code
:crewind        :cr[ewind]      go to the specified error, default first one
:cscope         :cs[cope]       execute cscope command
:cstag          :cst[ag]        use cscope to jump to a tag
:cunmap         :cu[nmap]       like ":unmap" but for Command-line mode
:cunabbrev      :cuna[bbrev]    like ":unabbrev" but for Command-line mode
:cunmenu        :cunme[nu]      remove menu for Command-line mode
:cwindow        :cw[indow]      open or close quickfix window
:delete         :d[elete]       delete lines
:delmarks       :delm[arks]     delete marks
:debug          :deb[ug]        run a command in debugging mode
:debuggreedy    :debugg[reedy]  read debug mode commands from normal input
:delcommand     :delc[ommand]   delete user-defined command
:delfunction    :delf[unction]  delete a user function
:diffupdate     :dif[fupdate]   update 'diff' buffers
:diffget        :diffg[et]      remove differences in current buffer
:diffoff        :diffo[ff]      switch off diff mode
:diffpatch      :diffp[atch]    apply a patch and show differences
:diffput        :diffpu[t]      remove differences in other buffer
:diffsplit      :diffs[plit]    show differences with another file
:diffthis       :diffthis       make current window a diff window
:digraphs       :dig[raphs]     show or enter digraphs
:display        :di[splay]      display registers
:djump          :dj[ump]        jump to #define
:dl             :dl             short for  :delete  with the 'l' flag
:del            :del[ete]l      short for  :delete  with the 'l' flag
:dlist          :dli[st]        list #defines
:doautocmd      :do[autocmd]    apply autocommands to current buffer
:doautoall      :doautoa[ll]    apply autocommands for all loaded buffers
:dp             :d[elete]p      short for  :delete  with the 'p' flag
:drop           :dr[op]         jump to window editing file or edit file in
                                current window
:dsearch        :ds[earch]      list one #define
:dsplit         :dsp[lit]       split window and jump to #define
:edit           :e[dit]         edit a file
:earlier        :ea[rlier]      go to older change, undo
:echo           :ec[ho]         echoes the result of expressions
:echoerr        :echoe[rr]      like :echo, show like an error and use history
:echohl         :echoh[l]       set highlighting for echo commands
:echomsg        :echom[sg]      same as :echo, put message in history
:echon          :echon          same as :echo, but without <EOL>
:else           :el[se]         part of an :if command
:elseif         :elsei[f]       part of an :if command
:emenu          :em[enu]        execute a menu by name
:endif          :en[dif]        end previous :if
:endfor         :endfo[r]       end previous :for
:endfunction    :endf[unction]  end of a user function
:endtry         :endt[ry]       end previous :try
:endwhile       :endw[hile]     end previous :while
:enew           :ene[w]         edit a new, unnamed buffer
:ex             :ex             same as ":edit"
:execute        :exe[cute]      execute result of expressions
```

```
:exit           :exi[t]          same as ":xit"
:exusage        :exu[sage]       overview of Ex commands
:file           :f[ile]          show or set the current file name
:files          :files           list all files in the buffer list
:filetype       :filet[ype]      switch file type detection on/off
:filter         :filt[er]        filter output of following command
:find           :fin[d]          find file in 'path' and edit it
:finally        :fina[lly]       part of a :try command
:finish         :fini[sh]        quit sourcing a Vim script
:first          :fir[st]         go to the first file in the argument list
:fixdel         :fix[del]        set key code of <Del>
:fold           :fo[ld]          create a fold
:foldclose      :foldc[lose]     close folds
:folddoopen     :foldd[oopen]    execute command on lines not in a closed fold
:folddoclosed   :folddoc[losed]  execute command on lines in a closed fold
:foldopen       :foldo[pen]      open folds
:for            :for             for loop
:function       :fu[nction]      define a user function
:global         :g[lobal]        execute commands for matching lines
:goto           :go[to]          go to byte in the buffer
:grep           :gr[ep]          run 'grepprg' and jump to first match
:grepadd        :grepa[dd]       like :grep, but append to current list
:gui            :gu[i]           start the GUI
:gvim           :gv[im]          start the GUI
:hardcopy       :ha[rdcopy]      send text to the printer
:help           :h[elp]          open a help window
:helpclose      :helpc[lose]     close one help window
:helpfind       :helpf[ind]      dialog to open a help window
:helpgrep       :helpg[rep]      like ":grep" but searches help files
:helptags       :helpt[ags]      generate help tags for a directory
:highlight      :hi[ghlight]     specify highlighting methods
:hide           :hid[e]          hide current buffer for a command
:history        :his[tory]       print a history list
:insert         :i[nsert]        insert text
:iabbrev        :ia[bbrev]       like ":abbrev" but for Insert mode
:iabclear       :iabc[lear]      like ":abclear" but for Insert mode
:if             :if              execute commands when condition met
:ijump          :ij[ump]         jump to definition of identifier
:ilist          :il[ist]         list lines where identifier matches
:imap           :im[ap]          like ":map" but for Insert mode
:imapclear      :imapc[lear]     like ":mapclear" but for Insert mode
:imenu          :ime[nu]         add menu for Insert mode
:inoremap       :ino[remap]      like ":noremap" but for Insert mode
:inoreabbrev    :inorea[bbrev]   like ":noreabbrev" but for Insert mode
:inoremenu      :inoreme[nu]     like ":noremenu" but for Insert mode
:intro          :int[ro]         print the introductory message
:isearch        :is[earch]       list one line where identifier matches
:isplit         :isp[lit]        split window and jump to definition of
                                 identifier
:iunmap         :iu[nmap]        like ":unmap" but for Insert mode
:iunabbrev      :iuna[bbrev]     like ":unabbrev" but for Insert mode
:iunmenu        :iunme[nu]       remove menu for Insert mode
:join           :j[oin]          join lines
:jumps          :ju[mps]         print the jump list
```

```
:k              :k              set a mark
:keepalt        :keepa[lt]      following command keeps the alternate file
:keepmarks      :kee[pmarks]    following command keeps marks where they are
:keepjumps      :keepj[umps]    following command keeps jumplist and marks
:keeppatterns   :keepp[atterns] following command keeps search pattern history
:lNext          :lN[ext]        go to previous entry in location list
:lNfile         :lNf[ile]       go to last entry in previous file
:list           :l[ist]         print lines
:laddexpr       :lad[dexpr]     add locations from expr
:laddbuffer     :laddb[uffer]   add locations from buffer
:laddfile       :laddf[ile]     add locations to current location list
:last           :la[st]         go to the last file in the argument list
:language       :lan[guage]     set the language (locale)
:later          :lat[er]        go to newer change, redo
:lbottom        :lbo[ttom]      scroll to the bottom of the location window
:lbuffer        :lb[uffer]      parse locations and jump to first location
:lcd            :lc[d]          change directory locally
:lchdir         :lch[dir]       change directory locally
:lclose         :lcl[ose]       close location window
:lcscope        :lcs[cope]      like ":cscope" but uses location list
:ldo            :ld[o]          execute command in valid location list entries
:lfdo           :lfd[o]         execute command in each file in location list
:left           :le[ft]         left align lines
:leftabove      :lefta[bove]    make split window appear left or above
:let            :let            assign a value to a variable or option
:lexpr          :lex[pr]        read locations from expr and jump to first
:lfile          :lf[ile]        read file with locations and jump to first
:lfirst         :lfir[st]       go to the specified location, default first one
:lgetbuffer     :lgetb[uffer]   get locations from buffer
:lgetexpr       :lgete[xpr]     get locations from expr
:lgetfile       :lg[etfile]     read file with locations
:lgrep          :lgr[ep]        run 'grepprg' and jump to first match
:lgrepadd       :lgrepa[dd]     like :grep, but append to current list
:lhelpgrep      :lh[elpgrep]    like ":helpgrep" but uses location list
:lhistory       :lhi[story]     list the location lists
:ll             :ll             go to specific location
:llast          :lla[st]        go to the specified location, default last one
:llist          :lli[st]        list all locations
:lmake          :lmak[e]        execute external command 'makeprg' and parse
                                error messages
:lmap           :lm[ap]         like ":map!" but includes Lang-Arg mode
:lmapclear      :lmapc[lear]    like ":mapclear!" but includes Lang-Arg mode
:lnext          :lne[xt]        go to next location
:lnewer         :lnew[er]       go to newer location list
:lnfile         :lnf[ile]       go to first location in next file
:lnoremap       :ln[oremap]     like ":noremap!" but includes Lang-Arg mode
:loadkeymap     :loadk[eymap]   load the following keymaps until EOF
:loadview       :lo[adview]     load view for current window from a file
:lockmarks      :loc[kmarks]    following command keeps marks where they are
:lockvar        :lockv[ar]      lock variables
:lolder         :lol[der]       go to older location list
:lopen          :lope[n]        open location window
:lprevious      :lp[revious]    go to previous location
:lpfile         :lpf[ile]       go to last location in previous file
```

```
:lrewind        :lr[ewind]      go to the specified location, default first one
:ls             :ls             list all buffers
:ltag           :lt[ag]         jump to tag and add matching tags to the
                                location list
:lunmap         :lu[nmap]       like ":unmap!" but includes Lang-Arg mode
:lua            :lua            execute  Lua  command
:luado          :luad[o]        execute Lua command for each line
:luafile        :luaf[ile]      execute  Lua  script file
:lvimgrep       :lv[imgrep]     search for pattern in files
:lvimgrepadd    :lvimgrepa[dd]  like :vimgrep, but append to current list
:lwindow        :lw[indow]      open or close location window
:move           :m[ove]         move lines
:mark           :ma[rk]         set a mark
:make           :mak[e]         execute external command 'makeprg' and parse
                                error messages
:map            :map            show or enter a mapping
:mapclear       :mapc[lear]     clear all mappings for Normal and Visual mode
:marks          :marks          list all marks
:match          :mat[ch]        define a match to highlight
:menu           :me[nu]         enter a new menu item
:menutranslate    :menut[ranslate] add a menu translation item
:messages       :mes[sages]     view previously displayed messages
:mkexrc         :mk[exrc]       write current mappings and settings to a file
:mksession      :mks[ession]    write session info to a file
:mkspell        :mksp[ell]      produce .spl spell file
:mkvimrc        :mkv[imrc]      write current mappings and settings to a file
:mkview         :mkvie[w]       write view of current window to a file
:mode           :mod[e]         show or change the screen mode
:mzscheme       :mz[scheme]     execute MzScheme command
:mzfile         :mzf[ile]       execute MzScheme script file
:nbclose        :nbc[lose]      close the current Netbeans session
:nbkey          :nb[key]        pass a key to Netbeans
:nbstart        :nbs[art]       start a new Netbeans session
:next           :n[ext]         go to next file in the argument list
:new            :new            create a new empty window
:nmap           :nm[ap]         like ":map" but for Normal mode
:nmapclear      :nmapc[lear]    clear all mappings for Normal mode
:nmenu          :nme[nu]        add menu for Normal mode
:nnoremap       :nn[oremap]     like ":noremap" but for Normal mode
:nnoremenu      :nnoreme[nu]    like ":noremenu" but for Normal mode
:noautocmd      :noa[utocmd]    following commands don't trigger autocommands
:noremap        :no[remap]      enter a mapping that will not be remapped
:nohlsearch     :noh[lsearch]   suspend 'hlsearch' highlighting
:noreabbrev     :norea[bbrev]   enter an abbreviation that will not be
                                remapped
:noremenu       :noreme[nu]     enter a menu that will not be remapped
:normal         :norm[al]       execute Normal mode commands
:noswapfile     :nos[wapfile]   following commands don't create a swap file
:number         :nu[mber]       print lines with line number
:nunmap         :nun[map]       like ":unmap" but for Normal mode
:nunmenu        :nunme[nu]      remove menu for Normal mode
:oldfiles       :ol[dfiles]     list files that have marks in the viminfo file
:open           :o[pen]         start open mode (not implemented)
:omap           :om[ap]         like ":map" but for Operator-pending mode
```

```
:omapclear      :omapc[lear]    remove all mappings for Operator-pending mode
:omenu          :ome[nu]        add menu for Operator-pending mode
:only           :on[ly]         close all windows except the current one
:onoremap       :ono[remap]     like ":noremap" but for Operator-pending mode
:onoremenu      :onoreme[nu]    like ":noremenu" but for Operator-pending mode
:options        :opt[ions]      open the options-window
:ounmap         :ou[nmap]       like ":unmap" but for Operator-pending mode
:ounmenu        :ounme[nu]      remove menu for Operator-pending mode
:ownsyntax      :ow[nsyntax]    set new local syntax highlight for this window
:packadd        :pa[ckadd]      add a plugin from 'packpath'
:packloadall    :packl[oadall]  load all packages under 'packpath'
:pclose         :pc[lose]       close preview window
:pedit          :ped[it]        edit file in the preview window
:perl           :pe[rl]         execute Perl command
:print          :p[rint]        print lines
:profdel        :profd[el]      stop profiling a function or script
:profile        :prof[ile]      profiling functions and scripts
:promptfind     :pro[mptfind]   open GUI dialog for searching
:promptrepl     :promptr[epl]   open GUI dialog for search/replace
:perldo         :perld[o]       execute Perl command for each line
:pop            :po[p]          jump to older entry in tag stack
:popup          :popu[p]        popup a menu by name
:ppop           :pp[op]         ":pop" in preview window
:preserve       :pre[serve]     write all text to swap file
:previous       :prev[ious]     go to previous file in argument list
:psearch        :ps[earch]      like ":ijump" but shows match in preview window
:ptag           :pt[ag]         show tag in preview window
:ptNext         :ptN[ext]        :tNext  in preview window
:ptfirst        :ptf[irst]       :trewind  in preview window
:ptjump         :ptj[ump]        :tjump  and show tag in preview window
:ptlast         :ptl[ast]        :tlast  in preview window
:ptnext         :ptn[ext]        :tnext  in preview window
:ptprevious     :ptp[revious]    :tprevious  in preview window
:ptrewind       :ptr[ewind]      :trewind  in preview window
:ptselect       :pts[elect]      :tselect  and show tag in preview window
:put            :pu[t]          insert contents of register in the text
:pwd            :pw[d]          print current directory
:py3            :py3            execute Python 3 command
:python3        :python3        same as :py3
:py3do          :py3d[o]        execute Python 3 command for each line
:py3file        :py3f[ile]      execute Python 3 script file
:python         :py[thon]       execute Python command
:pydo           :pyd[o]         execute Python command for each line
:pyfile         :pyf[ile]       execute Python script file
:pyx            :pyx            execute  python_x  command
:pythonx        :pythonx        same as :pyx
:pyxdo          :pyxd[o]        execute  python_x  command for each line
:pyxfile        :pyxf[ile]      execute  python_x  script file
:quit           :q[uit]         quit current window (when one window quit Vim)
:quitall        :quita[ll]      quit Vim
:qall           :qa[ll]         quit Vim
:read           :r[ead]         read file into the text
:recover        :rec[over]      recover a file from a swap file
:redo           :red[o]         redo one undone change
```

```
:redir          :redi[r]        redirect messages to a file or register
:redraw         :redr[aw]       force a redraw of the display
:redrawstatus   :redraws[tatus] force a redraw of the status line(s)
:registers      :reg[isters]    display the contents of registers
:resize         :res[ize]       change current window height
:retab          :ret[ab]        change tab size
:return         :retu[rn]       return from a user function
:rewind         :rew[ind]       go to the first file in the argument list
:right          :ri[ght]        right align text
:rightbelow     :rightb[elow]   make split window appear right or below
:ruby           :rub[y]         execute Ruby command
:rubydo         :rubyd[o]       execute Ruby command for each line
:rubyfile       :rubyf[ile]     execute Ruby script file
:rundo          :rund[o]        read undo information from a file
:runtime        :ru[ntime]      source vim scripts in 'runtimepath'
:rviminfo       :rv[iminfo]     read from viminfo file
:substitute     :s[ubstitute]   find and replace text
:sNext          :sN[ext]        split window and go to previous file in
                                argument list
:sandbox        :san[dbox]      execute a command in the sandbox
:sargument      :sa[rgument]    split window and go to specific file in
                                argument list
:sall           :sal[l]         open a window for each file in argument list
:saveas         :sav[eas]       save file under another name.
:sbuffer        :sb[uffer]      split window and go to specific file in the
                                buffer list
:sbNext         :sbN[ext]       split window and go to previous file in the
                                buffer list
:sball          :sba[ll]        open a window for each file in the buffer list
:sbfirst        :sbf[irst]      split window and go to first file in the
                                buffer list
:sblast         :sbl[ast]       split window and go to last file in buffer
                                list
:sbmodified     :sbm[odified]   split window and go to modified file in the
                                buffer list
:sbnext         :sbn[ext]       split window and go to next file in the buffer
                                list
:sbprevious     :sbp[revious]   split window and go to previous file in the
                                buffer list
:sbrewind       :sbr[ewind]     split window and go to first file in the
                                buffer list
:scriptnames    :scr[iptnames]  list names of all sourced Vim scripts
:scriptencoding  :scripte[ncoding]     encoding used in sourced Vim script
:scscope        :scs[cope]      split window and execute cscope command
:set            :se[t]          show or set options
:setfiletype    :setf[iletype]  set 'filetype', unless it was set already
:setglobal      :setg[lobal]    show global values of options
:setlocal       :setl[ocal]     show or set options locally
:sfind          :sf[ind]        split current window and edit file in 'path'
:sfirst         :sfir[st]       split window and go to first file in the
                                argument list
:shell          :sh[ell]        escape to a shell
:simalt         :sim[alt]       Win32 GUI: simulate Windows ALT key
:sign           :sig[n]         manipulate signs
```

```
:silent         :sil[ent]       run a command silently
:sleep          :sl[eep]        do nothing for a few seconds
:slast          :sla[st]        split window and go to last file in the
                                argument list
:smagic         :sm[agic]       :substitute with 'magic'
:smap           :smap           like ":map" but for Select mode
:smapclear      :smapc[lear]    remove all mappings for Select mode
:smenu          :sme[nu]        add menu for Select mode
:smile          :smi[le]        make the user happy
:snext          :sn[ext]        split window and go to next file in the
                                argument list
:snomagic       :sno[magic]     :substitute with 'nomagic'
:snoremap       :snor[emap]     like ":noremap" but for Select mode
:snoremenu      :snoreme[nu]    like ":noremenu" but for Select mode
:sort           :sor[t]         sort lines
:source         :so[urce]       read Vim or Ex commands from a file
:spelldump      :spelld[ump]    split window and fill with all correct words
:spellgood      :spe[llgood]    add good word for spelling
:spellinfo      :spelli[nfo]    show info about loaded spell files
:spellrepall    :spellr[epall]  replace all bad words like last  z=
:spellundo      :spellu[ndo]    remove good or bad word
:spellwrong     :spellw[rong]   add spelling mistake
:split          :sp[lit]        split current window
:sprevious      :spr[evious]    split window and go to previous file in the
                                argument list
:srewind        :sre[wind]      split window and go to first file in the
                                argument list
:stop           :st[op]         suspend the editor or escape to a shell
:stag           :sta[g]         split window and jump to a tag
:startinsert    :star[tinsert]  start Insert mode
:startgreplace   :startg[replace] start Virtual Replace mode
:startreplace   :startr[eplace] start Replace mode
:stopinsert     :stopi[nsert]   stop Insert mode
:stjump         :stj[ump]       do ":tjump" and split window
:stselect       :sts[elect]     do ":tselect" and split window
:sunhide        :sun[hide]      same as ":unhide"
:sunmap         :sunm[ap]       like ":unmap" but for Select mode
:sunmenu        :sunme[nu]      remove menu for Select mode
:suspend        :sus[pend]      same as ":stop"
:sview          :sv[iew]        split window and edit file read-only
:swapname       :sw[apname]     show the name of the current swap file
:syntax         :sy[ntax]       syntax highlighting
:syntime        :synti[me]      measure syntax highlighting speed
:syncbind       :sync[bind]     sync scroll binding
:t              :t              same as ":copy"
:tNext          :tN[ext]        jump to previous matching tag
:tabNext        :tabN[ext]      go to previous tab page
:tabclose       :tabc[lose]     close current tab page
:tabdo          :tabdo          execute command in each tab page
:tabedit        :tabe[dit]      edit a file in a new tab page
:tabfind        :tabf[ind]      find file in 'path', edit it in a new tab page
:tabfirst       :tabfir[st]     go to first tab page
:tablast        :tabl[ast]      go to last tab page
:tabmove        :tabm[ove]      move tab page to other position
```

```
:tabnew         :tabnew          edit a file in a new tab page
:tabnext        :tabn[ext]       go to next tab page
:tabonly        :tabo[nly]       close all tab pages except the current one
:tabprevious    :tabp[revious]   go to previous tab page
:tabrewind      :tabr[ewind]     go to first tab page
:tabs           :tabs            list the tab pages and what they contain
:tab            :tab             create new tab when opening new window
:tag            :ta[g]           jump to tag
:tags           :tags            show the contents of the tag stack
:tcl            :tc[l]           execute Tcl command
:tcldo          :tcld[o]         execute Tcl command for each line
:tclfile        :tclf[ile]       execute Tcl script file
:tearoff        :te[aroff]       tear-off a menu
:terminal       :ter[minal]      open a terminal window
:tfirst         :tf[irst]        jump to first matching tag
:throw          :th[row]         throw an exception
:tjump          :tj[ump]         like ":tselect", but jump directly when there
                                 is only one match
:tlast          :tl[ast]         jump to last matching tag
:tmapclear      :tmapc[lear]     remove all mappings for Terminal-Job mode
:tmap           :tma[p]          like ":map" but for Terminal-Job mode
:tmenu          :tm[enu]         define menu tooltip
:tnext          :tn[ext]         jump to next matching tag
:tnoremap       :tno[remap]      like ":noremap" but for Terminal-Job mode
:topleft        :to[pleft]       make split window appear at top or far left
:tprevious      :tp[revious]     jump to previous matching tag
:trewind        :tr[ewind]       jump to first matching tag
:try            :try             execute commands, abort on error or exception
:tselect        :ts[elect]       list matching tags and select one
:tunmap         :tunma[p]        like ":unmap" but for Terminal-Job mode
:tunmenu        :tu[nmenu]       remove menu tooltip
:undo           :u[ndo]          undo last change(s)
:undojoin       :undoj[oin]      join next change with previous undo block
:undolist       :undol[ist]      list leafs of the undo tree
:unabbreviate   :una[bbreviate]  remove abbreviation
:unhide         :unh[ide]        open a window for each loaded file in the
                                 buffer list
:unlet          :unl[et]         delete variable
:unlockvar      :unlo[ckvar]     unlock variables
:unmap          :unm[ap]         remove mapping
:unmenu         :unme[nu]        remove menu
:unsilent       :uns[ilent]      run a command not silently
:update         :up[date]        write buffer if modified
:vglobal        :v[global]       execute commands for not matching lines
:version        :ve[rsion]       print version number and other info
:verbose        :verb[ose]       execute command with 'verbose' set
:vertical       :vert[ical]      make following command split vertically
:vimgrep        :vim[grep]       search for pattern in files
:vimgrepadd     :vimgrepa[dd]    like :vimgrep, but append to current list
:visual         :vi[sual]        same as ":edit", but turns off "Ex" mode
:viusage        :viu[sage]       overview of Normal mode commands
:view           :vie[w]          edit a file read-only
:vmap           :vm[ap]          like ":map" but for Visual+Select mode
:vmapclear      :vmapc[lear]     remove all mappings for Visual+Select mode
```

:vmenu	:vme[nu]	add menu for Visual+Select mode
:vnew	:vne[w]	create a new empty window, vertically split
:vnoremap	:vn[oremap]	like ":noremap" but for Visual+Select mode
:vnoremenu	:vnoreme[nu]	like ":noremenu" but for Visual+Select mode
:vsplit	:vs[plit]	split current window vertically
:vunmap	:vu[nmap]	like ":unmap" but for Visual+Select mode
:vunmenu	:vunme[nu]	remove menu for Visual+Select mode
:windo	:windo	execute command in each window
:write	:w[rite]	write to a file
:wNext	:wN[ext]	write to a file and go to previous file in argument list
:wall	:wa[ll]	write all (changed) buffers
:while	:wh[ile]	execute loop for as long as condition met
:winsize	:wi[nsize]	get or set window size (obsolete)
:wincmd	:winc[md]	execute a Window (CTRL-W) command
:winpos	:winp[os]	get or set window position
:wnext	:wn[ext]	write to a file and go to next file in argument list
:wprevious	:wp[revious]	write to a file and go to previous file in argument list
:wq	:wq	write to a file and quit window or Vim
:wqall	:wqa[ll]	write all changed buffers and quit Vim
:wsverb	:ws[verb]	pass the verb to workshop over IPC
:wundo	:wu[ndo]	write undo information to a file
:wviminfo	:wv[iminfo]	write to viminfo file
:xit	:x[it]	write if buffer changed and quit window or Vim
:xall	:xa[ll]	same as ":wqall"
:xmapclear	:xmapc[lear]	remove all mappings for Visual mode
:xmap	:xm[ap]	like ":map" but for Visual mode
:xmenu	:xme[nu]	add menu for Visual mode
:xnoremap	:xn[oremap]	like ":noremap" but for Visual mode
:xnoremenu	:xnoreme[nu]	like ":noremenu" but for Visual mode
:xunmap	:xu[nmap]	like ":unmap" but for Visual mode
:xunmenu	:xunme[nu]	remove menu for Visual mode
:yank	:y[ank]	yank lines into a register
:z	:z	print some lines
:~	:~	repeat last ":substitute"

howto.txt For Vim version 8.1. Last change: 2006 Apr 02

VIM REFERENCE MANUAL by Bram Moolenaar

How to ... howdoi how-do-i howto how-to

tutor	get started
:quit	exit? I'm trapped, help me!
initialization	initialize Vim
vimrc-intro	write a Vim script file (vimrc)
suspend	suspend Vim
usr_11.txt	recover after a crash
07.4	keep a backup of my file when writing over it
usr_07.txt	edit files
23.4	edit binary files
usr_24.txt	insert text
deleting	delete text
usr_04.txt	change text
04.5	copy and move text
usr_25.txt	format text
30.6	format comments
30.2	indent C programs
25.3	automatically set indent
usr_26.txt	repeat commands
02.5	undo and redo
usr_03.txt	move around
word-motions	word motions
left-right-motions	left-right motions
up-down-motions	up-down motions
object-motions	text-object motions
various-motions	various motions
object-select	text-object selection
'whichwrap'	move over line breaks
'virtualedit'	move to where there is no text
usr_27.txt	specify pattern for searches
tags-and-searches	do tags and special searches
29.4	search in include'd files used to find variables, functions, or macros
K	look up manual for the keyword under cursor
03.7	scroll
'sidescroll'	scroll horizontally/sideways
'scrolloff'	set visible context lines
mode-switching	change modes
04.4	use Visual mode
'insertmode'	start Vim in Insert mode
40.1	map keys

```
24.7                    create abbreviations

ins-expandtab           expand a tab to spaces in Insert mode
i_CTRL-R                insert contents of a register in Insert mode
24.3                    complete words in Insert mode
25.1                    break a line before it gets too long

20.1                    do command-line editing
20.3                    do command-line completion
'cmdheight'             increase the height of command-line
10.3                    specify command-line ranges
40.3                    specify commands to be executed automatically
                        before/after reading/writing entering/leaving a
                        buffer/window

'autowrite'             write automatically
30.1                    speedup edit-compile-edit cycle or compile and fix
                        errors within Vim

options                 set options
auto-setting            set options automatically
term-dependent-settings  set options depending on terminal name
save-settings           save settings
:quote                  comment my .vim files
'helpheight'            change the default help height
'highlight'             set various highlighting modes
'title'                 set the window title
'icon'                  set window icon title
'report'                avoid seeing the change messages on every line
'shortmess'             avoid  hit-enter  prompts

mouse-using             use mouse with Vim
usr_08.txt              manage multiple windows and buffers
gui.txt                 use the gui

|You can't! (yet)|      do dishes using Vim

usr_06.txt              switch on syntax highlighting
2html.vim               convert a colored file to HTML
less                    use Vim like less or more with syntax highlighting

tips.txt	For Vim version 8.1. Last change: 2009 Nov 07

VIM REFERENCE MANUAL	by Bram Moolenaar

Tips and ideas for using Vim	tips

These are just a few that we thought would be helpful for many users.
You can find many more tips on the wiki. The URL can be found on
http://www.vim.org

Don't forget to browse the user manual, it also contains lots of useful tips
usr_toc.txt .

==========
Editing C programs	C-editing

There are quite a few features in Vim to help you edit C program files. Here
is an overview with tags to jump to:

usr_29.txt	Moving through programs chapter in the user manual.
usr_30.txt	Editing programs chapter in the user manual.
C-indenting	Automatically set the indent of a line while typing
	text.
=	Re-indent a few lines.
format-comments	Format comments.

:checkpath	Show all recursively included files.
[i	Search for identifier under cursor in current and
	included files.
[_CTRL-I	Jump to match for "[i"
[I	List all lines in current and included files where
	identifier under the cursor matches.
[d	Search for define under cursor in current and included
	files.

```
 CTRL-]                 Jump to tag under cursor (e.g., definition of a
                        function).
 CTRL-T                 Jump back to before a CTRL-] command.
 :tselect               Select one tag out of a list of matching tags.

 gd                     Go to Declaration of local variable under cursor.
 gD                     Go to Declaration of global variable under cursor.

 gf                     Go to file name under the cursor.

 %                      Go to matching (), {}, [], /* */, #if, #else, #endif.
 [/                     Go to previous start of comment.
 ]/                     Go to next end of comment.
 [#                     Go back to unclosed #if, #ifdef, or #else.
 ]#                     Go forward to unclosed #else or #endif.
 [(                     Go back to unclosed '('
 ])                     Go forward to unclosed ')'
 [{                     Go back to unclosed '{'
 ]}                     Go forward to unclosed '}'

 v_ab                   Select "a block" from "[(" to "])", including braces
 v_ib                   Select "inner block" from "[(" to "])"
 v_aB                   Select "a block" from "[{" to "]}", including brackets
 v_iB                   Select "inner block" from "[{" to "]}"

==============================================================================
Finding where identifiers are used                          ident-search

You probably already know that  tags  can be used to jump to the place where a
function or variable is defined.  But sometimes you wish you could jump to all
the places where a function or variable is being used.  This is possible in
two ways:
1. Using the  :grep  command.  This should work on most Unix systems,
   but can be slow (it reads all files) and only searches in one directory.
2. Using ID utils.  This is fast and works in multiple directories.  It uses a
   database to store locations.  You will need some additional programs for
   this to work.  And you need to keep the database up to date.

Using the GNU id-tools:

What you need:
- The GNU id-tools installed (mkid is needed to create ID and lid is needed to
  use the macros).
- An identifier database file called "ID" in the current directory.  You can
  create it with the shell command "mkid file1 file2 ..".

Put this in your .vimrc:
        map _u :call ID_search()<Bar>execute "/\\<" . g:word . "\\>"<CR>
        map _n :n<Bar>execute "/\\<" . g:word . "\\>"<CR>

        function! ID_search()
          let g:word = expand("<cword>")
          let x = system("lid --key=none ". g:word)
```

```
        let x = substitute(x, "\n", " ", "g")
        execute "next " . x
      endfun
```

To use it, place the cursor on a word, type "_u" and vim will load the file
that contains the word. Search for the next occurrence of the word in the
same file with "n". Go to the next file with "_n".

This has been tested with id-utils-3.2 (which is the name of the id-tools
archive file on your closest gnu-ftp-mirror).

[the idea for this comes from Andreas Kutschera]

==
Switching screens in an xterm   xterm-screens   xterm-save-screen

(From comp.editors, by Juergen Weigert, in reply to a question)

:> Another question is that after exiting vim, the screen is left as it
:> was, i.e. the contents of the file I was viewing (editing) was left on
:> the screen. The output from my previous like "ls" were lost,
:> ie. no longer in the scrolling buffer. I know that there is a way to
:> restore the screen after exiting vim or other vi like editors,
:> I just don't know how. Helps are appreciated. Thanks.
:
:I imagine someone else can answer this. I assume though that vim and vi do
:the same thing as each other for a given xterm setup.

They not necessarily do the same thing, as this may be a termcap vs.
terminfo problem. You should be aware that there are two databases for
describing attributes of a particular type of terminal: termcap and
terminfo. This can cause differences when the entries differ AND when of
the programs in question one uses terminfo and the other uses termcap
(also see +terminfo).

In your particular problem, you are looking for the control sequences
^[[?47h and ^[[?47l. These switch between xterms alternate and main screen
buffer. As a quick workaround a command sequence like

```
        echo -n "^[[?47h"; vim ... ; echo -n "^[[?47l"
```

may do what you want. (My notation ^[means the ESC character, further down
you'll see that the databases use \E instead).

On startup, vim echoes the value of the termcap variable ti (terminfo:
smcup) to the terminal. When exiting, it echoes te (terminfo: rmcup). Thus
these two variables are the correct place where the above mentioned control
sequences should go.

Compare your xterm termcap entry (found in /etc/termcap) with your xterm
terminfo entry (retrieved with "infocmp -C xterm"). Both should contain
entries similar to:

```
        :te=\E[2J\E[?47l\E8:ti=\E7\E[?47h:
```

PS: If you find any difference, someone (your sysadmin?) should better check
    the complete termcap and terminfo database for consistency.

NOTE 1: If you recompile Vim with FEAT_XTERM_SAVE defined in feature.h, the
builtin xterm will include the mentioned "te" and "ti" entries.

NOTE 2: If you want to disable the screen switching, and you don't want to
change your termcap, you can add these lines to your .vimrc:
```
:set t_ti= t_te=
```

==
Scrolling in Insert mode   scroll-insert

If you are in insert mode and you want to see something that is just off the
screen, you can use CTRL-X CTRL-E and CTRL-X CTRL-Y to scroll the screen.
                                                    i_CTRL-X_CTRL-E

To make this easier, you could use these mappings:
```
:inoremap <C-E> <C-X><C-E>
:inoremap <C-Y> <C-X><C-Y>
```
(Type this literally, make sure the '<' flag is not in 'cpoptions').
You then lose the ability to copy text from the line above/below the cursor
 i_CTRL-E .

Also consider setting 'scrolloff' to a larger value, so that you can always see
some context around the cursor. If 'scrolloff' is bigger than half the window
height, the cursor will always be in the middle and the text is scrolled when
the cursor is moved up/down.

==
Smooth scrolling   scroll-smooth

If you like the scrolling to go a bit smoother, you can use these mappings:
```
:map <C-U> <C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C-Y><C
:map <C-D> <C-E><C-E><C-E><C-E><C-E><C-E><C-E><C-E><C-E><C-E><C-E><C-E><C-E><C
```

(Type this literally, make sure the '<' flag is not in 'cpoptions').

==
Correcting common typing mistakes   type-mistakes

When there are a few words that you keep on typing in the wrong way, make
abbreviations that correct them. For example:
```
:ab teh the
:ab fro for
```

==
Counting words, lines, etc.   count-items

To count how often any pattern occurs in the current buffer use the substitute
command and add the 'n' flag to avoid the substitution. The reported number
of substitutions is the number of items. Examples:

```
:%s/./&/gn              characters
:%s/\i\+/&/gn           words
:%s/^//n                lines
```

```
        :%s/the/&/gn            "the" anywhere
        :%s/\<the\>/&/gn        "the" as a word

You might want to reset 'hlsearch' or do ":nohlsearch".
Add the 'e' flag if you don't want an error when there are no matches.

An alternative is using  v_g_CTRL-G  in Visual mode.

If you want to find matches in multiple files use  :vimgrep .

                                                        count-bytes
If you want to count bytes, you can use this:

        Visually select the characters (block is also possible)
        Use "y" to yank the characters
        Use the strlen() function:
                :echo strlen(@")
A line break is counted for one byte.

==============================================================================
Restoring the cursor position                           restore-position

Sometimes you want to write a mapping that makes a change somewhere in the
file and restores the cursor position, without scrolling the text.  For
example, to change the date mark in a file:
   :map <F2> msHmtgg/Last [cC]hange:\s*/e+1<CR>"_D"=strftime("%Y %b %d")<CR>p'tzt`s

Breaking up saving the position:
        ms      store cursor position in the 's' mark
        H       go to the first line in the window
        mt      store this position in the 't' mark

Breaking up restoring the position:
        't      go to the line previously at the top of the window
        zt      scroll to move this line to the top of the window
        `s      jump to the original position of the cursor

For something more advanced see  winsaveview()  and  winrestview() .

==============================================================================
Renaming files                                          rename-files

Say I have a directory with the following files in them (directory picked at
random :-):

buffer.c
charset.c
digraph.c
...

and I want to rename *.c *.bla.  I'd do it like this:

        $ vim
        :r !ls *.c
```

```
	:%s/\(.*\).c/mv & \1.bla
	:w !sh
	:q!
```

==========
Change a name in multiple files *change-name*

Example for using a script file to change a name in several files:

	Create a file "subs.vim" containing substitute commands and a :update
	command:
```
		:%s/Jones/Smith/g
		:%s/Allen/Peter/g
		:update
```

	Execute Vim on all files you want to change, and source the script for
	each argument:

```
		vim *.let
		argdo source subs.vim
```

See :argdo .

==========
Speeding up external commands *speed-up*

In some situations, execution of an external command can be very slow. This
can also slow down wildcard expansion on Unix. Here are a few suggestions to
increase the speed.

If your .cshrc (or other file, depending on the shell used) is very long, you
should separate it into a section for interactive use and a section for
non-interactive use (often called secondary shells). When you execute a
command from Vim like ":!ls", you do not need the interactive things (for
example, setting the prompt). Put the stuff that is not needed after these
lines:

```
	if ($?prompt == 0) then
		exit 0
	endif
```

Another way is to include the "-f" flag in the 'shell' option, e.g.:

```
	:set shell=csh\ -f
```

(the backslash is needed to include the space in the option).
This will make csh completely skip the use of the .cshrc file. This may cause
some things to stop working though.

==========
Useful mappings *useful-mappings*

Here are a few mappings that some people like to use.

map-backtick

```
:map ' `
```

Make the single quote work like a backtick. Puts the cursor on the column of a mark, instead of going to the first non-blank character in the line.

emacs-keys

For Emacs-style editing on the command-line:

```
" start of line
:cnoremap <C-A>         <Home>
" back one character
:cnoremap <C-B>         <Left>
" delete character under cursor
:cnoremap <C-D>         <Del>
" end of line
:cnoremap <C-E>         <End>
" forward one character
:cnoremap <C-F>         <Right>
" recall newer command-line
:cnoremap <C-N>         <Down>
" recall previous (older) command-line
:cnoremap <C-P>         <Up>
" back one word
:cnoremap <Esc><C-B>    <S-Left>
" forward one word
:cnoremap <Esc><C-F>    <S-Right>
```

NOTE: This requires that the '<' flag is excluded from 'cpoptions'. <>

format-bullet-list

This mapping will format any bullet list. It requires that there is an empty line above and below each list entry. The expression commands are used to be able to give comments to the parts of the mapping.

```
:let m =     ":map _f  :set ai<CR>"    " need 'autoindent' set
:let m = m . "{O<Esc>"                 " add empty line above item
:let m = m . "}{)^W"                   " move to text after bullet
:let m = m . "i     <CR>     <Esc>"    " add space for indent
:let m = m . "gq}"                     " format text after the bullet
:let m = m . "{dd"                     " remove the empty line
:let m = m . "5lDJ"                    " put text after bullet
:execute m                             |" define the mapping
```

(<> notation <> . Note that this is all typed literally. ^W is "^" "W", not CTRL-W. You can copy/paste this into Vim if '<' is not included in 'cpoptions'.)

Note that the last comment starts with |", because the ":execute" command doesn't accept a comment directly.

You also need to set 'textwidth' to a non-zero value, e.g.,

```
:set tw=70
```

A mapping that does about the same, but takes the indent for the list from the first line (Note: this mapping is a single long line with a lot of spaces):

```
        :map _f :set ai<CR>}{a                                                  <Es
```

collapse

These two mappings reduce a sequence of empty (;b) or blank (;n) lines into a single line

```
    :map ;b   GoZ<Esc>:g/^$/.,/./-j<CR>Gdd
    :map ;n   GoZ<Esc>:g/^[ <Tab>]*$/.,/[^ <Tab>]/-j<CR>Gdd
```

==========

Compressing the help files gzip-helpfile

For those of you who are really short on disk space, you can compress the help files and still be able to view them with Vim. This makes accessing the help files a bit slower and requires the "gzip" program.

(1) Compress all the help files: "gzip doc/*.txt".

(2) Edit "doc/tags" and change the ".txt" to ".txt.gz":

```
        :%s=\(\t.*\.txt\)\t=\1.gz\t=
```

(3) Add this line to your vimrc:

```
        set helpfile={dirname}/help.txt.gz
```

Where {dirname} is the directory where the help files are. The gzip plugin will take care of decompressing the files.
You must make sure that $VIMRUNTIME is set to where the other Vim files are, when they are not in the same location as the compressed "doc" directory. See $VIMRUNTIME .

==========

Executing shell commands in a window shell-window

See terminal .

Another solution is splitting your terminal screen or display window with the "splitvt" program. You can probably find it on some ftp server. The person that knows more about this is Sam Lantinga <slouken@cs.ucdavis.edu>.

Another alternative is the "window" command, found on BSD Unix systems, which supports multiple overlapped windows. Or the "screen" program, found at www.uni-erlangen.de, which supports a stack of windows.

==========

Hex editing hex-editing using-xxd

See section 23.4 of the user manual.

If one has a particular extension that one uses for binary files (such as exe, bin, etc), you may find it helpful to automate the process with the following bit of autocmds for your <.vimrc>. Change that "*.bin" to whatever comma-separated list of extension(s) you find yourself wanting to edit:

```
        " vim -b : edit binary using xxd-format!
        augroup Binary
```

```
          au!
          au BufReadPre  *.bin let &bin=1
          au BufReadPost *.bin if &bin | %!xxd
          au BufReadPost *.bin set ft=xxd | endif
          au BufWritePre *.bin if &bin | %!xxd -r
          au BufWritePre *.bin endif
          au BufWritePost *.bin if &bin | %!xxd
          au BufWritePost *.bin set nomod | endif
        augroup END
```

==========

Using <> notation in autocommands autocmd-<>

The <> notation is not recognized in the argument of an :autocmd. To avoid having to use special characters, you could use a self-destroying mapping to get the <> notation and then call the mapping from the autocmd. Example:

map-self-destroy

```
 " This is for automatically adding the name of the file to the menu list.
 " It uses a self-destroying mapping!
 " 1. use a line in the buffer to convert the 'dots' in the file name to \.
 " 2. store that in register '"'
 " 3. add that name to the Buffers menu list
 " WARNING: this does have some side effects, like overwriting the
 " current register contents and removing any mapping for the "i" command.
 "
 autocmd BufNewFile,BufReadPre * nmap i :nunmap i<CR>O<C-R>%<Esc>:.g/\./s/\./\\./g<CR>0"9y
 autocmd BufNewFile,BufReadPre * normal i
```

Another method, perhaps better, is to use the ":execute" command. In the string you can use the <> notation by preceding it with a backslash. Don't forget to double the number of existing backslashes and put a backslash before '"'.

```
  autocmd BufNewFile,BufReadPre * exe "normal O\<C-R>%\<Esc>:.g/\\./s/\\./\\\\./g\<CR>0\"9y
```

For a real buffer menu, user functions should be used (see :function), but then the <> notation isn't used, which defeats using it as an example here.

==========

Highlighting matching parens match-parens

This example shows the use of a few advanced tricks:
- using the CursorMoved autocommand event
- using searchpairpos() to find a matching paren
- using synID() to detect whether the cursor is in a string or comment
- using :match to highlight something
- using a pattern to match a specific position in the file.

This should be put in a Vim script file, since it uses script-local variables. It skips matches in strings or comments, unless the cursor started in string or comment. This requires syntax highlighting.

A slightly more advanced version is used in the matchparen plugin.

```
let s:paren_hl_on = 0
function s:Highlight_Matching_Paren()
  if s:paren_hl_on
    match none
    let s:paren_hl_on = 0
  endif

  let c_lnum = line('.')
  let c_col = col('.')

  let c = getline(c_lnum)[c_col - 1]
  let plist = split(&matchpairs, ':\|,')
  let i = index(plist, c)
  if i < 0
    return
  endif
  if i % 2 == 0
    let s_flags = 'nW'
    let c2 = plist[i + 1]
  else
    let s_flags = 'nbW'
    let c2 = c
    let c = plist[i - 1]
  endif
  if c == '['
    let c = '\['
    let c2 = '\]'
  endif
  let s_skip ='synIDattr(synID(line("."), col("."), 0), "name") ' .
        \ '=~?  "string\\|comment"'
  execute 'if' s_skip '| let s_skip = 0 | endif'

  let [m_lnum, m_col] = searchpairpos(c, '', c2, s_flags, s_skip)

  if m_lnum > 0 && m_lnum >= line('w0') && m_lnum <= line('w$')
    exe 'match Search /\(\%' . c_lnum . 'l\%' . c_col .
          \ 'c\)\|\(\%' . m_lnum . 'l\%' . m_col . 'c\)/'
    let s:paren_hl_on = 1
  endif
endfunction

autocmd CursorMoved,CursorMovedI * call s:Highlight_Matching_Paren()
autocmd InsertEnter * match none
```

vim:tw=78:ts=8:noet:ft=help:norl:

message.txt For Vim version 8.1. Last change: 2018 Feb 04

VIM REFERENCE MANUAL by Bram Moolenaar

This file contains an alphabetical list of messages and error messages that Vim produces. You can use this if you don't understand what the message means. It is not complete though.

==========

1. Old messages :messages :mes message-history

The ":messages" command can be used to view previously given messages. This is especially useful when messages have been overwritten or truncated. This depends on the 'shortmess' option.

:messages	Show all messages.
:{count}messages	Show the {count} most recent messages.
:messages clear	Clear all messages.
:{count}messages clear	Clear messages, keeping only the {count} most recent ones.

The number of remembered messages is fixed at 20 for the tiny version and 200 for other versions.

g<

The "g<" command can be used to see the last page of previous command output. This is especially useful if you accidentally typed <Space> at the hit-enter prompt. You are then back at the hit-enter prompt and can then scroll further back.
Note: If the output has been stopped with "q" at the more prompt, it will only be displayed up to this point.
The previous command output is cleared when another command produces output.
The "g<" output is not redirected.

If you are using translated messages, the first printed line tells who maintains the messages or the translations. You can use this to contact the maintainer when you spot a mistake.

If you want to find help on a specific (error) message, use the ID at the start of the message. For example, to get help on the message:

    E72: Close error on swap file

or (translated):

        E72: Errore durante chiusura swap file

Use:

        :help E72

If you are lazy, it also works without the shift key:

        :help e72

==
2. Error messages   error-messages   errors

When an error message is displayed, but it is removed before you could read
it, you can see it again with:
  :echo errmsg
Or view a list of recent messages with:
  :messages
See `:messages` above.

LIST OF MESSAGES
                        E222   E228   E232   E256   E293   E298   E304   E317
                        E318   E356   E438   E439   E440   E316   E320   E322
                        E323   E341   E473   E570   E685   E950
  Add to read buffer
  makemap: Illegal mode
  Cannot create BalloonEval with both message and callback
  Hangul automata ERROR
  block was not locked
  Didn't get block nr {N}?
  ml_upd_block0(): Didn't get block 0??
  pointer block id wrong {N}
  Updated too many blocks?
  get_varp ERROR
  u_undo: line numbers wrong
  undo list corrupt
  undo line missing
  ml_get: cannot find line {N}
  cannot find line {N}
  line number out of range: {N} past the end
  line count wrong in block {N}
  Internal error
  Internal error: {function}
  fatal error in cs_manage_matches
  Invalid count for del_bytes(): {N}

This is an internal error. If you can reproduce it, please send in a bug
report. bugs

  ATTENTION
  Found a swap file by the name ...

See ATTENTION .

E92
  Buffer {N} not found

The buffer you requested does not exist. This can also happen when you have
wiped out a buffer which contains a mark or is referenced in another way.
 :bwipeout

E95
  Buffer with this name already exists

You cannot have two buffers with the same name.

E72
  Close error on swap file

The swap-file , that is used to keep a copy of the edited text, could not be
closed properly. Mostly harmless.

E169
  Command too recursive

This happens when an Ex command executes an Ex command that executes an Ex
command, etc. The limit is 200 or the value of 'maxfuncdepth', whatever is
larger. When it's more there probably is an endless loop. Probably a
 :execute or :source command is involved.

E254
  Cannot allocate color {name}

The color name {name} is unknown. See gui-colors for a list of colors that
are available on most systems.

E458
  Cannot allocate colormap entry, some colors may be incorrect

This means that there are not enough colors available for Vim. It will still
run, but some of the colors will not appear in the specified color. Try
stopping other applications that use many colors, or start them after starting
gvim.
Browsers are known to consume a lot of colors. You can avoid this with
netscape by telling it to use its own colormap:
        netscape -install
Or tell it to limit to a certain number of colors (64 should work well):
        netscape -ncols 64
This can also be done with a line in your Xdefaults file:
        Netscape*installColormap: Yes
or
        Netscape*maxImageColors: 64

E79
  Cannot expand wildcards

A filename contains a strange combination of characters, which causes Vim to attempt expanding wildcards but this fails. This does NOT mean that no matching file names could be found, but that the pattern was illegal.

E459

Cannot go back to previous directory

While expanding a file name, Vim failed to go back to the previously used directory. All file names being used may be invalid now! You need to have execute permission on the current directory.

E190 E212

Cannot open "{filename}" for writing
Can't open file for writing

For some reason the file you are writing to cannot be created or overwritten. The reason could be that you do not have permission to write in the directory or the file name is not valid.

E166

Can't open linked file for writing

You are trying to write to a file which can't be overwritten, and the file is a link (either a hard link or a symbolic link). Writing might still be possible if the directory that contains the link or the file is writable, but Vim now doesn't know if you want to delete the link and write the file in its place, or if you want to delete the file itself and write the new file in its place. If you really want to write the file under this name, you have to manually delete the link or the file, or change the permissions so that Vim can overwrite.

E46

Cannot change read-only variable "{name}"

You are trying to assign a value to an argument of a function a:var or a Vim internal variable v:var which is read-only.

E90

Cannot unload last buffer

Vim always requires one buffer to be loaded, otherwise there would be nothing to display in the window.

E40

Can't open errorfile <filename>

When using the ":make" or ":grep" commands: The file used to save the error messages or grep output cannot be opened. This can have several causes:
- 'shellredir' has a wrong value.
- The shell changes directory, causing the error file to be written in another directory. This could be fixed by changing 'makeef', but then the make command is still executed in the wrong directory.
- 'makeef' has a wrong value.
- The 'grepprg' or 'makeprg' could not be executed. This cannot always be

detected (especially on MS-Windows). Check your $PATH.

Can't open file C:\TEMP\VIoD243.TMP

On MS-Windows, this message appears when the output of an external command was to be read, but the command didn't run successfully. This can be caused by many things. Check the 'shell', 'shellquote', 'shellxquote', 'shellslash' and related options. It might also be that the external command was not found, there is no different error message for that.

E12
Command not allowed from exrc/vimrc in current dir or tag search

Some commands are not allowed for security reasons. These commands mostly come from a .exrc or .vimrc file in the current directory, or from a tags file. Also see 'secure'.

E74
Command too complex

A mapping resulted in a very long command string. Could be caused by a mapping that indirectly calls itself.

CONVERSION ERROR

When writing a file and the text "CONVERSION ERROR" appears, this means that some bits were lost when converting text from the internally used UTF-8 to the format of the file. The file will not be marked unmodified. If you care about the loss of information, set the 'fileencoding' option to another value that can handle the characters in the buffer and write again. If you don't care, you can abandon the buffer or reset the 'modified' option.

E302
Could not rename swap file

When the file name changes, Vim tries to rename the swap-file as well. This failed and the old swap file is now still used. Mostly harmless.

E43 E44
Damaged match string
Corrupted regexp program

Something inside Vim went wrong and resulted in a corrupted regexp. If you know how to reproduce this problem, please report it. bugs

E208 E209 E210
Error writing to "{filename}"
Error closing "{filename}"
Error reading "{filename}"

This occurs when Vim is trying to rename a file, but a simple change of file name doesn't work. Then the file will be copied, but somehow this failed.

The result may be that both the original file and the destination file exist
and the destination file may be incomplete.

  Vim: Error reading input, exiting...

This occurs when Vim cannot read typed characters while input is required.
Vim got stuck, the only thing it can do is exit. This can happen when both
stdin and stderr are redirected and executing a script that doesn't exit Vim.

                                                                    E47
  Error while reading errorfile

Reading the error file was not possible. This is NOT caused by an error
message that was not recognized.

                                                                    E80
  Error while writing

Writing a file was not completed successfully. The file is probably
incomplete.

                                                                E13   E189
  File exists (add ! to override)
  "{filename}" exists (add ! to override)

You are protected from accidentally overwriting a file. When you want to
write anyway, use the same command, but add a "!" just after the command.
Example:
        :w /tmp/test
changes to:
        :w! /tmp/test

                                                                    E768
  Swap file exists: {filename} (:silent! overrides)

You are protected from overwriting a file that is being edited by Vim. This
happens when you use ":w! filename" and a swapfile is found.
- If the swapfile was left over from an old crashed edit session you may want
  to delete the swapfile. Edit {filename} to find out information about the
  swapfile.
- If you want to write anyway prepend ":silent!" to the command. For example:
        :silent! w! /tmp/test
 The special command is needed, since you already added the ! for overwriting
  an existing file.

                                                                    E139
  File is loaded in another buffer

You are trying to write a file under a name which is also used in another
buffer. This would result in two versions of the same file.

                                                                    E142
  File not written: Writing is disabled by 'write' option

The 'write' option is off. This makes all commands that try to write a file
generate this message. This could be caused by a -m commandline argument.
You can switch the 'write' option on with ":set write".

                                                                        E25
  GUI cannot be used: Not enabled at compile time

You are running a version of Vim that doesn't include the GUI code. Therefore
"gvim" and ":gui" don't work.

                                                                        E49
  Invalid scroll size

This is caused by setting an invalid value for the 'scroll', 'scrolljump' or
'scrolloff' options.

                                                                        E17
  "{filename}" is a directory

You tried to write a file with the name of a directory. This is not possible.
You probably need to append a file name.

                                                                        E19
  Mark has invalid line number

You are using a mark that has a line number that doesn't exist. This can
happen when you have a mark in another file, and some other program has
deleted lines from it.

                                                                E219   E220
  Missing {.
  Missing }.

Using a {} construct in a file name, but there is a { without a matching } or
the other way around. It should be used like this: {foo,bar}. This matches
"foo" and "bar".

                                                                        E315
  ml_get: invalid lnum: {number}

This is an internal Vim error. Please try to find out how it can be
reproduced, and submit a bug report bugreport.vim .

                                                                        E173
  {number} more files to edit

You are trying to exit, while the last item in the argument list has not been
edited. This protects you from accidentally exiting when you still have more
files to work on. See argument-list . If you do want to exit, just do it
again and it will work.

                                                                E23   E194
  No alternate file

No alternate file name to substitute for '#'

The alternate file is not defined yet. See alternate-file .

E32

No file name

The current buffer has no name. To write it, use ":w fname". Or give the buffer a name with ":file fname".

E141

No file name for buffer {number}

One of the buffers that was changed does not have a file name. Therefore it cannot be written. You need to give the buffer a file name:
	:buffer {number}
	:file {filename}

E33

No previous substitute regular expression

When using the '~' character in a pattern, it is replaced with the previously used pattern in a ":substitute" command. This fails when no such command has been used yet. See /~ . This also happens when using ":s/pat/%/", where the "%" stands for the previous substitute string.

E35

No previous regular expression

When using an empty search pattern, the previous search pattern is used. But that is not possible if there was no previous search.

E24

No such abbreviation

You have used an ":unabbreviate" command with an argument which is not an existing abbreviation. All variations of this command give the same message: ":cunabbrev", ":iunabbrev", etc. Check for trailing white space.

/dev/dsp: No such file or directory

Only given for GTK GUI with Gnome support. Gnome tries to use the audio device and it isn't present. You can ignore this error.

E31

No such mapping

You have used an ":unmap" command with an argument which is not an existing mapping. All variations of this command give the same message: ":cunmap", ":unmap!", etc. A few hints:
- Check for trailing white space.
- If the mapping is buffer-local you need to use ":unmap <buffer>".
  :map-<buffer>

E37 E89

No write since last change (add ! to override)
No write since last change for buffer {N} (add ! to override)

You are trying to abandon a file that has changes. Vim protects you from losing your work. You can either write the changed file with ":w", or, if you are sure, abandon it anyway, and lose all the changes. This can be done by adding a '!' character just after the command you used. Example:

```
:e other_file
```

changes to:

```
:e! other_file
```

E162

No write since last change for buffer "{name}"

This appears when you try to exit Vim while some buffers are changed. You will either have to write the changed buffer (with :w), or use a command to abandon the buffer forcefully, e.g., with ":qa!". Careful, make sure you don't throw away changes you really want to keep. You might have forgotten about a buffer, especially when 'hidden' is set.

[No write since last change]

This appears when executing a shell command while at least one buffer was changed. To avoid the message reset the 'warn' option.

E38

Null argument

Something inside Vim went wrong and resulted in a NULL pointer. If you know how to reproduce this problem, please report it. bugs

E41 E82 E83 E342

Out of memory!
Out of memory! (allocating {number} bytes)
Cannot allocate any buffer, exiting...
Cannot allocate buffer, using other one...

Oh, oh. You must have been doing something complicated, or some other program is consuming your memory. Be careful! Vim is not completely prepared for an out-of-memory situation. First make sure that any changes are saved. Then try to solve the memory shortage. To stay on the safe side, exit Vim and start again.

Buffers are only partly kept in memory, thus editing a very large file is unlikely to cause an out-of-memory situation. Undo information is completely in memory, you can reduce that with these options:

- 'undolevels' Set to a low value, or to -1 to disable undo completely. This helps for a change that affects all lines.
- 'undoreload' Set to zero to disable.

E339

Pattern too long

This happens on systems with 16 bit ints: The compiled regexp pattern is
longer than about 65000 characters. Try using a shorter pattern.
It also happens when the offset of a rule doesn't fit in the space available.
Try simplifying the pattern.

E45

'readonly' option is set (add ! to override)

You are trying to write a file that was marked as read-only. To write the
file anyway, either reset the 'readonly' option, or add a '!' character just
after the command you used. Example:
	:w
changes to:
	:w!

E294 E295 E301

Read error in swap file
Seek error in swap file read
Oops, lost the swap file!!!

Vim tried to read text from the swap-file , but something went wrong. The
text in the related buffer may now be corrupted! Check carefully before you
write a buffer. You may want to write it in another file and check for
differences.

E192

Recursive use of :normal too deep

You are using a ":normal" command, whose argument again uses a ":normal"
command in a recursive way. This is restricted to 'maxmapdepth' levels. This
example illustrates how to get this message:
	:map gq :normal gq<CR>
If you type "gq", it will execute this mapping, which will call "gq" again.

E22

Scripts nested too deep

Scripts can be read with the "-s" command-line argument and with the ":source"
command. The script can then again read another script. This can continue
for about 14 levels. When more nesting is done, Vim assumes that there is a
recursive loop somewhere and stops with this error message.

E319

Sorry, the command is not available in this version

You have used a command that is not present in the version of Vim you are
using. When compiling Vim, many different features can be enabled or
disabled. This depends on how big Vim has chosen to be and the operating
system. See +feature-list for when which feature is available. The
 :version command shows which feature Vim was compiled with.

E300

Swap file already exists (symlink attack?)

This message appears when Vim is trying to open a swap file and finds it already exists or finds a symbolic link in its place. This shouldn't happen, because Vim already checked that the file doesn't exist. Either someone else opened the same file at exactly the same moment (very unlikely) or someone is attempting a symlink attack (could happen when editing a file in /tmp or when 'directory' starts with "/tmp", which is a bad choice).

E432

Tags file not sorted: {file name}

Vim (and Vi) expect tags files to be sorted in ASCII order. Binary searching can then be used, which is a lot faster than a linear search. If your tags files are not properly sorted, reset the 'tagbsearch' option.
This message is only given when Vim detects a problem when searching for a tag. Sometimes this message is not given, even though the tags file is not properly sorted.

E460

The resource fork would be lost (add ! to override)

On the Macintosh (classic), when writing a file, Vim attempts to preserve all info about a file, including its resource fork. If this is not possible you get this error message. Append "!" to the command name to write anyway (and lose the info).

E424

Too many different highlighting attributes in use

Vim can only handle about 223 different kinds of highlighting. If you run into this limit, you have used too many :highlight commands with different arguments. A ":highlight link" is not counted.

E77

Too many file names

When expanding file names, more than one match was found. Only one match is allowed for the command that was used.

E303

Unable to open swap file for "{filename}", recovery impossible

Vim was not able to create a swap file. You can still edit the file, but if Vim unexpectedly exits the changes will be lost. And Vim may consume a lot of memory when editing a big file. You may want to change the 'directory' option to avoid this error. See swap-file .

E140

Use ! to write partial buffer

When using a range to write part of a buffer, it is unusual to overwrite the original file. It is probably a mistake (e.g., when Visual mode was active when using ":w"), therefore Vim requires using a ! after the command, e.g.:

":3,10w!".

  Warning: Cannot convert string "<Key>Escape,_Key_Cancel" to type
  VirtualBinding

Messages like this appear when starting up. This is not a Vim problem, your
X11 configuration is wrong. You can find a hint on how to solve this here:
http://groups.yahoo.com/group/solarisonintel/message/12179.
[this URL is no longer valid]

                                                                    W10
  Warning: Changing a readonly file

The file is read-only and you are making a change to it anyway. You can use
the FileChangedRO autocommand event to avoid this message (the autocommand
must reset the 'readonly' option). See 'modifiable' to completely disallow
making changes to a file.
This message is only given for the first change after 'readonly' has been set.

                                                                    W13
  Warning: File "{filename}" has been created after editing started

You are editing a file in Vim when it didn't exist, but it does exist now.
You will have to decide if you want to keep the version in Vim or the newly
created file. This message is not given when 'buftype' is not empty.

                                                                    W11
  Warning: File "{filename}" has changed since editing started

The file which you have started editing has got another timestamp and the
contents changed (more precisely: When reading the file again with the current
option settings and autocommands you would end up with different text). This
probably means that some other program changed the file. You will have to
find out what happened, and decide which version of the file you want to keep.
Set the 'autoread' option if you want to do this automatically.
This message is not given when 'buftype' is not empty.

There is one situation where you get this message even though there is nothing
wrong: If you save a file in Windows on the day the daylight saving time
starts. It can be fixed in one of these ways:
- Add this line in your autoexec.bat:
            SET TZ=-1
 Adjust the "-1" for your time zone.
- Disable "automatically adjust clock for daylight saving changes".
- Just write the file again the next day. Or set your clock to the next day,
  write the file twice and set the clock back.

If you get W11 all the time, you may need to disable "Acronis Active
Protection" or register Vim as a trusted service/application.

                                                                    W12
  Warning: File "{filename}" has changed and the buffer was changed in Vim as well

Like the above, and the buffer for the file was changed in this Vim as well. You will have to decide if you want to keep the version in this Vim or the one on disk. This message is not given when 'buftype' is not empty.

W16
Warning: Mode of file "{filename}" has changed since editing started

When the timestamp for a buffer was changed and the contents are still the same but the mode (permissions) have changed. This usually occurs when checking out a file from a version control system, which causes the read-only bit to be reset. It should be safe to reload the file. Set 'autoread' to automatically reload the file.

E211
File "{filename}" no longer available

The file which you have started editing has disappeared, or is no longer accessible. Make sure you write the buffer somewhere to avoid losing changes. This message is not given when 'buftype' is not empty.

W14
Warning: List of file names overflow

You must be using an awful lot of buffers. It's now possible that two buffers have the same number, which causes various problems. You might want to exit Vim and restart it.

E931
Buffer cannot be registered

Out of memory or a duplicate buffer number. May happen after W14. Looking up a buffer will not always work, better restart Vim.

E296 E297
Seek error in swap file write
Write error in swap file

This mostly happens when the disk is full. Vim could not write text into the swap-file . It's not directly harmful, but when Vim unexpectedly exits some text may be lost without recovery being possible. Vim might run out of memory when this problem persists.

connection-refused
Xlib: connection to "<machine-name:0.0" refused by server

This happens when Vim tries to connect to the X server, but the X server does not allow a connection. The connection to the X server is needed to be able to restore the title and for the xterm clipboard support. Unfortunately this error message cannot be avoided, except by disabling the +xterm_clipboard and +X11 features.

E10
\\ should be followed by /, ? or &

A command line started with a backslash or the range of a command contained a backslash in a wrong place. This is often caused by command-line continuation being disabled. Remove the 'C' flag from the 'cpoptions' option to enable it. Or use ":set nocp".

E471

  Argument required

This happens when an Ex command with mandatory argument(s) was executed, but no argument has been specified.

E474 E475

  Invalid argument
  Invalid argument: {arg}

An Ex command has been executed, but an invalid argument has been specified.

E488

  Trailing characters

An argument has been added to an Ex command that does not permit one.

E477 E478

  No ! allowed
  Don't panic!

You have added a "!" after an Ex command that doesn't permit one.

E481

  No range allowed

A range was specified for an Ex command that doesn't permit one. See
 cmdline-ranges .

E482 E483

  Can't create file {filename}
  Can't get temp file name

Vim cannot create a temporary file.

E484 E485

  Can't open file {filename}
  Can't read file {filename}

Vim cannot read a temporary file. Especially on Windows, this can be caused by wrong escaping of special characters for cmd.exe; the approach was changed with patch 7.3.443. Try using shellescape() for all shell arguments given to system() , or explicitly add escaping with ^. Also see 'shellxquote' and 'shellxescape'.

E464

  Ambiguous use of user-defined command

There are two user-defined commands with a common name prefix, and you used

Command-line completion to execute one of them. user-cmd-ambiguous
Example:
```
        :command MyCommand1 echo "one"
        :command MyCommand2 echo "two"
        :MyCommand
```

E492
```
  Not an editor command
```

You tried to execute a command that is neither an Ex command nor
a user-defined command.

E943
```
  Command table needs to be updated, run 'make cmdidxs'
```

This can only happen when changing the source code, when adding a command in
src/ex_cmds.h. The lookup table then needs to be updated, by running:
```
        make cmdidxs
```

==========
3. Messages messages

This is an (incomplete) overview of various messages that Vim gives:

hit-enter press-enter hit-return
press-return hit-enter-prompt

```
  Press ENTER or type command to continue
```

This message is given when there is something on the screen for you to read,
and the screen is about to be redrawn:
- After executing an external command (e.g., ":!ls" and "=").
- Something is displayed on the status line that is longer than the width of
  the window, or runs into the 'showcmd' or 'ruler' output.

-> Press <Enter> or <Space> to redraw the screen and continue, without that
   key being used otherwise.
-> Press ':' or any other Normal mode command character to start that command.
-> Press 'k', <Up>, 'u', 'b' or 'g' to scroll back in the messages. This
   works the same way as at the more-prompt . Only works when 'compatible'
   is off and 'more' is on.
-> Pressing 'j', 'f', 'd' or <Down> is ignored when messages scrolled off the
   top of the screen, 'compatible' is off and 'more' is on, to avoid that
   typing one 'j' or 'f' too many causes the messages to disappear.
-> Press <C-Y> to copy (yank) a modeless selection to the clipboard register.
-> Use a menu. The characters defined for Cmdline-mode are used.
-> When 'mouse' contains the 'r' flag, clicking the left mouse button works
   like pressing <Space>. This makes it impossible to select text though.
-> For the GUI clicking the left mouse button in the last line works like
   pressing <Space>.
{Vi: only ":" commands are interpreted}

If you accidentally hit <Enter> or <Space> and you want to see the displayed
text then use g< . This only works when 'more' is set.

To reduce the number of hit-enter prompts:
- Set 'cmdheight' to 2 or higher.
- Add flags to 'shortmess'.
- Reset 'showcmd' and/or 'ruler'.

If your script causes the hit-enter prompt and you don't know why, you may find the v:scrollstart variable useful.

Also see 'mouse'. The hit-enter message is highlighted with the hl-Question group.

more-prompt pager

```
-- More --
-- More -- SPACE/d/j: screen/page/line down, b/u/k: up, q: quit
```

This message is given when the screen is filled with messages. It is only given when the 'more' option is on. It is highlighted with the hl-MoreMsg group.

Type	effect
<CR> or <NL> or j or <Down>	one more line
d	down a page (half a screen)
<Space> or f or <PageDown>	down a screen
G	down all the way, until the hit-enter prompt
<BS> or k or <Up>	one line back (*)
u	up a page (half a screen) (*)
b or <PageUp>	back a screen (*)
g	back to the start (*)
q, <Esc> or CTRL-C	stop the listing
:	stop the listing and enter a command-line
<C-Y>	yank (copy) a modeless selection to the clipboard ("* and "+ registers)
{menu-entry}	what the menu is defined to in Cmdline-mode.
<LeftMouse> (**)	next page

Any other key causes the meaning of the keys to be displayed.

(*) backwards scrolling is {not in Vi}. Only scrolls back to where messages started to scroll.
(**) Clicking the left mouse button only works:
- For the GUI: in the last line of the screen.
- When 'r' is included in 'mouse' (but then selecting text won't work).

Note: The typed key is directly obtained from the terminal, it is not mapped and typeahead is ignored.

The g< command can be used to see the last page of previous command output. This is especially useful if you accidentally typed <Space> at the hit-enter prompt.

vim:tw=78:ts=8:noet:ft=help:norl:

quotes.txt For Vim version 8.1. Last change: 2018 Mar 29

VIM REFERENCE MANUAL by Bram Moolenaar

quotes

Here are some nice quotes about Vim that I collected from news and mail.

vim (vim) noun - Ebullient vitality and energy. [Latin, accusative of vis, strength] (Dictionary)

Vim is so much better than vi that a great many of my old vi :map's became immediately obsolete! (Tony Nugent, Australia)

Coming with a very GUI mindset from Windows, I always thought of people using Vi as some kind of outer space alien in human clothes. Once I tried I really got addicted by its power and now I found myself typing Vim keypresses in the oddest places! That's why I would like to see Vim embedded in every application which deals with text editing. (José Fonseca)

I was a 12-year emacs user who switched to Vim about a year ago after finally giving up on the multiple incompatible versions, flaky contributed packages, disorganized keystrokes, etc. And it was one of the best moves I ever made. (Joel Burton)

Although all of the programs were used during the preparation of the new and revised material, most of the editing was done with Vim versions 4.5 and 5.0 under GNU-Linux (Redhat 4.2). (Arnold Robbins, Israel, author of "Learning the Vi editor")

Out of all the open software i've ever seen and used, and i've seen a lot, Vim is the best, most useful and highest quality to work with, second only to the linux kernel itself. (Peter Jay Salzman)

It's well worth noting that the _entirety_ of SourceForge was written using Vim and its nifty PHP syntax highlighting. I think the entire SF.net tech staff uses Vim and we're all excited to have you aboard! (Tim Perdue)

Vim is one of a select bunch of tools for which I have no substitute. It is a brilliant piece of work! (Biju Chacko)

A previous girlfriend of mine switched to emacs. Needless to say, the relationship went nowhere. (Geoffrey Mann)

I rarely think about Vim, in the same way that I guess a fish rarely thinks about water. It's the environment in which everything else happens. I'm a fairly busy system administrator working on a lot of different platforms. Vim is the only thing that's consistent across all my systems, and it's just about the only thing that doesn't break from time to time. When a new system comes in the door without Vim, I install it right away. Great to have a tool that's the same everywhere, that's completely reliable, so I can ignore it and think about other things. (Pete Schaeffer)

Having recently succeeded in running Vim via telnet through a Nokia Communicator, I can now report that it works nicely on a Palm Pilot too. (Allan Kelly, Scotland)

You've done a tremendous job with 'VIM', Bram! The more I use it, the more impressed I get (I am an old 'vi' die hard who once started out with early versions of 'emacs' in the late 1970's and was relieved by finding 'vi' in the first UNIX I came across in 1983). In my opinion, it's about time 'VIM' replace 'emacs' as the standard for top editors. (Bo Thide', Sweden)

I love and use Vim heavily too. (Larry Wall)

Vi is like a Ferrari, if you're a beginner, it handles like a bitch, but once you get the hang of it, it's small, powerful and FAST! (Unknown)
Vim is like a new model Ferrari, and sounds like one too - "VIIIIIIMMM!" (Stephen Riehm, Germany)

Schon bei Nutzung eines Bruchteils der Vim-Funktionen wird der Benutzer recht schnell die Vorzuege dieses Editors kennen- und schaetzenlernen.
Translated: Even when only using a fraction of Vim-functions, the user will quickly get used to and appreciate the advantages of this editor. (Garry Glendown, conclusion of an article on Vim in iX magazine 9/1998)

I've recently acquired the O'Reilly book on Vi (it also discusses Vim in-depth), and I'm amazed at just how powerful this application is. (Jeffrey Rankin)

This guide was written using the Windows 9.x distribution of gvim, which is quite possibly the greatest thing to come along since God created the naked girl. (Michael DiBernardo)

Boy, I thought I knew almost everything about Vim, but every time I browse the online documentation, I hit upon a minor but cool aspect of a Vim feature that I didn't know before! I must say the documentation is one the finest I've ever seen in a product -- even better than most commercial products. (Gautam Mudunuri)

Vim 4.5 is really a fantastic editor. It has sooooo many features and more importantly, the defaults are so well thought out that you really don't have to change anything!! Words cannot express my amazement and gratitude to the creators of Vim. Keep it up. (Vikas, USA)

I wonder how long it will be before people will refer to other Vi editors as Vim clones? (Darren Hiebert)

I read about [auto-positioning-in-file-based-on-the-errors-from-make] in one of those "Perfect Programmer's Editor" threads and was delighted to discover that Vim already supports it. (Brendan Macmillan, Australia)

I just discovered Vim (5.0) and I'm telling everyone I know about it!
I tell them Vim stands for Vi for the new (M)illenium. Thanks so much! (Matt F. Valentine)

I think from now on "vi" should be called "Vim Imitation", not the other way around. (Rungun Ramanathan)

The Law of Vim:
For each member b of the possible behaviour space B of program P, there exists a finite time t before which at least one user u in the total user space U of program P will request b becomes a member of the allowed behaviour space B' (B' <= B).
In other words: Sooner or later everyone wants everything as an option.
(Negri)

Whenever I move to a new computing platform, the first thing I do is to port Vim. Lately, I am simply stunned by its ease of compilation using the configure facility. (A.M. Sabuncu, Turkey)

The options are really excellent and very powerful. (Anish Maharaj)

The Spring user-interface designs are in, and word from the boutiques is that 80x24 text-only mode is back with a *vengeance! Vi editor clone Vim burst onto March desk-tops with a dazzling show of pastel syntax highlights for its 5.0 look. Strident and customizable, Vim raises eyebrows with its interpretation of the classic Vi single-key macro collection.
http://www.ntk.net/index.cgi?back=archive98/now0327.txt&line=179#l

I just wanted to take this opportunity to let you know that Vim 5 ROCKS! Syntax highlighting: how did I survive without it?! Thank you for creating mankind's best editor! (Mun Johl, USA)

Thanks again for Vim. I use it every day on Linux. (Eric Foster-Johnson, author of the book "UNIX Programming Tools")

The BEST EDITOR EVER (Stuart Woolford)

I have used most of Vim's fancy features at least once, many frequently, and I can honestly say that I couldn't live with anything less anymore. My productivity has easily doubled compared to what it was when I used vi.
(Sitaram Chamarty)

I luv Vim. It is incredible. I'm naming my first-born Vimberly. (Jose Unpingco, USA)

Hint: "Vim" is "vi improved" - much better! (Sven Guckes, Germany)

I use Vim every day. I spend more time in Vim than in any other program... It's the best vi clone there is. I think it's great. (Craig Sanders, Australia)

I strongly advise using Vim--its infinite undo/redo saved me much grief.
(Terry Brown)

Thanks very much for writing what in my opinion is the finest text editor on the planet. If I were to get another cat, I would name it "Vim".
(Bob Sheehan, USA)

I typed :set all and the screen FILLED up with options. A whole screen of things to be set and unset. I saw some of my old friends like wrapmargin, modelines and showmode, but the screen was FILLED with new friends! I love them all! I love Vim! I'm so happy that I've found this editor! I feel like how I once felt when I started using vi after a couple of years of using ed. I never thought I'd forsake my beloved ed, but vi ... oh god, vi was great. And now, Vim. (Peter Jay Salzman, USA)

I am really happy with such a wonderful software package. Much better than almost any expensive, off the shelf program. (Jeff Walker)

Whenever I reread the Vim documentation I'm overcome with excitement at the power of the editor. (William Edward Webber, Australia)

Hurrah for Vim!! It is "at your fingertips" like vi, and has the extensions that vi sorely needs: highlighting for executing commands on blocks, an easily navigable and digestible help screen, and more. (Paul Pax)

The reason WHY I don't have this amazingly useful macro anymore, is that I now use Vim - and this is built in!! (Stephen Riehm, Germany)

I am a user of Vim and I love it. I use it to do all my programming, C, C++, HTML what ever. (Tim Allwine)

I discovered Vim after years of struggling with the original vi, and I just can't live without it anymore. (Emmanuel Mogenet, USA)

Emacs has not a bit of chance to survive so long as Vim is around. Besides, it also has the most detailed software documentation I have ever seen---much better than most commercial software! (Leiming Qian)

This version of Vim will just blow people apart when they discover just how fantastic it is! (Tony Nugent, Australia)

I took your advice & finally got Vim & I'm really impressed. Instant convert. (Patrick Killelea, USA)

Vim is by far my favorite piece of shareware and I have been particularly pleased with version 3.0. This is really a solid piece of work. (Robert Colon, USA)

Vim is a joy to use, it is so well thought and practical that I wonder why anybody would use visual development tools. Vim is powerful and elegant, it looks deceptively simple but is almost as complex as a 747 (especially when I look at my growing .vimrc), keep up that wonderful job, Vim is a centerpiece of the free software world. (Louis-David Mitterand, USA)

I cannot believe how great it is to use Vim. I think the guys at work are getting tired of hearing me bragging about it. Others eyes are lighting up. (Rick Croote)

Emacs takes way too much time to start up and run, it is too big and bulky for effective use and the interface is more confusing than it is of any help. Vim however is short, it is fast, it is powerful, it has a good interface and it

is all purpose. (Paal Ditlefsen Ekran)

From the first time I got Vim3.0, I was very enthusiastic. It has almost no problems. The swapfile handling and the backup possibilities are robust, also the protection against editing one file twice. It is very compatible to the real VI (and that is a MUST, because my brain is trained over years in using it). (Gert van Antwerpen, Holland)

Visual mode in Vim is a very powerful thing! (Tony Nugent, Australia)

I have to say that Vim is =THE= single greatest piece of source code to ever come across the net (Jim Battle, USA).

In fact, if you do want to get a new vi I'd suggest Vim-3.0. This is, by far, the best version of vi I've ever seen (Albert W. Schueller).

I should mention that Vim is a very good editor and can compete with anything (Ilya Beloozerov).

To tell the truth sometimes I used elvis, vile, xvi, calvin, etc. And this is the reason that I can state that Vim is the best! (Ferenc Deak, Hungary)

Vim is by far the best editor that I have used in a long time, and I have looked at just about every thing that is available for every platform that I use. Vim is the best on all of them. (Guy L. Oliver)

Vim is the greatest editor since the stone chisel. (Jose Unpingco, USA)

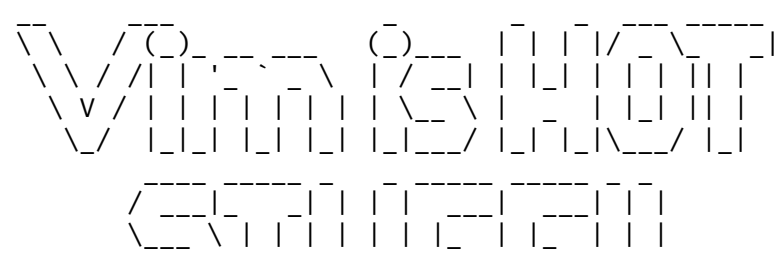
I would like to say that with Vim I am finally making the 'emacs to vi' transition - as an Editor it is so much better in many ways: keyboard layout, memory usage, text alteration to name 3. (Mark Adam)

In fact, now if I want to know what a particular setting does in vi, I fire up Vim and check out its help! (Nikhil Patel, USA)

As a vi user, Vim has made working with text a far more pleasant task than before I encountered this program. (Steinar Knutsen, Norway)

I use Vim since version 3.0. Since that time, it is the ONLY editor I use, with Solaris, Linux and OS/2 Warp. I suggest all my friends to use Vim, they try, and they continue using it. Vim is really the best software I have ever downloaded from the Internet, and the best editor I know of. (Marco Eccettuato, Italy)

In summary:



```

todo.txt For Vim version 8.1. Last change: 2018 May 17

VIM REFERENCE MANUAL by Bram Moolenaar

TODO list for Vim todo

This is a veeeery long list of known bugs, current work and desired
improvements. To make it a little bit accessible, the older items are grouped
by subject. In the first column of the line a classification is used to be
able to look for "the next thing to do":

Priority classification:
9 next point release
8 next release
7 as soon as possible
6 soon
5 should be included
4 nice to have
3 consider including
2 maybe not
1 probably not
- unclassified

votes-for-changes
See develop.txt for development plans. You can vote for which items should
be worked on, but only if you sponsor Vim development. See sponsor .

Issues can also be entered online: https://github.com/vim/vim/issues
Only use this for bug reports, not for questions! Those belong on the
maillist. Updates will be forwarded to the vim_dev maillist. Issues
entered there will not be repeated below, unless there is extra information.

The #1234 numbers refer to an issue or pull request on github. To see it in a
browser use: https://github.com/vim/vim/issues/1234

known-bugs
---------- Known bugs and current work -----------------------

Graduate FEAT_VREPLACE, it's not much code and a lot of #ifdefs

Prompt buffer:
- Add a command line history.
- delay next prompt until plugin gives OK?

Terminal debugger:
- Make prompt-buffer variant work better.
- When only gdb window exists, on "quit" edit another buffer.
- Termdebug does not work when Vim was build with mzscheme: gdb hangs just
  after "run". Everything else works, including communication channel. Not
  initializing mzscheme avoid the problem, thus it's not some #ifdef.

Terminal emulator window:

- When the job in the terminal doesn't use mouse events, let the scroll wheel
  scroll the scrollback, like a terminal does at the shell prompt. #2490
  And use modeless selection. #2962
- With a vertical split only one window is updated. (Linwei, 2018 Jun 2,
  #2977)
- When pasting should call vterm_keyboard_start_paste(), e.g. when using
  K_MIDDLEMOUSE, calling insert_reg().
- Users expect parsing the :term argument like a shell does, also support
  single quotes. E.g. with: :term grep 'alice says "hello"' (#1999)
- Win32: Redirecting input does not work, half of Test_terminal_redir_file()
  is disabled.
- Win32: Redirecting output works but includes escape sequences.
- Win32: Make terminal used for :!cmd in the GUI work better. Allow for
  redirection.
- Terminal API: Add more functionality? (Ozaki Kiichi 2018 May 13, #2907)
- When the job only outputs lines, we could handle resizing the terminal
  better: store lines separated by line breaks, instead of screen lines,
  then when the window is resized redraw those lines.
- Redrawing is slow with Athena and Motif. (Ramel Eshed)
- For the GUI fill termios with default values, perhaps like pangoterm:
  http://bazaar.launchpad.net/~leonerd/pangoterm/trunk/view/head:/main.c#L134
- When 'encoding' is not utf-8, or the job is using another encoding, setup
  conversions.

Does not build with MinGW out of the box:
- _stat64 is not defined, need to use "struct stat" in vim.h
- WINVER conflict, should use 0x0600 by default?

Patches for Python: #3162, #3263 (Ozaki Kiichi)
    Needs update.

Crash when mixing matchadd and substitute()? (Max Christian Pohle, 2018 May
13, #2910) Can't reproduce?

On Win32 when not in the console and t_Co >= 256, allow using 'tgc'.
(Nobuhiro Takasaki, #2833) Also check t_Co.

Errors found with random data:
    heap-buffer-overflow in alist_add (#2472)

Improve fallback for menu translations, to avoid having to create lots of
files that source the actual file. E.g. menu_da_de -> menu_da
Include part of #3242?

Inlcude Chinese-Taiwan translations. (bystar, #3261)

Using mouse for inputlist() doesn't work after patch 8.0.1756. (Dominique
Pelle, 2018 Jul 22, #3239) Also see 8.0.0722. Check both console and GUI.

More warnings from static analysis:
https://lgtm.com/projects/g/vim/vim/alerts/?mode=list

Pasting foo} causes Vim to behave weird. (John Little, 2018 Jun 17)
Related to bracketed paste. I cannot reproduce it.

Using ":file" in quickfix window during an autocommand doesn't work.
(Jason Franklin, 2018 May 23) Allow for using it when there is no argument.

Patch in pull request #2967: Allow white space in sign text. (Ben Jackson)
Test fails in AppVeyor.

Removing flags from 'cpoptions' breaks the Winbar buttons in termdebug.
(Dominique Pelle, 2018 Jul 16)

Problem with two buffers with the same name a/b, if it didn't exist before and
is created outside of Vim. (dskloetg, 2018 Jul 16, #3219)

```
Memory leak in test_assert:
==19127==    by 0x2640D7: alloc (misc2.c:874)
==19127==    by 0x2646D6: vim_strsave (misc2.c:1315)
==19127==    by 0x1B68D2: f_getcwd (evalfunc.c:4950)
And:

==23530==    by 0x2B16BE: mch_call_shell (os_unix.c:5383)
```

gethostbyname() is old, use getaddrinfo() if available. (#3227)

matchaddpos() gets slow with many matches. Proposal by Rick Howe, 2018 Jul
19.

Script generated by :mksession does not work well if there are windows with
modified buffers
  change "silent only" into "silent only!"
  change "edit fname" of first buffer to "hide edit fname"
  skip "badd fname" if "fname" is already in the buffer list
  remove remark about unloading buffers from documentation

Patch to make :help work for tags with a ?. (Hirohito Higashi, 2018 May 28)

Patch to have a stack trace in Ruby. (Masataka Pocke Kuwabara, 2018 Jul 30,
#3267)

Patch to adjust to DPI setting for GTK. (Roel van de Kraats, 2017 Nov 20,
#2357)

Patch to fix window size when using VTP. (Nobuhiro Takasaki, #3164)

Compiler warnings (geeknik, 2017 Oct 26):
- signed integer overflow in do_sub() (#2249)
- signed integer overflow in get_address() (#2248)
- signed integer overflow in getdecchrs() (#2254)
- undefined left shift in get_string_tv() (#2250)

Win32 console: <F11> and <F12> typed in Insert mode don't result in normal
characters. (#3246)

Patch for more quickfix refactoring. (Yegappan Lakshmanan, #2950)

Tests failing for "make testgui" with GTK:
- Test_setbufvar_options()
- Test_exit_callback_interval()

When using CTRL-W CR in the quickfix window, the jumplist in the opened window
is cleared, to avoid going back to the list of errors buffer (would have two
windows with it). Can we just remove the jump list entries for the quickfix
buffer?

Patch to stack and pop the window title and icon. (IWAMOTO Kouichi, 2018 Jun
22, #3059)
8   For xterm need to open a connection to the X server to get the window
    title, which can be slow. Can also get the title with "<Esc>[21t", no
    need to use X11 calls. This returns "<Esc>]l{title}<Esc>\".
Using title stack probably works better.

When a function is defined in the sandbox (with :function or as a lambda)
always execute it in the sandbox. (#3182)
Remove "safe" argument from call_vim_function(), it's always FALSE.

Make balloon_show() work outside of 'balloonexpr'? Users expect it to work:
#2948. (related to #1512?)
On Win32 it stops showing, because showState is already ShS_SHOWING.
balloon_show() does not work properly in the terminal. (Ben Jackson, 2017 Dec
20, #2481)
Also see #2352, want better control over balloon, perhaps set the position.

Try out background make plugin:
  https://github.com/AndrewVos/vim-make-background
or asyncmake:
  https://github.com/yegappan/asyncmake

Add a ModeChanged autocommand that has an argument indicating the old and new

mode. Also used for switching Terminal mode.

Add an option with file patterns, to be used when unloading a buffer: If there
is a match, remove entries for the buffer from marks, jumplist, etc. To be
used for git temp files.

Cursor in wrong position when line wraps. (#2540)

Patch for Lua support. (Kazunobu Kuriyama, 2018 May 26)

Make {skip} argument of searchpair() consistent with other places where we
pass an expression to evaluate. Allow passing zero for "never skip".

Add an option similar to 'lazyredraw' to skip redrawing while executing a
script or function.

Universal solution to detect if t_RS is working, using cursor position.
Koichi Iwamoto, #2126

Patch to fix profiling condition lines. (Ozaki Kiichi,, 2017 Dec 26, #2499)

When using a menu item while the "more" prompt is displayed doesn't work well.
E.g. after using help->version. Have a key that ends the "more" prompt and
does nothing otherwise?

MS-Windows: write may fail if another program is reading the file.
If 'readonly' is not set but the file appears to be readonly later, try again
(wait a little while).
CreateFile() returns ERROR_SHARING_VIOLATION (Linwei, 2018 May 5)

Should add a test for every command line argument. Check coverage for what is
missing: --nofork, -A , -b, -h, etc.

":au * * command" should not be allowed, only use * for event when listing or
deleting autocmds, not when adding them.

Quickfix window height is not kept with a vertical split. (Lifepillar, 2018
Jun 10, #2998)

Improve the installer for MS-Windows. There are a few alternatives:
- Add silent install option. (Shane Lee, #751)
- Installer from Cream (Steve Hall).
- Modern UI 2.0 for the Nsis installer. (Guopeng Wen)
    https://github.com/gpwen/vim-installer-mui2
- make it possible to do a silent install, see
    http://nsis.sourceforge.net/Docs/Chapter4.html#4.12
    Version from Guopeng Wen does this.
- MSI installer: https://github.com/petrkle/vim-msi/
- The one on Issue 279.
Problem: they all work slightly different (e.g. don't install vimrun.exe).
How to test that it works well for all Vim users?

Alternative manpager.vim. (Enno, 2018 Jan 5, #2529)

Patch to use NGETTEXT() in many more places. (Sergey Alyoshin, 2018 May 25)
Updated ptach May 27.

Does setting 'cursorline' cause syntax highlighting to slow down? Perhaps is mess up the cache? (Mike Lee Williams, 2018 Jan 27, #2539)
Also: 'foldtext' is evaluated too often. (Daniel Hahler, #2773)

With 'foldmethod' "indent" and appending an empty line, what follows isn't included in the existing fold. Deleting the empty line and undo fixes it. (Oleg Koshovetc, 2018 Jul 15, #3214)

When using :packadd files under "later" are not used, which is inconsistent with packages under "start". (xtal8, #1994)

Patch to support "xxd -ps". (Erik Auerswald, 2018 May 1)
Lacks a test.

Column number is wrong when using 'linebreak' and 'wrap'. (Keith Smiley, 2018 Jan 15, #2555)

":bufdo e" disabled syntax HL in windows other than the current. (BPJ)

Check argument of systemlist(). (Pavlov)

No maintainer for Vietnamese translations.
No maintainer for Simplified Chinese translations.

Python indenting: alternative way to indent arguments:
http://orchistro.tistory.com/236
Should be supported with a flag.

Starting job with cwd option, when the directory does not exist, gives a confusing error message. (Wang Shidong, 2018 Jan 2, #2519)

Add the debug command line history to viminfo.

Issue #686: apply 'F' in 'shortmess' to more messages. Also #3221.

Avoid that "sign unplace id" does a redraw right away, esp. when there is a sequence of these commands. (Andy Stewart, 2018 Mar 16)

ch_sendraw() with long string does not try to read in between, which may cause a deadlock if the reading side is waiting for the write to finish. (Nate Bosch, 2018 Jan 13, #2548)
Perhaps just make chunks of 1024 bytes?

Patch to include a cfilter plugin to filter quickfix/location lists.
(Yegappan Lakshmanan, 2018 May 12)

Add Makefiles to the runtime/spell directory tree, since nobody uses Aap.
Will have to explain the manual steps (downloading the .aff and .dic files, applying the diff, etc.

Pasting a register in Visual mode cannot be repeated. (Mahmoud Al-Qudsi, 2018

Apr 26, #2849)

User dictionary ~/.vim/spell/lang.utf-8.add not used for spell checking until a word is re-added to it. (Matej Cepl, 2018 Feb 6)

Fold at end of the buffer behaves inconsistently. (James McCoy, 2017 Oct 9)

With foldmethod=syntax and nofoldenable comment highlighting isn't removed. (Marcin Szewczyk, 2017 Apr 26)

Using 'wildignore' also applies to literally entered file name. Also with :drop (remote commands).

Patch to support ":tag <tagkind> <tagname". (emmrk, 2018 May 7, #2871)

Inserting a line in a CompleteDone autocommand may confuse undo. (micbou, 2018 Jun 18, #3027)

Implement option_save() and option_restore():
option_restore({list})   option_restore()
                Restore options previously saved by option_save().
                When buffer-local options have been saved, this function must
                be called when the same buffer is the current buffer.
                When window-local options have been saved, this function must
                be called when the same window is the current window.
                When in the wrong buffer and/or window an error is given and
                the local options won't be restored.

option_save({list})   option_save()
                Saves the options named in {list}. The returned value can be
                passed to option_restore(). Example:
                        let s:saved_options = option_save([
                            \ 'ignorecase',
                            \ 'iskeyword',
                            \ ])
                         au <buffer> BufLeave *
                            \ call option_restore(s:saved_options)
               The advantage over using `:let` is that global and local
                values are handled and the script ID is restored, so that
                `:verbose set` will show where the option was originally set,
                not where it was restored.

"gvim --remote" from a directory with non-word characters changes the current directory (Paulo Marcel Coelho Arabic, 2017 Oct 30, #2266)
Also see #1689.

ml_get error when using a Python script. (Yggdroot, 2017 Jun 1, #1737)
Lemonboy can reproduce (2017 Jun 5)

crash when removing an element while inside map(). (Nikolai Pavlov, 2018 Feb 17, #2652)

When 'virtualedit' is "all" and 'cursorcolumn' is set, the wrong column may be highlighted. (van-de-bugger, 2018 Jan 23, #2576)

Patch to parse ":line" in tags file and use it for search. (Daniel Hahler,
#2546) Fixes #1057. Missing a test.

":file" does not show anything when 'shortmess' contains 'F'. (#3070)

Patch to add winlayout() function. (Yegappan Lakshmanan, 2018 Jan 4)

No profile information for function that executes ":quit". (Daniel Hahler,
2017 Dec 26, #2501)

Get a "No Name" buffer when 'hidden' is set and opening a new window from the
quickfix list. (bfrg, 2018 Jan 22, #2574)

CTRL-X on zero gets stuck on 0xfffffffffffffffe. (Hengyang Zhao, #2746)

A function on a dictionary is not profiled. (ZyX, 2010 Dec 25)

Invalid range error when using BufWinLeave for closing terminal.
(Gabriel Barta, 2017 Nov 15, #2339)

Using an external diff is inefficient. Not all systems have a good diff
program available (esp. MS-Windows). Would be nice to have in internal diff
implementation. Can then also use this for displaying changes within a line.
Olaf Dabrunz is working on this. (10 Jan 2016)
9   Instead invoking an external diff program, use builtin code. One can be
    found here: http://www.ioplex.com/~miallen/libmba/dl/src/diff.c
    It's complicated and badly documented.
Alternative: use the xdiff library. Patch from Christian Brabandt, 2018 Mar
20, #2732)

ml_get errors with buggy script. (Dominique, 2017 Apr 30)

Error in emsg with buggy script. (Dominique, 2017 Apr 30)

Join truncates xml comment. (Dmitrii Tcyganok, 2017 Dec 24, #2494)
Requires 'formatoptions' to include "j". (Gary Johnson, 2017 Dec 24)

Patch to support hunspell. (Matej Cepl, Jan 2018, #2500) Based on older patch
in #846)
Doesn't work on Windows yet. Not ready to included, hard coded paths.

Win32 GUI: when running a fast timer, the cursor no longer blinks.
Was reported: cursor blinks in terminal on widows with a timer. (xtal8, #2142)

When a timer is running and typing CTRL-R on the command line, it is not
redrawn properly. (xtal8, 2017 Oct 23, #2241)

In an optional package the "after" directory is not scanned?
(Renato Fabbri, 2018 Feb 22)

Patch for Neovim concerning restoring when closing help window. (glacambre
neovim #7431)

Default install on MS-Windows should source defaults.vim.
Ask whether to use Windows or Vim key behavior?

Patch for improving detecting Ruby on Mac in configure. (Ilya Mikhaltsou, 2017 Nov 21)

When t_Co is changed from termresponse, the OptionSet autocmmand event isn't triggered. Use the code from the end of set_num_option() in set_color_count().

Add another autocommand like TermResponse that is fired for the other terminal responses, such as bg and fg. Use "bg", "fg", "blink", etc. for the name.

When using command line window, CmdlineLeave is triggered without CmdlineEnter. (xtal8, 2017 Oct 30, #2263)
Add some way to get the nested state. Although CmdwinEnter is obviously always nested.

matchit hasn't been maintained for a long time. #955.

Patch to add variable name after "scope add". (Eddie Lebow, 2018 Feb 7, #2620)
Maybe not needed?

Problem with 'delcombine'. (agguser, 2017 Nov 10, #2313)

MS-Windows: buffer completion doesn't work when using backslash (or slash) for a path separator. (xtal8, #2201)

Test runtime files.
Start with filetype detection: testdir/test_filetype.vim

Window not closed when deleting buffer. (Harm te Hennepe, 2017 Aug 27, #2029)

Add options_default() / options_restore() to set several options to Vim defaults for a plugin. Comments from Zyx, 2017 May 10.
Perhaps use a vimcontext / endvimcontext command block.

After using :noautocmd CursorMoved may still trigger. (Andy Stewart, 2017 Sep 13, #2084). Set old position after the command.

When bracketed paste is used, pasting at the ":append" prompt does not get the line breaks. (Ken Takata, 2017 Aug 22)

The ":move" command does not honor closed folds. (Ryan Lue, #2351)

Patch to fix increment/decrement not working properly when 'virtualedit' is set. (Hirohito Higashi, 2016 Aug 1, #923)

Patch to make gM move to middle of line. (Yasuhiro Matsumoto, Sep 8, #2070)

Cannot copy modeless selection when cursor is inside it. (lkintact, #2300)

Include Haiku port. (Adrien Destugues, Siarzhuk Zharski, 2013 Oct 24)
It can replace the BeOS code, which is likely not used anymore.

```
Now on github: #1856.  Updated Oct 2017
Got permission to include this under the Vim license.

Refactored HTML indent file. (Michael Lee, #1821)

Test_writefile_fails_conversion failure on Solaris because if different iconv
behavior.  Skip when "uname" returns "SunOS"? (Pavel Heimlich, #1872)

'tagrelative' is broken in specific situation. (xaizek, 2017 Oct 19, #2221)

All functions are global, which makes functions like get() and len() awkward.
For the future use the ~get() and ~len() syntax, e.g.:
    mylist~get(idx)
    mydict~get(idx)
    mystring~len()
Alternatives for ~:
    ^  list^get()    could also be used
    .  list.get()    already means concatenate
    $  list$get()    harder to read
    @  list@get()    harder to read
    ->  list->get()  two characters, used for lambda

The ++ options for the :edit command are also useful on the Vim command line.

When recovering a file, put the swap file name in b:recovered_swapfile.  Then
a command can delete it.

When a swap file exists, is not for a running process, is from the same
machine and recovering results in the same text, we could silently delete it.
#1237

Overlong utf-8 sequence is displayed wrong. (Harm te Hennepe, 2017 Sep 14,
#2089)  Patch with possible solution by Björn Linse.

The change list index is local to a buffer, but it doesn't make sense using it
for another buffer.  (lacygoll) Copy w_changelistidx to wininfo_S and back.

X11: Putting more than about 262040 characters of text on the clipboard and
pasting it in another Vim doesn't work.  (Dominique Pelle, 2008 Aug 21-23)
clip_x11_request_selection_cb() is called with zero value and length.
Also: Get an error message from free() in the process that owns the selection.
Seems to happen when the selection is requested the second time, but before
clip_x11_convert_selection_cb() is invoked, thus in X library code.
Kazunobu Kuriyama is working on a proper fix. (2017 Jul 25)

Include a few color schemes, based on popularity:
http://www.vim.org/scripts/script_search_results.php?keywords=&script_type=color+scheme&or
http://vimawesome.com/?q=tag:color-scheme
Use names that indicate their appearance (Christian Brabandt, 2017 Aug 3)
- monokai - Xia Crusoe (2017 Aug 4)
- seoul256 - Christian Brabandt (2017 Aug 3)
- gruvbox -  Christian Brabandt (2017 Aug 3) (simplified version from
      Lifepillar, 2018 Jan 22, #2573)
- janah - Marco Hinz (2017 Aug 4)
```

- apprentice - Romain Lafourcade (2017 Aug 6) remarks about help file #1964
Suggested by Hiroki Kokubun:
- [Iceberg](https://github.com/cocopon/iceberg.vim) (my one)
- [hybrid](https://github.com/w0ng/vim-hybrid)
Include solarized color scheme?, it does not support termguicolors.
- Sanitized version of pablo (Lifepillar, 2017 Nov 21)

Problem with three-piece comment. (Michael Lee, 2017 May 11, #1696)

Creating a partial with an autoload function is confused about the "self"
attribute of the function. For an unknown function assume "self" and make
that optiona? (Bjorn Linse, 2017 Aug 5)

Cindent: returning a structure has more indent for the second item.
(Sam Pagenkopf, 2017 Sep 14, #2090)

Completion mixes results from the current buffer with tags and other files.
Happens when typing CTRL-N while still search for results. E.g., type "b_" in
terminal.c and then CTRL-N twice.
Should do current file first and not split it up when more results are found.
(Also #1890)

Patch from Christian Brabandt to preserve upper case marks when wiping out a
buffer. (2013 Dec 9)
Also fixes #2166?

Patch to add argument to :cquit. (Thinca, 2014 Oct 12)

Python: After "import vim" error messages only show the first line of the
stack trace. (Yggdroot, 2017 Jul 28, #1887)

Profile of a dict function is lost when the dict is deleted. Would it be
possible to collect this? (Daniel Hahler, #2350)

Add `:filter` support for various commands (Marcin Szamotulski, 2017 Nov 12
#2322) Now in #2327?

When checking if a bufref is valid, also check the buffer number, to catch the
case of :bwipe followed by :new.

Patch to skip writing a temp file for diffing if the buffer is equal to the
existing file. (Akria Sheng, 2017 Jul 22)
Could also skip writing lines that are the same.

Patch with Files for Latvian language. (Vitolins, 2017 May 3, #1675)

MS-Windows: Opening same file in a second gvim hangs. (Sven Bruggemann, 2017
Jul 4)

Setting 'clipboard' to "unnamed" makes a global command very slow (Daniel
Drucker, 2017 May 8).
This was supposed to be fixed, did it break again somehow?
Christian cannot reproduce it.

Using composing char in mapping does not work properly. maparg() shows the
wrong thing. (Nikolai Pavlov, 2017 Jul 8, #1827)
Or is this not an actual problem?

Better TeX indent file. (Christian Brabandt, 2017 May 3)

Patch to use a separate code for BS on Windows. (Linwei, #1823)

Use gvimext.dll from the nightly build? (Issue #249)

'synmaxcol' works with bytes instead of screen cells. (Llandon, 2017 May 31,
#1736)

Problem with using :cd when remotely editing a file. (Gerd Wachsmuth, 2017 May
8, #1690)

Running test_gui and test_gui_init with Motif sometimes kills the window
manager. Problem with Motif?

Bogus characters inserted when triggering indent while changing text.
(Vitor Antunes, 2016 Nov 22, #1269)

Using "wviminfo /tmp/viminfo" does not store file marks that Vim knows about,
it only works when merging with an existing file. (Shougo, 2017 Jun 19, #1781)

Segmentation fault with complete(). (Lifepillar, 2017 Apr 29, #1668)
Check for "pat" to be NULL in search_for_exact_line()?
How did it get NULL? Comment by Christian, Apr 30.

Is it possible to keep the complete menu open when calling complete()?
(Prabir Shrestha, 2017 May 19, #1713)

Memory leak in test97? The string is actually freed. Weird.

Patch to add configure flags to skip rtl, farsi and arabic support.
(Diego Carrión, #1867)

assert_fails() can only check for the first error. Make it possible to have
it catch multiple errors and check all of them.

New value "uselast" for 'switchbuf'. (Lemonboy, 2017 Apr 23, #1652)

Add a toolbar in the terminal. Can be global, above all windows, or specific
for one window.

Make maparg() also return the raw rhs, so that it doesn't depend on 'cpo'.
(Brett Stahlman, 2017 May 23)
Even better: add a way to disable a mapping temporarily and re-enable it
later. This is for a sub-mode that is active for a short while (one buffer).
Still need maplist() to find the mappings. What can we use to identify a
mapping? Something unique would be better than the LHS.
Perhaps simpler: actually delete the mappings. Use maplist() to list matching
mappings (with a lhs prefix, like maparg()), mapdelete() to delete,
maprestore() to restore (using the output of maplist()).

Add an argument to :mkvimrc (or add another command) to skip mappings from
plugins (source is a Vim script). No need to put these in a .vimrc, they will
be defined when the plugin is loaded.

Use tb_set(winid, [{'text': 'stop', 'cb': callback, 'hi': 'Green'}])
    tb_highlight(winid, 'ToolBar')
    tb_get(winid)

json_encode(): should convert to utf-8. (Nikolai Pavlov, 2016 Jan 23)
What if there is an invalid character?

Json string with trailing \u should be an error. (Lcd)

import can't be used in define option when include matches too.
(Romain Lafourcade, 2017 Jun 18, #1519)

When session file has name in argument list but the buffer was deleted, the
buffer is not deleted when using the session file. (#1393)
Should add the buffer in hidden state.

When an item in the quickfix list has a file name that does not exist, behave
like the item was not a match for :cnext.

Wrong diff highlighting with three files. (2016 Oct 20, #1186)
Also get E749 on exit.
Another example in #1309

When deleting a mark or register, leave a tombstone, so that it's also deleted
when writing viminfo (and the delete was the most recent action). #1339

Suggestion to improve pt-br spell checking. (Marcelo D Montu, 2016 Dec 15,
#1330)

Error in test_startup_utf8 on Solaris. (Danek Duvall, 2016 Aug 17)

Completion for :!cmd shows each match twice. #1435

GTK: When adding a timer from 'balloonexpr' it won't fire, because
g_main_context_iteration() doesn't return. Need to trigger an event when the
timer expires.

Screen update bug related to matchparen. (Chris Heath, 2017 Mar 4, #1532)

Rule to use "^" for statusline does not work if a space is defined with
highlighting for both stl and stlnc. Patch by Ken Hamada (itchyny, 2016 Dec 11)

8   "stl" and "stlnc" in 'fillchars' don't work for multi-byte characters.
    Patch by Christian Wellenbrock, 2013 Jul 5.

Using CTRL-G_U in InsertCharPre causes trouble for redo. (Israel Chauca
Fuentes, 2017 Feb 12, #1470)

Add a "keytrans()" function, which turns the internal byte representation of a

key into a form that can be used for :map. E.g.
    let xx = "\<C-Home>"
    echo keytrans(xx)
    <C-Home>

Check for errors E704 and E705 only does VAR_FUNC, should also do VAR_PARTIAL.
(Nikolai Pavlov, 2017 Mar 13, #1557)
Make a function to check for function-like type?

Screen updated delayed when using CTRL-O u in Insert mode.
(Barlik, #1191) Perhaps because status message?

Implement optional arguments for functions.
    func Foo(start, count = 1 all = 1)
    call Foo(12)
    call Foo(12, all = 0)
    call Foo(12, 15, 0)

Change the Farsi code to work with UTF-8. Possibly combined with the Arabic
support, or similar.
Invalid read error in Farsi mode. (Dominique Pelle, 2009 Aug 2)

Add a command to take a range of lines, filter them and put the output
somewhere else. :{range}copy {dest} !cmd

Patch to fix that empty first tab is not in session.
(Hirohito Higashi, 2016 Nov 25, #1282)

Patch to add random number generator. (Hong Xu, 2010 Nov 8, update Nov 10)
Alternative from Christian Brabandt. (2010 Sep 19)
New one from Yasuhiro Matsumoto, #1277.

Patch to fix escaping of job arguments. (Yasuhiro Matsumoto, 2016 Oct 5)
Update Oct 14: https://gist.github.com/mattn/d47e7d3bfe5ade4be86062b565a4bfca
Update Aug 2017: #1954

The TermResponse event is not triggered when a plugin has set 'eventignore' to
"all". Netrw does this. (Gary Johnson, 2017 Jan 24)
Postpone the event until 'eventignore' is reset.

Expanding /**/ is slow. Idea by Luc Hermitte, 2017 Apr 14.

Once .exe with updated installer is available: Add remark to download page
about /S and /D options (Ken Takata, 2016 Apr 13)
Or point to nightly builds: https://github.com/vim/vim-win32-installer/releases

Problem passing non-UTF-8 strings to Python 3. (Björn Linse, 2016 Sep 11,
#1053) With patch, does it work?

Using --remote to open a file in which a # appears does not work on
MS-Windows. Perhaps in \# the \ is seen as a path separator. (Axel Bender,
2017 Feb 9) Can we expand wildcards first and send the path literally to the
receiving Vim? Or make an exception for #, it's not useful remotely.

":sbr" docs state it respects 'switchbuf', but "vsplit" does not cause a
vertical split. (Haldean Brown, 2017 Mar 1)

Use ADDR_OTHER instead of ADDR_LINES for many more commands.
Add tests for using number larger than number of lines in buffer.

Might be useful to have isreadonly(), like we have islocked().
Avoids exceptions, e.g. when using the b: namespace as a dict.

Patch to make v:shell_error writable. (Christian Brabandt, 2016 Sep 27)
Useful to restore it. Is there another solution?

"ci[" does not look for next [like ci" does look for next ".
(J.F. 2017 Jan 7)

Patch for wrong cursor position on wrapped line, involving breakindent.
(Ozaki Kiichi, 2016 Nov 25)
Does this also fix #1408 ?

'cursorline' and match interfere. (Ozaki Kiichi, 2017 Jun 23, #1792)

Patch for 'cursorlinenr' option. (Ozaki Kiichi, 2016 Nov 30)

Patch to be able to separately map CTRL-H and BS on Windows.
(Linwei, 2017 Jul 11, #1833)

When 'completeopt' has "noselect" does not insert a newline. (Lifepillar, 2017
Apr 23, #1653)

Window resizing with 'winfixheight': With a vertical split the height changes
anyway. (Tommy allen, 2017 Feb 21, #1502)

When adding an item to a new quickfix list make ":cnext" jump to that item.
Make a difference being at the first item and not having used :cnext at all.
(Afanasiy Fet, 2017 Jan 3)

Invalid behavior with NULL list. (Nikolai Pavlov, #768)
E.g. deepcopy(test_null_list())

Patch to make it possible to extend a list with itself.
(Nikolai Pavlov, 2016 Sep 23)

Patch to add Zstandard compressed file support. (Nick Terrell, 2016 Oct 24)

Patch to add MODIFIED_BY to MSVC build file. (Chen Lei, 2016 Nov 24, #1275)

Patch to change argument of :marks. (LemonBoy, 2017 Jan 29, #1426)

On Windows buffer completion sees backslash as escape char instead of path
separator. (Toffanim, 2016 Nov 24, #1274)

min() and max() spawn lots of error messages if sorted list/dictionary
contains invalid data (Nikolay Pavlov, 2016 Sep 4, #1039)

Should :vmap in matchit.vim be :xmap? (Tony Mechelynck)

Problem with whitespace in errorformat. (Gerd Wachsmuth, 2016 May 15, #807)

Undo problem: "g-" doesn't go back, gets stuck. (Björn Linse, 2016 Jul 18)

Add "unicode true" to NSIS installer. Doesn't work with Windows 95, which we
no longer support.

sort() is not stable when using numeric/float sort (Nikolay Pavlov, 2016 Sep
4#1038)

+channel:
- Add a separate timeout for opening a socket. Currently it's fixed at 50
  msec, which is too small for a remote connection. (tverniquet, #2130)
- Problem with stderr on Windows? (Vincent Rischmann, 2016 Aug 31, #1026)
- Writing raw mode to a buffer should still handle NL characters as line
  breaks. (Dmitry Zotikov, 2017 Aug 16)
- When out_cb executes :sleep, the close_cb may be invoked. (Daniel Hahler,
  2016 Dec 11, #1320)
- Implement job-term ?
- Channel test fails with Motif. Sometimes kills the X11 server.
- When a message in the queue but there is no callback, drop it after a while?
  Add timestamp to queued messages and callbacks with ID, remove after a
  minute. Option to set the droptime.
- Add an option to drop text of very long lines? Default to 1 Mbyte.
- Add remark about undo sync, is there a way to force it?
- When starting a job, have an option to open the server socket, so we know
  the port, and pass it to the command with --socket-fd {nr}. (Olaf Dabrunz,
  Feb 9) How to do this on MS-Windows?
- For connection to server, a "keep open" flag would be useful. Retry
  connecting in the main loop with zero timeout.
- job_start(): run job in a newly opened terminal (not a terminal window).
    With xterm could use -S{pty}.
    Although user could use "xterm -e 'cmd arg'".

Regexp problems:
- When search pattern has the base character both with and without combining
  character, search fails. E.g. "□□□□" in "□□□□□□□□□□□□". (agguser, #2312)
- [:space:] only matches ASCII spaces. Add [:white:] for all space-like
  characters, esp. including 0xa0. Use character class zero.
- Since 7.4.704 the old regex engine fails to match [[:print:]] in 0xf6.
  (Manuel Ortega, 2016 Apr 24)
  Test fails on Mac. Avoid using isalpha(), isalnum(), etc? Depends on
  LC_CTYPE
- The old engine does not find a match for "/\%#=1\(\)\{80}", the new engine
  matches everywhere.
- Using win_linetabsize() can still be slow. Cache the result, store col and
  vcol. Reset them when moving to another line.
- Very slow with a long line and Ruby highlighting. (John Whitley, 2014 Dec 4)
- Bug with pattern: '\vblock (\d+)\.\n.*\d+%(\1)@<!\.$'
  (Lech Lorens, 2014 Feb 3)
- Issue 164: freeze on regexp search.
- Ignorecase not handled properly for multi-byte characters. (Axel Bender,

  2013 Dec 11)
- Using \@> and \?. (Brett Stahlman, 2013 Dec 21) Remark from Marcin
  Szamotulski; Remark from Brett 2014 Jan 6 and 7.
- NFA regexp doesn't handle \%<v correctly. (Ingo Karkat, 2014 May 12)
- Does not work with NFA regexp engine:
  \%u, \%x, \%o, \%d followed by a composing character
- Search for \%d0\+ may fail with E363. (Christian Brabandt, 2016 Oct 4)
- \%'[does not work. '%'] does work. (Masaaki Nakamura, 2016 Apr 4)
- Bug relating to back references. (Ingo Karkat, 2014 Jul 24)
- New RE does not give an error for empty group: "\(\)\{2}" (Dominique Pelle,
  2015 Feb 7)
- Using back reference before the capturing group sometimes works with the old
  engine, can we do this with the new engine? E.g. with
  "/\%(<\1>\)\@<=.*\%(<\/\(\w\+\)>\)\@=" matching text inside HTML tags.
  This problem is probably the same: "\%(^\1.*$\n\)\@<=\(\d\+\).*$".
  (guotuofeng, 2015 Jun 22)
- Strange matching with "\(Hello\n\)\@<=A". (Anas Syed, 2015 Feb 12)
- Problem with \v(A)@<=b+\1c. (Issue 334)
- Diff highlighting can be very slow. (Issue 309)
- Using %> for a virtual column has a check based on 'tabsize'. Better would
  be to cache the result of win_linetabsize(col), storing both col and vcol,
  and use them to decide whether win_linetabsize() needs to be called. Reset
  col and vcol when moving to another line.
- this doesn't work: "syntax match ErrorMsg /.\%9l\%>20c\&\%<28c/". Leaving
  out the \& works. Seems any column check after \& fails.
- Difference between two engines: ".*\zs\/\@>\/" on text "///"
  (Chris Paul, 2016 Nov 13) New engine not greedy enough?
  Another one: echom matchstr(" sdfsfsf\n sfdsdfsdf",'[^\n]*')
  (2017 May 15, #1252)

Patch to add "cmdline" completion to getcompletion(). (Shougo, Oct 1, #1140)

Feature request: Complete members of a dictionary. (Luc Hermitte, 2017 Jan 4,
#1350)

Undo message is not always properly displayed. Patch by Ken Takata, 2013 oct
3. Doesn't work properly according to Yukihiro Nakadaira.
Also see #1635.

Patch for systemlist(), add empty item. (thinca, Sep 30, #1135)
Add an argument to choose binary or non-binary (like readfile()), when omitted
use the current behavior.
Include the test.

Patch to add tagfunc(). Cleaned up by Christian Brabandt, 2013 Jun 22.
New update 2017 Apr 10, #1628

When 'keywordprg' starts with ":" the argument is still escaped as a shell
command argument. (Romain Lafourcade, 2016 Oct 16, #1175)

Patch to support CamelCase for spell checking: See a lower-to-upper case
change as a word boundary. (btucker-MPCData, 2016 Nov 6, #1235)
patch for 'spellcamelcase' option: spellcheck each CamelCased word.
(Ben Tucker, 2016 Dec 2)

Idea from Sven: record sequence of keys. Useful to show others what they are
doing (look over the shoulder), and also to see what happened.
Probably list of keystrokes, with some annotations for mode changes.
Could store in logfile to be able to analyse it with an external command.
E.g. to see when's the last time a plugin command was used.

execute() cannot be used with command completion. (Daniel Hahler, 2016 Oct 1,
#1141)

cmap using execute() has side effects. (Killthemule, 2016 Aug 17, #983)

:map X may print invalid data. (Nikolay Pavlov, 2017 Jul 3, #1816)

Patch to order results from taglist(). (Duncan McDougall, 2016 Oct 25)

When using ":diffput" through a mapping, undo in the target buffer isn't
synced. (Ryan Carney, 2016 Sep 14)

Syntax highlighting for messages with RFC3339 timestamp (#946)
Did maintainer reply?

Patch to avoid problem with special characters in file name.
(Shougo, 2016 Sept 19, #1099) Not finished?

ml_get errors when reloading file. (Chris Desjardins, 2016 Apr 19)
Also with latest version.

Cannot delete a file with square brackets with delete(). (#696)

Patch to add ":syn foldlevel" to use fold level further down the line.
(Brad King, 2016 Oct 19, update 2017 Jan 30)

Completion for input() does not expand environment variables. (chdiza, 2016
Jul 25, #948)

Patch to add 'systemencoding', convert between 'encoding' and this for file
names, shell commands and the like. (Kikuchan, 2010 Oct 14)
Assume the system converts between the actual encoding of the filesystem to
the system encoding (usually utf-8).

Using ":tab drop file" does not trigger BufEnter or TabEnter events.
(Andy Stewart, 2017 Apr 27, #1660)
Autocommands blocked in do_arg_all(). Supposed to happen later?

'hlsearch' interferes with a Conceal match. (Rom Grk, 2016 Aug 9)

MS-Windows: use WS_HIDE instead of SW_SHOWMINNOACTIVE in os_win32.c?
Otherwise task flickers in taskbar.

Should make ":@r" handle line continuation. (Cesar Romani, 2016 Jun 26)
Also for ":@.".

Repeating 'opfunc' in a function only works once. (Tarmean, 2016 Jul 15, #925)

Have a way to get the call stack, in a function and from an exception.
#1125

Second problem in #966: ins_compl_add_tv() uses get_dict_string() multiple
times, overwrites the one buffer. (Nikolay Pavlov, 2016 Aug 5)

This does not work: :set cscopequickfix=a-
(Linewi, 2015 Jul 12, #914)

Possibly wrong value for seq_cur. (Florent Fayolle, 2016 May 15, #806)

Filetype plugin for awk. (Doug Kearns, 2016 Sep 5)

Patch to improve map documentation. Issue #799.

Patch for syntax folding optimization. (Shougo, 2016 Sep 6, #1045)

We can use '. to go to the last change in the current buffer, but how about
the last change in any buffer? Can we use ', (, is next to .)?

Ramel Eshed: system() is much slower than job_start(), why? (Aug 26)

When generating the Unicode tables with runtime/tools/unicode.vim the
emoji_width table has only one entry.

It's possible to add ",," to 'wildignore', an empty entry. Causes problems.
Reject the value? #710.

When doing "vi buf.md" a BufNew autocommand for *.md is not triggered.
Because of using the initial buffer? (Dun Peal, 2016 May 12)

Patch to add the :bvimgrep command. (Christian Brabandt, 2014 Nov 12)
Updated 2016 Jun 10, #858 Update 2017 Mar 28: use <buffer>

Add redrawtabline command. (Naruhiko Nishino, 2016 Jun 11)

Neovim patch for utfc_ptr2char_len() https://github.com/neovim/neovim/pull/4574
No test, needs some work to include.

Patch to improve indenting for C++ constructor with initializer list.
(Hirohito Higashi, 2016 Mar 31)

Zero-out krypt key information when no longer in use. (Ben Fritz, 2017 May 15)

Add stronger encryption. Could use libsodium (NaCl).
https://github.com/jedisct1/libsodium/
Possibly include the needed code so that it can be build everywhere.

Add a way to restart a timer. It's similar to timer_stop() and timer_start(),
but the reference remains valid.

Need to try out instructions in INSTALLpc.txt about how to install all
interfaces and how to build Vim with them.

Appveyor build with self-installing executable, includes getting most
interfaces: https://github.com/k-takata/vim/tree/chrisbra-appveyor-build
result: https://ci.appveyor.com/project/k-takata/vim/history

Problem that a previous silent ":throw" causes a following try/catch not to
work. (ZyX, 2013 Sep 28) With examples: (Malcolm Rowe, 2015 Dec 24)

Problem using ":try" inside ":execute". (ZyX, 2013 Sep 15)

Patch to make tests pass with EBCDIC. (Owen Leibman, 2016 Apr 10)

Add ":read :command", to insert the output of an Ex command?
Can already do it with ":$put =execute('command')".

When repeating the 'confirm' dialog one needs to press Enter. (ds26gte, 2016
Apr 17) #762

exists(":tearoff") does not tell you if the command is implemented. (Tony
Mechelynck) Perhaps use exists("::tearoff") to check?

Use vim.vim syntax highlighting for help file examples, but without ":" in
'iskeyword' for syntax.

Patch to make "%:h:h" return "." instead of the full path.
(Coot, 2016 Jan 24, #592)

Remove SPACE_IN_FILENAME ? What could possibly go wrong?

When command names are very long :command output is difficult to read. Use a
maximum for the column width? (#871)
Patcy by varmanishant, 2016 Jun 18, #876

Installation of .desktop files does not work everywhere.
It's now fixed, but the target directory probably isn't right.
Add configure check?
Should use /usr/local/share/applications or /usr/share/applications.
Or use $XDG_DATA_DIRS.
Also need to run update-desktop-database (Kuriyama Kazunobu, 2015 Nov 4)

Test object i{ and it do not behave the same. #1379
Do not include the linebreak at the start?

Patch to have text objects defined by arbitrary single characters. (Daniel
Thau, 2013 Nov 20, 2014 Jan 29, 2014 Jan 31)
Added tests (James McCoy, 2016 Aug 3). Still needs more work.

Feature request: add the "al" text object, to manipulate a screen line.
Especially useful when using 'linebreak'

":cd C:\Windows\System32\drivers\etc*" does not work, even though the
directory exists. (Sergio Gallelli, 2013 Dec 29)

In debug mode one can inspect variables, but not the function parameters
(starting with a:). (Luc Hermitte, 2017 Jan 4, #1352)

If ":bd" also closes a Tab page then the " mark is not set. (Harm te Hennepe, 2016 Apr 25, #780)

Patch to avoid redrawing tabline when the popup menu is visible.
(Christian Brabandt, 2016 Jan 28)

Patch to add {skip} argument to search(). (Christian Brabandt, 2016 Feb 24)
Update 2016 Jun 10, #861

Patch to be able to use hex numbers with :digraph. (Lcd, 2015 Sep 6)
Update Sep 7. Update by Christian Brabandt, 2015 Sep 8, 2016 Feb 1.

Patch to show search statistics. (Christian Brabandt, 2016 Jul 22)

When the CursorMovedI event triggers, and CTRL-X was typed, a script cannot restore the mode properly. (Andrew Stewart, 2016 Apr 20)
Do not trigger the event?

Using ":windo" to set options in all windows has the side effect that it changes the window layout and the current window. Make a variant that saves and restores. Use in the matchparen plugin.
Perhaps we can use ":windo <restore> {cmd}"?
Patch to add <restore> to :windo, :bufdo, etc. (Christian Brabandt, 2015 Jan 6, 2nd message)
Alternative: ":keeppos" command modifier: ":keeppos windo {cmd}".

Patch to fix that executable() may fail on very long filename in MS-Windows.
(Ken Takata, 2016 Feb 1)

Patch to fix display of listchars on the cursorline. (Nayuri Aohime, 2013)
Update suggested by Yasuhiro Matsumoto, 2014 Nov 25:
https://gist.github.com/presuku/d3d6b230b9b6dcfc0477

Patch to make the behavior of "w" more straightforward, but not Vi compatible.
With a 'cpo' flag. (Christian Brabandt, 2016 Feb 8)

Patch to add optionproperties(). (Anton Lindqvist, 2016 Mar 27, update Apr 13)

Patch to add TagNotFound autocommand. (Anton Lindqvist, 2016 Feb 3)

Patch to add Error autocommand. (Anton Lindqvist, 2016 Feb 17)
Only remembers one error.

GVim: when both Tab and CTRL-I are mapped, use CTRL-I not for Tab.

Unexpected delay when using CTRL-O u. It's not timeoutlen.
(Gary Johnson, 2015 Aug 28)

Instead of separately uploading patches to the ftp site, we can get them from github with a URL like this:
   https://github.com/vim/vim/compare/v7.4.920%5E...v7.4.920.diff
Diff for version.c contains more context, can't skip a patch.

Python: ":py raw_input('prompt')" doesn't work. (Manu Hack)

Comparing nested structures with "==" uses a different comparator than when comparing individual items.
Also, "'' == 0" evaluates to true, which isn't nice.
Add "===" to have a strict comparison (type and value match).
Add "==*" (?) to have a value match, but no automatic conversion, and v:true equals 1 and 1.0, v:false equals 0 and 0.0.?

Using uninitialized memory. (Dominique Pelle, 2015 Nov 4)

MS-Windows: When editing a file with a leading space, writing it uses the wrong name. (Aram, 2014 Nov 7) Vim 7.4.

Can't recognize the $ProgramFiles(x86) environment variable. Recognize it specifically? First try with the parens, then without.

Patch to add :mapgroup, put mappings in a group like augroup.
(Yasuhiro Matsumoto, 2016 Feb 19)

Value returned by virtcol() changes depending on how lines wrap. This is inconsistent with the documentation.

Value of virtcol() for '[and '] depend on multi-byte character.
(Luchr, #277)

Can we cache the syntax attributes, so that updates for 'relativenumber' and 'cursorline'/'cursorcolumn' are a lot faster? Thus store the attributes before combining them.

C highlighting: modern C allows: /* comment */ #ifdef
and also line continuation after #include.
I can't recommend it though.

Build with Python on Mac does not always use the right library.
(Kazunobu Kuriyama, 2015 Mar 28)

Patch to add arguments to argc() and argv(). (Yegappan Lakshmanan, 2016 Jan 24) Also need a way to get the global arg list? Update later on Jan 24 Update Mar 5. Update Apr 7. Update Jun 5.

To support Thai (and other languages) word boundaries, include the ICU library: http://userguide.icu-project.org/boundaryanalysis

When complete() first argument is before where insert started and 'backspace' is Vi compatible, the completion fails. (Hirohito Higashi, 2015 Feb 19)

Patch to use two highlight groups for relative numbers. (Shaun Brady, 2016 Jan 30)

MS-Windows: Crash opening very long file name starting with "\\".
(Christian Brock, 2012 Jun 29)

The OptionSet autocommand event is not always triggered. (Rick Howe, 2015 Sep

24): :diffthis, :diffoff.

":set all&" still does not handle all side effects. Centralize handling side
effects for when set by the user, on init and when reset to default.

":tag" does not jump to the right entry of a :tselect. (James Speros, 2015 Oct
9)

The argument for "-S" is not taken literally, the ":so" command expands
wildcards. Add a ":nowild" command modifier? (ZyX, 2015 March 4)

Proposal to make options.txt easier to read. (Arnaud Decara, 2015 Aug 5)
Update Aug 14.

When using --remote-tab on MS-Windows 'encoding' hasn't been initialized yet,
the file name ends up encoded wrong. (Raul Coronado, 2015 Dec 21)

Example in editing.txt uses $HOME with the expectation that it ends in a
slash. For me it does, but perhaps not for everybody. Add a function that
inserts a slash when needed? pathconcat(dir, path) (Thilo Six, 2015 Aug 12)

ml_updatechunk() is slow when retrying for another encoding. (John Little,
2014 Sep 11)

Patch to fix checking global option value when not using it.
(Arnaud Decara, 2015 Jul 23)

When 'showbreak' is set repeating a Visual operation counts the size of the
'showbreak' text as part of the operation. (Axel Bender, 2015 Jul 20)

Patch for multi-byte characters in langmap and applying a mapping on them.
(Christian Brabandt, 2015 Jun 12, update July 25)
Is this the right solution? Need to cleanup langmap behavior:
- in vgetorpeek() apply langmap to the typeahead buffer and put the result in
  a copy-buffer, only when langmap is appropriate for the current mode. Then
  check for mapping and let gotchars() work on the copy-buffer.
- Remove LANGMAP_ADJUST() in other parts of the code. Make sure the mode is
  covered by the above change.
So that replaying the register doesn't use keymap/langmap and still does the
same thing. Remarks on issue 543 (Roland Puntaier).
Also see #737: langmap not applied to replaying recording.

Patch to add grepfile(). (Scott Prager, 2015 May 26)
Work in progress.

Would be useful to have a treemap() or deepmap() function. Like map() but
when an item is a list or dict would recurse into it.

Patch for global-local options consistency. (Arnaud Decara, 2015 Jul 22)
Is this right?

Patch to make getregtype() return the right size for non-linux systems.
(Yasuhiro Matsumoto, 2014 Jul 8)
Breaks test_eval. Inefficient, can we only compute y_width when needed?

Patch to use different terminal mode settings for system(). (Hayaki Saito)
Does this work for everybody?

Patch for man.vim. (SungHyun Nam, 2015 May 20)
Doesn't work completely (Dominique Orban)

Patch to add a "literal" argument to bufnr(). (Olaf Dabrunz, 2015 Aug 4)

When a session file is created and there are "nofile" buffers, these are not
filled. Need to trigger BufReadCmd autocommands. Also handle deleting the
initial empty buffer better. (ZyX, 2015 March 8)

Extended file attributes lost on write (backupcopy=no). Issue 306.

Patch to add :lockjumps. (Carlo Baldassi, 2015 May 25)
OK to not block marks?

Mixup of highlighting when there is a match and SpellBad. (ZyX, 2015 Jan 1)

Patch on Issue 72: 'autochdir' causes problems for :vimgrep.

When two SIGWINCH arrive very quickly, the second one may be lost.
(Josh Triplett, 2015 Sep 17)

Make comments in the test Makefile silent. (Kartik Agaram, 2014 Sep 24)

Result of systemlist() does not show whether text ended in line break.
(Bjorn Linse, 2014 Nov 27)

When in 'comments' "n:x" follows after three-part comment directly it repeats
any one-character from the previous line. (Kartik Agaram, 2014 Sep 19)

Syntax highlighting slow (hangs) in SASS file. (Niek Bosch, 2013 Aug 21)

Adding "~" to 'cdpath' doesn't work for completion? (Davido, 2013 Aug 19)

Should be easy to highlight all matches with 'incsearch'. Idea by Itchyny,
2015 Feb 6.

Wrong scrolling when using incsearch. Patch by Christian Brabandt, 2014 Dec 4.
Is this a good solution?

Patch: Let rare word highlighting overrule good word highlighting.
(Jakson A. Aquino, 2010 Jul 30, again 2011 Jul 2)

Patch to add digits argument to round(). (Yasuhiro Matsumoto, 2015 Apr 26)

Can assign to s:type when a function s:type has been defined.
Also the other way around: define a function while a variable with that name
was already defined.
(Yasuhiro Matsumoto, 2014 Nov 3)

Patch for ordered dict. (Ozaki Kiichi, 2015 May 7)

Patch to make closed folds line up. (Charles Campbell, 2014 Sep 12)
Remark from Roland Eggner: does it cause crashes? (2014 Dec 12)
Updated patch by Roland Eggner, Dec 16
Updated patch from Charles, 2016 Jul 2

Patch to open folds for 'incsearch'. (Christian Brabandt, 2015 Jan 6)

Patch for building a 32bit Vim with 64bit MingW compiler.
(Michael Soyka, 2014 Oct 15)

Patch: On MS-Windows shellescape() may have to triple double quotes.
(Ingo Karkat, 2015 Jan 16)

Redo only remembers the last change. Could use "{count}g." to redo an older change. How does the user know which change? At least have a way to list them: ":repeats".

Patch for glob(), adding slash to normal files. (Ingo Karkat, 2014 Dec 22)

When entering and leaving the preview window autocommands are triggered, but these may not work well. Perhaps set a flag to indicate that the preview window is involved? (John Otter, 2015 Oct 27)

Using "." to repeat an Ex command puts that command in history. Probably should not happen. If the command is the result of a mapping it's not put in history either. (Jacob Niehus, 2014 Nov 2)
Patch from Jacob, Nov 2.

"hi link" does not respect groups with GUI settings only. (Mark Lodato, 2014 Jun 8)

Bug: Autocompleting ":tag/pat" replaces "/pat" with a match but does not insert a space. (Micha Mos, 2014 Nov 7)

No error for missing endwhile. (ZyX, 2014 Mar 20)

Patch to make extend() fail early when it might fail at some point.
(Olaf Dabrunz, 2015 May 2) Makes extend() slower, do we still want it?
Perhaps only the checks that can be done without looping over the dict or arguments.

Problem with transparent and matchgroup. Issue #475

Patch to add :arglocal and :arglists. (Marcin Szamotulski, 2014 Aug 6)

Spell files use a latin single quote. Unicode also has another single quote: 0x2019. (Ron Aaron, 2014 Apr 4)
New OpenOffice spell files support this with ICONV. But they are not compatible with Vim spell files. The old files can no longer be downloaded.

Spell checking: Add a feature to only consider two spaces after a dot to start a new sentence. Don't give the capitalization error when there is one space.

xterm should be able to pass focus changes to Vim, so that Vim can check for
buffers that changed. Perhaps in misc.c, function selectwindow().
Xterm 224 supports it!
Patch to make FocusGained and FocusLost work in modern terminals. (Hayaki
Saito, 2013 Apr 24) Update 2016 Aug 12.
Also see issue #609.
We could add the enable/disable sequences to t_ti/t_te or t_ks/t_ke.

Idea: For a window in the middle (has window above and below it), use
right-mouse-drag on the status line to move a window up/down without changing
its height? It's like dragging the status bar above it at the same time.

Patch to add a :domodeline command. (Christian Brabandt, 2014 Oct 21)

This does not give an error: (Andre Sihera, 2014 Mar 21)
    vim -u NONE 1 2 3 -c 'bufdo if 1 | echo 1'
This neither: (ZyX)
    vim -u NONE 1 2 3 -c 'bufdo while 1 | echo 1'

'viewdir' default on MS-Windows is not a good choice, it's a system directory.
Change 'viewdir' to "$HOME/vimfiles/view" and use 'viewdiralt' to also read
from?

Problem with upwards search on Windows (works OK on Linux). (Brett Stahlman,
2014 Jun 8)

Include a plugin manager with Vim? Neobundle seems to be the best currently.
Also Vundle: https://github.com/gmarik/vundle
Long message about this from ZyX, 2014 Mar 23. And following replies.
Also see http://vim-wiki.mawercer.de/wiki/topic/vim%20plugin%20managment.html
User view:
- Support multiple sources, basically any http:// URL. Or a central place that
  will work for everybody (github? redirects from vim.org?).
  Be able to look into the files before deciding to install.
- Be able to try out a plugin and remove it again with (almost) no traces.
- Each plugin needs a "manifest" file that has the version, dependencies
  (including Vim version and features), conflicts, list of files, etc.
  Updater uses that to decide what/how to update.
  Dependencies can use a URL for specific versions, or short name for scripts
  on vim.org.
- Once a plugin is installed it remembers where it came from, updater checks
  there. Can manually update when really needed.
- Must be possible to install for one user. Also system wide?
- Can edit plugin config with Vim. Can temporarily disable a plugin.
- Run the update manually, find latest version and install.
- Be able to download without special tools, must work for 95% of users.
Implementation:
- Avoid the 'runtimepath' getting long. Need some other way to keep each
  plugin separate.
- When installing or updating, first figure out what needs to be done. This
  may involve recursively fetching manifest files for dependencies. Then show
  the user what's going to change and ask for OK.
- Scripts on Vim.org must be able to consist of several files. Is zip format
  sufficient? Upload the manifest? Or refer to a site that has the manifest?

- Best is to fetch individual files or use a Vimball. Reduces dependency on
  tools that might be missing and allows inspection of the files before
  installing.
Out of scope:
- Overview of plugins, ratings, comments, etc. That's another world.
- Development work on plugins (although diff with distributed version would be
  useful).

Setting the spell file in a session only reads the local additions, not the
normal spell file. (Enno Nagel, 2014 Mar 29)

When typing the first character of a command, e.g. "f", then using a menu, the
menu item doesn't work. Clear typeahead when using a menu?

Editing an ascii file as ucs-2 or ucs-4 causes display errors.
(ZyX, 2014 Mar 30)

":Next 1 some-arg" does not complain about trailing argument. Also for
various other commands. (ZyX, 2014 Mar 30)

Patch to skip sort if no line matches the expression.
(Christian Brabandt, 2014 Jun 25)

VMS: Select() doesn't work properly, typing ESC may hang Vim. Use sys$qiow
instead. (Samuel Ferencik, 2013 Sep 28)

Patch for XDG base directory support. (Jean François Bignolles, 2014 Mar 4)
Remark on the docs. Should not be a compile time feature. But then what?

Completion of ":e" is ":earlier", should be ":edit". Complete to the matching
command instead of doing this alphabetically. (Mikel Jorgensen)

Patch to define macros for hardcoded values. (Elias Diem, 2013 Dec 14)

Several syntax file match "^\s*" which may get underlined if that's in the
highlight group. Add a "\zs" after it?

The undo file name can get too long. (Issue 346)
For the path use a hash instead of dir%dir%dir%name hash%name.

Patch to add ":undorecover", get as much text out of the undo file as
possible. (Christian Brabandt, 2014 Mar 12, update Aug 22)

Updated spec ftplugin. (Matěj Cepl, 2013 Oct 16)

Patch to right-align signs. (James Kolb (email james), 2013 Sep 23)

Patch to handle integer overflow. (Aaron Burrow, 2013 Dec 12)

Patch to add "ntab" item in 'listchars' to repeat first character. (Nathaniel
Braun, pragm, 2013 Oct 13) A better solution 2014 Mar 5.

7   Windows XP: When using "ClearType" for text smoothing, a column of yellow
    pixels remains when typing spaces in front of a "D" ('guifont' set to

    "lucida_console:h8").
Patch by Thomas Tuegel, also for GTK, 2013 Nov 24

:help gives example for z?, but it does not work. m? and t? do work.

Discussion about canonicalization of Hebrew. (Ron Aaron, 2011 April 10)

Checking runtime scripts: Thilo Six, 2012 Jun 6.

When evaluating expression in backticks, autoload doesn't work.
(Andy Wokula, 2013 Dec 14)

Using <nr>ifoobar<esc> can slow down Vim. Patch by Christian Brabandt, 2013 Dec 13. Only helps a bit, 10000ii<Esc> is still too slow.

GTK: problem with 'L' in 'guioptions' changing the window width.
(Aaron Cornelius, 2012 Feb 6)

Patch to add option that tells whether small deletes go into the numbered registers. (Aryeh Leib Taurog, 2013 Nov 18)

Javascript file where indent gets stuck on: GalaxyMaster, 2012 May 3.

The BufUnload event is triggered when re-using the empty buffer.
(Pokey Rule, 2013 Jul 22)
Patch by Marcin Szamotulski, 2013 Jul 22.

The CompleteDone autocommand needs some info passed to it:
- The word that was selected (empty if abandoned complete)
- Type of completion: tag, omnifunc, user func.

Patch to allow more types in remote_expr(). (Lech Lorens, 2014 Jan 5)
Doesn't work for string in list. Other way to pass all types of variables reliably?

Patch to add {lhs} to :mapclear: clear all maps starting with {lhs}.
(Christian Brabandt, 2013 Dec 9)

Exception caused by argument of return is not caught by try/catch.
(David Barnett, 2013 Nov 19)

Patch to fix that 'cedit' is recognized after :normal. (Christian Brabandt, 2013 Mar 19, later message)

Patch to view coverage of the tests. (Nazri Ramliy, 2013 Feb 15)

Patch to invert characters differently in GTK. (Yukihiro Nakadaira, 2013 May 5)

Patch to add "Q" and "A" responses to interactive :substitute. They are carried over when using :global. (Christian Brabandt, 2013 Jun 19)

Bug with 'cursorline' in diff mode. Line being scrolled into view gets highlighted as the cursor line. (Alessandro Ivaldi, 2013 Jun 4)

Two highlighting bugs. (ZyX, 2013 Aug 18)

Patch to support 'u' in interactive substitute. (Christian Brabandt, 2012 Sep 28) With tests: Oct 9.

Patch from Christian Brabandt to make the "buffer" argument for ":sign place" optional. (2013 Jul 12)

Dialog is too big on Linux too. (David Fishburn, 2013 Sep 2)

Patch to make fold updates much faster. (Christian Brabandt, 2012 Dec)

-   Add regex for 'paragraphs' and 'sections': 'parare' and 'sectre'. Combine
    the two into a regex for searching. (Ned Konz)
Patch by Christian Brabandt, 2013 Apr 20, unfinished.

Bug: findfile("any", "file:///tmp;") does not work.

In the ATTENTION message about an existing swap file, mention the name of the process that is running. It might actually be some other program, e.g. after a reboot.

patch to add "combine" flag to syntax commands. (so8res, 2012 Dec 6)

Syntax update problem in one buffer opened in two windows, bottom window is not correctly updated. (Paul Harris, 2012 Feb 27)

Patch to add getsid(). (Tyru, 2011 Oct 2) Do we want this? Update Oct 4.
Or use expand('<sid>')?

Patch to make confirm() display colors. (Christian Brabandt, 2012 Nov 9)

Patch to add functions for signs. (Christian Brabandt, 2013 Jan 27)

Patch to remove flicker from popup menu. (Yasuhiro Matsumoto, 2013 Aug 15)

Problem with refresh:always in completion. (Tyler Wade, 2013 Mar 17)

b:undo_ftplugin cannot call a script-local function. (Boris Danilov, 2013 Jan 7)

Win32: The Python interface only works with one version of Python, selected at compile time. Can this be made to work with version 2.1 and 2.2 dynamically?

Python: Be able to define a Python function that can be called directly from Vim script. Requires converting the arguments and return value, like with vim.bindeval().

Patch for :tabcloseleft, after closing a tab go to left tab. (William Bowers, 2012 Aug 4)

Patch to improve equivalence classes in regexp patterns.
(Christian Brabandt, 2013 Jan 16, update Jan 17)

Patch to add new regexp classes :ident:, :keyword:, :fname:.
(ichizok, 2016 Jan 12, #1373)

Patch with suggestions for starting.txt. (Tony Mechelynck, 2012 Oct 24)
But use Gnome instead of GTK?

Should be possible to enable/disable matchparen per window or buffer.
Add a check for b:no_match_paren in Highlight_matching_Pair() (Marcin
Szamotulski, 2012 Nov 8)

Session file creation: 'autochdir' causes trouble. Keep it off until after
loading all files.

MS-Windows resizing problems:
- Windows window on screen positioning: Patch by Yukihiro Nakadaira, 2012 Jun
  20. Uses getWindowRect() instead of GetWindowPlacement()
- Win32: When the taskbar is at the top of the screen creating the tabbar
  causes the window to move unnecessarily. (William E. Skeith III, 2012 Jan
  12) Patch: 2012 Jan 13 Needs more work (2012 Feb 2)

'iminsert' global value set when using ":setlocal iminsert"? (Wu, 2012 Jun 23)

Patch to append regexp to tag commands to make it possible to select one out
of many matches. (Cody Cutler, 2013 Mar 28)

The input map for CTRL-O in mswin.vim causes problems after CTRL-X CTRL-O.
Suggestion for another map. (Philip Mat, 2012 Jun 18)
But use "gi" instead of "a". Or use CTRL-\ CTRL-O.

When there are no command line arguments ":next" and ":argu" give E163, which
is confusing. Should say "the argument list is empty".

URXVT:
- will get stuck if byte sequence does not contain the expected semicolon.
- Use urxvt mouse support also in xterm. Explanations:
  http://www.midnight-commander.org/ticket/2662

Patch to have the fold and sign column and at the last line of the buffer.
(Marco Hinz, 2014 Sep 25)
Alternate suggestion: let all columns continue, also the number column.

Patch to add tests for if_xcmdsrv.c., Jul 8, need some more work. (Brian Burns)
New tests Jul 13. Update Jul 17. Discussion Jul 18.

When running Vim in silent ex mode, an existing swapfile causes Vim to wait
for a user action without a prompt. (Maarten Billemont, 2012 Feb 3)
Do give the prompt? Quit with an error?

Patch to list user digraphs. (Christian Brabandt, 2012 Apr 14)

Patch to add digraph() function. (Christian Brabandt, 2013 Aug 22, update Aug
24)

Patch for input method status. (Hirohito Higashi, 2012 Apr 18)

Update Vim app icon (for Gnome). (Jakub Steiner, 2013 Dec 6)

Patch to use .png icons for the toolbar on MS-Windows. (Martin Gieseking, 2013 Apr 18)

Patch for has('unnamedplus') docs. (Tony Mechelynck, 2011 Sep 27)
And one for gui_x11.txt.

":cd" doesn't work when current directory path contains "**".
finddir() has the same problem. (Yukihiro Nakadaira, 2012 Jan 10)
Requires a rewrite of the file_file_in_path code.

Should use has("browsefilter") in ftplugins. Requires patch 7.3.593.

Update for vim2html.pl. (Tyru, 2013 Feb 22)

Patch to sort functions starting with '<' after others. Omit dict functions, they can't be called. (Yasuhiro Matsumoto, 2011 Oct 11)

Patch to pass list to or(), and() and xor(). (Yasuhiro Matsumoto, 2012 Feb 8)

Patch to improve "it" and "at" text object matching. (Christian Brabandt, 2011 Nov 20)

Patch to improve GUI find/replace dialog. (Christian Brabandt, 2012 May 26)
Update Jun 2.

`] moves to character after insert, instead of the last inserted character. (Yukihiro Nakadaira, 2011 Dec 9)

Plugin for Modeleasy. (Massimiliano Tripoli, 2011 Nov 29)

BufWinLeave triggers too late when quitting last window in a tab page. (Lech Lorens, 2012 Feb 21)

Patch for 'transparency' option. (Sergiu Dotenco, 2011 Sep 17)
Only for MS-Windows. No documentation. Do we want this?

Patch to support cursor shape in Cygwin console. (Ben bgold, 2011 Dec 27)

On MS-Windows a temp dir with a & init causes system() to fail. (Ben Fritz, 2012 Jun 19)

'cursorline' is displayed too short when there are concealed characters and 'list' is set. (Dennis Preiser)
Patch 7.3.116 was the wrong solution.
Christian Brabandt has another incomplete patch. (2011 Jul 13)

With concealed text mouse click doesn't put the cursor in the right position. (Herb Sitz) Fix by Christian Brabandt, 2011 Jun 16. Doesn't work properly, need to make the change in where RET_WIN_BUF_CHARTABSIZE() is called.

Syntax region with 'concealends' and a 'cchar' value, 'conceallevel' set to 2, only one of the two ends gets the cchar displayed. (Brett Stahlman, 2010 Aug 21, Ben Fritz, 2010 Sep 14)

The :syntax cchar value can only be a single character. It would be useful to support combining characters. (Charles Campbell)

'cursorline' works on a text line only. Add 'cursorscreenline' for highlighting the screen line. (Christian Brabandt, 2012 Mar 31)

Win32: Patch to use task dialogs when available. (Sergiu Dotenco, 2011 Sep 17) New feature, requires testing. Made some remarks.

Win32: Patch for alpha-blended icons and toolbar height. (Sergiu Dotenco, 2011 Sep 17) Asked for feedback from others.

Win32: Cannot cd into a directory that starts with a space. (Andy Wokula, 2012 Jan 19)

Need to escape $HOME on Windows for fnameescape()? (ZyX, 2011 Jul 21, discussion 2013 Jul 4) Can't simply use a backslash, \$HOME has a different meaning already. Would be possible to use $$HOME where $HOME is to be used.

"2" in 'formatoptions' not working in comments. (Christian Corneliussen, 2011 Oct 26)

Bug in repeating Visual "u". (Lawrence Kesteloot, 2010 Dec 20)

With "unamedplus" in 'clipboard' pasting in Visual mode causes error for empty register. (Michael Seiwald, 2011 Jun 28) I can't reproduce it.

Windows keys not set properly on Windows 7? (cncyber, 2010 Aug 26)

When using a Vim server, a # in the path causes an error message. (Jeff Lanzarotta, 2011 Feb 17)

When there is a ">" in a line that "gq" wraps to the start of the next line, then the following line will pick it up as a leader. Should get the leader from the first line, not a wrapped line. (Matt Ackeret, 2012 Feb 27)

Using ":break" or something else that stops executing commands inside a ":finally" does not rethrow a previously uncaught exception. (ZyX, 2010 Oct 15)

Vim using lots of memory when joining lines. (John Little, 2010 Dec 3)

BT regexp engine: After trying a \@> match and failing, submatches are not cleared. See test64.

Patch to make "z=" work when 'spell' is off. Does this have nasty side effects? (Christian Brabandt, 2012 Aug 5, Update 2013 Aug 12)
Would also need to do this for spellbadword() and spellsuggest().

On 64 bit MS-Windows "long" is only 32 bits, but we sometimes need to store a

64 bits value. Change all number options to use nropt_T and define it to the
right type.

string() can't parse back "inf" and "nan". Fix documentation or fix code?
(ZyX, 2010 Aug 23)

When doing "redir => s:foo" in a script and then "redir END" somewhere else
(e.g. in a function) it can't find s:foo.
When a script contains "redir => s:foo" but doesn't end redirection, a
following "redir" command gives an error for not being able to access s:foo.
(ZyX, 2011 Mar 27)

When setqflist() uses a filename that triggers a BufReadCmd autocommand Vim
doesn't jump to the correct line with :cfirst. (ZyX, 2011 Sep 18)

Behavior of i" and a" text objects isn't logical. (Ben Fritz, 2013 Nov 19)

maparg() does not show the <script> flag. When temporarily changing a
mapping, how to restore the script ID?

Bug in try/catch: return with invalid compare throws error that isn't caught.
(ZyX, 2011 Jan 26)

When setting a local option value from the global value, add a script ID that
indicates this, so that ":verbose set" can give a hint. Check with options in
the help file.

After patch 7.3.097 still get E15. (Yukihiro Nakadaira, 2011 Jan 18)
Also for another example (ZyX, 2011 Jan 24)

Build problem with small features on Mac OS X 10.6. (Rainer, 2011 Jan 24)

"0g@$" puts '] on last byte of multi-byte. (ZyX, 2011 Jan 22)

Patch for :tabrecently. (Hirokazu Yoshida, 2012 Jan 30)

Problem with "syn sync grouphere". (Gustavo Niemeyer, 2011 Jan 27)

Loading autoload script even when usage is inside "if 0". (Christian Brabandt,
2010 Dec 18)

With a filler line in diff mode, it isn't displayed in the column with line
number, but it is in the sign column. Doesn't look right. (ZyX 2011 Jun 5)
Patch by Christian Brabandt, 2011 Jun 5. Introduces new problems.

Add jump() function. (Marcin Szamotulski, 2013 Aug 29)
Is this needed? CTRL-O and CTRL-I do the same, just more difficult to use.

8   Add a command to jump to the next character highlighted with "Error".
Patch by Christian Brabandt, uses]e [e]t and [t. 2011 Aug 9.

Add event for when the text scrolls. A bit like CursorMoved. Also a similar
one for insert mode. Use the event in matchparen to update the highlight if
the match scrolls into view.

7   Use "++--", "+++--" for different levels instead of "+---" "+----".
Patch by Christian Brabandt, 2011 Jul 27.
Update by Ben Fritz, with fix for TOhtml. (2011 Jul 30)

9   Add %F to 'errorformat': file name without spaces. Useful on Unix to
    avoid matching something up to a time 11:22:33.
Patch by Christian Brabandt, 2011 Jul 27.

Patch to add up to 99 match groups. (Christian Brabandt, 2010 Dec 22)
Also add named groups: \%{name}(re) and \%{name}g

In the sandbox it's not allowed to do many things, but it's possible to change
or set variables. Add a way to prevent variables from being changed in the
sandbox? E.g.: ":protect g:restore_settings".

GTK: drawing a double-width combining character over single-width characters
doesn't look right. (Dominique Pelle, 2010 Aug 8)

GTK: tear-off menu does not work. (Kurt Sonnenmoser, 2010 Oct 25)

Win32: tear-off menu does not work when menu language is German. (Markus
Bossler, 2011 Mar 2) Fixed by 7.3.095?

Wish for NetBeans commands:
    - make it possible to have 'defineAnnoType' also handle terminal colors.

Version of netbeans.c for use with MacVim. (Kazuki Sakamoto, 2010 Nov 18)

7.3.014 changed how backslash at end of line works, but still get a NUL when
there is one backslash. (Ray Frush, 2010 Nov 18) What does the original ex
do?

Searching mixed with Visual mode doesn't redraw properly. (James Vega, 2010 Nov
22)

New esperanto spell file can't be processed. (Dominique Pelle, 2011 Jan 30)
- move compflags to separate growarray?
- instead of a regexp use a hashtable. Expand '?', '*', '+'. What would be
  the maximum repeat for * and +?

"L'Italie" noted as a spell error at start of the sentence. (Dominique Pelle,
2011 Feb 27)

Editing a file with a ^M with 'ff' set to "mac", opening a help file, then the
^M is displayed as ^J sometimes. Getting 'ff' value from wrong window/buffer?

When Vim is put in the background (SIGTSTP) and then gets a SIGHUP it doesn't
exit. It exists as soon as back in the foreground. (Stephen Liang, 2011 Jan
9) Caused by vim_handle_signal(SIGNAL_BLOCK); in ui.c.

g` not working correctly when using :edit. It works OK when editing a file on
the command line. (Ingo Karkat, 2011 Jan 25)

Since patch 7.2.46 Yankring plugin has become very slow, eventually make Vim crash? (Raiwil, 2010 Nov 17)

Patch to add FoldedLineNr highlighting: different highlighting for the line number of a closed fold. (eXerigumo Clanjor, 2013 Jul 15)

Regexp engine performance:
- Profiling:
        ./vim -u NONE -s ~/vim/test/ruby.vim
        ./vim -u NONE -s ~/vim/test/loop.vim
        ./vim -u NONE -s ~/vim/test/alsa.vim
        ./vim -s ~/vim/test/todo.vim
        ./vim -s ~/vim/test/xml.vim
    Dominique Pelle: xmlSyncDT is particularly slow (Jun 7)
- More test files from the src/pkg/regexp/testdata directory in the Go repo.
- Performance tests:
  - Using asciidoc syntax. (Marek Schimara, 2013 Jun 6)
  - ~/vim/text/FeiqCfg.xml (file from Netjune)
  - ~/vim/text/edl.svg (also XML)
  - glts has five tests. (May 25)
  - ~/vim/test/slowsearch
  - ~/vim/test/rgb.vim
  - search for a.*e*exn in the vim executable. Go to last line to use 'hlsearch'.
  - Slow combination of folding and PHP syntax highlighting. Script to reproduce it. Caused by "syntax sync fromstart" in combination with patch 7.2.274. (Christian Brabandt, 2010 May 27) Generally, folding with 'foldmethod' set to "syntax" is slow. Do profiling to find out why.

Problem producing tags file when hebrew.frx is present. It has a BOM. Results in E670. (Tony Mechelynck, 2010 May 2)

'beval' option should be global-local.

Ruby: ":ruby print $buffer.number" returns zero.

setpos() does not restore cursor position after :normal. (Tyru, 2010 Aug 11)

7   The 'directory' option supports changing path separators to "%" to make file names unique, also support this for 'backupdir'. (Mikolaj Machowski)
    Patch by Christian Brabandt, 2010 Oct 21.
    Is this an update: related to: #179
    https://github.com/chrisbra/vim-mq-patches/blob/master/backupdir
    Fixed patch 2017 Jul 1.

With "tw=55 fo+=a" typing space before) doesn't work well. (Scott Mcdermott, 2010 Oct 24)

Messages in message.txt are highlighted as examples.

When using cp850 the NBSP (0xff) is not drawn correctly. (Brett Stahlman, 2010 Oct 22) 'isprint' is set to "@,161-255".

":echo "\x85" =~# '[\u0085]'" returns 1 instead of 0. (ZyX, 2010 Oct 3)

'cindent' not correct when 'list' is set. (Zdravi Korusef, 2010 Apr 15)

C-indenting: A matching { in a comment is ignored, but intermediate { are not checked to be in a comment. Implement FM_SKIPCOMM flag of findmatchlimit(). Issue 46.

Mac with X11: clipboard doesn't work properly. (Raf, 2010 Aug 16)

Using CompilerSet doesn't record where an option was set from. E.g., in the gcc compiler plugin. (Gary Johnson, 2010 Dec 13)

":helpgrep" does not put the cursor in the correct column when preceded by accented character. (Tony Mechelynck, 2010 Apr 15)

Don't call check_restricted() for histadd(), setbufvar(), settabvar(), setwinvar().

Patch for gVimExt to show an icon. (Dominik Riebeling, 2010 Nov 7)

When 'lines' is 25 and 'scrolloff' is 12, "j" scrolls zero or two lines instead of one. (Constantin Pan, 2010 Sep 10)

Gui menu edit/paste in block mode insert only inserts in one line (Bjorn Winckler, 2011 May 11)
Requires a map mode for Insert mode started from blockwise Visual mode.

Writing nested List and Dict in viminfo gives error message and can't be read back. (Yukihiro Nakadaira, 2010 Nov 13)

Problem with cursor in the wrong column. (SungHyun Nam, 2010 Mar 11)
Additional info by Dominique Pelle. (also on 2010 Apr 10)

CreateFile and CreateFileW are used without sharing, filewritable() fails when the file was already open (e.g. script is being sourced). Add FILE_SHARE_READ| FILE_SHARE_WRITE in mch_access()? (Phillippe Vaucher, 2010 Nov 2)

Is ~/bin (literally) in $PATH supposed to work? (Paul, 2010 March 29)
Looks like only bash can do it. (Yakov Lerner)

Cscope "cs add" stopped working somewhat before 7.2.438. (Gary Johnson, 2010 Jun 29) Caused by 7.2.433?

I often see pasted text (from Firefox, to Vim in xterm) appear twice.
Also, Vim in xterm sometimes loses copy/paste ability (probably after running an external command).

Jumplist doesn't work properly in Insert mode? (Jean Johner, 2010 Mar 20)

Problem with transparent cmdline. Also: Terminal title is wrong with non-ASCII character. (Lily White, 2010 Mar 7)

iconv() doesn't fail on an illegal character, as documented. (Yongwei Wu, 2009 Nov 15, example Nov 26) Add argument to specify whether iconv() should fail

or replace with a character and continue?

Add local time at start of --startuptime output.
Requires configure check for localtime().
Use format year-month-day hr:min:sec.

Patch to add "combine" to :syntax, combines highlight attributes. (Nate Soares, 2012 Dec 3)

Patch to make ":hi link" also take arguments. (Nate Soares, 2012 Dec 4)

Shell not recognized properly if it ends in "csh -f". (James Vega, 2009 Nov 3)
Find tail? Might have a / in argument. Find space? Might have space in path.

Test 51 fails when language set to German. (Marco, 2011 Jan 9)
Dominique can't reproduce it.

'ambiwidth' should be global-local.

":function f(x) keepjumps" creates a function where every command is executed like it has ":keepjumps" before it.

Coverity: Check if there are new reported defects:
https://scan.coverity.com/projects/241

Patch to support :undo absolute jump to file save number. (Christian Brabandt, 2010 Nov 5)

Patch to use 'foldnestmax' also for "marker" foldmethod. (Arnaud Lacombe, 2011 Jan 7)

Bug with 'incsearch' going to wrong line. (Wolfram Kresse, 2009 Aug 17)
Only with "vim -u NONE".

Problem with editing file in binary mode. (Ingo Krabbe, 2009 Oct 8)

With 'wildmode' set to "longest:full,full" and pressing Tab once the first entry in wildmenu is highlighted, that shouldn't happen. (Yuki Watanabe, 2011 Feb 12)

Display error when 'tabline' that includes a file name with double-width characters. (2010 Aug 14, bootleq)

Problem with stop directory in findfile(). (Adam Simpkins, 2009 Aug 26)

Using ']' as the end of a range in a pattern requires double escaping:
    /[@-\\]] (Andy Wokula, 2011 Jun 28)

Syntax priority problem. (Charles Campbell, 2011 Sep 15)

When completion inserts the first match, it may trigger the line to be folded.
Disable updating folds while completion is active? (Peter Odding, 2010 Jun 9)

When a:base in 'completefunc' starts with a number it's passed as a number,
not a string. (Sean Ma) Need to add flag to call_func_retlist() to force a
string value.

For running gvim on a USB stick: avoid the OLE registration. Use a command
line argument -noregister.

When using an expression in 'statusline' leading white space sometimes goes
missing (but not always). (ZyX, 2010 Nov 1)

When a mapping exists both for insert mode and lang-insert mode, the last one
doesn't work. (Tyru, 2010 May 6) Or is this intended?

Still a problem with ":make" in the wrong directory. Caused by ":bufdo".
(Ajit Thakkar, 2009 Jul 1) More information Jul 9, Jul 15.
Caused by "doautoall syntaxset BufEnter *" in syntax/nosyntax.vim ?
There also is a BufLeave/BufEnter aucmd to save/restore view.
Does the patch to save/restore globaldir work?

":bufdo normal gg" while 'hidden' is set leaves buffers without syntax
highlighting. Don't disable Syntax autocommands then? Or add a flag/modifier
to avoid changing 'eventignore'?

Patch for displaying 0x200c and 0x200d. (Ali Gholami Rudi, 2009 May 6)
Probably needs a bit of work.

Patch to add farsi handling to arabic.c (Ali Gholami Rudi, 2009 May 2)
Added test, updates, June 23.
Updated for 7.4: http://litcave.rudi.ir/farsi_vim.diff
With modification for Tatweel character: https://dpaste.de/VmFw
Remark from Ameretat Reith (2014 Oct 13)

List of encoding aliases. (Takao Fujiwara, 2009 Jul 18)
Are they all OK? Update Jul 22.

Win32: Improved Makefile for MSVC. (Leonardo Valeri Manera, 2010 Aug 18)

Win32: Expanding 'path' runs into a maximum size limit. (bgold12, 2009 Nov 15)

Win32: Patch for enabling quick edit mode in console. (Craig Barkhouse, 2010
Sep 1)

Win32: Patch for using .png files for icons. (Charles Peacech, 2012 Feb 5)

Putting a Visual block while 'visualedit' is "all" does not leave the cursor
on the first character. (John Beckett, 2010 Aug 7)

Setting 'tags' to "tagsdir/*" does not find "tagsdir/tags". (Steven K. Wong,
2009 Jul 18)

Patch to add "focusonly" to 'scrollopt', so that scrollbind also applies in
window that doesn't have focus. (Jonathon Mah, 2009 Jan 12)
Needs more work.

Problem with <script> mappings (Andy Wokula, 2009 Mar 8)

When starting Vim with "gvim -f -u non_existent_file > foo.txt" there are a few control characters in the output. (Dale Wiles, 2009 May 28)

'cmdwinheight' is only used in last window when 'winheight' is a large value. (Tony Mechelynck, 2009 Apr 15)

Status line containing winnr() isn't updated when splitting the window (Clark J. Wang, 2009 Mar 31)

When $VIMRUNTIME is set in .vimrc, need to reload lang files. Already done for GTK, how about others? (Ron Aaron, 2010 Apr 10)

Patch for GTK buttons X1Mouse and X2Mouse. (Christian J. Robinson, 2010 Aug 9)

Motif: Build on Ubuntu can't enter any text in dialog text fields.

":tab split fname" doesn't set the alternate file in the original window, because win_valid() always returns FALSE. Below win_new_tabpage() in ex_docmd.c.

Space before comma in function definition not allowed: "function x(a , b)" Give a more appropriate error message. Add a remark to the docs.

string_convert() should be able to convert between utf-8 and utf-16le. Used for GTK clipboard. Avoid requirement for iconv.

Now that colnr_T is int instead of unsigned, more type casts can be removed.

'delcombine' does not work for the command line. (Tony Mechelynck, 2009 Jul 20)

Don't load macmap.vim on startup, turn it into a plugin. (Ron Aaron, 2009 Apr 7) Reminder Apr 14.

Add "no_hlsearch" to winsaveview().

Cursorline highlighting combines with Search ('hlsearch') but not with SpellBad. (Jim Karsten, 2009 Mar 18)

When 'foldmethod' is "indent", adding an empty line below a fold and then indented text, creates a new fold instead of joining it with the previous one. (Evan Laforge, 2009 Oct 17)

Bug: When reloading a buffer changed outside of Vim, BufRead autocommands are applied to the wrong buffer/window. (Ben Fritz, 2009 Apr 2, May 11)
Ignore window options when not in the right window?
Perhaps we need to use a hidden window for applying autocommands to a buffer that doesn't have a window.

When using "ab foo bar" and mapping <Tab> to <Esc>, pressing <Tab> after foo doesn't trigger the abbreviation like <Esc> would. (Ramana Kumar, 2009 Sep 6)

getbufvar() to get a window-local option value for a buffer that's not displayed in a window should return the value that's stored for that buffer.

":he ctrl_u" can be auto-corrected to ":he ctrl-u".

There should be a way after an abbreviation has expanded to go back to what was typed. CTRL-G h ? Would also undo last word or line break inserted perhaps. And undo CTRL-W. CTRL-G l would redo.

Diff mode out of sync. (Gary Johnson, 2010 Aug 4)

Win32 GUI: last message from startup doesn't show up when there is an echoerr command. (Cyril Slobin, 2009 Mar 13)

Win32: completion of file name ":e c:\!test" results in ":e c:\\!test", which does not work. (Nieko Maatjes, 2009 Jan 8, Ingo Karkat, 2009 Jan 22)

opening/closing window causes other window with 'winfixheight' to change height. Also happens when there is another window in the frame, if it's not very high. (Yegappan Lakshmanan, 2010 Jul 22, Michael Peeters, 2010 Jul 22)

Directory wrong in session file, caused by ":lcd" in BufEnter autocommand. (Felix Kater, 2009 Mar 3)

Session file generates error upon loading, cause by --remote-silent-tab. (7tommm (ytommm) 2010 Nov 24)

Using ~ works OK on 'a' with composing char, but not on 0x0418 with composing char 0x0301. (Tony Mechelynck, 2009 Mar 4)

Searching for composing char works, but not when inside []. (ZyX, Benjamin R. Haskell, 2010 Aug 24)

This does not work yet: "a\(%C\)" (get composing characters into a submatch).

Inconsistent: starting with $LANG set to es_ES.utf-8 gives Spanish messages, even though locale is not supported. But ":lang messages es_ES.utf-8" gives an error and doesn't switch messages. (Dominique Pelle, 2009 Jan 26)

When $HOME contains special characters, such as a comma, escape them when used in an option. (Michael Hordijk, 2009 May 5)
Turn "esc" argument of expand_env_esc() into string of chars to be escaped.

Should make 'ignorecase' global-local, so that it makes sense setting it from a modeline.

Add cscope target to Makefile. (Tony Mechelynck, 2009 Jun 18, replies by Sergey Khorev)

Consider making YankRing or something else that keeps a list of yanked text part of standard Vim. The "1 to "9 registers are not sufficient.

After doing "su" $HOME can be the old user's home, thus ~root/file is not

correct. Don't use it in the swap file.

Completion for ":buf" doesn't work properly on Win32 when 'shellslash' is off.
(Henrik Ohman, 2009, Jan 29)

shellescape() depends on 'shellslash' for quoting. That doesn't work when
'shellslash' is set but using cmd.exe. (Ben Fritz)
Use a different option or let it depend on whether 'shell' looks like a
unix-like shell?

Bug: in Ex mode (after "Q") backslash before line break, when yanked into a
register and executed, results in <Nul>: instead of line break.
(Konrad Schwarz, 2010 Apr 16)

Have a look at patch for utf-8 line breaking. (Yongwei Wu, 2008 Mar 1, Mar 23)
Now at: http://vimgadgets.sourceforge.net/liblinebreak/

Greek sigma character should be lower cased depending on the context. Can we
make this work? (Dominique Pelle, 2009 Sep 24)

When changing 'encoding' convert all the swap file names, so that we can
still delete them. Also convert all buffer file names?

"gqip" in Insert mode has an off-by-one error, causing it to reflow text.
(Raul Coronado, 2009 Nov 2)

Update src/testdir/main.aap.

Something wrong with session that has "cd" commands and "badd", in such a way
that Vim doesn't find the edited file in the buffer list, causing the
ATTENTION message? (Tony Mechelynck, 2008 Dec 1)
Also: swap files are in ~/tmp/ One has relative file name ".mozilla/...".

Add v:motion_force. (Kana Natsuno, 2008 Dec 6)
Maybe call it v:motiontype.

MS-Windows: editing the first, empty buffer, 'ffs' set to "unix,dos", ":enew"
doesn't set 'ff' to "unix". (Ben Fritz, 2008 Dec 5) Reusing the old buffer
probably causes this.

'scrollbind' is not respected when deleting lines or undo. (Milan Vancura,
2009 Jan 16)

Document that default font in Athena can be set with resources:
   XtDefaultFont: "9x15"
   XtDefaultFontSet: "9x15"
(Richard Sherman, 2009 Apr 12)

Having "Syntax" in 'eventignore' for :bufdo may cause problems, e.g. for
":bufdo e" when buffers are open in windows. ex_listdo(eap) could set the
option only for when jumping to another buffer, not when the command argument
is executed.

":pedit %" with a BufReadPre autocommand causes the cursor to move to the

first line. (Ingo Karkat, 2008 Jul 1) Ian Kelling is working on this.
Similar problem with ":e". (Marc Montu, 2014 Apr 22)

Wildmenu not deleted: "gvim -u NONE", ":set nocp wildmenu cmdheight=3
laststatus=2", CTRL-D CTRL-H CTRL-H CTRL-H. (A.Politz, 2008 April 1)
Works OK with Vim in an xterm.

Cursor line moves in other window when using CTRL-W J that doesn't change
anything. (Dasn, 2009 Apr 7)

On Unix "glob('does not exist~')" returns the string. Without the "~" it
doesn't. (John Little, 2008 Nov 9)
Shell expansion returns unexpanded string?
Don't use shell when "~" is not at the start?

When using ":e ++enc=foo file" and the file is already loaded with
'fileencoding' set to "bar", then do_ecmd() uses that buffer, even though the
fileencoding differs. Reload the buffer in this situation? Need to check for
the buffer to be unmodified.
Unfinished patch by Ian Kelling, 2008 Jul 11. Followup Jul 14, need to have
another look at it.

c.vim: XXX in a comment is colored yellow, but not when it's after "#if 0".
(Ilya Dogolazky, 2009 Aug 7)

You can type ":w ++bad=x fname", but the ++bad argument is ignored. Give an
error message? Or is this easy to implement? (Nathan Stratton Treadway, 2008
Aug 20) This is in ucs2bytes(), search for 0xBF. Using the ++bad argument is
at the other match for 0xBF.

When adding "-complete=file" to a user command this also changes how the
argument is processed for <f-args>. (Ivan Tishchenko, 2008 Aug 19)

Win32: associating a type with Vim doesn't take care of space after a
backslash? (Robert Vibrant, 2008 Jun 5)

When 'rightleft' is set, cursorcolumn isn't highlighted after the end of a
line. It's also wrong in folds. (Dominique Pelle, 2010 Aug 21)

Using an insert mode expression mapping, cursor is not in the expected
position. (ZyX, 2010 Aug 29)

After using <Tab> for command line completion after ":ta blah" and getting E33
(no tags file), further editing the command to e.g., ":echo 'blah'", the
command is not executed. Fix by Ian Kelling?

":help s/~" jumps to *s/\~*, while ":help s/\~" doesn't find anything. (Tim
Chase) Fix by Ian Kelling, 2008 Jul 14.

When mapping : to ; and ; to :, @; doesn't work like @: and @: doesn't work
either. Matt Wozniski: nv_at() calls do_execreg() which uses
put_in_typebuf(). Char mapped twice?

Despite adding save_subexpr() this still doesn't work properly:

Regexp: matchlist('12a4aaa', '^\(.\{-}\)\(\%5c\@<=a\+\)\(.\+\)\?')
Returns ['12a4', 'aaa', '4aaa'], should be ['12a4', 'aaa', '']
Backreference not cleared when retrying after \@<= fails?
(Brett Stahlman, 2008 March 8)

Problem with remote_send(). (Charles Campbell, 2008 Aug 12)

ftplugin for help file should set 'isk' to help file value.

Win32: remote editing fails when the current directory name contains "[".
(Ivan Tishchenko, Liu Yubao) Suggested patch by Chris Lubinski: Avoid
escaping characters where the backslash is not removed later. Asked Chris for
an alternate solution, also for src/ex_getln.c.
This also fails when the file or directory name contains "%". (Thoml, 2008
July 7)
Using --remote-silent while the current directory has a # in the name does not
work, the # needs to be escaped. (Tramblay Bruno, 2012 Sep 15)

When using remote-silent the -R flag is not passed on. (Axel Bender, 2012 May
31)

Win32: A --remote command that has a directory name starting with a (doesn't
work, the backslash is removed, assuming that it escapes the (. (Valery
Kondakoff, 2009 May 13)

Win32: Using "gvim --remote-tab-silent elŝuti.txt" doesn't work, the
multi-byte character isn't passed and edits elsuti.txt.
(Raúl Núñez de Arenas Coronado, 2015 Dec 18)

Problem with 'langmap' being used on the rhs of a mapping. (Nikolai Weibull,
2008 May 14)
Possibly related problem: Alexey Muranov, 2015 Apr 2

Problem with CTRL-F. (Charles Campbell, 2008 March 21)
Only happens with "gvim -geometry "160x26+4+27" -u NONE -U NONE prop.c".
'lines' is 54. (2008 March 27)

Problem with pointer wrapping around in getvcol(). (Wolfgang Kroworsch, 2008
Oct 19) Check for "col" being "MAXCOL" separately?

Unexpectedly inserting a double quote. (Anton Woellert, 2008 Mar 23)
Works OK when 'cmdheight' is 2.

8   Use a mechanism similar to omni completion to figure out the kind of tab
    for CTRL-] and jump to the appropriate matching tag (if there are
    several).
    Alternative: be able to define a function that takes the tag name and uses
    taglist() to find the right location. With indication of using CTRL-] so
    that the context can be taken into account. (Robert Webb)
Patch by Christian Brabandt, 2013 May 31.

The utf class table is missing some entries:
        0x2212, minus sign
        0x2217, star

```
        0x2500, bar
        0x26ab, circle

Visual line mode doesn't highlight properly when 'showbreak' is used and the
line doesn't fit. (Dasn, 2008 May 1)

GUI: In Normal mode can't yank the modeless selection.  Make "gy" do this?
Works like CTRL-Y in Command line mode.

Mac: Move Carbon todo items to os_mac.txt.  Note that this version is frozen,
try the Cocoa version.

Mac: After a ":vsplit" the left scrollbar doesn't appear until 'columns' is
changed or the window is resized.

GTK: when setting 'columns' in a startup script and doing ":vertical diffsplit"
the window isn't redrawn properly, see two vertical bars.

Mac: Patch for configure: remove arch from ruby link args. (Knezevic, 2008
Mar 5)  Alternative: Kazuki Sakamoto, Mar 7.

Mac: trouble compiling with Motif, requires --disable-darwin. (Raf, 2008 Aug
1)  Reply by Ben Schmidt.

C't: On utf-8 system, editing file with umlaut through Gnome results in URL
with %nn%nn, which is taken as two characters instead of one.
Try to reproduce at work.

Patch for default choice in file changed dialog. (Bjorn Winckler, 2008 Oct 19)
Is there a way to list all the files first?

When 'smartcase' is set and using CTRL-L to add to the search pattern it may
result in no matches.  Convert chars to lower case? (Erik Wognsen, 2009 Apr
16)

Fail to edit file after failed register access.  Error flag remains set?
(Lech Lorens, 2010 Aug 30)

Patch for redo register. (Ben Schmidt, 2007 Oct 19)
Await response to question to make the register writable.

Problem with 'ts' set to 9 and 'showbreak' to ">>>". (Matthew Winn, 2007 Oct
1)

In the swapfile dialog, add a H(elp) option that gives more info about what
each choice does.  Similar to  ":help swap-exists-choices"

try/catch not working for argument of return. (Matt Wozniski, 2008 Sep 15)

try/catch not working when inside a for loop. (ZyX, 2011 Jan 25)

":tab help" always opens a new tab, while ":help" re-uses an existing window.
Would be more consistent when an existing tab is re-used. (Tony Mechelynck)
```

Add ":nofold". Range will apply without expanding to closed fold.

Using Aap to build Vim: add remarks about how to set personal preferences.
Example on http://www.calmar.ws/tmp/aap.html

Syntax highlighting wrong for transparent region. (Doug Kearns, 2007 Feb 26)
Bug in using a transparent syntax region. (Hanlen in vim-dev maillist, 2007
Jul 31)

C syntax: {} inside () causes following {} to be highlighted as error.
(Michalis Giannakidis, 2006 Jun 1)

When 'diffopt' has "context:0" a single deleted line causes two folds to merge
and mess up syncing. (Austin Jennings, 2008 Jan 31)

Gnome improvements: Edward Catmur, 2007 Jan 7
    Also use Save/Discard for other GUIs

New PHP syntax file, use it? (Peter Hodge)

":echoe" in catch block stops processing, while this doesn't happen outside of
a catch block. (ZyX, 2011 Jun 2)

'foldcolumn' in modeline applied to wrong window when using a session. (Teemu
Likonen, March 19)

Test 54 uses shell commands, that doesn't work on non-Unix systems. Use some
other way to test buffer-local autocommands.

The documentation mentions the priority for ":2match" and ":3match", but it
appears the last one wins. (John Beckett, 2008 Jul 22) Caused by adding
matchadd()? Suggested patch by John, 2008 Jul 24.

When 'encoding' is utf-8 the command line is redrawn as a whole on every
character typed. (Tyler Spivey, 2008 Sep 3) Only redraw cmdline for
'arabicshape' when there is a character on the command line for which
(ARABIC_CHAR(u8c)) is TRUE.

Cheng Fang made javacomplete. (2007 Aug 11)
Asked about latest version: 0.77.1 is on www.vim.org.

More AmigaOS4 patches. (Peter Bengtsson, Nov 9)

Amiga patches with vbcc. (Adrien Destugues, 2010 Aug 30)
http://pulkomandy.ath.cx/drop/vim73_vbcc_amiga.diff

Insert mode completion: When editing the text and pressing CTRL-N again goes
back to originally completed text, edited text is gone. (Peng Yu, 2008 Jul 24)
Suggestion by Ben Schmidt, 2008 Aug 6.

Problem with compound words? (Bert, 2008 May 6)
No warning for when flags are defined after they are used in an affix.

Screen redrawing when continuously updating the buffer and resizing the

terminal. (Yakov Lerner, 2006 Sept 7)

Add option settings to help ftplugin. (David Eggum, 2006 Dec 18)

Autoconf problem: when checking for iconv library we may add -L/usr/local/lib, but when compiling further tests -liconv is added without the -L argument, that may fail (e.g., sizeof(int)). (Blaine, 2007 Aug 21)

When opening quickfix window, disable spell checking?

Problem with ".add" files when using two languages and restarting Vim. (Raul Coronado, 2008 Oct 30)

Popup menu redraw: Instead of first redrawing the text and then drawing the popup menu over it, first draw the new popup menu, remember its position and size and then redraw the text, skipping the characters under the popup menu. This should avoid flicker. Other solution by A.Politz, 2007 Aug 22.

When a register contains illegal bytes, writing viminfo in utf-8 and reading it back doesn't result in utf-8. (Devin Bayer)

Command line completion: Scanning for tags doesn't check for typed key now and then? Hangs for about 5 seconds. Appears to be caused by finding include files with "foo/**" in 'path'. (Kalisiak, 2006 July 15)
Additional info: When using the wildcards ** globing, vim hangs indefinitely on lots of directories. The file-searching globing, like in ":set path=/**" does not hang as often as with globing with wildcards , like in ":1find /**/file". This is for files that unix "find" can find very quickly. Merging the 2 kinds of globing might make this an easier fix. (Ian Kelling, 2008 July 4)

When the file name has parenthesis, e.g., "foo (bar).txt", ":!ls '%'" has the parenthesis escaped but not the space. That's inconsistent. Either escape neither or both. No escaping might be best, because it doesn't depend on particularities of the shell. (Zvi Har'El, 2007 Nov 10) (Teemu Likonen, 2008 Jun 3)
However, for backwards compatibility escaping might be necessary. Check if the user put quotes around the expanded item?

A throw in a function causes missing an endif below the call. (Spiros Bousbouras, 2011 May 16)

Error E324 can be given when a cron script has wiped out our temp directory. Give a clear error message about this (and tell them not to wipe out /tmp).

Color for cUserLabel should differ from case label, so that a mistake in a switch list is noticed:

```
    switch (i)
    {
    case 1:
    foobar:
    }
```

Look at http://www.gtk-server.org/ . It has a Vim script implementation.

Netbeans problem. Use "nc -l 127.0.0.1 55555" for the server, then run gvim
with "gvim -nb:localhost:55555:foo". From nc do: '1:editFile!0 "foo"'. Then
go to Insert mode and add a few lines. Then backspacing every other time
moves the cursor instead of deleting. (Chris Kaiser, 2007 Sep 25)

Windows installer could add a "open in new tab of existing Vim" menu entry.
GvimExt: patch to add "Edit with single Vim &tabbed" menu entry.
Just have two choices, always using one Vim and selecting between using an
argument list or opening each file in a separate tab.
(Erik Falor, 2008 May 21, 2008 Jun 26)

Windows installer: licence text should not use indent, causes bad word wrap.
(Benjamin Fritz, 2010 Aug 16)

Dos uninstal may delete vim.bat from the wrong directory (e.g., when someone
makes his own wrapper). Add a magic string with the version number to the
.bat file and check for it in the uninstaller. E.g.
          # uninstall key: vim7.3*

Changes for Win32 makefile. (Mike Williams, 2007 Jan 22, Alexei Alexandrov,
2007 Feb 8)

Win32: Can't complete shell command names. Why is setting xp_context in
set_one_cmd_context() inside #ifndef BACKSLASH_IN_FILENAME?

Win32: Patch for cscope external command. (Mike Williams, 2007 Aug 7)

Win32: XPM support only works with path without spaces. Patch by Mathias
Michaelis, 2006 Jun 9. Another patch for more path names, 2006 May 31.
New version: http://members.tcnet.ch/michaelis/vim/patches.zip (also for other
patches by Mathias, see mail Feb 22)

Win32: compiling with normal features and OLE fails. Patch by Mathias
Michaelis, 2006 Jun 4.

Win32: after "[I" showing matches, scroll wheel messes up screen. (Tsakiridis,
2007 Feb 18)
Patch by Alex Dobrynin, 2007 Jun 3. Also fixes other scroll wheel problems.

Win32: using CTRL-S in Insert mode doesn't remove the "+" from the tab pages
label. (Tsakiridis, 2007 Feb 18) Patch from Ian Kelling, 2008 Aug 6.

Win32: using "gvim --remote-tab-silent fname" sometimes gives an empty screen
with the more prompt. Caused by setting the guitablabel? (Thomas Michael
Engelke, 2007 Dec 20 - 2008 Jan 17)

Win32: patch for fullscreen mode. (Liushaolin, 2008 April 17)

Win32: When 'shell' is bash shellescape() doesn't always do the right thing.
Depends on 'shellslash', 'shellquote' and 'shellxquote', but shellescape()
only takes 'shellslash' into account.

Menu item that does "xxd -r" doesn't work when 'fileencoding' is utf-16.

Check for this and use iconv? (Edward L. Fox, 2007 Sep 12)
Does the conversion in the other direction work when 'fileencodings' is set
properly?

Cursor displayed in the wrong position when using 'numberwidth'. (James Vega,
2007 Jun 21)

When $VAR contains a backslash expand('$VAR') removes it. (Teemu Likonen, 2008
Jun 18)

If the variable "g:x#y#z" exists completion after ":echo g:x#" doesn't work.

Feature request: Command to go to previous tab, like what CTRL-W p does for
windows. (Adam George)

F1 - F4 in an xterm produce a different escape sequence when used with a
modifier key. Need to catch three different sequences. Use K_ZF1, like
K_ZHOME? (Dickey, 2007 Dec 2)

In debug mode, using CTRL-R = to evaluate a function causes stepping through
the function. (Hari Krishna Dara, 2006 Jun 28)

C++ indenting wrong with "=". (James Kanze, 2007 Jan 26)

":lockvar" should use copyID to avoid endless loop.

When using --remote-silent and the file name matches 'wildignore' get an E479
error. without --remote-silent it works fine. (Ben Fritz, 2008 Jun 20)

GVim: dialog for closing Vim should check if Vim is busy writing a file. Then
use a different dialog: "busy saving, really quit? yes / no".

Check other interfaces for changing curbuf in a wrong way. Patch like for
if_ruby.c.

":helpgrep" should use the directory from 'helpfile'.

The need_fileinfo flag is messy. Instead make the message right away and put
it in keep_msg?

Editing a file remotely that matches 'wildignore' results in a "no match"
error. Should only happen when there are wildcards, not when giving the file
name literally, and esp. if there is only one name.

Test 61 fails sometimes. This is a timing problem: "sleep 2" sometimes takes
longer than 2 seconds.

Using ":au CursorMoved * cmd" invokes mch_FullName(), which can be slow.
Can this be avoided? (Thomas Waba, 2008 Aug 24)
Also for ":w" without a file name.
The buffer has the full path in ffname, should pass this to the autocommand.

"vim -C" often has 'nocompatible', because it's set in some startup script.
Set 'compatible' after startup is done? Patch by James Vega, 2008 Feb 7.

VMS: while editing a file found in complex, Vim will save file into the first
directory of the path and not to the original location of the file.
(Zoltan Arpadffy)

VMS: VFC files are in some cases truncated during reading (Zoltan Arpadffy)

input() completion should not insert a backslash to escape a space in a file
name?

Ruby completion is insecure. Can this be fixed?

When 'backupskip' is set from $TEMP special characters need to be escaped.
(patch by Grembowietz, 2007 Feb 26, not quite right)
Another problem is that file_pat_to_reg_pat() doesn't recognize "\\", so "\\("
will be seen as a path separator plus "\(".

gvim d:\path\path\(FILE).xml should not remove the \ before the (.
This also fails with --remote.

When doing ":quit" the Netbeans "killed" event isn't sent. (Xavier de Gaye,
2008 Nov 10) call netbeans_file_closed() at the end of buf_freeall(), or in
all places where buf_freeall() is called?

aucmd_prepbuf() should also use a window in another tab page.

When unloading a buffer in a BufHidden autocommand the hidden flag is reset?
(Bob Hiestand, 2008 Aug 26, Aug 27)

Substituting an area with a line break with almost the same area does change
the Visual area. Can this be fixed? (James Vega, 2006 Sept 15)

GUI: When combining fg en bg make sure they are not equal.

Spell checking: Add a way to specify punctuation characters. Add the
superscript numbers by default: 0x2070, 0xb9, 0xb2, 0xb3, 0x2074 - 0x2079.

Spell checking in popup menu: If the only problem is the case of the first
character, don't offer "ignore" and "add to word list".

Use different pt_br dictionary for spell checking. (Jackson A. Aquino, 2006
Jun 5)

Use different romanian dictionary for spell checking. (Andrei Popescu, Nov
2008) Use http://downloads.sourceforge.net/rospell/ro_RO.3.2.zip
Or the hunspell-ro.3.2.tar.gz file, it also has a iso-8859-2 list.

In a C file with spell checking, in "% integer" "nteger" is seen as an error,
but "]s" doesn't find it. "nteger" by itself is found. (Ralf Wildenhues, 2008
Jul 22)

There should be something about spell checking in the user manual.

Spell menu: When using the Popup menu to select a replacement word,

":spellrepeat" doesn't work. SpellReplace() uses setline(). Can it use "z="
somehow? Or use a new function.

Mac: Using gvim: netrw window disappears. (Nick Lo, 2006 Jun 21)

Add an option to specify the character to use when a double-width character is
moved to the next line. Default '>', set to a space to blank it out. Check
that char is single width when it's set (compare with 'listchars').

The generated vim.bat can avoid the loop for NT. (Carl Zmola, 2006 Sep 3)

When showing a diff between a non-existent file and an existing one, with the
cursor in the empty buffer, the other buffer only shows the last line. Change
the "insert" into a change from one line to many? (Yakov Lerner, 2008 May 27)

These two abbreviations don't give the same result:
```
	let asdfasdf = "xyz\<Left>"
	cabbr XXX <C-R>=asdfasdf<CR>
	cabbr YYY xyz<Left>
```

Michael Dietrich: maximized gvim sometimes displays output of external command
partly. (2006 Dec 7)

In FileChangedShell command it's no longer allowed to switch to another
buffer. But the changed buffer may differ from the current buffer, how to
reload it then?

For Aap: include a config.arg.example file with hints how to use config.arg.

Command line completion when 'cmdheight' is maximum and 'wildmenu' is set,
only one buffer line displayed, causes display errors.

Completing with 'wildmenu' and using <Up> and <Down> to move through directory
tree stops unexpectedly when using ":cd " and entering a directory that
doesn't contain other directories.

Default for 'background' is wrong when using xterm with 256 colors.
Table with estimates from Matteo Cavalleri, 2014 Jan 10.

Setting 'background' resets the Normal background color:
```
   highlight Normal ctermbg=DarkGray
   set background=dark
```
This is undesired, 'background' is supposed to tell Vim what the background
color is, not reset it.

Linux distributions:
- Suggest compiling xterm with --enable-tcap-query, so that nr of colors is
  known to Vim. 88 colors instead of 16 works better. See ":help
  xfree-xterm".
- Suggest including bare "vi" and "vim" with X11, syntax, etc.

Completion menu: For a wrapping line, completing a long file name, only the
start of the path is shown in the menu. Should move the menu to the right to
show more text of the completions. Shorten the items that don't fit in the

middle?

Accessing file#var in a function should not need the g: prepended.

When exiting detects a modified buffer, instead of opening the buffer in the current tab, use an existing tab, if possible. Like finding a window where the buffer is displayed. (Antonios Tsakiridis)

When ":cn" moves to an error in the same line the message isn't shortened. Only skip shortening for ":cc"?

Write "making vim work better" for the docs (mostly pointers): nice
    - sourcing $VIMRUNTIME/vimrc_example.vim
    - setting 'mouse' to "a"
    - getting colors in xterm
    - compiling Vim with X11, GUI, etc.

Problem with ":call" and dictionary function. Hari Krishna Dara, Charles Campbell 2006 Jul 06.

Syntax HL error caused by "containedin". (Peter Hodge, 2006 Oct 6)

A custom completion function in a ":command" cannot be a Funcref. (Andy Wokula, 2007 Aug 25)

Problem with using :redir in user command completion function? (Hari Krishna Dara, 2006 June 21)

Another resizing problem when setting 'columns' and 'lines' to a very large number. (Tony Mechelynck, 2007 Feb 6)

After starting Vim, using '0 to jump somewhere in a file, ":sp" doesn't center the cursor line. It works OK after some other commands.

Win32: Is it possible to have both postscript and Win32 printing?

Problem with 'cdpath' on MS-Windows when a directory is equal to $HOME. (2006 Jul 26, Gary Johnson)

Using UTF-8 character with ":command" does not work properly. (Matt Wozniski, 2008 Sep 29)

In the Netbeans interface add a "vimeval" function, so that the other side can check the result of has("patch13").

Cursor line at bottom of window instead of halfway after saving view and restoring. Only with 'nowrap'. (Robert Webb, 2008 Aug 25)

Netrw has trouble executing autocommands only for a directory. Add <isdir> and <notisdir> to autocommand patterns? Also <isfile>?

Add command modifier that skips wildcard expansion, so that you don't need to put backslashes before special chars, only for white space.

Syntax HL: open two windows on the same C code, delete a ")" in one window, resulting in highlighted "{" in that window, not in the other.

In mswin.vim: Instead of mapping <C-V> for Insert mode in a complicated way, can it be done like ":imap <C-V> <MiddleMouse>" without negative side effects?

GTK: when the Tab pages bar appears or disappears while the window is maximized the window is no longer maximized. Patch that has some idea but doesn't work from Geoffrey Antos, 2008 May 5.
Also: the window may no longer fit on the screen, thus the command line is not visible.

When right after "vim file", "M" then CTRL-W v the windows are scrolled differently and unexpectedly. Caused by patch 7.2.398?

The magic clipboard format "VimClipboard2" appears in several places. Should be only one.

Win32, NTFS: When editing a specific infostream directly and 'backupcopy' is "auto" should detect this situation and work like 'backupcopy' is "yes". File name is something like "c:\path\foo.txt:bar", includes a colon. (Alex Jakushev, 2008 Feb 1)

Small problem displaying diff filler line when opening windows with a script. (David Luyer, 2007 Mar 1 ~/Mail/oldmail/mool/in.15872)

Is it allowed that 'backupext' is empty? Problems when backup is in same dir as original file? If it's OK don't compare with 'patchmode'. (Thierry Closen)

Patch for supporting count before CR in quickfix window. (AOYAMA Shotaro, 2007 Jan 1)

Patch for adding ":lscscope". (Navdeep Parhar, 2007 Apr 26; update 2008 Apr 23)

":mkview" isn't called with the right buffer argument. Happens when using tabs and the autocommand "autocmd BufWinLeave * mkview". (James Vega, 2007 Jun 18)

When completing from another file that uses a different encoding completion text has the wrong encoding. E.g., when 'encoding' is utf-8 and file is latin1. Example from Gombault Damien, 2007 Mar 24.

Syntax HL: When using "nextgroup" and the group has an empty match, there is no search at that position for another match. (Lukas Mai, 2008 April 11)

In gvim the backspace key produces a backspace character, but on Linux the VERASE key is Delete. Set VERASE to Backspace? (patch by Stephane Chazelas, 2007 Oct 16)

TermResponse autocommand isn't always triggered when using vimdiff. (Aron Griffis, 2007 Sep 19)

Create a gvimtutor.1 file and change Makefiles to install it.

When 'encoding' is utf-8 typing text at the end of the line causes previously typed characters to be redrawn. Caused by patch 7.1.329. (Tyler Spivey, 2008 Sep 3, 11)

When Vim in an xterm owns the selection and the user does ":shell" Vim doesn't respond to selection requests. Invoking XtDisownSelection() before executing the shell doesn't help. Would require forking and doing a message loop, like what happens for the GUI.

":vimgrep" does not recognize a recursive symlink. Is it possible to detect this, at least for Unix (using device/inode)?

When switching between windows the cursor is often put in the middle.
Remember the relative position and restore that, just like lnum and col are restored. (Luc St-Louis)

Patch to support horizontal scroll wheel in GTK. Untested. (Bjorn Winckler, 2010 Jun 30)

Add an option for a minimal text length before inserting a line break for 'textwidth'. Avoids very short lines when a very long word follows.
(Kartik Agaram)

Better plugin support (not plugin manager, see elsewhere for that):
- Avoid use of feedkeys, add eval functions where needed:
  - manipulating the Visual selection?
- Add createmark(): add a mark like mM, but return a unique ID. Need some way to clean them up again... Use a name + the script ID.
  Add createmark(, 'c') to track inserts/deletes before the column.
- Plugins need to make a lot of effort, lots of mappings, to know what happened before pressing the key that triggers a plugin action. How about keeping the last N pressed keys, so that they do not need to be mapped?
- equivalent of netbeans_beval_cb(). With an autocommand?
- Add something to enable debugging when a remote message is received.

More patches:
- Another patch for Javascript indenting. (Hari Kumar, 2010 Jul 11)
   Needs a few tests.
- Add 'cscopeignorecase' option. (Liang Wenzhi, 2006 Sept 3)
- Load intl.dll too, not only libintl.dll. (Mike Williams, 2006 May 9, docs patch May 10)
- Extra argument to strtrans() to translate special keys to their name (Eric Arnold, 2006 May 22)
- 'threglookexp' option: only match with first word in thesaurus file. (Jakson A. Aquino, 2006 Jun 14)
- Mac: indicate whether a buffer was modified. (Nicolas Weber, 2006 Jun 30)
- Allow negative 'nrwidth' for left aligning. (Nathan Laredo, 2006 Aug 16)
- ml_append_string(): efficiently append to an existing line. (Brad Beveridge, 2006 Aug 26) Use in some situations, e.g., when pasting a character at a time?
- recognize hex numbers better. (Mark Manning, 2006 Sep 13)

- Add <AbbrExpand> key, to expand an abbreviation in a mapping. (Kana Natsuno, 2008 Jul 17)
- Add 'wspara' option, also accept blank lines like empty lines for "{" and "}". (Mark Lundquist, 2008 Jul 18)
- Patch to add CTRL-T to delete part of a path on cmdline. (Adek, 2008 Jul 21)
- Instead of creating a copy of the tutor in all the shell scripts, do it in vimtutor.vim. (Jan Minar, 2008 Jul 20)
- When fsync() fails there is no hint about what went wrong. Patch by Ben Schmidt, 2008 Jul 22.
- testdir/Make_dos_sh.mak for running tests with MingW. (Bill Mccarthy, 2008 Sep 13)
- Replace ccomplete.vim by cppcomplete.vim from www.vim.org? script 1520 by Vissale Neang. (Martin Stubenschrott) Asked Vissale to make the scripts more friendly for the Vim distribution.
  New version received 2008 Jan 6.
  No maintenance in two years...
- Patch to open dropped files in new tabs. (Michael Trim, 2010 Aug 3)

Awaiting updated patches:
9 Mac unicode patch (Da Woon Jung, Eckehard Berns):
  8 Add patch from Muraoka Taro (Mar 16) to support input method on Mac?
    New patch 2004 Jun 16
  - selecting proportional font breaks display
  - UTF-8 text causes display problems. Font replacement causes this.
  - Command-key mappings do not work. (Alan Schmitt)
  - With 'nopaste' pasting is wrong, with 'paste' Command-V doesn't work. (Alan Schmitt)
  - remove 'macatsui' option when this has been fixed.
  - when 'macatsui' is off should we always convert to "macroman" and ignore 'termencoding'?
9 HTML indenting can be slow. Caused by using searchpair(). Can search() be used instead? A.Politz is looking into a solution.
8 Win32: Add minidump generation. (George Reilly, 2006 Apr 24)
7 Completion of network shares, patch by Yasuhiro Matsumoto.
  Update 2004 Sep 6.
  How does this work? Missing comments.
8 Add a few more command names to the menus. Patch from Jiri Brezina (28 feb 2002). Will mess the translations...
7 ATTENTION dialog choices are more logical when "Delete it" appears before "Quit". Patch by Robert Webb, 2004 May 3.
- Include flipcase patch: ~/vim/patches/wall.flipcase2 ? Make it work for multi-byte characters.
- Win32: add options to print dialog. Patch from Vipin Aravind.
- Patch to add highlighting for whitespace. (Tom Schumm, 2003 Jul 5)
  use the patch that keeps using HLF_8 if HLF_WS has not
  been given values.
  Add section in help files for these highlight groups?
8 "fg" and "bg" don't work in an xterm. Get default colors from xterm with an ESC sequence.
  xterm can send colors for many things. E.g. for the cursor:
    <Esc>]12;?<Bel>
  Can use this to get the background color and restore the colors on exit.
7 Add "DefaultFG" and "DefaultBG" for the colors of the menu. (Marcin

    Dalecki has a patch for Motif and Carbon)
-   Add possibility to highlight specific columns (for Fortran). Or put a
    line in between columns (e.g., for 'textwidth').
    Patch to add 'hlcolumn' from Vit Stradal, 2004 May 20.
8   Add functions:
    gettext()   Translate a message. (Patch from Yasuhiro Matsumoto)
                        Update 2004 Sep 10
                        Another patch from Edward L. Fox (2005 Nov 24)
                        Search in 'runtimepath'?
                        More docs needed about how to use this.
                        How to get the messages into the .po files?
    confirm()   add "flags" argument, with 'v' for vertical
                            layout and 'c' for console dialog. (Haegg)
                            Flemming Madsen has a patch for the 'c' flag
                            (2003 May 13)
    raisewin()   raise gvim window (see HierAssist patch for
                            Tcl implementation ~/vim/HierAssist/)
    taglist()   add argument to specify maximum number of matches.
                        useful for interactive things or completion.
    col('^')   column of first non-white character.
                        Can use "len(substitute(getline('.'), '\S.*', '', ''))
                        + 1", but that's ugly.
7   Add patch from Benoit Cerrina to integrate Vim and Perl functions
    better. Now also works for Ruby (2001 Nov 10)
-   Patch from Herculano de Lima Einloft Neto for better formatting of the
    quickfix window (2004 dec 2)
7   When 'rightleft' is set, the search pattern should be displayed right
    to left as well? See patch of Dec 26. (Nadim Shaikli)
8   Option to lock all used memory so that it doesn't get swapped to disk
    (uncrypted). Patch by Jason Holt, 2003 May 23. Uses mlock.
7   Add ! register, for shell commands. (patch from Grenie)
8   In the gzip plugin, also recognize *.gz.orig, *.gz.bak, etc. Like it's
    done for filetype detection. Patch from Walter Briscoe, 2003 Jul 1.
7   Add a "-@ filelist" argument: read file names from a file. (David
    Kotchan has a patch for it)
7   Add ":justify" command. Patch from Vit Stradal 2002 Nov 25.
-   findmatch() should be adjusted for Lisp. See remark at
    get_lisp_indent(). Esp. \(and \) should be skipped. (Dorai Sitaram,
    incomplete patch Mar 18)
-   For GUI Find/Replace dialog support using a regexp. Patch for Motif
    and GTK by degreneir (nov 10 and nov 18).
-   Patch for "paranoid mode" by Kevin Collins, March 7. Needs much more work.

Vi incompatibility:
-   Try new POSIX tests, made after my comments. (Geoff Clare, 2005 April 7)
    Version 1.5 is in ~/src/posix/1.5. (Lynne Canal)
8   With undo/redo only marks in the changed lines should be changed. Other
    marks should be kept. Vi keeps each mark at the same text, even when it
    is deleted or restored. (Webb)
    Also: A mark is lost after: make change, undo, redo and undo.
    Example: "{d''" then "u" then "d''": deletes an extra line, because the ''
    position is one line down. (Veselinovic)
8   When stdin is not a tty, and Vim reads commands from it, an error should

make Vim exit.
7 Unix Vim (not gvim): Typing CTRL-C in Ex mode should finish the line (currently you can continue typing, but it's truncated later anyway). Requires a way to make CTRL-C interrupt select() when in cooked input.
8 When loading a file in the .exrc, Vi loads the argument anyway. Vim skips loading the argument if there is a file already. When no file argument given, Vi starts with an empty buffer, Vim keeps the loaded file. (Bearded)
6 In Insert mode, when using <BS> or <Del>, don't wipe out the text, but only move back the cursor. Behaves like '$' in 'cpoptions'. Use a flag in 'cpoptions' to switch this on/off.
8 When editing a file which is a symbolic link, and then opening another symbolic link on the same file, Vim uses the name of the first one. Adjust the file name in the buffer to the last one used? Use several file names in one buffer???
Also: When first editing file "test", which is symlink to "test2", and then editing "test2", you end up editing buffer "test" again. It's not logical that the name that was first used sticks with the buffer.
7 The ":undo" command works differently in Ex mode. Edit a file, make some changes, "Q", "undo" and _all_ changes are undone, like the ":visual" command was one command.
On the other hand, an ":undo" command in an Ex script only undoes the last change (e.g., use two :append commands, then :undo).
7 The ":map" command output overwrites the command. Perhaps it should keep the ":map" when it's used without arguments?
7 CTRL-L is not the end of a section? It is for Posix! Make it an option.
7 Implement 'prompt' option. Init to off when stdin is not a tty.
7 Add a way to send an email for a crashed edit session. Create a file when making changes (containing name of the swap file), delete it when writing the file. Supply a program that can check for crashed sessions (either all, for a system startup, or for one user, for in a .login file).
7 Vi doesn't do autoindenting when input is not from a tty (in Ex mode).
7 "z3<CR>" should still use the whole window, but only redisplay 3 lines.
7 ":tag xx" should move the cursor to the first non-blank. Or should it go to the match with the tag? Option?
7 Implement 'autoprint'/'ap' option.
7 Add flag in 'cpoptions' that makes <BS> after a count work like <Del> (Sayre).
7 Add flag in 'cpoptions' that makes operator (yank, filter) not move the cursor, at least when cancelled. (default Vi compatible).
7 This Vi-trick doesn't work: "Q" to go to Ex mode, then "g/pattern/visual". In Vi you can edit in visual mode, and when doing "Q" you jump to the next match. Nvi can do it too.
7 Support '\' for line continuation in Ex mode for these commands: (Luebking)

```
    g/./a\              g/pattern1/ s/pattern2/rep1\\
    line 1\             line 2\\
    line 2\             line 3\\
    .                   line4/
```

6 ":e /tmp/$tty" doesn't work. ":e $uid" does. Is $tty not set because of the way the shell is started?
6 Vi compatibility (optional): make "ia<CR><ESC>10." do the same strange thing. (only repeat insert for the first line).

GTK+ GUI known bugs:

9   Crash with X command server over ssh. (Ciaran McCreesh, 2006 Feb 6)
8   GTK 2: Combining UTF-8 characters not displayed properly in menus (Mikolaj
    Machowski) They are displayed as separate characters. Problem in
    creating a label?
8   GTK 2: Combining UTF-8 characters are sometimes not drawn properly.
    Depends on the font size, "monospace 13" has the problem. Vim seems to do
    everything right, must be a GTK bug. Is there a way to work around it?
9   Can't paste a Visual selection from GTK-gvim to vim in xterm or Motif gvim
    when it is longer than 4000 characters. Works OK from gvim to gvim and
    vim to vim. Pasting through xterm (using the shift key) also works.
    It starts working after GTK gvim loses the selection and gains it again.
-   Gnome2: When moving the toolbar out of the dock, so that it becomes
    floating, it can no longer be moved. Therefore making it float has been
    blocked for now.

Win32 GUI known bugs:
-   Win32: tearoff menu window should have a scrollbar when it's taller than
    the screen.
8   The -P argument doesn't work very well with many MDI applications.
    The last argument of CreateWindowEx() should be used, see MSDN docs.
    Tutorial: http://win32assembly.online.fr/tut32.html
8   In eval.c, io.h is included when MSWIN32 is defined. Shouldn't this be
    WIN32? Or can including io.h be moved to vim.h? (Dan Sharp)
6   Win32 GUI: With "-u NONE -U NONE" and doing "CTRL-W v" "CTRL-W o", the ":"
    of ":only" is highlighted like the cursor. (Lipelis)
8   When 'encoding' is "utf-8", should use 'guifont' for both normal and wide
    characters to make Asian languages work. Win32 fonts contain both
    type of characters.
7   When font smoothing is enabled, redrawing can become very slow. The reason
    appears to be drawing with a transparent background. Would it be possible
    to use an opaque background in most places?
7   The cursor color indicating IME mode doesn't work properly. (Shizhu Pan,
    2004 May 9)
8   Win32: When clicking on the gvim title bar, which gives it focus, produces
    a file-changed dialog, after clicking on a button in that dialog the gvim
    window follows the mouse. The button-up event is lost. Only with
    MS-Windows 98?
    Try this: ":set sw ts", get enter-prompt, then change the file in a
    console, go back to Vim and click "reload" in the dialog for the changed
    file: Window moves with the cursor!
    Put focus event in input buffer and let generic Vim code handle it?
8   Win32 GUI: With maximized window, ":set go-=r" doesn't use the space that
    comes available. (Poucet) It works OK on Win 98 but doesn't work on Win
    NT 4.0. Leaves a grey area where the scrollbar was. ":set go+=r" also
    doesn't work properly.
8   When Vim is minimized and when maximizing it a file-changed dialog pops
    up, Vim isn't maximized. It should be done before the dialog, so that it
    appears in the right position. (Webb)
9   When selecting at the more-prompt or hit-enter-prompt, the right mouse
    button doesn't give popup menu.
    At the hit-enter prompt CTRL-Y doesn't work to copy the modeless
    selection.
    On the command line, don't get a popup menu for the right mouse button.

Let the middle button paste selected text (not the clipboard but the non-Visual selection)? Otherwise CTRL-Y has to be used to copy the text.

8 When 'grepprg' doesn't execute, the error only flashes by, the user can hardly see what is wrong. (Moore)
Could use vimrun with an "-nowait" argument to only wait when an error occurs, but "command.com" doesn't return an error code.

8 When the 'shell' cannot be executed, should give an appropriate error msg. Esp. for a filter command, currently it only complains the file could not be read.

7 Add an option to add one pixel column to the character width? Lucida Console italic is wider than the normal font ("d" overlaps with next char). Opposite of 'linespace': 'columnspace'.

7 At the hit-enter prompt scrolling now no longer works. Need to use the keyboard to get around this. Pretend <CR> was hit when the user tries to scroll?

7 Scrollbar width doesn't change when selecting other windows appearance. Also background color of Toolbar and rectangle below vert. scrollbar.

6 Drawing text transparently doesn't seem to work (when drawing part cursor).

8 CTRL key doesn't always work in combination with ALT key. It does work for function keys, not for alphabetic characters. Perhaps this is because CTRL-ALT is used by Windows as AltGr?

8 CTRL-- doesn't work for AZERTY, because it's CTRL-[for QWERTY. How do we know which keyboard is being used?

7 When scrolling, and a background color is dithered, the dither pattern doesn't always join correctly between the scrolled area and the new drawn area (Koloseike).

8 When gui_init_font() is called with "*", p_guifont is freed while it might still be used somewhere. This is too tricky, do the font selection first, then set the new font by name (requires putting all logfont parameters in the font name).

Athena and Motif:

6 New Motif toolbar button from Marcin Dalecki:
- When the mouse pointer is over an Agide button the red becomes black. Something with the way colors are specified in the .xpm file.
- The pixmap is two pixels smaller than it should be. The gap is filled with grey instead of the current toolbar background color.

9 Can configure be changed to disable netbeans if the Xpm library is required and it's missing?

8 When using the resource "Vim*borderwidth 2" the widgets are positioned wrong.

9 XIM is disabled by default for SGI/IRIX. Fix XIM so that 'imdisable' can be off by default.

9 XIM doesn't work properly for Athena/Motif. (Yasuhiro Matsumoto) For now, keep XIM active at all times when the input method has the preediting flag.

8 X11: A menu that contains an umlaut is truncated at that character. Happens when the locale is "C", which uses ASCII instead of IS0-8859-1. Is there a way to use latin1 by default? Gnome_init() seems to do this.

8 Perhaps use fontsets for everything?

6 When starting in English and switching the language to Japanese, setting the locale with ":lang", 'guifontset' and "hi menu font=", deleting all menus and setting them again, the menus don't use the new font. Most of

    the tooltips work though...
7   Motif: when using a file selection dialog, the specified file name is not
    always used (when specifying a filter or another directory).
8   When 'encoding' is different from the current locale (e.g., utf-8) the
    menu strings don't work. Requires conversion from 'encoding' to the
    current locale. Workaround: set 'langmenu'.

Athena GUI:
9   The first event for any button in the menu or toolbar appears to get lost.
    The second click on a menu does work.
9   When dragging the scrollbar thumb very fast, focus is only obtained in
    the scrollbar itself. And the thumb is no longer updated when moving
    through files.
7   The file selector is not resizable. With a big font it is difficult to
    read long file names. (Schroeder)
4   Re-write the widget attachments and code so that we will not have to go
    through and calculate the absolute position of every widget every time the
    window is refreshed/changes size. This will help the "flashing-widgets"
    problem during a refresh.
5   When starting gvim with all the default colors and then typing
    ":hi Menu guibg=cyan", the menus change color but the background of the
    pullright pixmap doesn't change colors.
    If you type ":hi Menu guibg=cyan font=anyfont", then the pixmap changes
    colors as it should.
    Allocating a new pixmap and setting the resource doesn't change the
    pullright pixmap's colors. Why? Possible Athena bug?

Motif GUI:
-   gui_mch_browsedir() is missing, browsedir() doesn't work nicely.
7   Use XmStringCreateLocalized() instead of XmStringCreateSimple()?
    David Harrison says it's OK (it exists in Motif 1.2).
8   Lesstif: When deleting a menu that's torn off, the torn off menu becomes
    very small instead of disappearing. When closing it, Vim crashes.
    (Phillipps)

GUI:
9   On Solaris, creating the popup menu causes the right mouse button no
    longer to work for extending the selection. (Halevy)
9   When running an external program, it can't always be killed with CTRL-C.
    e.g., on Solaris 5.5, when using "K" (Keech). Other 'guipty' problems on
    Solaris 2.6. (Marley)
9   On Solaris: Using a "-geometry" argument, bigger than the window where Vim
    is started from, causes empty lines below the cmdline. (raf)
8   X11 GUI: When menu is disabled by excluding 'm' from 'guioptions', ALT key
    should not be used to trigger a menu (like the Win32 version).
8   When setting 'langmenu', it should be effective immediately. Store both
    the English and the translated text in the menu structure. Re-generate
    the translation when 'langmenu' has changed.
8   Basic flaw in the GUI code: NextScreen is updated before calling
    gui_write(), but the GUI code relies on NextScreen to represent the state
    of where it is processing the output.

Need better separation of Vim core and GUI code.
8 When fontset support is enabled, setting 'guifont' to a single font doesn't work.
8 Menu priority for sub-menus for: Amiga.
8 When translating menus ignore the part after the Tab, the shortcut. So that the same menu item with a different shortcut (e.g., for the Mac) are still translated.
8 Add menu separators for Amiga.
8 Add way to specify the file filter for the browse dialog. At least for browse().
8 Add dialog for search/replace to other GUIs? Tk has something for this, use that code? Or use console dialog.
8 When selecting a font with the font dialog and the font is invalid, the error message disappears too quick.
7 More features in the find/replace dialog:
- regexp on/off
- search in selection/buffer/all buffers/directory
when all buffers/directory is used:
- filter for file name
when directory is used:
- subdirectory on/off
- top directory browser
8 gui_check_colors() is not called at the right moment. Do it much later, to avoid problems.
8 gui_update_cursor() is called for a cursor shape change, even when there are mappings to be processed. Only do something when going to wait for input. Or maybe every 100 ms?
8 X11: When the window size is reduced to fit on screen, there are blank lines below the text and bottom scrollbar. "gvim -geometry 80x78+0+0". When the "+0+0" is omitted it works.
8 When starting an external command, and 'guipty' set, BS and DEL are mixed up. Set erase character somehow?
8 A dead circumflex followed by a space should give the '^' character (Rommel). Look how xterm does this.
Also: Bednar has some code for dead key handling.
Also: Nedit 5.0.2 with USE_XMIM does it right. (Gaya)
8 The compose key doesn't work properly (Cepas). Both for Win32 and X11.
7 The cursor in an inactive window should be hollow. Currently it's not visible.
7 GUI on Solaris 2.5.1, using /usr/dt/..: When gvim starts, cursor is hollow, after window lowered/raised it's OK. (Godfrey)
7 When starting GUI with ":gui", and window is made smaller because it doesn't fit on the screen, there is an extra redraw.
8 When setting font with .Xdefaults, there is an extra empty line at the bottom, which disappears when using ":set guifont=<Tab>". (Chadzelek)
8 When font shape changes, but not the size, doing ":set font=" does not redraw the screen with the new font. Also for Win32.
When the size changes, on Solaris 2.5 there isn't a redraw for the remaining part of the window (Phillipps).
- Flashes really badly in certain cases when running remotely from a Sun.
4 Re-write the code so that the highlighting isn't changed multiple times when doing a ":hi clear". The color changes happen three or more times currently. This is very obvious on a 66Mhz 486.

```
Win32 console:
8   Should $USERPROFILE be preferred above $HOMEDRIVE/$HOMEPATH?  No, but it's
    a good fallback, thus use:
            $HOME
            $HOMEDRIVE$HOMEPATH
            SHGetSpecialFolderPath(NULL, lpzsPath, CSIDL_APPDATA, FALSE);
            $USERPROFILE
            SHGetSpecialFolderPath(NULL, lpzsPath, CSIDL_COMMON_APPDATA, FALSE);
            $ALLUSERSPROFILE
            $SYSTEMDRIVE\
            C:\
8   Win32 console: <M-Up> and <M-Down> don't work. (Geddes)  We don't have
    special keys for these.  Should use modifier + key.
8   Win32 console: caps-lock makes non-alpha keys work like with shift.
    Should work like in the GUI version.
8   Environment variables in DOS are not case sensitive.  Make a define for
    STRCMP_ENV(), and use it when comparing environment var names.
8   Setting 'shellslash' has no immediate effect.  Change all file names when
    it is set/reset?  Or only use it when actually executing a shell command?
8   When editing a file on a Samba server, case might matter.  ":e file"
    followed by ":e FILE" will edit "file" again, even though "FILE" might be
    another one.  Set last used name in buflist_new()?  Fix do_ecmd(), etc.
8   When a buffer is editing a file like "ftp://mach/file", which is not going
    to be used like a normal file name, don't change the slashes to
    backslashes. (Ronald Hoellwarth)

Win32 console:
9   When editing a file by its short file name, it should be expanded into its
    long file name, to avoid problems like these: (Mccollister)
     1) Create a file called ".bashrc" using some other editor.
     2) Drag that file onto a shortcut or the actual executable.
     3) Note that the file name is something like BASHRC~1
     4) Go to File->Save As menu item and type ".bashrc" as the file name.
     5) Press "Yes" to indicate that I want to overwrite the file.
     6) Note that the message "File exists (add ! to override)" is displayed
        and the file is not saved.
    Use FindFirstFile() to expand a file name and directory in the path to its
    long name.
8   Also implement 'conskey' option for the Win32 console version?  Look at
    how Xvi does console I/O under Windows NT.
7   Re-install the use of $TERM and support the use of different terminals,
    besides the console.
8   Use of <altgr> modifier doesn't work?  5.3 was OK. (Garcia-Suarez/Guckes)
9   Mapping <C-S-Tab> doesn't work correctly.  How to see the difference with
    <C-S-i>?
9   tmpnam() uses file in root of file system: "\asdf".  That doesn't work on
    a Netware network drive.  Use same function as for Win32 GUI?
8   In os_win32.h, HAVE_STRICMP and HAVE_STRNICMP are defined only if __GNUC__
    is not defined.  Shouldn't that be the other way around?

Amiga:
```

8   In mch_inchar() should use convert_input_safe() to handle incomplete byte
    sequences.
9   In mch_expandpath() a "*" is to be expanded, but "*" isn't. Remove
    backslashes in result.
8   Executing a shell, only one option for 'shell' is separated. Should do
    all options, using white space separation.

Macintosh:
-   GUI: gui_mch_browsedir() is missing.
7   Loading the Perl library only works on OS/X 10.2 or 10.3, never on both.
    Load the Perl library dynamically see Python sources file dynload_mac
    (Jack)
    dynamic linking: http://developer.apple.com/technotes/tn2002/tn2064.html
8   inputdialog() doesn't resize when giving more text lines. (David Fishburn,
    2006 Sept 28)
8   Define vim_mkdir() for Macintosh.
8   Define mch_writable() for Macintosh.
9   When DiskLock is running, using a swap file causes a crash. Appears to be
    a problem with writing a file that starts with a dot. (Giacalone)
9   In mac_expandpath() check that handling of backslashes is done properly.

"Small" problems:
-   Can't disable terminal flow control, to enable the use of CTRL-S and
    CTRL-Q. Add an option for it?
-   When using e_secure in do_one_cmd() mention the command being executed,
    otherwise it's not clear where it comes from.
-   When the quickfix window is open and executing ":echo 'hello'" using the
    Command-line window, the text is immediately removed by the redrawing.
    (Michael Henry, 2008 Nov 1)
    Generic solution: When redrawing while there is a message on the
    cmdline, don't erase the display but draw over the existing text.
    Other solution, redraw after closing the cmdline window, before executing
    the command.
9   For Turkish vim_tolower() and vim_toupper() also need to use utf_
    functions for characters below 0x80. (Sertacyildiz)
9   When the last edited file is a help file, using '0 in a new Vim doesn't
    edit the file as a help file. 'filetype' is OK, but 'iskeyword' isn't,
    file isn't readonly, etc.
8   When an ":edit" is inside a try command and the ATTENTION prompt is used,
    the :catch commands are always executed, also when the file is edited
    normally. Should reset did_emsg and undo side effects. Also make sure
    the ATTENTION message shows up. Servatius Brandt works on this.
7   Vimtutor leaves escape sequence in terminal. This is the xterm response to
    requesting the version number. (Yasuhiro Matsumoto)
8   When redirecting and using ":silent" the current column for displaying and
    redirection can be different. Use a separate variable to hold the column
    for redirection.
7   The messages for "vim --help" and "vim --version" don't use
    'termencoding'.
-   Could the hit-enter prompt be avoided when a message only overlaps the
    'showcmd' area? Clear that area when the next cmd is typed.
8   When 'scrollbind' is set, a window won't scroll horizontally if the cursor

line is too short. Add a word in 'scrollopt' to allow moving the cursor to longer line that is visible. A similar thing is done for the GUI when using the horizontal scrollbar.

7 VisVim can only open one file. Hard to solve: each opened file is passed with a separate invocation, would need to use timestamps to know the invocations belong together.

8 When giving a ":bwipeout" command a file-changed dialog may popup for this buffer, which is pointless. (Mike Williams)

8 On MS-Windows ":make" doesn't show output while it is working. Use the tee.exe from http://unxutils.sourceforge.net/ ? About 16 Kbyte in the UnxUtils.zip archive.
Is it better than what we have in src/tee?

8 When doing Insert mode completion a mapping cannot recursively call edit(), because the completion information is global. Put everything in an allocated structure?

8 Command line completion: buffers "foo.txt" and "../b/foo.txt", completing ":buf foo<Tab>" doesn't find the second one. (George V. Reilly)

7 mb_off2cells() doesn't work correctly on the tail byte of a double-byte character. (Yasuhiro Matsumoto) It should return 1 when used on a tail byte, like for utf-8. Store second byte of double-byte in ScreenLines2[] (like for DBCS_JPNU) and put a zero in the second byte (like for UTF-8).

7 Inside a function with "perl <<EOF" a line with "$i++" is recognized as an ":insert" command, causing the following "endfunction" not to be found. Add skipping this perl construction inside function definitions.

7 When 'ttimeoutlen' is 10 and 'timeoutlen' is 1000, there is a keycode "<Esc>a" and a mapping <Esc>x", when typing "<Esc>a" with half a second delay should not be interpreted as a keycode. (Hans Ginzel)

7 ":botright 1 new" twice causes all window heights to be changed. Make the bottom window only bigger as much as needed.

7 The Cygwin and MingW makefiles define "PC", but it's not used anywhere. Remove? (Dan Sharp)

9 User commands use the context of the script they were defined in. This causes a "s:var" argument to unexpectedly use a variable in the defining script, not the calling script. Add an argument to ":command": "-keepcontext". Do replace <SID>, so that a function in the defining script can be called.

8 The Japanese message translations for MS-Windows are called ja.sjis.po, but they use encoding cp932. Rename the file and check that it still works.

8 A very long message in confirm() can't be quit. Make this possible with CTRL-C.

8 "gf" always excludes trailing punctuation characters. file_name_in_line() is currently fixed to use ".,:;!". Add an option to make this configurable?

8 'hkmap' should probably be global-local.

8 Using ":s" in a function changes the previous replacement string. Save "old_sub" in save_search_patterns()?

8 Should allow multi-byte characters for the delimiter: ":s+a+b+" where "+" is a multi-byte character.

8 When appending to a file and 'patchmode' isn't empty, a backup file is always written, even when the original file already exists.

9 When getting focus while writing a large file, could warn for this file being changed outside of Vim. Avoid checking this while the file is being written.

7 The message in bt_dontwrite_msg() could be clearer.
8 The script ID that is stored with an option and displayed with ":verbose set" isn't reset when the option is set internally. For example when 'foldlevel' is set from 'foldlevelstart'.
8 Also store the line number with the script ID and use it for ":verbose", so that "set nocompatible" is found when it changes other option values. When an option is set indirectly mention the command? E.g. when ":diffsplit" sets 'foldmethod'.
8 In the fileformat dialog, "Cancel" isn't translated. Add a global variable for this. (Eduardo Fernandez)
9 When editing a file with 'readonly' set, there is no check for an existing swap file. Then using ":write" (without making any changes) doesn't give a warning either. Should check for an existing swap file without creating one. Unfinished patch by Ian Kelling, 2008 July 14.
7 When 'showbreak' is set, the amount of space a Tab occupies changes. Should work like 'showbreak' is inserted without changing the Tabs.
7 When 'mousefocus' is set and switching to another window with a typed command, the mouse pointer may be moved to a part of the window that's covered by another window and we lose focus. Only move in the y direction, not horizontally?
8 ":hardcopy":
- Using the cterm_color[] table is wrong when t_colors is > 16.
- Need to handle unprintable characters.
- Win32: On a B&W printer syntax highlighting isn't visible. Perform dithering to make grey text?
- Add a flag in 'printoptions' to add an empty page to make the total number even. "addempty"? (Mike Williams)
- Respect 'linebreak'. Perhaps also 'showbreak'?
- Should interpret CTRL-L as a page break.
- Grey line numbers are not always readable. Add field in 'printoptions'. Default to black when no syntax highlighting.
- Be able to print a window in diff mode.
- Be able to specify a colorscheme to use for printing. And a separate one for B&W printing (if that can be detected).
8 When 'virtualedit' is "block,insert" and encoding is "utf-8", selecting a block of one double-wide character, then "d" deletes only half of it.
8 When 'virtualedit' is set, should "I" in blockwise visual mode also insert in lines that don't extend into the block?
8 With 'virtualedit' set, in Insert mode just after the end of line, CTRL-O yh does not yank the last character of the line. (Pavel Papushev) Doing "hl" first appears to make it work.
8 With 'virtualedit' set it's possible to move into the blank area from 'linebreak'.
8 With 'virtualedit' set and 'selection' "exclusive", a Visual selection that ends in or after a tab, "d" doesn't delete (part of) the tab. (Helmut Stiegler)
9 When jumping to a tag, the search pattern is put in the history. When 'magic' is on, the pattern may not work. Translate the pattern depending on p_magic when putting it in the history? Alternative: Store value of 'magic' in history. (Margo)
9 optwin.vim: Restoring a mapping for <Space> or <CR> is not correct for ":noremap". Add "mapcmd({string}, {mode})? Use code from ":mkexrc".
9 incsearch is incorrect for "/that/<Return>/this/;//" (last search pattern isn't updated).

```
9   term_console is used before it is set (msdos, Amiga).
9   Get out-of-memory for ":g/^/,$s//@/" on 1000 lines, this is not handled
    correctly.  Get many error messages while redrawing the screen, which
    cause another redraw, etc.
8   [<C-I> doesn't work when '*' is in 'iskeyword'.  find_pattern_in_path()
    must escape special characters in the pattern.
8   Vim can overwrite a read-only file with ":w!".  ":w" can't overwrite an
    existing file, "w!" can, but perhaps not a read-only file?  Then use
    ":w!!" for that.
    Or ask for permission to overwrite it (if file can be made writable) and
    restore file to readonly afterwards.
    Overwriting a file for which a swap file exists is similar issue.
7   When compiled with "xterm_clipboard", startup can be slower and might get
    error message for invalid $DISPLAY.  Try connecting to the X server in the
    background (forked), so that Vim starts up quicker?  Connect as soon as
    the clipboard is to be used (Visual select mode starts, paste from
    clipboard)
7   X11: Some people prefer to use CLIPBOARD instead of PRIMARY for the normal
    selection.  Add an "xclipboard" argument to the 'clipboard' option? (Mark
    Waggoner)
6   When the xterm reports the number of colors, a redraw occurs.  This is
    annoying on a slow connection.  Wait for the xterm to report the number of
    colors before drawing the screen.  With a timeout.
8   When the builtin xterm termcap contains codes that are not wanted, need a
    way to avoid using the builtin termcap.
8   Xterm sends ^[[H for <Home> and ^[[F for <End> in some mode.  Also
    recognize these keys?  Mostly useful for xterm simulators, like gnometerm.
    See http://dickey.his.com/xterm/xterm.faq.html#xterm_pc_style.
8   For xterm also recognize keypad up/down/left/right and insert.
8   '[ and '] should be set to start/end of line when using a linewise operator
    (e.g., ":w").
8   CTRL-A can't handle big "long" numbers, they become negative.  Check for
    "-" character, if not present, use unsigned long.
8   Add suspending with CTRL-Z at the "more" prompt, and when executing a long
    script in do_cmdline().
8   When using 'hidden', many swap files will be open.  When Vim runs into the
    maximum number of open files, error messages will appear.  Detect that
    this problem is present, and close any hidden files that don't have
    changes.
8   With 'viminfo' set such that the ".viminfo" file is written on a FAT
    filesystem, an illegal file name may be created: ".vim".
8   For each buffer that is opened, the viminfo file is opened and read to
    check for file marks.  This can be slow.
7   In xterm, recognize both vt100 and vt220 cursor keys.  Change
    add_termcode() to not remove an existing entry for a name, when it's
    needed.
    Need a generic solution to recognize different codes for the same key.
8   Core dump within signal function: gdb doesn't show stack backtrace!  Option
    to skip catch_signals()?
9   Repeating a "cw" with "." doesn't work if the text was pasted from the
    clipboard. (Thomas Jones)  It's because the menu/toolbar item exits Insert
    mode and uses "gP".  How to fix this without breaking inserting a block of
    text?
8   In Replace mode pasting from the clipboard (using menu or toolbar) inserts
```

all the text. Add ":rmenu"?
8 Pasting with the mouse in Replace mode inserts the text, instead of overwriting, when it is more than one line. Same for using <C-R>.
9 CTRL-E and CTRL-Y don't work in small window when 'so' is 4 and lines are wrapping (Acevedo/in.226). E.g., when using CTRL-E, window height 7, window might actually scroll down when last line of buffer is displayed. --> Remember if the previous command was "cursor follows screen" or "screen follow cursor" and use this in cursupdate().
7 tilde_replace() can only handle "~/", should also do "~user/". Get the list of home directories (from /etc/passwd? Use getpwent()) and use some clever algorithm to match a path with that. Find common strings in the list?
8 When dragging status line with mouse, sometimes a jump when first clicking on the status line (caused by 'winheight'). Select window on button up, instead of on button down.
8 Dragging the status line doesn't scroll but redraw.
9 Evaluating 'statusline' in build_stl_str_hl() does not properly check for reaching the end of the available buffer. Patch to dynamically allocate the buffer for % items. (Eric Arnold, 2006 May 14)
8 When performing incremental search, should abort searching as soon as a character is typed.
8 When the value of $MAKE contains a path, configure can't handle this. It's an autoconf bug. Remove the path from $MAKE to work around it.
8 How to set VIMRC_FILE to \"something\" for configure? Why does this not work: CFLAGS='-DVIMRC_FILE=\"/mydir/myfile\"' ./configure
8 The temporary file is sometimes not writable. Check for this, and use an alternate name when it isn't. Or add the 'temptemplate' option: template for the temp file name ":set temptemplate=/usr/tmp/?????.tmp". Also: Win32 version uses Windows temp directory, which might not work for cygwin bash.
7 Get error "*, \+ or \(operand could be empty" for pattern "\(.\)\1\{3}". Remember flags for backreferences.
7 When switching to Daylight Saving Time, Vim complains that a file has been changed since last read. Can we use a function that uses GMT?
7 When completing an environment variable after a '$', check for file names that contain a '$' after all have been found.
8 When "cm" termcap entry is missing, starting gvim shouldn't complain about it. (Lohner) Try out with "vt100" entry, cm replaced with cX.
7 When an include file starts with "../", the check for already visiting this file doesn't work. Need to simplify the file name.
7 The names and comments for the arguments of do_browse() are confusing. "dflt" isn't the default file name when "initdir" is not NULL and "initdir" is the default path to be used.
7 When 'scrolloff' is exactly half the window height, "j" causes a scroll of two lines at a time. "k" doesn't do this. (Cory T. Echols)
8 When write_viminfo() is used while there are many orphaned viminfo tempfiles writing the viminfo file fails. Give a clear error message so that the user knows he has to delete the files.
7 It's possible to redefine a script-local function with ":func <SNR>123_Test()". (Krishna) Disallow this.

I can't reproduce these (if you can, let me know how!):

9	NT 4.0 on NTFS file system: Editing ".bashrc" (drag and drop), file
	disappears. Editing ".xyz" is OK. Also, drag&drop only works for three
	files. (McCollister)

Problems that will (probably) not be solved:
-	GTK: when using the popup menu with spelling suggestions and releasing the
	right mouse button before the menu appears selecting an item with the
	right mouse button has no effect. GTK does not produce an event for this.
-	GTK 2: Cannot use the file selector. When using it many things become
	slow. This is caused by some code in GTK that writes
	~/.recently-used.xbel every time an event is handled. It assumes the main
	loop is never quit, which is a wrong assumption. Also, it overwrites the
	file with different file permissions, which is a privacy issue. This
	needs to be fixed in GTK. A solution in Vim would be really complicated.
	(2008 Jul 31) This appears to be fixed in Vim 7.3.
-	xterm title: The following scenario may occur (esp. when running the Vim
	test script): Vim 1 sets the title to "file1", then restores the title to
	"xterm" with an ESC sequence when exiting. Vim 2 obtains the old title
	with an X library call, this may result in "file1", because the window
	manager hasn't processed the "xterm" title yet. Can apparently only be
	worked around with a delay.
-	In a terminal with 'mouse' set such that the mouse is active when entering
	a command line, after executing a shell command that scrolls up the
	display and then pressing ":": Selecting text with the mouse works like
	the display wasn't scrolled. Vim doesn't know how much the external
	command scrolled up the display. Use Shift to select text.
-	X windows: When $DISPLAY points to a X server where there is no access
	permission, trying to connect to the X server causes an error message.
	XtOpenDisplay() prints this directly, there is no way to avoid it.
-	X windows: Setting 'guifontset' to an illegal value sometimes crashes Vim.
	This is caused by a fault in a X library function, can't be solved in Vim.
-	Win32 tcl: has("tcl") hangs when the tcl84.dll is from cygwin.
-	Motif: When adding a menu item "Find this &Symbol", the "s" in "this" will
	be underlined, instead of in "Symbol". Motif doesn't let us specify which
	character gets the highlighting.
-	Moving the cursor removes color in color-xterm. This is a color-xterm
	problem! color-xterm ver. 6.1 beta 3 and later work properly.
-	In zsh, "gvim&" changes the terminal settings. This is a zsh problem.
	(Jennings)
-	Problem with HPterm under X: old contents of window is lost (Cosentino).
-	Amiga: When using quickfix with the Manx compiler we only get the first 25
	errors. How do we get the rest?
-	Amiga: The ":cq" command does not always abort the Manx compiler. Why?
-	Linux: A file with protection r--rw-rw- is seen readonly for others. The
	access() function in GNU libc is probably wrong.
-	When doing a CTRL-Z and typing a command for the shell, while Vim is busy
	(e.g. writing a file), the command for the shell is sometimes eaten by Vim,
	because the terminal mode is changed from RAW to CBREAK.
-	An old version of GNU tgoto can't handle the terminfo code for "AF". The
	"%p1" is interpreted as "%p" and "1", causing color not to be working.
	Fix: Change the "%p1" in the "AF" and "AB" terminfo entries to "%p".
	(Benzinger).
-	When running an external command from the GUI, typeahead is going to that

program, not to Vim. It looks like the shell eats the characters, Vim
can't get back what the external command didn't use.
- Win32 GUI: Error code from external command not returned in shell_error.
  It appears that cmd.exe and command.com don't return an error code.
- Win32 GUI: The Toolbar is a bit too high when the flat style is being
  used. We don't have control over the height of the Toolbar.
- Win32: All files created on the day of switching from winter to summer
  time cause "changed since editing started" messages. It goes away when
  the file is written again the next day, or the timezone is adjusted.
  DJGPP version is OK. (Zaimi) Looks like a problem with the Win32 library.
  Rebooting doesn't help. Time stamps look OK in directory. (Penn)
  Is this on FAT (stores wall clock time) or NTFS (stores UTS)?
- Win32, MS-Windows XP: $HOME uses the wrong drive when the user profiles
  are not on the boot disk. This is caused by a wrong value of $HOMEDRIVE.
  This is a bug in XP, see MSKB article 818134.
- Win32, MS-Windows: expanding plugin/**/*.vim also picks up
  dir/ctags.vim,v. This is because the short file name is something like
  "ctags~1.vim" and that matches the pattern.
- SunOS 5.5.1 with Motif: The file open dialog does not have a horizontal
  scroll bar for the "files" selection. This is a problem in the Motif
  libraries, get a patch from Sun.
- Solaris 2.6 with GTK and Perl: gvim crashes when started. Problem with X
  input method called from GDK code. Without Perl it doesn't crash.
- VMS: Vimdiff doesn't work with the VMS diff, because the output looks
  different. This makes test 47 fail. Install a Unix-compatible diff.
- Win32 GUI: mouse wheel always scrolls rightmost window. The events arrive
  in Vim as if the rightmost scrollbar was used.
- GTK with Gnome: Produces an error message when starting up:
      Gdk-WARNING **: locale not supported by C library
  This is caused by the gnome library gnome_init() setting $LC_CTYPE to
  "en_US". Not all systems support this locale name, thus causing the
  error. Hopefully a newer version of GTK/Gnome fixes this problem.
- GTK 2: With this mapping the hit-enter prompt is _sometimes_ below the
  screen, at other times there is a grey area below the command line:
      :nmap <F11> :if &guioptions=~'m' \| set guioptions-=m \| else \| set guioptions+=m
- GTK: When pasting a selection from Vim to xclipboard gvim crashes with a
  ABRT signal. Probably an error in the file gdkselection.c, the assert
  always fails when XmbTextListToTextProperty() fails. (Tom Allard)
- GTK 2: gives an assertion error for every non-builtin icon in the toolbar.
  This is a GTK 2.4.x bug, fixed in GTK 2.4.2. (Thomas de Grenier de Latour)
- When using an xterm that supports the termresponse feature, and the 't_Co'
  termcap option was wrong when Vim started, it will be corrected when the
  termresponse is received. Since the number of colors changes, the
  highlighting needs to be initialized again. This may cause colors defined
  in the vimrc file to be lost.
- On Windows NT 4.0 the number of files passed to Vim with drag&drop and
  "Edit with Vim" is limited. The maximum command line length is 255 chars.

--------------------- extensions and improvements ----------------------
                                                    extensions-improvements

Most interesting new features to be added when all bugs have been fixed:
- Using ":exe edit fname" has escaping problems. Use ":edit ++(fname)".
  Thus use "++=" to give arguments as expressions, comma separated as if

    calling a function.
    With options: ":edit ++(['!', '++enc=abc'], ['+/pat'], fname)".
    Alternative: Make a function for Ex commands: cmd_edit().
-   Add COLUMN NUMBERS to ":" commands ":line1,line2[col1,col2]cmd". Block
    can be selected with CTRL-V. Allow '$' (end of line) for col2.
-   ECLIPSE plugin. Problem is: the interface is very complicated. Need to
    implement part in Java and then connect to Vim. Some hints from Alexandru
    Roman, 2004 Dec 15. Should then also work with Oracle Jdeveloper, see JSR
    198 standard http://www.jcp.org/en/jsr/detail?id=198.
    Eclim does it: http://eclim.sourceforge.net/ (Eric Van Dewoestine)
    Plugin that uses a terminal emulator: http://vimplugin.sf.net
    And another one: http://www.satokar.com/viplugin/index.php
-   STICKY CURSOR: Add a way of scrolling that leaves the cursor where it is.
    Especially when using the scrollbar. Typing a cursor-movement command
    scrolls back to where the cursor is.
-   Scroll commands by screen line. g CTRL-E and g CTRL-Y ? Requires the
    first line to be able to start halfway.
8   Add a command to jump to a certain kind of tag. Allow the user to specify
    values for the optional fields. E.g., ":tag size type=m".
    Also allow specifying the file and command, so that the result of
    taglist() can be used.
-   X11: Make it possible to run Vim inside a window of another program.
    This can be done with XReparentWindow(). But how exactly?

Documentation:
8   List of Vim runtime directories. dotvim.txt from Charles Campbell, 2007
    Feb 20.
8   The GUI help should explain the Find and Find/Replace dialogs. Add a link
    to it from ":promptrepl" and ":promptfind".
8   List of options should mention whether environment variables are expanded
    or not.
8   Extend usr_27.txt a bit. (Adam Seyfarth)
9   Make the Reference Manual more precise. For each command mention:
    - change to cursor position and curswant
    - if it can be undone (u/CTRL-R) and redone (.)
    - how it works for folded lines
    - how it works with multi-byte characters
9   In change.txt, remark about Javadoc isn't right. Right alignment would
    work too.
8   Spread the windows commands over the other files. For example, ":stag"
    should be with ":tag". Cross-link with tags to avoid too much double
    text.
8   Add tags for all features, e.g. "gui_running".
7   MS-Windows: When a wrong command is typed with an ALT key, give a hint to
    look at the help for 'winaltkeys'.
7   Add a help.vim plugin that maps <Tab> to jump to the next tag in || and
    <C-Tab> (and <S-Tab>) to the previous tag.
    Patch by Balazs Kezes, 2007 Dec 30. Remark from A. Politz.
-   Check text editor compendium for vi and Vim remarks.

Help:
-   First try using the ":help" argument literally, before using it as a

pattern. And then match it as part of a tag.
- When a help item has multiple matches make it possible to use ":tn" to go to the other matches.
- Support a way to view (and edit) .info files.
- Implement a "sticky" help window, some help text lines that are always displayed in a window with fixed height. (Guckes) Use "~/.vimhelp" file, user can edit it to insert his favorite commands, new account can contain a default contents.
- Make 'winminheight' a local option, so that the user can set a minimal height for the help window (and other windows).
- ":help :s^I" should expand to ":help :substitute".
- Make the help key (<F1>) context sensitive?
- Learn mode: show short help while typing commands.

User Friendlier:
8 Windows install with install.exe: Use .exe instead of .bat files for links, so that command line arguments are passed on unmodified? (Walter Briscoe)
8 Windows install: Be able to associate Vim with a selection of file types?
8 Windows uninstall: Have uninstal.c delete the vimfiles directories that dosinst.c creates. List the contents of the directory (recursively) if the user asks for it. Requires an implementation of "rm -rf".
8 Remember the name of the vimrc file that was used (~/.vimrc, $VIM/_vimrc, $HOME/_vimrc, etc.) and add "edit vimrc" to the File menu.
- Add a way to save local settings and mappings into a new plugin file. ":mkplugin <file>"?
- Add mappings local to a window: ":map <window> ..."?
9 Add buffer-local menu. Should offer a choice between removing the menu or disabling it. Be careful that tear-offs don't disappear (keep one empty item?).
Alternative: use BufEnter and BufLeave autocommands.
8 make a vimtutor script for Amiga and other systems.
7 When Vim detects a file is being edited elsewhere and it's a gvim session of the same user it should offer a "Raise" button, so that the other gvim window can be displayed. (Eduard)
8 Support saving and restoring session for X windows? It should work to do ":mksession" and use "-S fname" for the restart command. The gui_x11_wm_protocol_handler() already takes care of the rest.
global_event_filter() for GTK.

Tab pages:
9 GUI implementation for the tab pages line for other systems.
7 GUI: Control over the appearance of the text in the labels (bold, color, font, etc.)
8 Make GUI menu in tab pages line configurable. Like the popup menu.
8 balloons for the tab page labels that are shortened to show the full path.
7 :tabdup   duplicate the tab with all its windows.
7 Option to put tab line at the left or right? Need an option to specify its width. It's like a separate window with ":tabs" output.
8 Add local options for each tab page? E.g., 'diffopt' could differ between tab pages.
7 Add local highlighting for each tab page?

7	Add local directory for tab pages? How would this interfere with
	window-local directories?

Spell checking:
-	Support more regions? Caolan McNamara argues it's needed for es_XX.
	https://bugzilla.redhat.com/bugzilla/show_bug.cgi?id=219777
-	Unicode defines another quote character: 0x2019. Use it as an equivalent
	of a single quote, thus use it as a word character like a quote and match
	with words, replacing the curly quote with a single quote.
-	Could filter é things for HTML before doing spell checking.
	Similarly for TeX.
-	The Hungarian spell file uses four extra characters in the FOL/UPP/LOW
	items than other spell files with the ISO-8859-2 encoding, that causes
	problem when changing 'spelllang'. There is no obvious way to fix this.
-	Considering Hunspell 1.1.4:
	What does MAXNGRAMSUGS do?
	Is COMPLEXPREFIXES necessary when we have flags for affixes?
-	Support spelling words in CamelCase as if they were two separate words.
	Requires some option to enable it. (Timothy Knox)
-	There is no Finnish spell checking file. For openoffice Voikko is now
	used, which is based on Malaga: http://home.arcor.de/bjoern-beutel/malaga/
	(Teemu Likonen)
8	":mkspell" still takes much too long in Hungarian dictionary from
	hunspell. Only solution appears to be to postpone secondary suffixes.
8	Handle postponed prefix with COMPOUNDPERMITFLAG or COMPOUNDFORBIDFLAG.
	WFP_COMPPERMIT and WFP_COMPFORBID
8	implement use of <compoptions> in .spl file:
	implement CHECKCOMPOUNDREP: when a compound word seems to be OK apply REP
	items and check if the result is a valid word.
	implement CHECKCOMPOUNDDUP
	implement CHECKCOMPOUNDTRIPLE
	Add CHECKCOMPOUNDCASE: when compounding make leading capital lower case.
	How is it supposed to work?
-	Add a command the repeats]s and z=, showing the misspelled word in its
	context. Thus to spell-check a whole file.
-	suggestion for "KG" to "kg" when it's keepcase.
-	For flags on affixes: Use a "AFFCOMPSET" flag; means the compound flags of
	the word are not used.
-	Support breakpoint character ? 0xb7 and ignore it? Makes it possible to
	use same wordlist for hyphenation.
-	Compound word is accepted if nr of words is <= COMPOUNDWORDMAX OR nr of
	syllables <= COMPOUNDSYLMAX. Specify using AND in the affix file?
-	NEEDCOMPOUND also used for affix? Or is this called ONLYINCOMPOUND now?
	Or is ONLYINCOMPOUND only for inside a compound, not at start or end?
-	Do we need a flag for the rule that when compounding is done the following
	word doesn't have a capital after a word character, even for Onecap words?
-	New hunspell home page: http://hunspell.sourceforge.net/
	- Version 1.1.0 is out now, look into that.
	- Lots of code depends on LANG, that isn't right. Enable each mechanism
	  in the affix file separately.
	- Example with compounding dash is bad, gets in the way of setting
	  COMPOUNDMIN and COMPOUNDWORDMAX to a reasonable value.
	- PSEUDOROOT == NEEDAFFIX

    - COMPOUNDROOT -> COMPOUNDED? For a word that already is a compound word
            Or use COMPOUNDED2, COMPOUNDED3, etc.
-   CIRCUMFIX: when a word uses a prefix marked with the CIRCUMFIX flag, then
    the word must also have a suffix marked with the CIRCUMFIX flag. It's a
    bit primitive, since only one flag is used, which doesn't allow matching
    specific prefixes with suffixes.
    Alternative:
        PSFX {flag} {pchop} {padd} {pcond} {schop} {sadd}[/flags] {scond}
    We might not need this at all, you can use the NEEDAFFIX flag and the
    affix which is required.
-   When a suffix has more than one syllable, it may count as a word for
    COMPOUNDWORDMAX.
-   Add flags to count extra syllables in a word. SYLLABLEADD1 SYLLABLEADD2,
    etc.? Or make it possible to specify the syllable count of a word
    directly, e.g., after another slash: /abc/3
-   MORPHO item in affix file: ignore TAB and morphological field after
    word/flags and affix.
-   Implement multiple flags for compound words and CMP item?
    Await comments from other spell checking authors.
-   Also see tklspell: http://tkltrans.sourceforge.net/
8   Charles Campbell asks for method to add "contained" groups to existing
    syntax items (to add @Spell).
    Add ":syntax contains {pattern} add=@Spell" command? A bit like ":syn
    cluster" but change the contains list directly for matching syntax items.
-   References: MySpell library (in OpenOffice.org).

        http://whiteboard.openoffice.org/source/browse/whiteboard/lingucomponent/source/spe
      author: Kevin Hendricks <kevin.hendricks@sympatico.ca>
8   It is currently not possible to mark "can not" as rare, because "can" and
    "not" are good words. Find a way to let "rare" overrule "good"?
8   Make "en-rare" spell file? Ask Charles Campbell.
8   The English dictionaries for different regions are not consistent in their
    use of words with a dash.
7   Insert mode completion mechanism that uses the spell word lists.
8   Add hl groups to 'spelllang'?
        :set spelllang=en_us,en-rare/SpellRare,en-math/SpellMath
    More complicated: Regions with different languages? E.g., comments
    in English, strings in German (po file).

Diff mode:
9   When making small changes, e.g. deleting a character, update the diff.
    Possibly without running diff.
8   Also show difference with the file when editing started? Should show what
    can be undone. (Tom Popovich)

Folding:
    (commands still available: zI zJ zK zp zP zq zQ zV zy zY;
    secondary: zB zS zT zZ, z=)
8   Vertical folds: looks like vertically split windows, but the cursor moves
    through the vertical separator, separator moves when scrolling.
8   Add "z/" and "z?" for searching in not folded text only.
8   When a closed fold is displayed open because of 'foldminlines', the
    behavior of commands is still like the fold is closed. How to make the

    user aware of this?
8   Add an option 'foldskip' with values like 'foldopen' that specifies which
    commands skip over a closed fold.
8   "H" and "L" count buffer lines instead of window lines. (Servatius Brandt)
8   Add a way to add fold-plugins. Johannes Zellner has one for VB.
7   When using manual folding, the undo command should also restore folds.
-   Allow completely hiding a closed fold. E.g., by setting 'foldtext' to an
    empty string. Require showing a character in 'foldcolumn' to avoid the
    missing line goes unnoticed.
    How to implement this?
-   When pressing the down arrow of a scrollbar, a closed fold doesn't scroll
    until after a long time. How to make scrolling with closed folds
    smoother?
-   When creating a session, also store folds for buffers in the buffer list,
    using the wininfo in wi_folds.
-   When currently editing the first file in the argument list the session
    file can contain:
        args version.c main.c
        edit version.c
    Can editing version.c twice be avoided?
-   'foldmethod' "textobject": fold on sections and paragraph text objects.
-   "zuf": undo change in manual fold. "zUf" redo change in manual fold. How
    to implement this?
-   "zJ" command: add the line or fold below the fold in the fold under the
    cursor.
-   'foldmethod' "syntax": "fold=3" argument: set fold level for a region or
    match.
-   Apply a new foldlevel to a range of lines. (Steve Litt)

Multi-byte characters:
-   When editing a file with both utf-8 and latin1 text Vim always falls back
    to latin1. Add a command to convert the latin1 characters to utf-8?
        :unmix utf-8,latin1 filename
    Would only work when 'encoding' is utf-8.
9   When the tail byte of a double-byte character is illegal (e.g., a CR), the
    display is messed up (Yasuhiro Matsumoto). Should check for illegal
    double-byte characters and display them differently (display each single
    byte).
9   'fenc' in modeline problem: add option to reload the file when 'fenc' is
    set to a different value in a modeline? Option can be default on. Could
    it be done with an autocommand?
8   Add an item in 'fileencodings' to check the first lines of a file for
    the encoding. See Python PEP: http://www.python.org/peps/pep-0263.html.
    To avoid getting a wrong encoding only accept something Emacs-like:
    "-*- coding: enc-na_me.foo -*-" and "-*- coding= enc-na_me.foo -*-"
    Match with "-*-\s*coding[:=]\s*\([::word::-_.]\+\)\s*-*-" and use first
    item.
8   Add an item in 'fileencodings' to check the first line of an XML file for
    the encoding. <?xml version="1.0" encoding="UTF-8"?> Or "charset=UTF-8"?
    For HTML look for "charset=utf-8".
8   The quickfix file is read without conversion, thus in 'encoding'. Add an
    option to specify the encoding of the errorfile and convert it. Also for
    ":grep" and ":helpgrep".
    More generic solution: support a filter (e.g., by calling a function).

8 When a file was converted from 'fileencoding' to 'encoding', a tag search
should also do this on the search pattern. (Andrzej M. Ostruszka)
8 When filtering changes the encoding 'fileencoding' may not work. E.g.,
when using xxd and 'fileencoding' is "utf-16". Add an option to set a
different fileencoding for filter output?
7 When converting a file fails, mention which byte could not be converted,
so that the user can fix the problem.
8 Add configure option to be able to disable using the iconv library. (Udo
Schweigert)
9 'aleph' should be set to 1488 for Unicode. (Zvi Har'El)
8 Should add test for using various commands with multi-byte characters.
8 'infercase' doesn't work with multi-byte characters.
8 toupper() function doesn't handle byte count changes.
7 Searching and composing characters:
When searching, should order of composing characters be ignored?
Add a special item to match with a composing character, so that composing
characters can be manipulated.
8 Should implement 'delcombine' for command line editing.
8 Detect overlong UTF-8 sequences and handle them like illegal bytes.
8 ":s/x/\u\1/" doesn't work, making uppercase isn't done for multi-byte
characters.
8 UTF-8: "r" in Visual mode doesn't take composing characters.
8 UTF-8: When there is a precomposed character in the font, use it instead
of a character and a composing character. See xterm for an example.
7 When a character can't be displayed, display its digraph instead.
'display' option to specify this.
7 Use ideas for nl_langinfo() from Markus Kuhn in enc_default():
(www.cl.cam.ac.uk/~mgk25/ucs/langinfo.c)
- GTK and Win32: Allow selecting fonts for 'guifontset' with the
fontselector somehow.
- GTK and Win32: make it possible to set the font for the menu to make it
possible to have 'encoding' different from the current locale.
- dbcs_class() only works for Japanese and Korean. Implement this for
other encodings. The "euc-jp" and "euc-kr" choices might be wrong.
- Find some way to automatically select the right GUI font or fontset,
depending on the default value of 'encoding'.
Irrelevant in the GTK+ 2 GUI so long as UTF-8 is used.
For Windows, the charset_pairs[] table could be used. But how do we know
if a font exists?
- Do keyboard conversion from 'termencoding' to 'encoding' with
convert_input() for Mac GUI.
- Add mnemonics from RFC1345 longer than two characters.
Support CTRL-K _{mnemonic}_
- Make 'breakat' accept multi-byte characters. Problem: can't use a lookup
table anymore (breakat_flags[]).
Simplistic solution: when 'formatoptions' contains "m" also break a line
at a multi-byte character >= 0x100.
- Add the possibility to enter mappings which are used whenever normal text
could be entered. E.g., for "f" command. But not in Normal mode. Sort
of opposite of 'langmap'. Use ":amap" command?
- When breaking a line, take properties of multi-byte characters into
account. The "linebreak" program from Bruno Haible can do it:
ftp://ftp.ilog.fr/pub/Users/haible/gnu/linebreak-0.1.tar.gz
But it's very complicated...

```
Printing:
7   Implement "undercurl" for printing.
-   Add "page width" to wrap long lines.
-   Win32: use a font dialog for setting 'printfont'.  Can reuse the code for
    the 'guifont' dialog, put the common code in a separate function.
-   Add the file timestamp to the page header (with an option). (George
    Reilly)
-   Win32: when 'printfont' is empty use 'guifont'.
-   Unix: Use some dialog box to do the obvious settings (paper size, printer
    name, portrait/landscape, etc).
-   PostScript: Only works for text that can be converted to an 8-bit
    character set.  How to support Unicode fully?
-   Allow specifying the paper size, instead of using a standard size.  Same
    units as for the margins.
-   Support right-to-left text?
8   Make the foreground color darkening function preserve the hue of the
    color.

Syntax highlighting:
8   Make ":syn off" use 'runtimepath' instead of $VIMRUNTIME. (Gary Johnson)
    Should do the same for ":syn on" and ":syn manual".
8   Support "containedin" argument for ":syn include", so that the defined
    cluster can be added to existing syntax items.
8   C syntax: Don't highlight {} as errors inside () when used like this:
    "({ something })", often used in GCC code.
7   Add a "startgroup" to a region.  Used like "nextgroup" inside the region,
    preferred item at the start of the region. (Charles Campbell)
8   When editing a new file without a name and giving it a name (by writing
    it) and 'filetype' is not set, detect the filetype.  Avoid doing it for
    ":wq file".
7   For "nextgroup" we have skipwhite, skipnl and skipempty.  It would be
    really nice to be able to skip with a pattern.  Or skip with a syntax
    group. (Nikolai Weibull, 2007 Feb 27)
8   Make conversion to HTML faster (Write it in C or pre-compile the script).
9   There is still a redraw bug somewhere.  Probably because a cached state is
    used in a wrong way.  I can't reproduce it...
7   Be able to change only the background highlighting.  Useful for Diff* and
    Search highlighting.
7   When 'number' is set highlight the number of the current line.
    Must be enabled with an option, because it slows down display updating.
8   Allow the user to add items to the Syntax menu sorted, without having to
    change this for each release.
8   Add a "matchcontains" for regions: items contained in the start or end
    pattern, but not in the body.
8   Add a "keepend-contained" argument: Don't change the end of an item this
    one is contained in.  Like "keepend" but specified on the contained item,
    instead of the containing item.
8   cpp.vim: In C++ it's allowed to use {} inside ().
8   Some syntax files set 'iskeyword', they should use "syn iskeyword".
    Also need a separate 'iskeyword' for the command line, e.g., in a help
    window ":e /asdf/asdf/" CTRL-W works different.
```

8 Add specific syntax item to match with parens/braces that don't have a
"%" match. :syntax nomatch cMatchError (,{,[,),},] [contained]
8 Highlight the text between two matching parens (e.g., with a grey
background) when on one of the parens or in between them.
Option for the matchparen plugin?
8 When using a cterm, and no ctermfg or ctermbg are defined, use start/stop
sequences. Add remark in docs that :if 'term' == "term-name" should be
used.
8 Add @spell cluster to String and Comment groups for many languages. Will
allow spell checking. (Fleiner)
8 When listing syntax items, try to sort the keywords alphabetically. And
re-insert the [] if possible.
8 Make it possible to use color of text for Visual highlight group (like for
the Cursor).
8 It would be useful to make the highlight group name an expression. Then
when there is a match, the expression would be evaluated to find out what
highlight group to use. Could be used to check if the shell used in a
password file appears in /etc/shells. (Nikolai Weibull)
syn match =s:checkShell(v:match) contained 'pattern'
8 Make it possible to only highlight a sub-expression of a match. Like
using "\1" in a ":s" command.
8 Support for deleting syntax items:
:syn keyword cTodo remove this
:syn match cTodo remove "pattern"
:syn region cString remove start="this" end="that"
8 Add possibility to sync on something else, when the syncing in one way
doesn't find match. For HTML: When no {script} is found, try looking for
a '<'. (Fleiner)
7 Replace the synchronizing method with a state machine specification?
Should be able to start at any line in the file, search forwards or
backwards, and use the result of matching a pattern.
7 Use parsing like awk, so that e.g., a (without a matching) can be
detected.
8 Make it possible to use "inverted" highlighting, invert the original
character. For Visual mode. (xterm-selection already does this).
8 Highlight non-printable characters with "SpecialChar", linked to
"Special". Display them with the digraph characters, if possible.
8 Highlight the clipboard-selection with a highlight group.
8 Be able to reset highlighting to its original (default) values.
7 Be able to write current highlighting to a file as commands, similar to
":mkvimrc".
8 Improve c.vim:
- Add check for unterminated strings, with a variable to switch it on:
"c_strict_ansi".
- Detect unbalanced "#endif". Requires looking back a long way...
8 Add an option to restrict the updating of syntax highlighting to the
current line while in Insert mode.
8 When guessing value of 'background', the syntax file has already been
loaded (from the .gvimrc). After changing 'background', load it again?
8 Add ":syn resync" command, to re-parse the whole file until the current
display position.
8 Should support "me" offset for a region start pattern. To be used to
allow searching for the end pattern inside the match of the end pattern.
Example: syn region pikeXX start="([^{]" end=")" should work on "()".

```
8   When using a regexp for "contains=", should delay matching with it until
    redrawing happens.  Set a flag when a group is added, check this flag when
    highlighting starts.
7   It's possible for an item to be transparent, so that the colors of an item
    lower on the stack is used.  Also do this with highlighting, so that the
    user can set transparent highlighting?  E.g. a number in a C comment would
    get the color of a comment, a number in an assignment Normal. (Nikolai
    Weibull)
7   Add "semitrans": Add highlighting.  E.g., make the text bold, but keep the
    colors.  And add colors, so that Green+Red becomes Yellow.
    E.g. for this html:
        <B> bold text <I> italic+bold text </B> italic text </I>
7   CTRL-] checks the highlight group for finding out what the tag is.
7   Add an explanation how a list of words can be used to highlight misspelled
    words.
8   Add more command line completion for :syntax.
8   Add more command line completion for :highlight.
7   Should find a better way to parse the :syntax and :highlight commands.
    Use tables or lists that can be shared by parsing for execution and
    completion?
8   Add ColorSchemePost autocommand event, so that scripts can set up their
    highlighting. (Salman Halim)
7   Add a few sets of colors (e.g. Borland Turbo C one).  With a menu to
    select one of the sets.
8   Add offsets to sub-matches: "\(a*\) *"he=e1-1
    'e' is end of match 'e1' is end of sub-match 1, 's2' is start of submatch
    2, etc.
8   In Insert mode, when there are typeahead characters, postpone the
    highlighting (for "." command).
8   Syncing on comments isn't 100% correct when / / lines mix with / * and * /.
    For example: What about a line that starts with / / and contains * /?
8   Ignore / * and  * / inside strings, when syncing.
7   Build a few more syntax files from the file "/usr/share/misc/vgrindefs":
    ISP, LDL, Icon, ratfor.  And check "nedit/source/highlight.c".
6   Add possibility to have background color continue until the right edge of
    the window.  Useful for comment blocks and function headings. (Rogall)
-   Make it possible to add "contains" items for all items in a group.  Useful
    when extending an already existing syntax file.
-   Add line-continuation pattern for non-syncing items too?
-   Add possibility to highlight the whole line, including the right margin
    (for comment blocks).
-   Add 'hlmatch' option: List of flags:
    'c': highlight match for character under the cursor.
    'b': highlight the previous (, and its match.
    'a': highlight all text from the previous ( until its match.
         Also for {}, <>, etc.?
    'e': highlight all braces without a match (slow?)
    OR: add an argument "cursor" to the syntax command, which means that the
    region/match/keyword is only highlighted when the cursor is on it.
    (Campbell)
    Or do it like Elvis: define text objects and how to highlight them around
    the cursor. (Iain Truskett)
7   Make it possible to use all words in the tags files as Keyword.
    Can also be done with a script (but it's slow).
```

```
7   Make it possible to call a ":" command when a match is found.  Should
    allow for adding keywords from the text (e.g. variables that are set).
    And allows for sections with different highlighting.
7   Add highlight group for commandline: "Commandline".  Make sure it
    highlights the command line while typing a command, and any output from
    messages.  And external commands?
8   Make a version that works like less, but with highlighting: read stdin for
    text, exit at end of file, don't allow editing, etc.  moreim?  lessim?
7   SpecialKey highlighting overrules syntax highlighting.  Can't give an
    unprintable char another color.  Would be useful for ^M at end of line.

Vim script language:
8   Make the filename and line number available to script functions, so that
    they can give useful debugging info.  The whole call stack would be ideal.
    At least use this for error messages.
7   Execute a function with standard option values.  No need to save and
    restore option values.  Especially useful for new options.  Problem: how
    to avoid a performance penalty (esp. for string options)?
8   Add referring to key options with "&t_xx".  Both for "echo &t_xx" and
    ":let &t_xx =".  Useful for making portable mappings.
-   Add ":let var ?= value", conditional assignment.  Patch by Dave Eggum,
    2006 Dec 11.
-   range for ":exec", pass it on to the executed command.  (Webb)
8   ":{range}source": source the lines from the current file.
        You can already yank lines and use :@" to execute them.
        Most of do_source() would not be used, need a new function.
        It's easy when not doing breakpoints or profiling.
    Requires copying the lines into a list and then creating a function to
    execute lines from the list.  Similar to getnextac().
7   ":include" command: just like ":source" but doesn't start a new scriptID?
    Will be tricky for the list of script names.
8   Have a look at VSEL.  Would it be useful to include? (Bigham)
8   Have a prefix for a function to make it unique.  When using packages it
    can be the plugin name.
    Perhaps also have a way to remove everything that the package added?
    including autocommands.
7   Pre-parse or compile Vim scripts into a bytecode.
    1. Put the bytecode with the original script, with an ":if
       has('bytecode')" around it, so that it's only used with a Vim that
       supports it.  Update the code with a command, can be used in an
       autocommand.
    2. Use a ".vic" file (like Python use .pyc).  Create it when writing a
       .vim file.  Problem: distribution.
    3. Use a cache directory for each user.  How to recognize which cached
       file belongs to a sourced script?
7   Add argument to winwidth() to subtract the space taken by 'foldcolumn',
    signs and/or 'number'.
6   Add ++ and -- operators?  They only work on variables (lvals), how to
    implement this?
8   Add functions:
        has(":command")         Check if ":command" works.  compare function
                                with "ex_ni".  E.g. for ":simalt".
        escape()                Add argument to specify what to escape with.
```

```
        modestack()             Instead of just the current mode return the
                                stack of Insert / CTRL-O / :normal things.
        realname()              Get user name (first, last, full)
                                user_fullname() patch by Nikolai Weibull, Nov
                                3 2002
                                Only add this when also implemented for
                                non-Unix systems, otherwise a shell cmd could
                                be used.
                                get_user_name() gets login name.
        menuprop({name}, {idx}, {what})
                                Get menu property of menu {name} item {idx}.
                                menuprop("", 1, "name") returns "File".
                                menuprop("File", 1, "n") returns "nmenu
                                File.Open..." argument.
                                Patch by Ilya Sher, 2004 Apr 22
                                Return a list of menus and/or a dictionary
                                with properties instead.
        mapname({idx}, mode)    return the name of the idx'th mapping.
                                Patch by Ilya Sher, 2004 Mar 4.
                                Return a list instead.
        char2hex()              convert char string to hex string.
        crypt()                 encrypt string
        decrypt()               decrypt string
        base64enc()             base 64 encoding
        base64dec()             base 64 decoding
        attributes()            return file protection flags "drwxrwxrwx"
        filecopy(from, to)      Copy a file
        shorten(fname)          shorten a file name, like home_replace()
        perl(cmd)               call Perl and return string
        inputrl()               like input() but right-to-left
        typed()                 return the characters typed and consumed (to
                                find out what happened)
        virtualmode()           add argument to obtain whether "$" was used in
                                Visual block mode.
        getacp()                Win32: get codepage (Glenn Maynard)
        libcall()               Allow more than one argument.
        libcallext()            Like libcall(), but using a callback function
                                to allow the library to execute a command or
                                evaluate an expression.
7   Make bufname("'0") return the buffer name from mark '0.  How to get the
    column and line number?  col("'0") currently returns zero.
8   argc() returns 0 when using "vim -t tag".  How to detect that no file was
    specified in any way?  To be able to jump to the last edited file.
8   Pass the command line arguments to Vim scripts in some way.  As v:args
    List?  Or extra parameter to argv()?
8   Add command arguments with three dashes, passed on to Vim scripts.
9   Add optional arguments to user functions:
        :func myFunc(arg1, arg2, arg3 = "blah", arg4 = 17)
6   User functions: Functions local to buffer "b:func()"?
8   For Strings add ":let var[{expr}] = {expr}".  When past the end of "var"
    just ignore.
8   The "= register should be writable, if followed by the name of a variable,
    option or environment variable.
8   ":let &option" should list the value of the option.
```

```
8   ":let Func().foo = value" should work, also when "foo" doesn't exist.
    Also: ":let Func()[foo] = value" should work.  Same for a List.
7   Add synIDlist(), making the whole list of syntax items on the syntax stack
    available as a List.
8   Add autocommand-event for when a variable is changed:
        :au VarChanged {varname} {commands}
8   Add "has("gui_capable")", to check if the GUI can be started.
8   Add possibility to use variables like registers: characterwise (default),
    linewise (when ending in '\n'), blockwise (when ending in '\001').  reg0,
    rega, reg%, etc.  Add functions linewise({expr}), blockwise({expr}) and
    charwise({expr}).
7   Make it possible to do any command on a string variable (make a buffer
    with one line, containing the string).  Maybe add an (invisible) scratch
    buffer for this?
        result = scratch(string, command)
        result = apply(string, command)
        result = execute(string, command)
    "command" would use <> notation.
    Does scratch buffer have a number?  Or re-use same number?
7   Add function to generate unique number (date in milliseconds).

Robustness:
6   Add file locking.  Lock a file when starting to edit it with flock() or
    fcntl().  This patch has advisory file locking while reading/writing
    the file for Vim 5.4: ~/vim/patches/kahn_file_locking .
    The patch is incomplete (needs support for more systems, autoconf).
    Andy doesn't have time to work on it.
    Disadvantage: Need to find ways to gracefully handle failure to obtain a
    lock.  When to release a lock: When buffer is unloaded?

Performance:
7   For string variables up to 3 bytes don't allocate memory, use v_list
    itself as a character array.  Use VAR_SSTRING (short string).
7   Add 'lazysize' option: Above this size Vim doesn't load everything before
    starting to edit a file.  Things like 'fileencodings' only work up to this
    size, modelines only work at the top.  Useful for large log files where
    you only want to look at the first few pages.  Use zero to disable it.
8   move_lines() copies every line into allocated memory, making reloading a
    buffer a lot slower than re-editing the file.  Can the memline be locked
    so that we don't need to make a copy?  Or avoid invoking ml_updatechunk(),
    that is taking a lot of time.  (Ralf Wildenhues, 2008 Jul 7)
    With a patch, but does it work?
8   Turn b_syn_ic and b_syn_containedin into b_syn_flags.
9   Loading menu.vim still takes quite a bit of time.  How to make it faster?
8   in_id_list() takes much time for syntax highlighting.  Cache the result?
7   setpcmark() shifts the jumplist, this takes quite a bit of time when
    jumping around.  Instead use an index for the start?
8   When displaying a space with only foreground highlighting, it's the same
    as a space without attributes.  Avoid displaying spaces for the "~" lines
    when starting up in a color terminal.
8   Avoid alloc() for scratch buffer use, esp. in syntax.c.  It's very slow on
    Win16.
```

```
8   Profiling shows that in_id_list() is used very often for C code.  Can this
    function be improved?
8   For an existing file, the page size of the swap file is always the
    default, instead of using the block size of the device, because the swap
    file is created only after setting the block size in mf_open().  How can
    this be improved?
8   Set default for 'ttyscroll' to half a screen height?  Should speed up
    MS-DOS version. (Negri)
7   C syntax highlighting gets a lot slower after ":set foldmethod=syntax".
    (Charles Campbell)  Inserting a "{" is very slow. (dman)
7   HTML syntax highlighting is slow for long lines.  Try displaying
    http://www.theregister.co.uk/content/4/22908.html. (Andre Pang)
7   Check how performance of loading the wordlist can be improved (adding a
    lot of abbreviations).
7   Compile Ex commands to byte codes.  Store byte codes in a vim script file
    at the end, after "compiled:.  Make it look like a single comment line
    for old Vim versions.  Insert first line "Vim script compiled <timestamp>.
    Only used compiled code when timestamp matches the file stat.
    Add command to compile a vim script and add it to the file in-place.
    Split Ex command executing into a parsing and executing phase.
    Use compiled code for functions, while loops, etc.
8   When defining autocommands (e.g., from $VIMRUNTIME/filetype.vim), need to
    compare each pattern with all existing patterns.  Use a hash code to avoid
    using strcmp() too often?
7   Include turbo_loader patches, speeding up reading a file?
    Speed up reading a file by reading it into a fixed-size buffer, creating
    the list of indexes in another buffer, and then copying the result into a
    memfile block with two copies.  Then read the next block into another
    fixed-size buffer, create the second list of indexes and copy text from
    the two blocks to the memfile block.
7   do_cmdline(): Avoid that the command line is copied to allocated memory
    and freed again later all the time.  For while loops, and for when called
    with an argument that can be messed with.
    Generic solution: Make a struct that contains a pointer and a flag that
    indicates if the pointer should be freed when replaced.
7   Check that the file size is not more than "sizeof(long)".
-   Further improve finding mappings in maphash[] in vgetorpeek()
8   Syntax highlighting is slow when deleting lines.  Try in
    $VIMRUNTIME/filetype.vim.
-   "out of memory" after deleting (1,$d) and changing (:%s/^/> /) a lot of
    lines (27000) a few times.  Memory fragmentation?
-   Have a look at how pdksh does memory allocation (alloc.c). (Dalecki)
-   Do profiling on:
    - :g/pat/normal cmd
    - deleting 10Mbyte worth of lines (netscape binary)
    - "[i" and "[d" (Yegappan Lakshmanan)
    - ":g/^/m0" on a 450Kbyte file.  And the "u".
    - highlighting "~/vim/test/longline.tex", "~/vim/test/scwoop.tcl" and
      "~/vim/test/lockup.pl".
    - loading a syntax file to highlight all words not from a dictionary.
    - editing a Vim script with syntax highlighting on (loading vim.vim).
7   Screen updating can be further improved by only redrawing lines that were
    changed (and lines after them, when syntax highlighting was used, and it
    changed).
```

```
    - On each change, remember start and end of the change.
    - When inserting/deleting lines, remember begin, end, and line count.
-   Use macros/duarte/capicua for profiling.  Nvi 1.71 is the fastest!
-   When using a file with one long line (1Mbyte), then do "$hhhh", is still
    very slow.  Avoid calling getvcol() for each "h"?
-   Executing a register, e.g. "10000@@" is slow, because ins_typebuf has to
    move the previous commands forward each time.  Pass count from
    normal_cmd() down to do_execreg().
-   Avoid calls to plines() for cursor line, use w_cline_height.
-   After ":set nowrap" remove superfluous redraw with wrong hor. offset if
    cursor is right of the screen.
8   Make CTRL-C on Unix generate a signal, avoid using select() to check for a
    CTRL-C (it's slow).

Code size:
8   GUI: When NO_CONSOLE is defined, more code can be excluded.
-   Put getline() and cookie in a struct, so only one argument has to be
    passed to do_cmdline() and other functions.
8   Make a GUI-only version for Unix?
8   In buf_write _() isn't needed when setting errmsg, do it once when using
    it.
7   When compiling with a GUI-only version, the code for cterm colors can be
    left out.
8   When compiled with a GUI-only version, the termcap entries for terminals
    can be removed.
8   Can the check for libelf in configure.ac be removed?

Messages:
8   When using ":q" in a changed file, the error says to "add !".  Add the
    command so that beginners understand it: "use :q!".
8   For 'verbose' level 12 prints commands from source'ed files.  How to skip
    lines that aren't executed?  Perhaps move the echoing to do_cmdline()?
8   Use 'report' for ":bdel"?  (Krishna)  To avoid these messages when using a
    script.
-   Delete message after new command has been entered and have waited for key.
    Perhaps after ten seconds?
-   Make message history available in "msg" variables: msg1, msg2, .. msg9.
8   When reading from stdin allow suppressing the "reading from stdin"
    message.
9   Check handling of overwriting of messages and delays:
    Very wrong: errors while redrawing cause endless loop.
    When switching to another file and screen scrolls because of the long
    message and return must be typed, don't scroll the screen back before
    redrawing.
8   When address range is wrong you only get "Invalid range".  Be a bit more
    specific: Negative, beyond last line, reverse range?  Include the text.
8   Make it possible to ignore errors for a moment ('errorignore'?).  Another
    option to switch off giving error messages ('errorquiet'?).  Also an option
    not to give any messages ('quiet')?  Or ":quiet on", ":quiet off".
    Careful: For a severe error (out of memory), and when the user starts
    typing, error messages must be switched back on.
    Also a flag to ignore error messages for shell commands (for mappings).
```

```
-   Option to set time for emsg() sleep.  Interrupt sleep when key is typed?
    Sleep before second message?
8   In Ex silent mode or when reading commands from a file, what exactly is
    not printed and what is?  Check ":print", ":set all", ":args", ":vers",
    etc.  At least there should be no prompt. (Smulders)  And don't clear the
    screen when reading commands from stdin. (Kendall)
    --> Make a difference between informative messages, prompts, etc. and
        error messages, printing text, etc.
8   Window should be redrawn when resizing at the hit-enter prompt.
    Also at the ":tselect" prompt.  Find a generic solution for redrawing when
    a prompt is present (with a callback function?).

Screen updating:
7   Add a string to the 'display' option to make CTRL-E and CTRL-Y scroll one
    screen line, also if this means the first line doesn't start with the
    first character (like what happens with a single line that doesn't fit).
-   screen_line():
    - insert/delete character stuff.
    - improve delete rest of line (spaces at end of line).
-   When moving or resizing window, try to avoid a complete redraw (esp. when
    dragging the status line with the mouse).
-   When 'lazyredraw' set, don't echo :ex commands?  Need a flag to redraw when
    waiting for a character.
8   Add a ":refresh [winnr]" command, to force updating a window.  Useful from
    an event handler where ":normal" can't be used.  Also useful when
    'lazyredraw' is set in a mapping.

Scrolling:
8   Add "zy" command: scroll horizontally to put the cursor in the middle.
6   Add option to set the overlap for CTRL-F and CTRL-B. (Garhi)
-   extend 'scrollbind' option: 'scrollopt' words "search", "relative", etc..
    Also 'e'xecute some commands (search, vertical movements) in all bound
    windows.
7   Add 'scrollbind' feature to make the offset of one window with the next
    one equal to the window height.  When editing one file in both windows it
    looks like each window displays a page of the buffer.
-   Allow scrolling by dragging with the mouse (grab a character and move it
    up/down).  Like the "hand" in Acrobat reader.  Use Alt-LeftMouse for this?
    (Goldfarb)
-   Add command to execute some commands (search, vertical movements) in all
    bound windows.
-   Add 'search' option to 'scrollopt' to allow 'scrollbind' windows to
    be bound by regexp searches
-   Add "z>" and "z<": scroll sideways one screenful. (Campbell)
-   Add option to set the number of lines when not to scroll, instead of the
    fixed number used now (for terminals that scroll slow with a large number
    of lines but not with a single line).

Autoconf:
8   Should use acconfig.h to define prototypes that are used by autoheader.
8   Some compilers don't give an error for "-OPT:Olimit" but a warning. (Webb)
    Add a check for the warning, so that "Olimit" can be added automatically?
```

```
-   Autoconf: Use @datadir@ for the system independent files.  Make sure the
    system dependent and system independent files are separated. (Leitner).
-   Add autoconf check for waitpid()/wait4().
-   Remove fcntl() from autoconf, all systems have it?
-   Set default for 'dictionary', add search for dictionary to autoconf.

Perl interface:
8   Rename typemap file to something else?
7   Make buffers accessed as Perl arrays. (Clark)
7   Make it possible to compile with non-ANSI C?
6   Tcl/Tk has the "load" command: load a shared library (.so or .dll).

Shared libraries:
8   libcall() can keep the library around instead of always calling dlclose().
    (Jason Felice, 2018 Mar 20)
6   Add support for loading shared libraries, and calling functions in it.
        :libload internal-name libname
        :libunload internal-name
        :liblist
        :libcall internal-name function(arg1, arg2, ...)
        :libcall function(arg1, arg2, ...)
    libcall() can have only one integer or String argument at the moment.
6   Have a look on how Perl handles loading dynamic libraries.

Tags:
9   With ":set tags=./tags,../tags" and a tag appears in both tags files it is
    added twice.  Requires figuring out the actual file name for each found
    match.  Remove tag_fname from the match and combine it with the fname in
    the match (without expanding or other things that take time).  When
    'tagrelative' is off tag_fname isn't needed at all.
8   For 'tags' wildcard in the file name is not supported, only in the path.
    This is due to it using  file-searching . Suboptimal solution would be to
    make the filename or the whole option use  wildcards  globing, better
    would be to merge the 2 kinds of globing. originally (Erik Falor, 2008
    April 18), updated (Ian Kelling, 2008 July 4)
7   Can CTRL-] (jump to tag) include a following "." and "->" to restrict the
    number of possible matches? Check tags file for an item that has members.
    (Flemming Madsen)
8   Scope arguments for ":tag", e.g.: ":tag class:cPage open", like Elvis.
8   When output of ":tselect" is long, getting the more-prompt, should be able
    to type the tag number directly.
7   Add the possibility to use the "-t {tag}" argument multiple times.  Open a
    window for each tag.
7   Make output of ":tselect" a bit nicer.  Use highlighting?
7   Highlight the "tag 1 of >2" message.  New highlight group, or same as "hit
    bottom" search message.
7   When using ":tag" at the top of the tag stack, should add another entry,
    so CTRL-T can bring you back to where you are now AND to where you were
    before the previous ":tag" command. (Webb)
-   When doing "[^I" or "[^D" add position to tag stack.
-   Add command to put current position to tag stack: ":tpush".
```

-   Add functions to save and restore the tag stack? Or a command to switch
    to another tag stack? So that you can do something else and come back to
    what you were working on.
7   When using CTRL-] on someClass::someMethod, separate class from method and
    use ":ta class:someClass someMethod".
    Include C++ tags changes (Bertin). Change "class::func" tag into "func"
    with "class=class"? Docs in oldmail/bertin/in.xxx.
7   Add ":tagargs", to set values for fields:
        :tagargs class:someclass file:version.c
        :tagargs clear
    These are then the default values (changes the order of priority in tag
    matching).
7   Support for "gtags" and "global"? With ":rtag" command?
    There is an example for how to do this in Nvi.
    Or do it like Elvis: 'tagprg' and 'tagprgonce' options. (Yamaguchi)
    The Elvis method is far more flexible, do it that way.
7   Support "col:99" extra field, to position the cursor in that column. With
    a flag in 'cpoptions' to switch it off again.
7   Better support for jumping to where a function or variable is used. Use
    the id-utils, with a connection to "gid" (Emacs can do it too). Add
    ":idselect", which uses an "ID" database (made by "mkid") like "tselect".

Win32 GUI:
8   Make debug mode work while starting up (vim -D). Open console window for
    the message and input?
7   GvimExt: when there are several existing Vims, move the list to a submenu.
    (Mike McCollister)
8   When using "Edit with Vim" for one file it changes directory, when several
    files are selected and using "Edit with single Vim" the directory isn't
    changed. At least change directory when the path is the same for all
    files. Perhaps just use the path of the first file or use the longest
    common part of the path.
8   Add font argument to set the lfCharSet. (Bobcik)
8   Somehow automatically detect the system language and set $LANG, so that
    gettext and menus work.
8   Could keep console open to run multiple commands, to avoid the need to hit
    return in every console.
    Also: Look at how Emacs does run external commands:
        http://www.cs.washington.edu/homes/voelker/ntemacs.html.
8   Need a separate PopUp menu for modeless selection. Need two new commands:
    Copy selection to clipboard, Paste selection (as typed text).
8   Support copy/paste for other file formats. At least HTML, perhaps RTF.
    Add "copy special" and "paste special" commands?
7   Use different default colors, to match the current Windows color scheme.
    Sys_WindowText, Sys_Window, etc. (Lionel Schaffhauser)
7   Use <C-Tab> to cycle through open windows (e.g., the find dialog).
7   <Esc> should close a dialog.
7   Keep the console for external commands open. Don't wait for a key to be
    hit. Re-open it when the user has closed it anyway. Or use a prepended
    command: ":nowait {cmd}", or ":quiet", which executes {cmd} without any
    prompts.
7   Should be able to set an option so that when you double click a file that
    is associated with Vim, you can either get a new instance of Vim, or have

    the file added into an already running Vim.
7   The "-P" argument only works for the current codepage. Use wide
    functions to find the window title.

GUI:
8   Make inputdialog() work for Photon, Amiga.
-   <C--> cannot be mapped. Should be possible to recognize this as a
    normal "-" with the Ctrl modifier.
7   Implement ":popup" for other systems than Windows.
8   Implement ":tearoff" for other systems than Win32 GUI.
6   Implement ":untearoff": hide a torn-off menu.
8   When using the scrollbar to scroll, don't move the cursor position. When
    moving the cursor: scroll to the cursor position.
9   Make <S-Insert> paste from the clipboard by default. (Kunze)
7   Menu local to a buffer, like mappings. Or local to a filetype?
8   In Buffers menu, add a choice whether selecting a buffer opens it in the
    current window, splits the window or uses ":hide".
8   Dragging the mouse pointer outside of a Vim Window should make the text
    scroll. Return a value from gui_send_mouse_event() to the machine
    specific code to indicate the time in which the event should be repeated.
8   Make it possible to ignore a mouse click when it's used to give Vim (gvim)
    window focus. Also when a mouse click is used to bring a window to front.
8   Make the split into system independent code and system specific code more
    explicit. There are too many #ifdefs in gui.c.
    If possible, separate the Vim code completely from the GUI code, to allow
    running them in separate processes.
7   X11: Support cursorColor resource and "-cr" argument.
8   X11 (and others): CTRL-; is not different from ';'. Set the modifier mask
    to include CTRL for keys where CTRL produces the same ASCII code.
7   Add some code to handle proportional fonts on more systems? Need to draw
    each character separately (like xterm). Also for when a double-width font
    is not exactly double-width. (Maeda)
8   Should take font from xterm where gvim was started (if no other default).
8   Selecting font names in X11 is difficult, make a script or something to
    select one.
8   Visual highlighting should keep the same font (bold, italic, etc.).
8   Add flag to 'guioptions' to not put anything in the clipboard at all?
8   Should support a way to use keys that we don't recognize yet. Add a
    command that adds entries to special_keys somehow. How do we make this
    portable (X11, Win32, ..)?
7   Add a flag to 'guioptions' that tells not to remove inactive menu items.
    For systems where greying-out or removing menu items is very slow. The
    menu items would remain visibly normally, but not do anything.
7   Add ":minimize" and ":maximize", which iconize the window and back.
    Useful when using gvim to run a script (e.g. 2html.vim).
7   X11: Is it possible to free allocated colors, so that other programs can
    use them again? Otherwise, allow disabling allocating the default colors.
    Or allocate an own colormap (check UAE). With an option to use it. For
    the commandline, "-install" is mostly used for X11 programs.
7   Should support multi-column menus.
-   Should add option for where to put the "Help" menu: like Motif at the far
    right, or with the other menus (but still at the right).
-   Add menu item to "Keep Insert mode".

8 ":mkgvimrc" command, that includes menus.
6 Big change: Move GUI to separate program "vimgui", to make startup of vim a lot faster, but still be able to do "vim -g" or ":gui".
7 More explicit mouse button binding instead of 'mousemodel'?
7 Add option to set the position of the window on the screen. 'windowpos', which has a value of "123,456": <x>,<y>.
Or add a command, like ":winsize"?
7 Add toolbar for more GUIs.
8 Make it possible to use "amenu icon=BuiltIn##", so that the toolbar item name can be chosen free.
7 Make it possible to put the toolbar on top, left, right and/or bottom of the window? Allows for softkey-like use.
6 Separate the part of Vim that does the editing from the part that runs the GUI. Communicate through a pseudo-tty. Vim starts up, creates a pty that is connected to the terminal. When the GUI starts, the pty is reconnected to the GUI process. When the GUI stops, it is connected to the terminal again. Also use the pty for external processes, it looks like a vt100 terminal to them. Vim uses extra commands to communicate GUI things.
7 Motif: For a confirm() dialog <Enter> should be ignored when no default button selected, <Esc> should close the dialog.
7 When using a pseudo-tty Vim should behave like some terminal (vt52 looks simple enough). Terminal codes to/from shell should be translated.
- Would it be useful to be able to quit the GUI and go back to the terminal where it was started from?
7 Support "-visual <type>" command line argument.

Autocommands:
9 Rework the code from FEAT_OSFILETYPE for autocmd-osfiletypes to use 'filetype'. Only for when the current buffer is known.
- Put autocommand event names in a hashtable for faster lookup?
8 When the SwapExists event is triggered, provide information about the swap file, e.g., whether the process is running, file was modified, etc. Must be possible to check the situation that it's probably OK to delete the swap file. (Marc Merlin)
8 When all the patterns for an event are "*" there is no need to expand buffer names to a full path. This can be slow for NFS.
7 For autocommand events that trigger multiple times per buffer (e.g., CursorHold), go through the list once and cache the result for a specific buffer. Invalidate the cache when adding/deleting autocommands or changing the buffer name.
7 Add TagJump event: do something after jumping to a tag.
8 Add "TagJumpFile" autocommand: When jumping to another file for a tag. Can be used to open "main.c.gz" when "main.c" isn't found.
8 Use another option than 'updatetime' for the CursorHold event. The two things are unrelated for the user (but the implementation is more difficult).
7 Add autocommand event for when a buffer cannot be abandoned. So that the user can define the action taking (autowrite, dialog, fail) based on the kind of file. (Yakov Lerner) Or is BufLeave sufficient?
8 Autocommand for when modified files have been found, when getting input focus again (e.g., FileChangedFocus).
Check when: getting focus, jumping to another buffer, ...

```
8   Autocommands should not change registers.  And marks?  And the jumplist?
    And anything else?  Add a command to save and restore these things.
8   Add autocommands, user functions and user commands to ":mkvimrc".
6   Add KeymapChanged event, so that the effects of a different keymap can be
    handled (e.g., other font) (Ron Aaron)
7   When trying to open a directory, trigger an OpenDirectory event.
7   Add file type in front of file pattern: <d> for directory, <l> for link,
    <x> for executable, etc.  With commas to separate alternatives.  The
    autocommand is only executed when both the file type AND the file pattern
    match. (Leonard)
5   Add option that specifies extensions which are to be discarded from the
    file name.  E.g. 'ausuffix', with ".gz,.orig".  Such that file.c.gz will
    trigger the "*.c" autocommands.  (Belabas)
7   Add something to break the autocommands for the current event, and for
    what follows.  Useful for a "BufWritePre" that wants to avoid writing the
    file.
8   When editing "tt.gz", which is in DOS format, 'fileformat' stays at
    "unix", thus writing the file changes it.  Somehow detect that the read
    command used dos fileformat.  Same for 'fileencoding'.
-   Add events to autocommands:
    Error           - When an error happens
    ModeChange      - after changing mode (before waiting for a char)
    VimLeaveCheck    - Before Vim decides to exit, so that it can be cancelled
                       when exiting isn't a good idea.
    CursorHoldC     - CursorHold while command-line editing
    WinMoved        - when windows have been moved around, e.g, ":wincmd J"
    SearchPost      - After doing a search command (e.g. to do "M")
    PreDirChanged/PostDirChanged
                    - Before/after ":cd" has been used (for changing the
                      window title)
    ShutDown        - when the system is about to shut down
    InsertCharPost  - user typed a character in Insert mode, after inserting
                      the char.
    BufModified     - When a buffer becomes modified, or unmodified (for
                      putting a [+] in the window title or checking out the
                      file from CVS).
    BufFirstChange  - When making a change, when 'modified' is set.  Can be
                      used to do a :preserve for remote files.
    BufChange       - after a change was made.  Set some variables to indicate
                      the position and number of inserted/deleted lines, so
                      that marks can be updated.  HierAssist has patch to add
                      BufChangePre, BufChangePost and RevertBuf. (Shah)
    ViewChanged     - triggered when the text scrolls and when the window size
                      changes.
    WinResized      - After a window has been resized
    WinClose        - Just before closing a window
-   Write the file now and then ('autosave'):
                                  'autosave'   'as'   'noautosave'   'noas'
    'autosave' 'as' number  (default 0)
            Automatically write the current buffer to file N seconds after the
            last change has been made and when  'modified'  is still set.
            Default: 0 = do not autosave the buffer.
    Alternative: have 'autosave' use 'updatetime' and 'updatecount' but make
    them save the file itself besides the swapfile.
```

```
Omni completion:
-   Add a flag to 'complete' to be able to do omni completion with CTRL-N (and
    mix it with other kinds of completion).
-   Ideas from the Vim 7 BOF at SANE:
        - For interpreted languages, use the interpreter to obtain information.
          Should work for Java (Eclipse does this), Python, Tcl, etc.
          Richard Emberson mentioned working on an interface to Java.
        - Check Readline for its completion interface.
-   Ideas from others:
        http://www.wholetomato.com/
        http://www.vim.org/scripts/script.php?script_id=747
            http://sourceforge.net/projects/insenvim
                or http://insenvim.sourceforge.net
            Java, XML, HTML, C++, JSP, SQL, C#
            MS-Windows only, lots of dependencies (e.g. Perl, Internet
                explorer), uses .dll shared libraries.
            For C++ uses $INCLUDE environment var.
            Uses Perl for C++.
            Uses ctags to find the info:
                ctags -f $allTagsFile --fields=+aiKmnsSz --language-force=C++ --C++-kinds=+
        www.vim.org script 1213 (Java Development Environment) (Fuchuan Wang)
        IComplete: http://www.vim.org/scripts/script.php?script_id=1265
            and http://stud4.tuwien.ac.at/~e0125672/icomplete/
        http://cedet.sourceforge.net/intellisense.shtml (for Emacs)
        Ivan Villanueva has something for Java.
        Emacs: http://www.xref-tech.com/xrefactory/more_c_completion.html
        Completion in .NET framework SharpDevelop: http://www.icsharpcode.net
-   Pre-expand abbreviations, show which abbrevs would match?

Insert mode completion/expansion:
-   GUI implementation of the popup menu.
7   When searching in other files the name flash by, too fast to read.  Only
    display a name every second or so, like with ":vimgrep".
7   When expanding file names with an environment variable, add the match with
    the unexpanded var.  So $HOME/tm expands to "/home/guy/tmp" and
    "$HOME/tmp"
8   When there is no word before the cursor but something like "sys." complete
    with "sys.".  Works well for C and similar languages.
9   ^X^L completion doesn't repeat correctly.  It uses the first match with
    the last added line, instead of continuing where the last match ended.
    (Webb)
8   Add option to set different behavior for Insert mode completion:
    - ignore/match case
    - different characters than 'iskeyword'
8   Add option 'isexpand', containing characters when doing expansion (so that
    "." and "\" can be included, without changing 'iskeyword'). (Goldfarb)
    Also: 'istagword': characters used for CTRL-].
    When 'isexpand' or 'istagword' are empty, use 'iskeyword'.
    Alternative: Use a pattern so that start and end of a keyword can be
    defined, only allow dash in the middle, etc.
8   Add a command to undo the completion, go back to the original text.
```

```
7   Completion of an abbreviation: Can leave letters out, like what Instant
    text does: www.textware.com
8   Use the class information in the tags file to do context-sensitive
    completion.  After "foo." complete all member functions/variables of
    "foo".  Need to search backwards for the class definition of foo.
    Should work for C++ and Java.
    Even more context would be nice: "import java.^N" -> "io", "lang", etc.
7   When expanding $HOME/dir with ^X^F keep the $HOME (with an option?).
7   Add CTRL-X command in Insert mode like CTRL-X CTRL-N, that completes WORDS
    instead of words.
8   Add CTRL-X CTRL-R: complete words from register contents.
8   Add completion of previously inserted texts (like what CTRL-A does).
    Requires remembering a number of insertions.
8   Add 'f' flag to 'complete': Expand file names.
    Also apply 'complete' to whole line completion.
-   Add a flag to 'complete' to only scan local header files, not system
    header files. (Andri Moell)
-   Make it possible to search include files in several places.  Use the
    'path' option?  Can this be done with the dictionary completion (use
    wildcards in the file name)?
-   Make CTRL-X CTRL-K do a binary search in the dictionary (if it's sorted).
-   Speed up CTRL-X CTRL-K dictionary searching (don't use a regexp?).
-   Set a mark at the position where the match was found (file mark, could
    be in another file).
-   Add CTRL-A command in CTRL-X mode: show all matches.
-   Make CTRL-X CTRL-L use the 'complete' option?
-   Add command in CTRL-X mode to add following words to the completed string
    (e.g. to complete "Pointer->element" with CTRL-X CTRL-P CTRL-W CTRL-W)
-   CTRL-X CTRL-F: Use 'path' to find completions.
-   CTRL-X CTRL-F: Option to use forward slashes on MS-Windows?
-   CTRL-X CTRL-F: Don't replace "$VIM" with the actual value. (Kelly)
-   Allow listing all matches in some way (and picking one from the list).

Command line editing:
7   Add commands (keys) to delete from the cursor to the end of the command
    line.
8   Custom completion of user commands can't use the standard completion
    functions.  Add a hook to invoke a user function that returns the type of
    completion to be done: "file", "tag", "custom", etc.
-   Add flags to 'whichwrap' for command line editing (cursor right at end of
    lines wraps to start of line).
-   Make editing the command line work like Insert mode in a single-line view
    on a buffer that contains the command line history.  But this has many
    disadvantages, only implement it when these can be solved.  Elvis has run
    into these, see remarks from Steve (~/Mail/oldmail/kirkendall/in.00012).
    - Going back in history and editing a line there would change the history.
      Would still need to keep a copy of the history elsewhere.  Like the
      cmdwin does now already.
    - Use CTRL-O to execute one Normal mode command.  How to switch to normal
      mode for more commands?  <Esc> should cancel the command line.  CTRL-T?
    - To allow "/" and "= need to recursively call getcmdline(), overwrite the
      cmdline.  But then we are editing a command-line again.  How to avoid
      that the user gets confused by the stack of command lines?
```

```
    - Use edit() for normal cmdline editing?  Would have to integrate
      getcmdline() into edit().  Need to solve conflicts between Insert mode
      and Command-line mode commands.  Make it work like Korn shell and tcsh.
      Problems:
        - Insert: completion with 'wildchar'
        - Insert: use cmdline abbreviations
        - Insert: CTRL-D deletes indent instead of listing matches
        - Normal: no CTRL-W commands
        - Normal: no ":" commands?
        - Normal: allow Visual mode only within one line.
    - where to show insert/normal mode message?  Change highlighting of
      character in first column?
    - Implementation ideas:
      - Set "curwin" and "curbuf" to the command line window and buffer.
      - curwin->w_topline is always equal to curwin->w_cursor.lnum.
      - never set 'number', no folding, etc.  No status line.
      - sync undo after entering a command line?
      - use NV_NOCL flag for commands that are not allowed in Command-line
        Mode.

Command line completion:
8   Change expand_interactively into a flag that is passed as an argument.
8   With command line completion after '%' and '#', expand current/alternate
    file name, so it can be edited.  Also with modifiers, such as "%:h".
8   When completing command names, either sort them on the long name, or list
    them with the optional part inside [].
8   Add an option to ignore case when doing interactive completion.  So that
    ":e file<Tab>" also lists "Filelist" (sorted after matching case matches).
7   Completion of ":map x ": fill in the current mapping, so that it can be
    edited. (Sven Guckes)
-   For 'wildmenu': Simplify "../bar" when possible.
-   When using <Up> in wildmenu mode for a submenu, should go back to the
    current menu, not the first one.  E.g., ":emenu File.Save<Up>".
8   When using backtick expansion, the external command may write a greeting
    message.  Add an option or commands to remove lines that match a regexp?
7   When listing matches of files, display the common path separately from the
    file names, if this makes the listing shorter. (Webb)
-   Add command line completion for ":ilist" and friends, show matching
    identifiers (Webb).
8   Add command line completion for "old value" of a command.  ":args <key>"
    would result in the current list of arguments, which you can then edit.
7   Add command line completion with CTRL-X, just like Insert mode completion.
    Useful for ":s/word/xx/".
-   Add command to go back to the text as it was before completion started.
    Also to be used for <Up> in the command line.
-   Add 'wildlongest' option: Key to use to find longest common match for
    command line completion (default CTRL-L), like 'wildchar'. (Cregut)
    Also: when there are several matches, show them line a CTRL-D.

Command line history:
-   Add "KeyWasTyped" flag: It's reset before each command and set when a
    character from the keyboard is consumed. Value is used to decide to put a
```

```
    command line in history or not. Put line in history if it didn't
    completely result from one mapping.
-   When using ":browse", also put the resulting edit command in the history,
    so that it can be repeated. (Demirel)

Insert mode:
9   When 'autoindent' is set, hitting <CR> twice, while there is text after
    the cursor, doesn't delete the autoindent in the resulting blank line.
    (Rich Wales) This is Vi compatible, but it looks like a bug.
8   When using CTRL-O in Insert mode, then executing an insert command
    "a" or "i", should we return to Insert mode after <Esc>? (Eggink)
    Perhaps it can be allowed a single time, to be able to do
    "<C-O>10axyz<Esc>".  Nesting this further is confusing.
    ":map <F2> 5aabc<Esc>" works only once from Insert mode.
8   When using CTRL-G CTRL-O do like CTRL-\ CTRL-O, but when returning with
    the cursor in the same position and the text didn't change continue the
    same change, so that "." repeats the whole insert.
7   Use CTRL-G <count> to repeat what follows.  Useful for inserting a
    character multiple times or repeating CTRL-Y.
-   Make 'revins' work in Replace mode.
7   Use 'matchpairs' for 'showmatch': When inserting a character check if it
    appears in the rhs of 'matchpairs'.
-   In Insert mode (and command line editing?): Allow undo of the last typed
    character.  This is useful for CTRL-U, CTRL-W, delete and backspace, and
    also for characters that wrap to the next line.
    Also: be able to undo CTRL-R (insert register).
    Possibly use 'backspace'="whole" for a mode where at least a <CR> that
    inserts autoindent is undone by a single <BS>.
-   Use CTRL-G in Insert mode for an extra range of commands, like "g" in
    Normal mode.
-   Make 'paste' work without resetting other options, but override their
    value.  Avoids problems when changing files and modelines or autocommands
    are used.
-   When typing CTRL-V and a digit higher than 2, only expect two digits.
-   Insert binary numbers with CTRL-V b.
-   Make it possible to undo <BS>, <C-W> and <C-U>.  Bash uses CTRL-Y.

'cindent', 'smartindent':
9   Wrapping a variable initialization should have extra indent:
        char * veryLongName =
                "very long string"
    Also check if "cino=+10" is used correctly.
8   Lisp indenting: "\\" confuses the indenter. (Dorai Sitaram, 2006 May 17)
8   Why are continuation lines outside of a {} block not indented?  E.g.:
        long_type foo =
        value;
8   Java: Inside an anonymous class, after an "else" or "try" the indent is
    too small. (Vincent Bergbauer)
    Problem of using {} inside (), 'cindent' doesn't work then.
8   In C++ it's possible to have {} inside (): (Kirshna)
                func(
                        new String[] {
```

```
                        "asdf",
                        "asdf"
                    }
                );
```

8 In C++ a function isn't recognized inside a namespace:
(Chow Loong Jin)

```
    namespace {
        int
             func(int arg) {
             }
    }
```

6 Add 'cino' flag for this function argument layout: (Spencer Collyer)

```
        func( arg1
            , arg2
            , arg3
            );
```

7 Add separate "(0" option into inside/outside a function (Zellner):

```
    func(
       int x)       // indent like "(4"
    {
       if (a
           && b)    // indent like "(0"
```

9 Using "{" in a comment: (Helmut Stiegler)

```
if (a)
{
        if (b)
        {
                // {
        }
        } <-- this is indented incorrect
```

Problem is that find_start_brace() checks for the matching brace to be in a comment, but not braces in between. Requires adding a comment check to findmatchlimit().

- Make smartindenting configurable. Add 'sioptions', e.g. '#' setting the indent to 0 should be switched on/off.

7 Support ANSI style function header, with each argument on its own line.

- "[p" and "]p" should use 'cindent' code if it's on (only for the first line).
- Add option to 'cindent' to set indent for comments outside of {}?
- Make a command to line up a comment after a code line with a previous comment after a code line. Can 'cindent' do this automatically?
- When 'cindent'ing a '}', showmatch is done before fixing the indent. It looks better when the indent is fixed before the showmatch. (Webb)
- Add option to make indenting work in comments too (for commented-out code), unless the line starts with "*".
- Don't use 'cindent' when doing formatting with "gq"?
- When formatting a comment after some text, insert the '*' for the new line (indent is correct if 'cindent' is set, but '*' doesn't get inserted).

8 When 'comments' has both "s1:/*,mb:*,ex:*/" and "s1:(*,mb:*,ex:*)", the 'x' flag always uses the first match. Need to continue looking for more matches of "*" and remember all characters that could end the comment.

- For smartindent: When typing 'else' line it up with matching 'if'.
- 'smartindent': allow patterns in 'cinwords', for e.g. TeX files, where lines start with "\item".

```
-   Support this style of comments (with an option): (Brown)
        /* here is a comment that
        is just autoindented, and
        nothing else */
-   Add words to 'cinwords' to reduce the indent, e.g., "end" or "fi".
7   Use Tabs for the indent of starting lines, pad with spaces for
    continuation lines.  Allows changing 'tabstop' without messing up the
    indents.
    Patch by Lech Lorens, 2010 Mar.  Update by James McCoy, 2014 Mar 15.

Java:
8   Can have {} constructs inside parens.  Include changes from Steve
    Odendahl?
8   Recognize "import java.util.Vector" and use $CLASSPATH to find files for
    "[i" commands and friends.
-   For files found with 'include': handle "*" in included name, for Java.
    (Jason)
-   How to make a "package java.util" cause all classes in the package to be
    searched?  Also for "import java.util.*". (Mark Brophy)

'comments':
8   When formatting C comments that are after code, the "*" isn't repeated
    like it's done when there is no code.  And there is no automatic wrapping.
    Recognize comments that come after code.  Should insert the comment leader
    when it's "#" or "//".
    Other way around: when a C command starts with "* 4" the "*" is repeated
    while it should not.  Use syntax HL comment recognition?
7   When using "comments=fg:--", Vim inserts three spaces for a new line.
    When hitting a TAB, these spaces could be removed.
7   The 'n'esting flag doesn't do the indenting of the last (rightmost) item.
6   Make strings in 'comments' option a RE, to be able to match more
    complicated things. (Phillipps)  Use a special flag to indicate that a
    regexp is used.
8   Make the 'comments' option with "/* * */" lines only repeat the "*" line
    when there is a "/*" before it?  Or include this in 'cindent'?

Virtual edit:
8   Make the horizontal scrollbar work to move the text further left.
7   Allow specifying it separately for Tabs and beyond end-of-line?

Text objects:
8   Add text object for fold, so that it can be yanked when it's open.
8   Add test script for text object commands "aw", "iW", etc.
8   Add text object for part of a CamelHumpedWord and under_scored_word.
    (Scott Graham)  "ac" and "au"?
8   Add a text object for any kind of quoting, also with multi-byte
    characters.  Option to specify what quotes are recognized (default: all)
    use "aq" and "iq".  Use 'quotepairs' to define pairs of quotes, like
    'matchpairs'?
8   Add text object for any kind of parens, also multi-byte ones.
```

8   Add a way to make an ":omap" for a user-defined text object. Requires
    changing the starting position in oap->start.
8   Add "gp" and "gP" commands: insert text and make sure there is a single
    space before it, unless at the start of the line, and after it, unless at
    the end of the line or before a ".".
7   Add objects with backwards extension? Use "I" and "A". Thus "2dAs"
    deletes the current and previous sentence. (Jens Paulus)
7   Add "g{" and "g}" to move to the first/last character of a paragraph
    (instead of the line just before/after a paragraph as with "{" and "}").
6   Ignore comment leaders for objects. Make "das" work in reply-email.
5   Make it possible to use syntax group matches as a text object. For
    example, define a "ccItem" group, then do "da<ccItem>" to delete one.
    Or, maybe just define "dai", delete-an-item, to delete the syntax item the
    cursor is on.

Select mode:
8   In blockwise mode, typed characters are inserted in front of the block,
    backspace deletes a column before the block. (Steve Hall)
7   Alt-leftmouse starts block mode selection in MS Word.
    See http://vim.wikia.com/wiki/Use_Alt-Mouse_to_select_blockwise.
7   Add Cmdline-select mode. Like Select mode, but used on the command line.
    - Change gui_send_mouse_event() to pass on mouse events when 'mouse'
      contains 'C' or 'A'.
    - Catch mouse events in ex_getln.c. Also shift-cursor, etc., like in
      normal_cmd().
    - remember start and end of selection in cmdline_info.
    - Typing text replaces the selection.

Visual mode:
8   Support using "." in Visual mode. Use the operator applied to the Visual
    selection, if possible.
-   When dragging the Visual selection with the mouse and 'scrolloff' is zero,
    behave like 'scrolloff' is one, so that the text scrolls when the pointer
    is in the top line.
-   Displaying size of Visual area: use 24-33 column display.
    When selecting multiple lines, up to about a screenful, also count the
    characters.
8   When using "I" or "A" in Visual block mode, short lines do not get the new
    text. Make it possible to add the text to short lines too, with padding
    where needed.
7   With a Visual block selected, "2x" deletes a block of double the width,
    "3y" yanks a block of triple width, etc.
7   When selecting linewise, using "itext" should insert "text" at the start
    of each selected line.
8   What is "R" supposed to do in Visual mode?
8   Make Visual mode local to the buffer. Allow changing to another buffer.
    When starting a new Visual selection, remove the Visual selection in any
    other buffer. (Ron Aaron)
8   Support dragging the Visual area to drop it somewhere else. (Ron Aaron,
    Ben Godfrey)
7   Support dragging the Visual area to drop it in another program, and
    receive dropped text from another program. (Ben Godfrey)

7   With blockwise Visual mode and "c", "C", "I", "A", etc., allow the use of
    a <CR>. The entered lines are repeated over the Visual area.
7   Filtering a block should only apply to the block, not to the whole lines.
    When the number of lines is increased, add lines. When decreased, pad with
    spaces or delete? Use ":`<,`>" on the command line.
8   After filtering the Visual area, make "gv" select the filtered text?
    Currently "gv" only selects a single line, not useful.
7   Don't move the cursor when scrolling? Needed when the selection should
    stay the same. Scroll to the cursor at any movement command. With an
    option!
7   In Visual block mode, need to be able to define a corner on a position
    that doesn't have text? Also: when using the mouse, be able to select
    part of a TAB. Even more: Add a mode where the cursor can be on a screen
    position where there is no text. When typing, add spaces to fill the gap.
    Other solution: Always use curswant, so that you can move the cursor to
    the right column, and then use up/down movements to select the line,
    without changing the column.
6   ":left" and ":right" should work in Visual block mode.
7   CTRL-I and CTRL-O should work in Visual mode, but only jump to marks in the
    current buffer.
6   In non-Block mode, "I" should insert the same text in front of each line,
    before the first non-blank, "gI" in column 1.
6   In non-Block mode, "A" should append the same text after each line.
6   When in blockwise visual selection (CTRL-V), allow cursor to be placed
    right of the line. Could also allow cursor to be placed anywhere on a TAB
    or other special character.
6   Add commands to move selected text, without deselecting.

More advanced repeating commands:
-   Add "." command for visual mode: redo last visual command (e.g. ":fmt").
-   Add command to repeat last movement. Including count.
-   Add "." command after operator: repeat last command of same operator. E.g.
    "c." will repeat last change, also when "x" used since then (Webb).
    "y." will repeat last yank.
    "c2." will repeat the last but one change?
    Also: keep history of Normal mode commands, add command to list the history
    and/or pick an older command.
-   History stack for . command? Use "g." command.

Mappings and Abbreviations:
8   When "0" is mapped (it is a movement command) this mapping should not be
    used after typing another number, e.g. "20l". (Charles Campbell)
    Is this possible without disabling the mapping of the following command?
8   Should mapping <C-A> and <C-S-A> both work?
7   ":abbr b byte", append "b " to an existing word still expands to "byte".
    This is Vi compatible, but can we avoid it anyway?
8   To make a mapping work with a prepended "x to select a register, store the
    last _typed_ register name and access it with "&.
8   Add ":amap", like ":amenu".
7   Add a mapping that works always, for remapping the keyboard.
8   Add ":cab!", abbreviations that only apply to Command-line mode and not to
    entering search strings.

8   Add a flag to ":abbrev" to eat the character that triggers the
    abbreviation. Thus "abb ab xxx" and typing "ab<Space>" inserts "xxx" and
    not the <Space>.
8   Give a warning when using CTRL-C in the lhs of a mapping. It will never
    (?) work.
7   Add <0x8f> (hex), <033> (octal) and <123> (decimal) to <> notation?
7   When someone tries to unmap with a trailing space, and it fails, try
    unmapping without the trailing space. Helps for ":unmap xx | unmap yy".
6   Context-sensitive abbreviations: Specify syntax group(s) in which the
    abbreviations are to be used.
-   Add mappings that take arguments. Could work like the ":s" command. For
    example, for a mouse escape sequence:
        :mapexp <Esc>{\([0-9]*\),\([0-9]*\);   H\1j\2l
-   Add optional <Number> argument for mappings:
    :map <Number>q   ^W^W<Number>G
    :map <Number>q<Number>t ^W^W<Number1-1>G<Number2>l
    :map q<Char>   :s/<Char>/\u\0/g
    Or implicit:
    :map q   <Register>d<Number>$
-   Add command to repeat a whole mapping ("." only repeats the last change in
    a mapping). Also: Repeat a whole insert command, including any mappings
    that it included. Sort-of automatic recording?
-   Include an option (or flag to 'cpoptions') that makes errors in mappings
    not flush the rest of the mapping (like nvi does).
-   Use context sensitiveness of completion to switch abbreviations and
    mappings off for :unab and :unmap.
6   When using mappings in Insert mode, insert characters for incomplete
    mappings first, then remove them again when a mapping matches. Avoids
    that characters that are the start of some mapping are not shown until you
    hit another character.
-   Add mappings for replace mode: ":rmap". How do we then enter mappings for
    non-replace Insert mode?
-   Add separate mappings for Visual-character/block/line mode?
-   Add 'mapstop' command, to stop recursive mappings.
-   List mappings that have a raw escape sequence both with the name of the key
    for that escape sequence (if there is one) and the sequence itself.
-   List mappings: Once with special keys listed as <>, once with meta chars as
    <M-a>, once with the byte values (octal?). Sort of "spell mapping" command?
-   When entering mappings: Add the possibility to enter meta keys like they
    are displayed, within <>: <M-a>, <~@> or <|a>.
-   Allow multiple arguments to :unmap.
-   Command to show keys that are not used and available for mapping
    ":freekeys".
-   Allow any character except white space in abbreviations lhs (Riehm).

Incsearch:
-   Add a limit to the number of lines that are searched for 'incsearch'?
-   When no match is found and the user types more, the screen is redrawn
    anyway. Could skip that. Esp. if the line wraps and the text is scrolled
    up every time.
-   Temporarily open folds to show where the search ends up. Restore the
    folds when going to another line.
-   When incsearch used and hitting return, no need to search again in many

```
    cases, saves a lot of time in big files. (Slootman wants to work on this?)
    When not using special characters, can continue search from the last match
    (or not at all, when there was no match).  See oldmail/webb/in.872.

Searching:
9   Should have an option for :vimgrep to find lines without a match.
8   Add "g/" and "gb" to search for a pattern in the Visually selected text?
    "g?" is already used for rot13.
    The vis.vim script has a ":S" command that does something like this.
    Can use "g/" in Normal mode, uses the '< to '> area.
    Use "&/" for searching the text in the Visual area?
9   Add "v" offset: "/pat/v": search for pattern and start Visual mode on the
    matching text.
8   Add a modifier to interpret a space like "\_s\+" to make it much easier to
    search for a phrase.
8   Add a mechanism for recursiveness: "\@(([^()]*\@g[^()]*)\)".  \@g stands
    for "go recursive here" and \@( \) marks the recursive part.
    Perl does it this way:
            $paren = qr/ \(( [^()] | (??{ $paren }) )* \) /x;
    Here $paren is evaluated when it's encountered.  This is like a regexp
    inside a regexp.  In the above terms it would be:
            \@((\([^()]\|\@g\)*)\)
8   Show the progress every second.  Could use the code that checks for CTRL-C
    to find out how much time has passed.  Or use SIGALRM.  Where to show the
    number?
7   Support for approximate-regexps to find similar words (agrep
    http://www.tgries.de/agrep/ tre: http://laurikari.net/tre/index.html).
8   Add an item for a big character range, so that one can search for a
    chinese character: \z[234-1234]  or \z[XX-YY] or \z[0x23-0x234].
7   Add an item stack to allow matching ().  One side is "push X on
    the stack if previous atom matched".  Other side is "match with top of
    stack, pop it when it matches".  Use "\@pX" and "\@m"?
        Example: \((\@p).\{-}\@m\)*
7   Add a flag to "/pat/" to discard an error.  Useful to continue a mapping
    when a search fails.  Could be "/pat/E" (e is already used for end offset).
7   Add pattern item to use properties of Unicode characters.  In Perl it's
    "\p{L}" for a letter.  See Regular Expression Pocket Reference.
8   Would it be possible to allow ":23,45/pat/flags" to search for "pat" in
    lines 23 to 45?  Or does this conflict with Ex range syntax?
8   Allow identical pairs in 'matchpairs'.  Restrict the search to the current
    line.
7   Allow longer pairs in 'matchpairs'.  Use matchit.vim as an
    example.
8   Make it possible to define the character that "%" checks for in
    #if/#endif.  For nmake it's !if/!endif.
-   For "%" command: set hierarchy for which things include other things that
    should be ignored (like "*/" or "#endif" inside /* */).
    Also: use "%" to jump from start to end of syntax region and back.
    Alternative: use matchit.vim
8   A pattern like "\([^a]\+\)\+" takes an awful long time.  Recognize that
    the recursive "\+" is meaningless and optimize for it.
    This one is also very slow on "/* some comment */": "^\/\*\(.*[^/]\)*$".
7   Recognize "[a-z]", "[0-9]", etc. and replace them with the faster "\l" and
```

"\d".
7 Add a way to specify characters in <C-M> or <Key> form. Could be \%<C-M>.
8 Add an argument after ":s/pat/str/" for a range of matches. For example, ":s/pat/str/#3-4" to replace only the third and fourth "pat" in a line.
8 When 'iskeyword' is changed the matches from 'hlsearch' may change. (Benji Fisher) redraw if some options are set while 'hlsearch' is set?
8 Add an option not to use 'hlsearch' highlighting for ":s" and ":g" commands. (Kahn) It would work like ":noh" is used after that command. Also: An extra flag to do this once, and a flag to keep the existing search pattern.
- Make 'hlsearch' a local/global option, so that it can be disabled in some of the windows.
- Add \%h{group-name}; to search for a specific highlight group.
Add \%s{syntax-group}; to search for a specific syntax group.
- Support Perl regexp. Use PCRE (Perl Compatible RE) package. (Shade)
Or translate the pattern to a Vim one.
Don't switch on with an option for typed commands/mappings/functions, it's too confusing. Use "\@@" in the pattern, to avoid incompatibilities.
8 Add a way to access the last substitute text, what is used for ":s//~/".
Can't use the ~ register, it's already used for drag & drop.
- Remember flags for backreferenced items, so that "*" can be used after it. Check with "\(\S\)\1\{3}". (Hemmerling)
8 Flags that apply to the whole pattern.
This works for all places where a regexp is used.
Add "\q" to not store this pattern as the last search pattern?
- Add flags to search command (also for ":s"?):
i ignore case
I use case
p use Perl regexp syntax (or POSIX?)
v use Vi regexp syntax
f forget pattern, don't keep it for "n" command
F remember pattern, keep it for "n" command
Perl uses these too:
e evaluate the right side as an expression (Perl only)
m multiple line expression (we don't need it)
o compile only once (Perl only)
s single line expression (we don't need it)
x extended regexp (we don't need it)
When used after ":g" command, backslash needed to avoid confusion with the following command.
Add 'searchflags' for default flags (replaces 'gdefault').
- Add command to display the last used substitute pattern and last used pattern. (Margo) Maybe make it accessible through a register (like "/ for search string)?
7 Use T-search algorithm, to speed up searching for strings without special characters. See C't article, August 1997.
- Add 'fuzzycase' option, so that case doesn't matter, and '-' and '_' are equivalent (for Unix filenames).
- Add 'v' flag to search command: enter Visual mode, with the matching text as Visual area. (variation on idea from Bertin)
- Searching: "/this//that/" should find "that" after "this".
- Add global search commands: Instead of wrapping at the end of the buffer, they continue in another buffer. Use flag after search pattern:

```
    a   for the next file in the argument list
    f   for file in the buffer list
    w   for file edited in a window.
    e.g. "/pat/f".  Then "n" and "N" work through files too.  "f" flag also for
    ":s/pat/foo/f"???  Then when 'autowrite' and 'hidden' are both not set, ask
    before saving files: "Save modified buffer "/path/file"? (Yes/Hide/No
    Save-all/hide-All/Quit) ".
-   ":s/pat/foo/3": find 3rd match of "pat", like sed. (Thomas Koehler)
7   When searching with 'n' give message when getting back where the search
    first started.  Remember start of search in '/ mark.
7   Add option that scrolls screen to put cursor in middle of screen after
    search always/when off-screen/never.  And after a ":tag" command.  Maybe
    specify how many lines below the screen causes a redraw with the cursor in
    the middle (default would be half a screen, zero means always).
6   Support multiple search buffers, so macros can be made without side
    effects.
7   From xvim: Allow a newline in search patterns (also for :s, can delete
    newline).  Add BOW, EOW, NEWL, NLORANY, NLBUTANY, magic 'n' and 'r', etc.
    [not in xvim:] Add option to switch on matches crossing ONE line boundary.
7   Add ":iselect", a combination of ":ilist" and ":tselect". (Aaron) (Zellner)
    Also ":dselect".

Undo:
9   ":gundo" command: global undo.  Undoes changes spread over multiple files
    in the order they were made.  Also ":gredo".  Both with a count.  Useful
    when tests fail after making changes and you forgot in which files.
9   After undo/redo, in the message show whether the buffer is modified or
    not.
8   Search for pattern in undo tree, showing when it happened and the text
    state, so that you can jump to it.
8   Undo tree: visually show the tree somehow (Damian Conway)
    Show only the leaves, indicating how many changed from the branch and the
    timestamp?
    Put branch with most recent change on the left, older changes get more
    indent?
-   Make it possible to undo all the commands from a mapping, including a
    trailing unfinished command, e.g. for ":map K iX^[r".
-   When accidentally hitting "R" instead of Ctrl-R, further Ctrl-R is not
    possible, even when typing <Esc> immediately. (Grahn)  Also for "i", "a",
    etc.  Postpone saving for undo until something is really inserted?
8   When Inserting a lot of text, it can only be undone as a whole.  Make undo
    sync points at every line or word.  Could recognize the start of a new
    word (white space and then non-white space) and backspacing.
    Can already use CTRL-G u, but that requires remapping a lot of things.
8   Make undo more memory-efficient: Compare text before and after change,
    only remember the lines that really changed.
7   Add undo for a range of lines.  Can change these back to a previous
    version without changing the rest of the file.  Stop doing this when a
    change includes only some of these lines and changes the line count.  Need
    to store these undo actions as a separate change that can be undone.
-   For u_save() include the column number. This can be used to set '[ and '].
    And in the future the undo can be made more efficient (Webb).
-   In out-of-memory situations: Free allocated space in undo, and reduce the
```

    number of undo levels (with confirmation).
-   Instead of [+], give the number of changes since the last write: [+123].
    When undoing to before the last write, change this to a negative number:
    [-99].
-   With undo with simple line delete/insert: optimize screen updating.
-   When executing macro's: Save each line for undo only once.
-   When doing a global substitute, causing almost all lines to be changed,
    undo info becomes very big. Put undo info in swap file??

Buffer list:
7   Command to execute a command in another buffer: ":inbuf {bufname} {cmd}".
    Also for other windows: ":inwin {winnr} {cmd}". How to make sure that
    this works properly for all commands, and still be able to return to the
    current buffer/window? E.g.: ":inbuf xxx only".
8   Add File.{recent_files} menu entries: Recently edited files.
    Ron Aaron has a plugin for this: mru.vim.
8   Unix: Check all uses of fnamecmp() and fnamencmp() if they should check
    inode too.
7   Add another number for a buffer, which is visible for the user. When
    creating a new buffer, use the lowest number not in use (or the highest
    number in use plus one?).
7   Offer some buffer selection from the command line? Like using ":ls" and
    asking for a buffer number. (Zachmann)
-   When starting to edit a file that is already in the buffer list, use the
    file name argument for the new short file name. (Webb)
-   Add an option to make ":bnext" and ":bprev" wrap around the end of the
    buffer list. Also for ":next" and ":prev"?
7   Add argument to ":ls" which is a pattern for buffers to list.
    E.g. ":ls *.c". (Thompson)
7   Add expansion of buffer names, so that "*.c" is expanded to all buffer
    names. Needed for ":bdel *.c", ":bunload *.c", etc.
8   Support for <afile> where a buffer name is expected.
7   Add an option to mostly use slashes in file names. Separately for
    internal use and for when executing an external program?
8   Some file systems are case-sensitive, some are not. Besides
    'wildignorecase' there might be more parts inside
    CASE_INSENSITIVE_FILENAME that are useful on Unix.

Swap (.swp) files:
8   If writing to the swap file fails, should try to open one in another
    directory from 'dir'. Useful in case the file system is full and when
    there are short file name problems.
8   Also use the code to try using a short file name for the backup and swap
    file for the Win32 and Dos 32 bit versions.
8   When a file is edited by root, add $LOGNAME to know who did su.
8   When the edited file is a symlink, try to put the swap file in the same
    dir as the actual file. Adjust FullName(). Avoids editing the same file
    twice (e.g. when using quickfix). Also try to make the name of the backup
    file the same as the actual file?
    Use the code for resolve()?
7   When using 64 bit inode numbers, also store the top 32 bits. Add another
    field for this, using part of bo_fname[], to keep it compatible.

7 When editing a file on removable media, should put swap file somewhere
  else. Use something like 'r' flag in 'viminfo'. 'diravoid'?
  Also: Be able to specify minimum disk space, skip directory when not
  enough room.
7 Add a configure check for which directory should be used: /tmp, /var/tmp
  or /var/preserve.
- Add an option to create a swap file only when making the first change to
  the buffer. (Liang) Or only when the buffer is not read-only.
- Add option to set "umask" for backup files and swap files (Antwerpen).
  'backupumask' and 'swapumask'? Or 'umaskbackup' and 'umaskswap'?
- When editing a readonly file, don't use a swap file but read parts from the
  original file. Also do this when the file is huge (>'maxmem'). We do
  need to load the file once to count the number of lines? Perhaps keep a
  cached list of which line is where.

Viminfo:
7 Can probably remove the code that checks for a writable viminfo file,
  because we now do the chown() for root, and others can't overwrite someone
  else's viminfo file.
8 When there is no .viminfo file and someone does "su", runs Vim, a
  root-owned .viminfo file is created. Is there a good way to avoid this?
  Perhaps check the owner of the directory. Only when root?
8 Add argument to keep the list of buffers when Vim is started with a file
  name. (Schild)
8 Keep the last used directory of the file browser (File/Open menu).
8 Remember the last used register for "@@".
8 Remember the redo buffer, so that "." works after restarting.
8 Remember a list of last accessed files. To be used in the
  "File.Open Recent" menu. Default is to remember 10 files or so.
  Also remember which files have been read and written. How to display
  this?
7 Also store the ". register (last inserted text).
7 Make it possible to store buffer names in viminfo file relative to some
  directory, to make them portable over a network. (Aaron)
6 Store a snapshot of the currently opened windows. So that when quitting
  Vim, and then starting again (without a file name argument), you see the
  same files in the windows. Use ":mksession" code?
- Make marks present in .viminfo usable as file marks: Display a list of
  "last visited files" and select one to jump to.

Modelines:
8 Before trying to execute a modeline, check that it looks like one (valid
  option names). If it's very wrong, silently ignore it.
  Ignore a line that starts with "Subject: ".
- Add an option to whitelist options that are allowed in a modeline. This
  would allow careful users to use modelines, e.g., only allowing
  'shiftwidth'.
- Add an option to let modelines only set local options, not global ones
  such as 'encoding'.
- When an option value is coming from a modeline, do not carry it over to
  another edited file? Would need to remember the value from before the
  modeline setting.

```
-   Allow setting a variable from a modeline?  Only allow using fixed strings,
    no function calls, to avoid a security problem.
-   Allow ":doauto BufRead x.cpp" in modelines, to execute autocommands for
    .cpp files.
-   Support the "abbreviate" command in modelines (Kearns).  Careful for
    characters after <Esc>, that is a security leak.
-   Add option setting to ask user if he wants to have the modelines executed
    or not.  Same for .exrc in local dir.

Sessions:
8   DOS/Windows: ":mksession" generates a "cd" command where "aa\#bb" means
    directory "#bb" in "aa", but it's used as "aa#bb". (Ronald Hoellwarth)
7   When there is a "help.txt" window in a session file, restoring that
    session will not get the "LOCAL ADDITIONS" back.
8   With ":mksession" always store the 'sessionoptions' option, even when
    "options" isn't in it. (St-Amant)
8   When using ":mksession", also store a command to reset all options to
    their default value, before setting the options that are not at their
    default value.
7   With ":mksession" also store the tag stack and jump history. (Michal
    Malecki)
7   Persistent variables: "p:var"; stored in viminfo file and sessions files.

Options:
7   ":with option=value | command": temporarily set an option value and
    restore it after the command has executed.
8   Make "old" number options that really give a number of effects into string
    options that are a comma separated list.  The old number values should
    also be supported.
8   Add commands to save and restore an option, which also preserves the flag
    that marks if the option was set.  Useful to keep the effect of setting
    'compatible' after ":syntax on" has been used.
7   There is 'titleold', why is there no 'iconold'? (Chazelas)
7   Make 'scrolloff' a global-local option, so that it can be different in the
    quickfix window, for example. (Gary Holloway)
    Also do 'sidescrolloff'.

External commands:
8   When filtering text, redirect stderr so that it can't mess up the screen
    and Vim doesn't need to redraw it.  Also for ":r !cmd".
4   Set separate shell for ":sh", piping "range!filter", reading text "r !ls"
    and writing text "w !wc". (Deutsche)  Allow arguments for fast start (e.g.
    -f).
4   Allow direct execution, without using a shell.
4   Run an external command in the background.  But how about I/O in the GUI?
    Careful: don't turn Vim into a shell!
4   Add feature to disable using a shell or external commands.

Multiple Windows:
7   "vim -oO file ..." use both horizontal and vertical splits.
```

8 Add CTRL-W T: go to the top window in the column of the current window.
   And CTRL-W B: go to bottom window.
7 Use CTRL-W <Tab>, like alt-tab, to switch between buffers. Repeat <Tab>
   to select another buffer (only loaded ones?), <BS> to go back, <Enter> to
   select buffer, <Esc> to go back to original buffer.
7 Make it possible to edit a new buffer in the preview window. A script can
   then fill it with something. ":popen"?
7 Add a 'tool' window: behaves like a preview window but there can be
   several. Don't count it in only_one_window(). (Alexei Alexandrov)
6 Add an option to resize the shell when splitting and/or closing a window.
   ":vsp" would make the shell wider by as many columns as needed for the new
   window. Specify a maximum size (or use the screen size). ":close" would
   shrink the shell by as many columns as come available. (Demirel)
7 When starting Vim several times, instantiate a Vim server, that allows
   communication between the different Vims. Feels like one Vim running with
   multiple top-level windows. Esp. useful when Vim is started from an IDE
   too. Requires some form of inter process communication.
- Support a connection to an external viewer. Could call the viewer
   automatically after some seconds of non-activity, or with a command.
   Allow some way of reporting scrolling and cursor positioning in the viewer
   to Vim, so that the link between the viewed and edited text can be made.

Marks:
8 Add ten marks for last changed files: ':0, ':1, etc. One mark per file.
8 When cursor is first moved because of scrolling, set a mark at this
   position. (Rimon Barr) Use '-.
8 Add a command to jump to a mark and make the motion inclusive. g'm and g`m?
8 The '" mark is set to the first line, even when doing ":next" a few times.
   Only set the '" mark when the cursor was really moved in a file.
8 Make `` and '', which would position the new cursor position in the middle
   of the window, restore the old topline (or relative position) from when
   the mark was set.
7 Make a list of file marks in a separate window. For listing all buffers,
   matching tags, errors, etc. Normal commands to move around. Add commands
   to jump to the mark (in current window or new window). Start it with
   ":browse marks"?
6 Add a menu that lists the Marks like ":marks". (Amerige)
7 For ":jumps", ":tags" and ":marks", for not loaded buffers, remember the
   text at the mark. Highlight the column with the mark.
7 Highlight each mark in some way (With "Mark" highlight group).
   Or display marks in a separate column, like 'number' does.
7 Use d"m to delete rectangular area from cursor to mark m (like Vile's \m
   command).
7 Try to keep marks in the same position when:
   - replacing with a line break, like in ":s/pat/^M/", move marks after the
     line break column to the next line. (Acevedo)
   - inserting/deleting characters in a line.
5 Include marks for start/end of the current word and section. Useful in
   mappings.
6 Add "unnamed mark" feature: Like marks for the ":g" command, but place and
   unplace them with commands before doing something with the lines.
   Highlight the marked lines somehow.

Digraphs:
7 Make "ga" show the keymap for a character, if it exists.
  Also show the code of the character after conversion to 'fileencoding'.
- Use digraph table to tell Vim about the collating sequence of special
  characters?
8 Add command to remove one or more (all) digraphs. (Brown)
7 Support different sets of digraphs (depending on the character set?). At
  least Latin1/Unicode, Latin-2, MS-DOS (esp. for Win32).

Writing files:
- In vim_rename(), should lock "from" file when deleting "to" file for
  systems other than Amiga. Avoids problems with unexpected longname to
  shortname conversion.
8 write mch_isdevice() for Amiga, Mac, VMS, etc.
8 When appending to a file, Vim should also make a backup and a 'patchmode'
  file.
8 'backupskip' doesn't write a backup file at all, a bit dangerous for some
  applications. Add 'backupelsewhere' to write a backup file in another
  directory? Or add a flag to 'backupdir'?
6 Add an option to write a new, numbered, backup file each time. Like
  'patchmode', e.g., 'backupmode'.
6 Make it possible to write 'patchmode' files to a different directory.
  E.g., ":set patchmode=~/backups/*.orig". (Thomas)
6 Add an option to prepend something to the backup file name. E.g., "#".
  Or maybe allow a function to modify the backup file name?
8 Only make a backup when overwriting a file for the first time. Avoids
  losing the original when writing twice. (Slootman)
7 On non-Unix machines, also overwrite the original file in some situations
  (file system full, it's a link on an NFS partition).
7 When editing a file, check that it has been change outside of Vim more
  often, not only when writing over it. E.g., at the time the swap file is
  flushed. Or every ten seconds or so (use the time of day, check it before
  waiting for a character to be typed).
8 When a file was changed since editing started, show this in the status
  line of the window, like "[time]".
  Make it easier to reload all outdated files that don't have changes.
  Automatic and/or with a command.

Substitute:
8 Substitute with hex/unicode number "\%xff" and "\%uabcd". Just like
  "\%uabcd" in search pattern.
8 Make it easier to replace in all files in the argument list. E.g.:
  ":argsub/oldword/newword/". Works like ":argdo %s/oldword/newword/g|w".
- :s///p prints the line after a substitution.
- With :s///c replace \&, ~, etc. when showing the replacement pattern.
8 With :s///c allow scrolling horizontally when 'nowrap' is effective.
  Also allow a count before the scrolling keys.
- Add number option to ":s//2": replace second occurrence of string? Or:
  :s///N substitutes N times.
- Add answers to ":substitute" with 'c' flag, used in a ":global", e.g.:
  ":g/pat1/s/pat2/pat3/cg": 'A' do all remaining replacements, 'Q' don't do

    any replacements, 'u' undo last substitution.
7   Substitute in a block of text. Use {line}.{column} notation in an Ex
    range, e.g.: ":1.3,$.5s" means to substitute from line 1 column 3 to the
    last line column 5.
5   Add commands to bookmark lines, display bookmarks, remove bookmarks,
    operate on lines with bookmarks, etc. Like ":global" but with the
    possibility to keep the bookmarks and use them with several commands.
    (Stanislav Sitar)

Mouse support:
8   Add 'o' flag to 'mouse'?
7   Be able to set a 'mouseshape' for the popup menu.
8   Add 'mouse' flag, which sets a behavior like Visual mode, but automatic
    yanking at the button-up event. Or like Select mode, but typing gets you
    out of Select mode, instead of replacing the text. (Bhaskar)
-   Implement mouse support for the Amiga console.
-   Using right mouse button to extend a blockwise selection should attach to
    the nearest corner of the rectangle (four possible corners).
-   Precede mouse click by a number to simulate double clicks?!?
-   When mouse click after 'r' command, get character that was pointed to.

Argument list:
6   Add command to put all filenames from the tag files in the argument list.
    When given an argument, only use the files where that argument matches
    (like `grep -l ident`) and jump to the first match.
6   Add command to form an args list from all the buffers?

Registers:
8   Don't display empty registers with ":display". (Etienne)
8   Add put command that overwrites existing text. Should also work for
    blocks. Useful to move text around in a table. Works like using "R ^R r"
    for every line.
6   When yanking into the unnamed registers several times, somehow make the
    previous contents also available (like it's done for deleting). What
    register names to use? g"1, g"2, etc.?
-   When appending to a register, also report the total resulting number of
    lines. Or just say "99 more lines yanked", add the "more".
-   When inserting a register in Insert mode with CTRL-R, don't insert comment
    leader when line wraps?
-   The ":@r" commands should take a range and execute the register for each
    line in the range.
-   Add "P" command to insert contents of unnamed register, move selected text
        to position of previous deleted (to swap foo and bar in " + foo")
8   Should be able to yank and delete into the "/ register.
    How to take care of the flags (offset, magic)?

Debug mode:
8   Add breakpoints for setting an option
8   Add breakpoints for assigning to a variable.
7   Store the history from debug mode in viminfo.

7   Make the debug mode history available with histget() et al.

Various improvements:
7   Add plugins for formatting? Should be able to make a choice depending on
    the language of a file (English/Korean/Japanese/etc.).
    Setting the 'langformat' option to "chinese" would load the
    "format/chinese.vim" plugin.
    The plugin would set 'formatexpr' and define the function being called.
    Edward L. Fox explains how it should be done for most Asian languages.
    (2005 Nov 24)
    Alternative: patch for utf-8 line breaking. (Yongwei Wu, 2008 Feb 23)
7   [t to move to previous xml/html tag (like "vatov"),]t to move to next
    ("vatv").
7   [< to move to previous xml/html tag, e.g., previous <li>.]< to move to
    next <li>,]< to next , [< to previous .
8   Add ":rename" command: rename the file of the current buffer and rename
    the buffer. Buffer may be modified.
7   Instead of filtering errors with a shell script it should be possible to
    do this with Vim script. A function that filters the raw text that comes
    from the 'makeprg'?
-   Add %b to 'errorformat': buffer number. (Yegappan Lakshmanan / Suresh
    Govindachar)
7   Add a command that goes back to the position from before jumping to the
    first quickfix location. ":cbefore"?
7   Allow a window not to have a statusline. Makes it possible to use a
    window as a buffer-tab selection.
8   Allow non-active windows to have a different statusline. (Yakov Lerner)
7   Add an invisible buffer which can be edited. For use in scripts that want
    to manipulate text without changing the window layout.
8   Add a command to revert to the saved version of file; undo or redo until
    all changes are gone.
6   "vim -q -" should read the list of errors from stdin. (Gautam Mudunuri)
8   Add "--remote-fail": When contacting the server fails, exit Vim.
    Add "--remote-self": When contacting the server fails, do it in this Vim.
    Overrules the default of "--remote-send" to fail and "--remote" to do it
    in this Vim.
8   When Vim was started without a server, make it possible to start one, as
    if the "--servername" argument was given. ":startserver <name>"?
8   No address range can be used before the command modifiers. This makes
    them difficult to use in a menu for Visual mode. Accept the range and
    have it apply to the following command.
8   Add the possibility to set 'fileformats' to force a format and strip other
    CR characters. For example, for "dos" files remove CR characters at the
    end of the line, so that a file with mixed line endings is cleaned up.
    To just not display the CR characters: Add a flag to 'display'?
7   Some compilers give error messages in which the file name does not have a
    path. Be able to specify that 'path' is used for these files.
7   Xterm sends <Esc>O3F for <M-End>. Similarly for other <M-Home>, <M-Left>,
    etc. Combinations of Alt, Ctrl and Shift are also possible. Recognize
    these to avoid inserting the raw byte sequence, handle like the key
    without modifier (unless mapped).
6   Add "gG": like what "gj" is to "j": go to the N'th window line.
8   Add command like ":normal" that accepts <Key> notation like ":map".

```
9   Support ACLs on more systems.
7   Add ModeMsgVisual, ModeMsgInsert, etc. so that each mode message can be
    highlighted differently.
7   Add a message area for the user.  Set some option to reserve space (above
    the command line?).  Use an ":echouser" command to display the message
    (truncated to fit in the space).
7   Add %s to 'keywordprg': replace with word under the cursor. (Zellner)
8   Support printing on Unix.  Can use "lpansi.c" as an example. (Bookout)
8   Add put command that replaces the text under it.  Esp. for blockwise
    Visual mode.
7   Enhance termresponse stuff: Add t_CV(?): pattern of term response, use
    regexp: "\e\[[>?][0-9;]*c", but only check just after sending t_RV.
7   Add "g|" command: move to N'th column from the left margin (after wrapping
    and applying 'leftcol').  Works as "|" like what "g0" is to "0".
7   Support setting 'equalprg' to a user function name.
7   Highlight the characters after the end-of-line differently.
7   When 'whichwrap' contains "l", "$dl" should join lines?
8   Add an argument to configure to use $CFLAGS and not modify it? (Mooney)
8   Enabling features is a mix of configure arguments and defines in
    feature.h.  How to make this consistent?  Feature.h is required for
    non-unix systems.  Perhaps let configure define CONF_XXX, and use #ifdef
    CONF_XXX in feature.h?  Then what should min-features and max-features do?
8   Add "g^E" and "g^Y", to scroll a screen-full line up and down.
8   Add ":confirm" handling in open_exfile(), for when file already exists.
8   When quitting with changed files, make the dialog list the changed file
    and allow "write all", "discard all", "write some".  The last one would
    then ask "write" or "discard" for each changed file.  Patch in HierAssist
    does something like this. (Shah)
7   Use growarray for replace stack.
7   Have a look at viH (Hellenic or Greek version of Vim).  But a solution
    outside of Vim might be satisfactory (Haritsis).
3   Make "2d%" work like "d%d%" instead of "d2%"?
7   "g CTRL-O" jumps back to last used buffer.  Skip CTRL-O jumps in the same
    buffer.  Make jumplist remember the last ten accessed buffers?
7   Make it possible to set the size of the jumplist (also to a smaller number
    than the default). (Nikolai Weibull)
-   Add code to disable the CAPS key when going from Insert to Normal mode.
-   Set date/protection/etc. of the patchfile the same as the original file.
-   Use growarray for termcodes[] in term.c
-   Add <window-99>, like <cword> but use filename of 99'th window.
7   Add a way to change an operator to always work characterwise-inclusive
    (like "v" makes the operator characterwise-exclusive).  "x" could be used.
-   Make a set of operations on list of names: expand wildcards, replace home
    dir, append a string, delete a string, etc.
-   Remove using mktemp() and use tmpname() only?  Ctags does this.
-   When replacing environment variables, and there is one that is not set,
    turn it into an empty string?  Only when expanding options? (Hiebert)
-   Option to set command to be executed instead of producing a beep (e.g. to
    call "play newbeep.au").
-   Add option to show the current function name in the status line.  More or
    less what you find with "[[k", like how 'cindent' recognizes a function.
    (Bhatt).
-   "[r" and "]r": like "p" and "P", but replace instead of insert (esp. for
    blockwise registers).
```

```
-   Add 'timecheck' option, on by default.  Makes it possible to switch off the
    timestamp warning and question. (Dodt).
-   Add an option to set the time after which Vim should check the timestamps
    of the files.  Only check when an event occurs (e.g., character typed,
    mouse moved).  Useful for non-GUI versions where keyboard focus isn't
    noticeable.
-   Make 'smartcase' work even though 'ic' isn't set (Webb).
7   When formatting text, allow to break the line at a number of characters.
    Use an option for this: 'breakchars'?  Useful for formatting Fortran code.
-   Add flag to 'formatoptions' to be able to format book-style paragraphs
    (first line of paragraph has larger indent, no empty lines between
    paragraphs).  Complements the '2' flag.  Use '>' flag when larger indent
    starts a new paragraph, use '<' flag when smaller indent starts a new
    paragraph.  Both start a new paragraph on any indent change.
8   The 'a' flag in 'formatoptions' is too dangerous.  In some way only do
    auto-formatting in specific regions, e.g. defined by syntax highlighting.
8   Allow using a trailing space to signal a paragraph that continues on the
    next line (MIME text/plain; format=flowed, RFC 2646).  Can be used for
    continuous formatting.  Could use 'autoformat' option, which specifies a
    regexp which triggers auto-formatting (for one line).
    ":set autoformat=\\s$".
-   Be able to redefine where a sentence stops.  Use a regexp pattern?
-   Support multi-byte characters for sentences.  Example from Ben Peterson.
7   Add command "g)" to go to the end of a sentence, "g(" to go back to the
    end of a sentence. (Servatius Brandt)
-   Be able to redefine where a paragraph starts.  For "[[" where the '{' is
    not in column 1.
6   Add ":cdprev": go back to the previous directory.  Need to remember a
    stack of previous directories.  We also need ":cdnext".
7   Should ":cd" for MS-DOS go to $HOME, when it's defined?
-   Make "gq<CR>" work on the last line in the file.  Maybe for every operator?
-   Add more redirecting of Ex commands:
        :redir #>  bufname
        :redir #>> bufname   (append)
-   Give error message when starting :redir: twice or using END when no
    redirection was active.
-   Setting of options, specifically for a buffer or window, with
    ":set window.option" or ":set buffer.option=val".  Or use ":buffer.set".
    Also: "buffer.map <F1> quit".
6   Would it be possible to change the color of the cursor in the Win32
    console?  (Klaus Hast)
-   Add :delcr command:

                                :delcr
     :[range]delcr[!]   Check [range] lines (default: whole buffer) for lines
                        ending in <CR>.  If all lines end in <CR>, or [!] is
                        used, remove the <CR> at the end of lines in [range].
                        A CTRL-Z at the end of the file is removed.  If
                        [range] is omitted, or it is the whole file, and all
                        lines end in <CR> 'textmode' is set.  {not in Vi}
-   Should integrate addstar() and file_pat_to_reg_pat().
-   When working over a serial line with 7 bit characters, remove meta
    characters from 'isprint'.
-   Use fchdir() in init_homedir(), like in FullName().
-   In win_update(), when the GUI is active, always use the scrolling area.
```

    Avoid that the last status line is deleted and needs to be redrawn.
-   That "cTx" fails when the cursor is just after 'x' is Vi compatible, but
    may not be what you expect. Add a flag in 'cpoptions' for this? More
    general: Add an option to allow "c" to work with a null motion.
-   Give better error messages by using errno (strerror()).
-   Give "Usage:" error message when command used with wrong arguments (like
    Nvi).
-   Make 'restorescreen' option also work for xterm (and others), replaces the
    SAVE_XTERM_SCREEN define.
7   Support for ":winpos" In xterm: report the current window position.
-   Give warning message when using ":set t_xx=asdf" for a termcap code that
    Vim doesn't know about. Add flag in 'shortmess'?
6   Add ":che <file>", list all the include paths which lead to this file.
-   For a commandline that has several commands (:s, :d, etc.) summarize the
    changes all together instead of for each command (e.g. for the rot13
    macro).
-   Add command like "[I" that also shows the tree of included files.
-   ":set sm^L" results in ":set s", because short names of options are also
    expanded. Is there a better way to do this?
-   Add ":@!" command, to ":@" like what ":source!" is to ":source".
8   Add ":@:!": repeat last command with forceit set.
-   Add 't_normal': Used whenever t_me, t_se, t_ue or t_Zr is empty.
-   ":cab map test ^V| je", ":cunab map" doesn't work. This is vi compatible!
-   CTRL-W CTRL-E and CTRL-W CTRL-Y should move the current window up or down
    if it is not the first or last window.
-   Include-file-search commands should look in the loaded buffer of a file (if
    there is one) instead of the file itself.
7   Change 'nrformats' to include the leader for each format. Example:
        nrformats=hex:$,binary:b,octal:0
    Add setting of 'nrformats' to syntax files.
-   'path' can become very long, don't use NameBuff for expansion.
-   When unhiding a hidden buffer, put the same line at top of the window as
    the one before hiding it. Or: keep the same relative cursor position (so
    many percent down the windows).
-   Make it possible for the 'showbreak' to be displayed at the end of the
    line. Use a comma to separate the part at the end and the start of the
    line? Highlight the linebreak characters, add flag in 'highlight'.
    Make 'showbreak' local to a window.
-   Some string options should be expanded if they have wildcards, e.g.
    'dictionary' when it is "*.h".
-   Use a specific type for number and boolean options, making it possible to
    change it for specific machines (e.g. when a long is 64 bit).
-   Add option for <Insert> in replace mode going to normal mode. (Nugent)
-   Add a next/previous possibility to "[^I" and friends.
-   Add possibility to change the HOME directory. Use the directory from the
    passwd file? (Antwerpen)
8   Add commands to push and pop all or individual options. ":setpush tw",
    ":setpop tw", ":setpush all". Maybe pushing/popping all options is
    sufficient. ":setflush" resets the option stack?
    How to handle an aborted mapping? Remember position in tag stack when
    mapping starts, restore it when an error aborts the mapping?
-   Change ":fixdel" into option 'fixdel', t_del will be adjusted each time
    t_bs is set? (Webb)
-   "gc": goto character, move absolute character positions forward, also

counting newlines. "gC" goes backwards (Weigert).
- When doing CTRL-^, redraw buffer with the same topline. (Demirel) Store cursor row and window height to redraw cursor at same percentage of window (Webb).
- Besides remembering the last used line number of a file, also remember the column. Use it with CTRL-^ et. al.
- Check for non-digits when setting a number option (careful when entering hex codes like 0xff).
- Add option to make "." redo the "@r" command, instead of the last command executed by it. Also to make "." redo the whole mapping. Basically: redo the last TYPED command.
- Support URL links for ^X^F in Insert mode, like for "gf".
- Support %name% expansion for "gf" on Windows.
- Make "gf" work on "file://c:/path/name". "file:/c:/" and "file:///c:/" should also work?
- Add 'urlpath', used like 'path' for when "gf" used on a URL?
8 When using "gf" on an absolute file name, while editing a remote file (starts with scp:// or http://) should prepend the method and machine name.
- When finding a URL or file name, and it doesn't exist, try removing a trailing '.'.
- Add ":path" command modifier. Should work for every command that takes a file name argument, to search for the file name in 'path'. Use find_file_in_path().
- Highlight control characters on the screen: Shows the difference between CTRL-X and "^" followed by "X" (Colon).
- Integrate parsing of cmdline command and parsing for expansion.
- Create a program that can translate a .swp file from any machine into a form usable by Vim on the current machine.
- Add ":noro" command: Reset 'ro' flag for all buffers, except ones that have a readonly file. ":noro!" will reset all 'ro' flags.
- Add a variant of CTRL-V that stops interpretation of more than one character. For entering mappings on the command line where a key contains several special characters, e.g. a trailing newline.
- Make '2' option in 'formatoptions' also work inside comments.
- Add 's' flag to 'formatoptions': Do not break when inside a string. (Dodt)
- When window size changed (with the mouse) and made too small, set it back to the minimal size.
- Add "]>" and "[<", shift comment at end of line (command; /* comment */).
- Should not call cursorcmd() for each vgetc() in getcmdline().
- ":split file1 file2" adds two more windows (Webb).
- Don't give message "Incomplete last line" when editing binary file.
- Add ":a", ":i" for preloading of named buffers.
- When entering text, keep other windows on same buffer updated (when a line entered)?
- Check out how screen does output optimizing. Apparently this is possible as an output filter.
- In dosub() regexec is called twice for the same line. Try to avoid this.
- Window updating from memline.c: insert/delete/replace line.
- Optimize ml_append() for speed, esp. for reading a file.
- V..c should keep indent when 'ai' is set, just like [count]cc.
- Updatescript() can be done faster with a string instead of a char.
- Screen updating is inefficient with CTRL-F and CTRL-B when there are long lines.

- Uppercase characters in Ex commands can be made lowercase?
8 Add option to show characters in text not as "|A" but as decimal ("^129"), hex ("\x81") or octal ("\201") or meta (M-x). Nvi has the 'octal' option to switch from hex to octal. Vile can show unprintable characters in hex or in octal.
7 Tighter integration with xxd to edit binary files. Make it more easy/obvious to use. Command line argument?
- How does vi detect whether a filter has messed up the screen? Check source. After ":w !command" a wait_return?
- Improve screen updating code for doput() (use s_ins()).
- With 'p' command on last line: scroll screen up (also for terminals without insert line command).
- Use insert/delete char when terminal supports it.
- Optimize screen redraw for slow terminals.
- Optimize "dw" for long row of spaces (say, 30000).
- Add "-d null" for editing from a script file without displaying.
- In Insert mode: Remember the characters that were removed with backspace and re-insert them one at a time with <key1>, all together with <key2>.
- Amiga: Add possibility to set a keymap. The code in amiga.c does not work yet.
- Implement 'redraw' option.
- Add special code to 'sections' option to define something else but '{' or '}' as the start of a section (e.g. one shiftwidth to the right).
7 Allow using Vim in a pipe: "ls | vim -u xxx.vim - | yyy". Only needs implementing ":w" to stdout in the buffer that was read from stdin. Perhaps writing to stdout will work, since stderr is used for the terminal I/O.
8 Allow opening an unnamed buffer with ":e !cmd" and ":sp !cmd". Vile can do it.
- Add commands like]] and [[that do not include the line jumped to.
- When :unab without matching "from" part and several matching "to" parts, delete the entry that was used last, instead of the first in the list.
- Add text justification option.
- Set boolean options on/off with ":set paste=off", ":set paste=on".
- After "inv"ing an option show the value: ":set invpaste" gives "paste is off".
- Check handling of CTRL-V and '\' for ":" commands that do not have TRLBAR.
- When a file cannot be opened but does exist, give error message.
- Amiga: When 'r' protection bit is not set, file can still be opened but gives read errors. Check protection before opening.
- When writing check for file exists but no permission, "Permission denied".
- If file does not exist, check if directory exists.
- Settings edit mode: make file with ":set opt=xx", edit it, parse it as ex commands.
- ":set -w all": list one option per line.
- Amiga: test for 'w' flag when reading a file.
- :table command (Webb)
- Add new operator: clear, make area white (replace with spaces): "g ".
- Add command to ":read" a file at a certain column (blockwise read?).
- Add sort of replace mode where case is taken from the old text (Goldfarb).
- Allow multiple arguments for ":read", read all the files.
- Support for tabs in specific columns: ":set tabcol=8,20,34,56" (Demirel).
- Add 'searchdir' option: Directories to search for file name being edited (Demirel).

```
-   Modifier for the put command: Change to linewise, charwise, blockwise, etc.
-   Add commands for saving and restoring options ":set save" "set restore",
    for use in macro's and the like.
-   Keep output from listings in a window, so you can have a look at it while
    working in another window.  Put cmdline in a separate window?
-   Add possibility to put output of Ex commands in a buffer or file, e.g. for
    ":set all".  ":r :set all"?
-   When the 'equalalways' option is set, creating a new window should not
    result in windows to become bigger.  Deleting a window should not result in
    a window to become smaller (Webb).
-   When resizing the whole Vim window, the windows inside should be resized
    proportionally (Webb).
-   Include options directly in option table, no indirect pointers.  Use
    mkopttab to make option table?
-   When doing ":w dir", where "dir" is a directory name, write the current
    file into that directory, with the current file name (without the path)?
-   Support for 'dictionary's that are sorted, makes access a lot faster
    (Haritsis).
-   Add "^Vrx" on the command line, replace with contents of register x.  Used
    instead of CTRL-R to make repeating possible. (Marinichev)
-   Add "^Vb" on the command line, replace with word before or under the
    cursor?
-   Support mapping for replace mode and "r" command (Vi doesn't do this)?
8   Sorting of filenames for completion is wrong on systems that ignore
    case of filenames.  Add 'ignorefncase' option.  When set, case in
    filenames is ignored for sorting them. Patch by Mike Williams:
    ~/vim/patches/ignorefncase.  Also change what matches?  Or use another
    option name.
8   Should be able to compile Vim in another directory, with $(srcdir) set to
    where the sources are. Add $(srcdir) in the Makefile in a lot of places.
    (Netherton)
6   Make it configurable when "J" inserts a space or not.  Should not add a
    space after "(", for example.
5   When inserting spaces after the end-of-line for 'virtualedit', use tabs
    when the user wants this (e.g., add a "tab" field to 'virtualedit').
    (Servatius Brandt)

From Elvis:
-   Use "instman.sh" to install manpages?
-   Add ":alias" command.
-   Search patterns:
      \@        match word under cursor.
    but do:
      \@w       match the word under the cursor?
      \@W       match the WORD under the cursor?
8   ":window" command:
    :win +      next window (up)
    :win ++     idem, wrapping
    :win -      previous window (down)
    :win --     idem, wrapping
    :win nr     to window number "nr"
    :win name   to window editing buffer "name"
7   ":cc" compiles a single file (default: current one).  'ccprg'   option is
```

```
    program to use with ":cc".  Use ":compile" instead of ":cc"?

From xvi:
-   CTRL-_ : swap 8th bit of character.
-   Add egrep-like regex type, like xvi (Ned Konz) or Perl (Emmanuel Mogenet)

From vile:
-   When horizontal scrolling, use '>' for lines continuing right of a window.
-   Support putting .swp files in /tmp: Command in rc.local to move .swp files
    from /tmp to some directory before deleting files.

Far future and "big" extensions:
-   Instead of using a Makefile and autoconf, use a simple shell script to
    find the C compiler and do everything with C code.  Translate something
    like an Aap recipe and configure.ac to C.  Avoids depending on Python,
    thus will work everywhere.  With batch file to find the C compiler it
    would also work on MS-Windows.
-   Make it easy to setup Vim for groups of users: novice vi users, novice
    Vim users, C programmers, xterm users, GUI users,...
-   Change layout of blocks in swap file: Text at the start, with '\n' in
    between lines (just load the file without changes, except for Mac).
    Indexes for lines are from the end of the block backwards.  It's the
    current layout mirrored.
-   Make it possible to edit a register, in a window, like a buffer.
-   Add stuff to syntax highlighting to change the text (upper-case keywords,
    set indent, define other highlighting, etc.).
-   Mode to keep C-code formatted all the time (sort of on-line indent).
-   Several top-level windows in one Vim session.  Be able to use a different
    font in each top-level window.
-   Allow editing above start and below end of buffer (flag in 'virtualedit').
-   Smart cut/paste: recognize words and adjust spaces before/after them.
-   Add open mode, use it when terminal has no cursor positioning.
-   Special "drawing mode": a line is drawn where the cursor is moved to.
    Backspace deletes along the line (from jvim).
-   Support for underlining (underscore-BS-char), bold (char-BS-char) and other
    standout modes switched on/off with , 'overstrike' option (Reiter).
-   Add vertical mode (Paul Jury, Demirel): "5vdw" deletes a word in five
    lines, "3vitextESC" will insert "text" in three lines, etc..
4   Recognize l, #, p as 'flags' to EX commands:
    :g/RE/#l shall print lines with line numbers and in list format.
    :g/RE/dp shall print lines that are deleted.
    POSIX: Commands where flags shall apply to all lines written: list,
    number, open, print, substitute, visual, &, z.  For other commands, flags
    shall apply to the current line after the command completes.  Examples:
    :7,10j #l Join the lines 7-10 and print the result in list
-   Allow two or more users to edit the same file at the same time.  Changes
    are reflected in each Vim immediately.  Could work with local files but
    also over the internet.  See http://www.codingmonkeys.de/subethaedit/.

develop.txt For Vim version 8.1. Last change: 2018 May 02

VIM REFERENCE MANUAL by Bram Moolenaar

Development of Vim. development

This text is important for those who want to be involved in further developing Vim.

See the file README.txt in the "src" directory for an overview of the source code.

Vim is open source software. Everybody is encouraged to contribute to help improving Vim. For sending patches a unified diff "diff -u" is preferred.
You can create a pull request on github, but it's not required.
Also see http://vim.wikia.com/wiki/How_to_make_and_submit_a_patch.

==
1. Design goals design-goals

Most important things come first (roughly).

Note that quite a few items are contradicting. This is intentional. A balance must be found between them.

VIM IS... VI COMPATIBLE design-compatible

First of all, it should be possible to use Vim as a drop-in replacement for Vi. When the user wants to, he can use Vim in compatible mode and hardly notice any difference with the original Vi.

Exceptions:
- We don't reproduce obvious Vi bugs in Vim.
- There are different versions of Vi. I am using Version 3.7 (6/7/85) as a reference. But support for other versions is also included when possible. The Vi part of POSIX is not considered a definitive source.
- Vim adds new commands, you cannot rely on some command to fail because it didn't exist in Vi.
- Vim will have a lot of features that Vi doesn't have. Going back from Vim to Vi will be a problem, this cannot be avoided.
- Some things are hardly ever used (open mode, sending an e-mail when crashing, etc.). Those will only be included when someone has a good reason why it should be included and it's not too much work.
- For some items it is debatable whether Vi compatibility should be maintained. There will be an option flag for these.

VIM IS... IMPROVED design-improved

The IMproved bits of Vim should make it a better Vi, without becoming a
completely different editor. Extensions are done with a "Vi spirit".
- Use the keyboard as much as feasible. The mouse requires a third hand,
  which we don't have. Many terminals don't have a mouse.
- When the mouse is used anyway, avoid the need to switch back to the
  keyboard. Avoid mixing mouse and keyboard handling.
- Add commands and options in a consistent way. Otherwise people will have a
  hard time finding and remembering them. Keep in mind that more commands and
  options will be added later.
- A feature that people do not know about is a useless feature. Don't add
  obscure features, or at least add hints in documentation that they exist.
- Minimize using CTRL and other modifiers, they are more difficult to type.
- There are many first-time and inexperienced Vim users. Make it easy for
  them to start using Vim and learn more over time.
- There is no limit to the features that can be added. Selecting new features
  is one based on (1) what users ask for, (2) how much effort it takes to
  implement and (3) someone actually implementing it.

VIM IS... MULTI PLATFORM design-multi-platform

Vim tries to help as many users on as many platforms as possible.
- Support many kinds of terminals. The minimal demands are cursor positioning
  and clear-screen. Commands should only use key strokes that most keyboards
  have. Support all the keys on the keyboard for mapping.
- Support many platforms. A condition is that there is someone willing to do
  Vim development on that platform, and it doesn't mean messing up the code.
- Support many compilers and libraries. Not everybody is able or allowed to
  install another compiler or GUI library.
- People switch from one platform to another, and from GUI to terminal
  version. Features should be present in all versions, or at least in as many
  as possible with a reasonable effort. Try to avoid that users must switch
  between platforms to accomplish their work efficiently.
- That a feature is not possible on some platforms, or only possible on one
  platform, does not mean it cannot be implemented. [This intentionally
  contradicts the previous item, these two must be balanced.]

VIM IS... WELL DOCUMENTED design-documented

- A feature that isn't documented is a useless feature. A patch for a new
  feature must include the documentation.
- Documentation should be comprehensive and understandable. Using examples is
  recommended.
- Don't make the text unnecessarily long. Less documentation means that an
  item is easier to find.

VIM IS... HIGH SPEED AND SMALL IN SIZE design-speed-size

Using Vim must not be a big attack on system resources. Keep it small and

fast.
- Computers are becoming faster and bigger each year. Vim can grow too, but
  no faster than computers are growing. Keep Vim usable on older systems.
- Many users start Vim from a shell very often. Startup time must be short.
- Commands must work efficiently. The time they consume must be as small as
  possible. Useful commands may take longer.
- Don't forget that some people use Vim over a slow connection. Minimize the
  communication overhead.
- Items that add considerably to the size and are not used by many people
  should be a feature that can be disabled.
- Vim is a component among other components. Don't turn it into a massive
  application, but have it work well together with other programs.

VIM IS... MAINTAINABLE   design-maintain

- The source code should not become a mess. It should be reliable code.
- Use the same layout in all files to make it easy to read coding-style .
- Use comments in a useful way! Quoting the function name and argument names
  is NOT useful. Do explain what they are for.
- Porting to another platform should be made easy, without having to change
  too much platform-independent code.
- Use the object-oriented spirit: Put data and code together. Minimize the
  knowledge spread to other parts of the code.

VIM IS... FLEXIBLE   design-flexible

Vim should make it easy for users to work in their preferred styles rather
than coercing its users into particular patterns of work. This can be for
items with a large impact (e.g., the 'compatible' option) or for details. The
defaults are carefully chosen such that most users will enjoy using Vim as it
is. Commands and options can be used to adjust Vim to the desire of the user
and its environment.

VIM IS... NOT   design-not

- Vim is not a shell or an Operating System. It does provide a terminal
  window, in which you can run a shell or debugger. E.g. to be able to do
  this over an ssh connection. But if you don't need a text editor with that
  it is out of scope (use something like screen or tmux instead).
  A satirical way to say this: "Unlike Emacs, Vim does not attempt to include
  everything but the kitchen sink, but some people say that you can clean one
  with it. ;-)"
  To use Vim with gdb see: http://www.agide.org and http://clewn.sf.net.
- Vim is not a fancy GUI editor that tries to look nice at the cost of
  being less consistent over all platforms. But functional GUI features are
  welcomed.

==
2. Coding style   coding-style

These are the rules to use when making changes to the Vim source code. Please

stick to these rules, to keep the sources readable and maintainable.

This list is not complete. Look in the source code for more examples.

MAKING CHANGES style-changes

The basic steps to make changes to the code:
1. Get the code from github. That makes it easier to keep your changed
   version in sync with the main code base (it may be a while before your
   changes will be included). You do need to spend some time learning git,
   it's not the most user friendly tool.
2. Adjust the documentation. Doing this first gives you an impression of how
   your changes affect the user.
3. Make the source code changes.
4. Check ../doc/todo.txt if the change affects any listed item.
5. Make a patch with "git diff". You can also create a pull request on
   github, but it's the diff that matters.
6. Make a note about what changed, preferably mentioning the problem and the
   solution. Send an email to the vim-dev maillist with an explanation and
   include the diff. Or create a pull request on github.

C COMPILER style-compiler ANSI-C C89 C99

The minimal C compiler version supported is C89, also known as ANSI C.
Later standards, such as C99, are not widely supported, or at least not 100%
supported. Therefore we use only some of the C99 features and disallow some
(at least for now).

Please don't make changes everywhere to use the C99 features, it causes merge
problems for existing patches. Only use them for new and changed code.

Comments

Traditionally Vim uses /* comments */. We intend to keep it that way,
especially for file and function headers. For new code or lines of code that
change, it is allowed to use // comments. Especially when it comes after
code:

```
        int some_var;  // single line comment useful here
```

Enums

The last item in an enum may have a trailing comma. C89 didn't allow this.

Types

"long long" is allowed and can be expected to be 64 bits. Use %lld in printf
formats. Also "long long unsigned" with %llu.

Not to be used

These C99 features are not to be used, because not enough compilers support
them:

- Declaration after Statements (MSVC 2012 does not support it). All
  declarations need to be at the start of the block.
- Variable length arrays (even in C11 this is an optional feature).
- _Bool and _Complex types.
- "inline" (it's hardly ever needed, let the optimizer do its work)
- flexible array members: Not supported by HP-UX C compiler (John Marriott)

USE OF COMMON FUNCTIONS style-functions

Some functions that are common to use, have a special Vim version. Always
consider using the Vim version, because they were introduced with a reason.

NORMAL NAME	VIM NAME	DIFFERENCE OF VIM VERSION
free()	vim_free()	Checks for freeing NULL
malloc()	alloc()	Checks for out of memory situation
malloc()	lalloc()	Like alloc(), but has long argument
strcpy()	STRCPY()	Includes cast to (char *), for char_u * args
strchr()	vim_strchr()	Accepts special characters
strrchr()	vim_strrchr()	Accepts special characters
isspace()	vim_isspace()	Can handle characters > 128
iswhite()	vim_iswhite()	Only TRUE for tab and space
memcpy()	mch_memmove()	Handles overlapped copies
bcopy()	mch_memmove()	Handles overlapped copies
memset()	vim_memset()	Uniform for all systems

NAMES style-names

Function names can not be more than 31 characters long (because of VMS).

Don't use "delete" or "this" as a variable name, C++ doesn't like it.

Because of the requirement that Vim runs on as many systems as possible, we
need to avoid using names that are already defined by the system. This is a
list of names that are known to cause trouble. The name is given as a regexp
pattern.

is.*()	POSIX, ctype.h
to.*()	POSIX, ctype.h
d_.*	POSIX, dirent.h
l_.*	POSIX, fcntl.h
gr_.*	POSIX, grp.h
pw_.*	POSIX, pwd.h
sa_.*	POSIX, signal.h
mem.*	POSIX, string.h
str.*	POSIX, string.h
wcs.*	POSIX, string.h
st_.*	POSIX, stat.h
tms_.*	POSIX, times.h
tm_.*	POSIX, time.h
c_.*	POSIX, termios.h
MAX.*	POSIX, limits.h

```
__.*            POSIX, system
_[A-Z].*        POSIX, system
E[A-Z0-9]*      POSIX, errno.h

.*_t            POSIX, for typedefs.  Use .*_T instead.

wait            don't use as argument to a function, conflicts with types.h
index           shadows global declaration
time            shadows global declaration
new             C++ reserved keyword
try             Borland C++ doesn't like it to be used as a variable.

clear           Mac curses.h
echo            Mac curses.h
instr           Mac curses.h
meta            Mac curses.h
newwin          Mac curses.h
nl              Mac curses.h
overwrite       Mac curses.h
refresh         Mac curses.h
scroll          Mac curses.h
typeahead       Mac curses.h

basename()      GNU string function
dirname()       GNU string function
get_env_value() Linux system function
```

VARIOUS style-various

```
Typedef'ed names should end in "_T":
    typedef int some_T;
Define'ed names should be uppercase:
    #define SOME_THING
Features always start with "FEAT_":
    #define FEAT_FOO

Don't use '\"', some compilers can't handle it.  '"' works fine.

Don't use:
    #if HAVE_SOME
Some compilers can't handle that and complain that "HAVE_SOME" is not defined.
Use
    #ifdef HAVE_SOME
or
    #if defined(HAVE_SOME)
```

STYLE style-examples

```
General rule: One statement per line.

Wrong:      if (cond) a = 1;
```

```
OK:         if (cond)
                a = 1;

Wrong:      while (cond);

OK:         while (cond)
                ;

Wrong:      do a = 1; while (cond);

OK:         do
                a = 1;
            while (cond);

Wrong:      if (cond) {
               cmd;
               cmd;
            } else {
               cmd;
               cmd;
            }

OK:         if (cond)
            {
               cmd;
               cmd;
            }
            else
            {
               cmd;
               cmd;
            }
```

Use ANSI (new style) function declarations with the return type on a separate indented line.

```
Wrong:  int function_name(int arg1, int arg2)

OK:     /*
         * Explanation of what this function is used for.
         *
         * Return value explanation.
         */
            int
        function_name(
            int         arg1,           /* short comment about arg1 */
            int         arg2)           /* short comment about arg2 */
        {
            int         local;          /* comment about local */

            local = arg1 * arg2;
```

SPACES AND PUNCTUATION style-spaces

No space between a function name and the bracket:

```
Wrong:  func (arg);
OK:     func(arg);
```

Do use a space after if, while, switch, etc.

```
Wrong:  if(arg)         for(;;)
OK:     if (arg)        for (;;)
```

Use a space after a comma and semicolon:

```
Wrong:  func(arg1,arg2);        for (i = 0;i < 2;++i)
OK:     func(arg1, arg2);       for (i = 0; i < 2; ++i)
```

Use a space before and after '=', '+', '/', etc.

```
Wrong:  var=a*5;
OK:     var = a * 5;
```

In general: Use empty lines to group lines of code together. Put a comment just above the group of lines. This makes it easier to quickly see what is being done.

```
OK:     /* Prepare for building the table. */
        get_first_item();
        table_idx = 0;

        /* Build the table */
        while (has_item())
            table[table_idx++] = next_item();

        /* Finish up. */
        cleanup_items();
        generate_hash(table);
```

==========

3. Design decisions design-decisions

Folding

Several forms of folding should be possible for the same buffer. For example, have one window that shows the text with function bodies folded, another window that shows a function body.

Folding is a way to display the text. It should not change the text itself. Therefore the folding has been implemented as a filter between the text stored in a buffer (buffer lines) and the text displayed in a window (logical lines).

Naming the window

The word "window" is commonly used for several things: A window on the screen,
the xterm window, a window inside Vim to view a buffer.
To avoid confusion, other items that are sometimes called window have been
given another name. Here is an overview of the related items:

screen	The whole display. For the GUI it's something like 1024x768 pixels. The Vim shell can use the whole screen or part of it.
shell	The Vim application. This can cover the whole screen (e.g., when running in a console) or part of it (xterm or GUI).
window	View on a buffer. There can be several windows in Vim, together with the command line, menubar, toolbar, etc. they fit in the shell.

Spell checking develop-spell

When spell checking was going to be added to Vim a survey was done over the
available spell checking libraries and programs. Unfortunately, the result
was that none of them provided sufficient capabilities to be used as the spell
checking engine in Vim, for various reasons:

- Missing support for multi-byte encodings. At least UTF-8 must be supported,
  so that more than one language can be used in the same file.
  Doing on-the-fly conversion is not always possible (would require iconv
  support).
- For the programs and libraries: Using them as-is would require installing
  them separately from Vim. That's mostly not impossible, but a drawback.
- Performance: A few tests showed that it's possible to check spelling on the
  fly (while redrawing), just like syntax highlighting. But the mechanisms
  used by other code are much slower. Myspell uses a hashtable, for example.
  The affix compression that most spell checkers use makes it slower too.
- For using an external program like aspell a communication mechanism would
  have to be setup. That's complicated to do in a portable way (Unix-only
  would be relatively simple, but that's not good enough). And performance
  will become a problem (lots of process switching involved).
- Missing support for words with non-word characters, such as "Etten-Leur" and
  "et al.", would require marking the pieces of them OK, lowering the
  reliability.
- Missing support for regions or dialects. Makes it difficult to accept
  all English words and highlight non-Canadian words differently.
- Missing support for rare words. Many words are correct but hardly ever used
  and could be a misspelled often-used word.
- For making suggestions the speed is less important and requiring to install
  another program or library would be acceptable. But the word lists probably
  differ, the suggestions may be wrong words.

Spelling suggestions develop-spell-suggestions

For making suggestions there are two basic mechanisms:
1. Try changing the bad word a little bit and check for a match with a good
   word. Or go through the list of good words, change them a little bit and
   check for a match with the bad word. The changes are deleting a character,
   inserting a character, swapping two characters, etc.

2. Perform soundfolding on both the bad word and the good words and then find
   matches, possibly with a few changes like with the first mechanism.

The first is good for finding typing mistakes. After experimenting with hashtables and looking at solutions from other spell checkers the conclusion was that a trie (a kind of tree structure) is ideal for this. Both for reducing memory use and being able to try sensible changes. For example, when inserting a character only characters that lead to good words need to be tried. Other mechanisms (with hashtables) need to try all possible letters at every position in the word. Also, a hashtable has the requirement that word boundaries are identified separately, while a trie does not require this. That makes the mechanism a lot simpler.

Soundfolding is useful when someone knows how the words sounds but doesn't know how it is spelled. For example, the word "dictionary" might be written as "daktonerie". The number of changes that the first method would need to try is very big, it's hard to find the good word that way. After soundfolding the words become "tktnr" and "tkxnry", these differ by only two letters.

To find words by their soundfolded equivalent (soundalike word) we need a list of all soundfolded words. A few experiments have been done to find out what the best method is. Alternatives:
1. Do the sound folding on the fly when looking for suggestions. This means
   walking through the trie of good words, soundfolding each word and
   checking how different it is from the bad word. This is very efficient for
   memory use, but takes a long time. On a fast PC it takes a couple of
   seconds for English, which can be acceptable for interactive use. But for
   some languages it takes more than ten seconds (e.g., German, Catalan),
   which is unacceptable slow. For batch processing (automatic corrections)
   it's too slow for all languages.
2. Use a trie for the soundfolded words, so that searching can be done just
   like how it works without soundfolding. This requires remembering a list
   of good words for each soundfolded word. This makes finding matches very
   fast but requires quite a lot of memory, in the order of 1 to 10 Mbyte.
   For some languages more than the original word list.
3. Like the second alternative, but reduce the amount of memory by using affix
   compression and store only the soundfolded basic word. This is what Aspell
   does. Disadvantage is that affixes need to be stripped from the bad word
   before soundfolding it, which means that mistakes at the start and/or end
   of the word will cause the mechanism to fail. Also, this becomes slow when
   the bad word is quite different from the good word.

The choice made is to use the second mechanism and use a separate file. This way a user with sufficient memory can get very good suggestions while a user who is short of memory or just wants the spell checking and no suggestions doesn't use so much memory.

Word frequency

For sorting suggestions it helps to know which words are common. In theory we could store a word frequency with the word in the dictionary. However, this requires storing a count per word. That degrades word tree compression a lot. And maintaining the word frequency for all languages will be a heavy task.

Also, it would be nice to prefer words that are already in the text. This way the words that appear in the specific text are preferred for suggestions.

What has been implemented is to count words that have been seen during displaying. A hashtable is used to quickly find the word count. The count is initialized from words listed in COMMON items in the affix file, so that it also works when starting a new file.

This isn't ideal, because the longer Vim is running the higher the counts become. But in practice it is a noticeable improvement over not using the word count.

==
4. Assumptions design-assumptions

Size of variables:
char   8 bit signed
char_u   8 bit unsigned
int   32 or 64 bit signed (16 might be possible with limited features)
unsigned   32 or 64 bit unsigned (16 as with ints)
long   32 or 64 bit signed, can hold a pointer

Note that some compilers cannot handle long lines or strings. The C89 standard specifies a limit of 509 characters.

 vim:tw=78:ts=8:noet:ft=help:norl:

debug.txt For Vim version 8.1. Last change: 2017 Jul 15

VIM REFERENCE MANUAL by Bram Moolenaar

Debugging Vim debug-vim

This is for debugging Vim itself, when it doesn't work properly.
For debugging Vim scripts, functions, etc. see debug-scripts

==

1. Location of a crash, using gcc and gdb debug-gcc gdb

When Vim crashes in one of the test files, and you are using gcc for
compilation, here is what you can do to find out exactly where Vim crashes.
This also applies when using the MingW tools.

1. Compile Vim with the "-g" option (there is a line in the src/Makefile for
   this, which you can uncomment). Also make sure "strip" is disabled (do not
   install it, or use the line "STRIP = /bin/true").

2. Execute these commands (replace "11" with the test that fails):
        cd testdir
        gdb ../vim
        run -u unix.vim -U NONE -s dotest.in test11.in

3. Check where Vim crashes, gdb should give a message for this.

4. Get a stack trace from gdb with this command:
        where
  You can check out different places in the stack trace with:
        frame 3
  Replace "3" with one of the numbers in the stack trace.

==

2. Locating memory leaks debug-leaks valgrind

If you suspect Vim is leaking memory and you are using Linux, the valgrind
tool is very useful to pinpoint memory leaks.

First of all, build Vim with EXITFREE defined. Search for this in MAKEFILE
and uncomment the line.

Use this command to start Vim:

        valgrind --log-file=valgrind.log --leak-check=full ./vim

Note: Vim will run much slower. If your .vimrc is big or you have several plugins you need to be patient for startup, or run with the "--clean" argument.

There are often a few leaks from libraries, such as getpwuid() and XtVaAppCreateShell(). Those are unavoidable. The number of bytes should be very small a Kbyte or less.

==

3. Windows Bug Reporting debug-win32

If the Windows version of Vim crashes in a reproducible manner, you can take some steps to provide a useful bug report.

3.1 GENERIC

You must obtain the debugger symbols (PDB) file for your executable: gvim.pdb for gvim.exe, or vim.pdb for vim.exe. The PDB should be available from the same place that you obtained the executable. Be sure to use the PDB that matches the EXE (same date).

If you built the executable yourself with the Microsoft Visual C++ compiler, then the PDB was built with the EXE.

Alternatively, if you have the source files, you can import Make_ivc.mak into Visual Studio as a workspace. Then select a debug configuration, build and you can do all kinds of debugging (set breakpoints, watch variables, etc.).

If you have Visual Studio, use that instead of the VC Toolkit and WinDbg.

For other compilers, you should always use the corresponding debugger: TD for a Vim executable compiled with the Borland compiler; gdb (see above debug-gcc) for the Cygwin and MinGW compilers.

3.2 Debugging Vim crashes with Visual Studio 2005/Visual C++ 2005 Express debug-vs2005

First launch vim.exe or gvim.exe and then launch Visual Studio. (If you don't have Visual Studio, follow the instructions at get-ms-debuggers to obtain a free copy of Visual C++ 2005 Express Edition.)

On the Tools menu, click Attach to Process. Choose the Vim process.

In Vim, reproduce the crash. A dialog will appear in Visual Studio, telling you about the unhandled exception in the Vim process. Click Break to break into the process.

Visual Studio will pop up another dialog, telling you that no symbols are loaded and that the source code cannot be displayed. Click OK.

Several windows will open. Right-click in the Call Stack window. Choose Load

Symbols. The Find Symbols dialog will open, looking for (g)vim.pdb. Navigate to the directory where you have the PDB file and click Open.

At this point, you should have a full call stack with vim function names and line numbers. Double-click one of the lines and the Find Source dialog will appear. Navigate to the directory where the Vim source is (if you have it.)

If you don't know how to debug this any further, follow the instructions at ":help bug-reports". Paste the call stack into the bug report.

If you have a non-free version of Visual Studio, you can save a minidump via the Debug menu and send it with the bug report. A minidump is a small file (<100KB), which contains information about the state of your process. Visual C++ 2005 Express Edition cannot save minidumps and it cannot be installed as a just-in-time debugger. Use WinDbg, debug-windbg , if you need to save minidumps or you want a just-in-time (postmortem) debugger.

debug-windbg

3.3 Debugging Vim crashes with WinDbg

See get-ms-debuggers to obtain a copy of WinDbg.

As with the Visual Studio IDE, you can attach WinDbg to a running Vim process. You can also have your system automatically invoke WinDbg as a postmortem debugger. To set WinDbg as your postmortem debugger, run "windbg -I".

To attach WinDbg to a running Vim process, launch WinDbg. On the File menu, choose Attach to a Process. Select the Vim process and click OK.

At this point, choose Symbol File Path on the File menu, and add the folder containing your Vim PDB to the sympath. If you have Vim source available, use Source File Path on the File menu. You can now open source files in WinDbg and set breakpoints, if you like. Reproduce your crash. WinDbg should open the source file at the point of the crash. Using the View menu, you can examine the call stack, local variables, watch windows, and so on.

If WinDbg is your postmortem debugger, you do not need to attach WinDbg to your Vim process. Simply reproduce the crash and WinDbg will launch automatically. As above, set the Symbol File Path and the Source File Path.

To save a minidump, type the following at the WinDbg command line:

```
.dump vim.dmp
```

debug-minidump

3.4 Opening a Minidump

If you have a minidump file, you can open it in Visual Studio or in WinDbg.

In Visual Studio 2005: on the File menu, choose Open, then Project/Solution. Navigate to the .dmp file and open it. Now press F5 to invoke the debugger. Follow the instructions in debug-vs2005 to set the Symbol File Path.

In WinDbg: choose Open Crash Dump on the File menu. Follow the instructions in debug-windbg to set the Symbol File Path.

get-ms-debuggers

3.5 Obtaining Microsoft Debugging Tools

The Debugging Tools for Windows (including WinDbg) can be downloaded from
    http://www.microsoft.com/whdc/devtools/debugging/default.mspx
This includes the WinDbg debugger.

Visual C++ 2005 Express Edition can be downloaded for free from:
    http://msdn.microsoft.com/vstudio/express/visualC/default.aspx

uganda.txt For Vim version 8.1. Last change: 2018 May 17

VIM REFERENCE MANUAL by Bram Moolenaar

uganda Uganda copying copyright license

SUMMARY

iccf ICCF

Vim is Charityware. You can use and copy it as much as you like, but you are encouraged to make a donation for needy children in Uganda. Please see kcc below or visit the ICCF web site, available at these URLs:

        http://iccf-holland.org/
        http://www.vim.org/iccf/
        http://www.iccf.nl/

You can also sponsor the development of Vim. Vim sponsors can vote for features. See sponsor . The money goes to Uganda anyway.

The Open Publication License applies to the Vim documentation, see manual-copyright .

=== begin of license ===

VIM LICENSE

I) There are no restrictions on distributing unmodified copies of Vim except
    that they must include this license text. You can also distribute
    unmodified parts of Vim, likewise unrestricted except that they must
    include this license text. You are also allowed to include executables
    that you made from the unmodified Vim sources, plus your own usage
    examples and Vim scripts.

II) It is allowed to distribute a modified (or extended) version of Vim,
    including executables and/or source code, when the following four
    conditions are met:
    1) This license text must be included unmodified.
    2) The modified Vim must be distributed in one of the following five ways:
       a) If you make changes to Vim yourself, you must clearly describe in
          the distribution how to contact you. When the maintainer asks you
          (in any way) for a copy of the modified Vim you distributed, you
          must make your changes, including source code, available to the
          maintainer without fee. The maintainer reserves the right to
          include your changes in the official version of Vim. What the
          maintainer will do with your changes and under what license they
          will be distributed is negotiable. If there has been no negotiation
          then this license, or a later version, also applies to your changes.
          The current maintainer is Bram Moolenaar <Bram@vim.org>. If this
          changes it will be announced in appropriate places (most likely
          vim.sf.net, www.vim.org and/or comp.editors). When it is completely
          impossible to contact the maintainer, the obligation to send him
          your changes ceases. Once the maintainer has confirmed that he has
          received your changes they will not have to be sent again.

b) If you have received a modified Vim that was distributed as
   mentioned under a) you are allowed to further distribute it
   unmodified, as mentioned at I). If you make additional changes the
   text under a) applies to those changes.
c) Provide all the changes, including source code, with every copy of
   the modified Vim you distribute. This may be done in the form of a
   context diff. You can choose what license to use for new code you
   add. The changes and their license must not restrict others from
   making their own changes to the official version of Vim.
d) When you have a modified Vim which includes changes as mentioned
   under c), you can distribute it without the source code for the
   changes if the following three conditions are met:
   - The license that applies to the changes permits you to distribute
     the changes to the Vim maintainer without fee or restriction, and
     permits the Vim maintainer to include the changes in the official
     version of Vim without fee or restriction.
   - You keep the changes for at least three years after last
     distributing the corresponding modified Vim. When the maintainer
     or someone who you distributed the modified Vim to asks you (in
     any way) for the changes within this period, you must make them
     available to him.
   - You clearly describe in the distribution how to contact you. This
     contact information must remain valid for at least three years
     after last distributing the corresponding modified Vim, or as long
     as possible.
e) When the GNU General Public License (GPL) applies to the changes,
   you can distribute the modified Vim under the GNU GPL version 2 or
   any later version.
3) A message must be added, at least in the output of the ":version"
   command and in the intro screen, such that the user of the modified Vim
   is able to see that it was modified. When distributing as mentioned
   under 2)e) adding the message is only required for as far as this does
   not conflict with the license used for the changes.
4) The contact information as required under 2)a) and 2)d) must not be
   removed or changed, except that the person himself can make
   corrections.

III) If you distribute a modified version of Vim, you are encouraged to use
     the Vim license for your changes and make them available to the
     maintainer, including the source code. The preferred way to do this is
     by e-mail or by uploading the files to a server and e-mailing the URL.
     If the number of changes is small (e.g., a modified Makefile) e-mailing a
     context diff will do. The e-mail address to be used is
     <maintainer@vim.org>

IV) It is not allowed to remove this license from the distribution of the Vim
     sources, parts of it or from a modified version. You may use this
     license for previous Vim releases instead of the license that they came
     with, at your option.

=== end of license ===

Note:

- If you are happy with Vim, please express that by reading the rest of this
  file and consider helping needy children in Uganda.

- If you want to support further Vim development consider becoming a
  sponsor . The money goes to Uganda anyway.

- According to Richard Stallman the Vim license is GNU GPL compatible.
  A few minor changes have been made since he checked it, but that should not
  make a difference.

- If you link Vim with a library that goes under the GNU GPL, this limits
  further distribution to the GNU GPL. Also when you didn't actually change
  anything in Vim.

- Once a change is included that goes under the GNU GPL, this forces all
  further changes to also be made under the GNU GPL or a compatible license.

- If you distribute a modified version of Vim, you can include your name and
  contact information with the "--with-modified-by" configure argument or the
  MODIFIED_BY define.

==
Kibaale Children's Centre   kcc   Kibaale   charity

Kibaale Children's Centre (KCC) is located in Kibaale, a small town in the
south of Uganda, near Tanzania, in East Africa. The area is known as Rakai
District. The population is mostly farmers. Although people are poor, there
is enough food. But this district is suffering from AIDS more than any other
part of the world. Some say that it started there. Estimations are that 10
to 30% of the Ugandans are infected with HIV. Because parents die, there are
many orphans. In this district about 60,000 children have lost one or both
parents, out of a population of 350,000. And this is still continuing.

The children need a lot of help. The KCC is working hard to provide the needy
with food, medical care and education. Food and medical care to keep them
healthy now, and education so that they can take care of themselves in the
future. KCC works on a Christian base, but help is given to children of any
religion.

The key to solving the problems in this area is education. This has been
neglected in the past years with president Idi Amin and the following civil
wars. Now that the government is stable again, the children and parents have
to learn how to take care of themselves and how to avoid infections. There is
also help for people who are ill and hungry, but the primary goal is to
prevent people from getting ill and to teach them how to grow healthy food.

Most of the orphans are living in an extended family. An uncle or older
sister is taking care of them. Because these families are big and the income
(if any) is low, a child is lucky if it gets healthy food. Clothes, medical
care and schooling is beyond its reach. To help these needy children, a
sponsorship program was put into place. A child can be financially adopted.
For a few dollars a month KCC sees to it that the child gets indispensable
items, is healthy, goes to school and KCC takes care of anything else that
needs to be done for the child and the family that supports it.

Besides helping the child directly, the environment where the child grows up needs to be improved. KCC helps schools to improve their teaching methods. There is a demonstration school at the centre and teacher trainings are given. Health workers are being trained, hygiene education is carried out and households are stimulated to build a proper latrine. I helped setting up a production site for cement slabs. These are used to build a good latrine. They are sold below cost price.

There is a small clinic at the project, which provides children and their family with medical help. When needed, transport to a hospital is offered. Immunization programs are carried out and help is provided when an epidemic is breaking out (measles and cholera have been a problem).

donate

Summer 1994 to summer 1995 I spent a whole year at the centre, working as a volunteer. I have helped to expand the centre and worked in the area of water and sanitation. I learned that the help that the KCC provides really helps. When I came back to Holland, I wanted to continue supporting KCC. To do this I'm raising funds and organizing the sponsorship program. Please consider one of these possibilities:

1. Sponsor a child in primary school: 17 euro a month (or more).
2. Sponsor a child in secondary school: 25 euro a month (or more).
3. Sponsor the clinic: Any amount a month or quarter
4. A one-time donation

Compared with other organizations that do child sponsorship the amounts are very low. This is because the money goes directly to the centre. Less than 5% is used for administration. This is possible because this is a small organization that works with volunteers. If you would like to sponsor a child, you should have the intention to do this for at least one year.

How do you know that the money will be spent right? First of all you have my personal guarantee as the author of Vim. I trust the people that are working at the centre, I know them personally. Furthermore, the centre has been co-sponsored and inspected by World Vision, Save the Children Fund and is now under the supervision of Pacific Academy Outreach Society. The centre is visited about once a year to check the progress (at our own cost). I have visited the centre myself many times, starting in 1993. The visit reports are on the ICCF web site.

If you have any further questions, send me e-mail: <Bram@vim.org>.

The address of the centre is:

```
                Kibaale Children's Centre
                p.o. box 1658
                Masaka, Uganda, East Africa
```

Sending money: iccf-donations

Check the ICCF web site for the latest information! See iccf for the URL.

USA: The methods mentioned below can be used.

Sending a check to the Nehemiah Group Outreach Society (NGOS) is no longer possible, unfortunately. We are looking for another way to get you an IRS tax receipt.
For sponsoring a child contact KCF in Canada (see below). US checks can be sent to them to lower banking costs.

Canada: Contact Kibaale Children's Fund (KCF) in Surrey, Canada. They take care of the Canadian sponsors for the children in Kibaale. KCF forwards 100% of the money to the project in Uganda. You can send them a one time donation directly. Please send me a note so that I know what has been donated because of Vim. Ask KCF for information about sponsorship.

Kibaale Children's Fund c/o Pacific Academy
10238-168 Street
Surrey, B.C. V4N 1Z4
Canada
Phone: 604-581-5353

If you make a donation to Kibaale Children's Fund (KCF) you will receive a tax receipt which can be submitted with your tax return.

Holland: Transfer to the account of "Stichting ICCF Holland" in Lisse. This will allow for tax deduction if you live in Holland.

Postbank, nr. 4548774
IBAN: NL95 INGB 0004 5487 74

Germany: It is possible to make donations that allow for a tax return. Check the ICCF web site for the latest information:

http://iccf-holland.org/germany.html

World: Use a postal money order. That should be possible from any country, mostly from the post office. Use this name (which is in my passport): "Abraham Moolenaar". Use Euro for the currency if possible.

Europe: Use a bank transfer if possible. Your bank should have a form that you can use for this. See "Others" below for the swift code and IBAN number.
Any other method should work. Ask for information about sponsorship.

Credit Card: You can use PayPal to send money with a Credit card. This is the most widely used Internet based payment system. It's really simple to use. Use this link to find more info:

https://www.paypal.com/en_US/mrb/pal=XAC62PML3GF8Q

The e-mail address for sending the money to is:

Bram@iccf-holland.org

For amounts above 400 Euro ($500) sending a check is preferred.

Others: Transfer to one of these accounts if possible:

Postbank, account 4548774
Swift code: INGB NL 2A
IBAN: NL95 INGB 0004 5487 74

```
                        under the name "stichting ICCF Holland", Lisse
                    If that doesn't work:
                    Rabobank Lisse, account 3765.05.117
                                Swift code: RABO NL 2U
                        under the name "Bram Moolenaar", Lisse
                Otherwise, send a check in euro or US dollars to the address
                below.  Minimal amount: $70 (my bank does not accept smaller
                amounts for foreign check, sorry)

Address to send checks to:
                        Bram Moolenaar
                        Finsterruetihof 1
                        8134 Adliswil
                        Switzerland

This address is expected to be valid for a long time.

 vim:tw=78:ts=8:ft=help:norl:
```

starting.txt For Vim version 8.1. Last change: 2018 May 05

VIM REFERENCE MANUAL by Bram Moolenaar

Starting Vim starting

==========

1. Vim arguments vim-arguments

Most often, Vim is started to edit a single file with the command

```
vim filename
```
-vim

More generally, Vim is started with:

```
vim [option | filename] ..
```

Option arguments and file name arguments can be mixed, and any number of them can be given. However, watch out for options that take an argument.

For compatibility with various Vi versions, see cmdline-arguments .

Exactly one out of the following five items may be used to choose how to start editing:

-file ---

filename One or more file names. The first one will be the current file and read into the buffer. The cursor will be positioned on the first line of the buffer.
To avoid a file name starting with a '-' being interpreted as an option, precede the arglist with "--", e.g.:
```
vim -- -filename
```
All arguments after the "--" will be interpreted as file names, no other options or "+command" argument can follow.
For behavior of quotes on MS-Windows, see win32-quotes .

--

- This argument can mean two things, depending on whether Ex mode is to be used.

Starting in Normal mode:

```
                vim -
                ex -v -
            Start editing a new buffer, which is filled with text
             that is read from stdin.  The commands that would normally be
             read from stdin will now be read from stderr.  Example:
                find . -name "*.c" -print | vim -
            The buffer will not be marked as modified, so that it's easy
             to exit.  Be careful to mark it as modified if you don't want
             to accidentally lose it.  Example:
                ls | view -

             Starting in Ex mode:
                ex -
                vim -e -
                exim -
                vim -E
            Start editing in silent mode.  See  -s-ex .

                                                          -t   -tag
-t {tag}        A tag.  "tag" is looked up in the tags file, the associated
                file becomes the current file, and the associated command is
                executed.  Mostly this is used for C programs, in which case
                "tag" often is a function name.  The effect is that the file
                containing that function becomes the current file and the
                cursor is positioned on the start of the function (see
                 tags ).

                                                          -q   -qf
-q [errorfile]  QuickFix mode.  The file with the name [errorfile] is read
                and the first error is displayed.  See  quickfix .
                If [errorfile] is not given, the 'errorfile' option is used
                for the file name.  See 'errorfile' for the default value.
                {not in Vi}

(nothing)       Without one of the four items above, Vim will start editing a
                new buffer.  It's empty and doesn't have a file name.

The startup mode can be changed by using another name instead of "vim", which
is equal to giving options:
ex      vim -e      Start in Ex mode (see  Ex-mode ).                ex
exim    vim -E      Start in improved Ex mode (see  Ex-mode ).       exim
                        (normally not installed)
view    vim -R      Start in read-only mode (see  -R ).              view
gvim    vim -g      Start the GUI (see  gui ).                       gvim
gex     vim -eg     Start the GUI in Ex mode.                      gex
gview   vim -Rg     Start the GUI in read-only mode.               gview
rvim    vim -Z      Like "vim", but in restricted mode (see  -Z )    rvim
rview   vim -RZ     Like "view", but in restricted mode.           rview
rgvim   vim -gZ     Like "gvim", but in restricted mode.           rgvim
rgview  vim -RgZ    Like "gview", but in restricted mode.          rgview
evim    vim -y      Easy Vim: set 'insertmode' (see  -y )            evim
eview   vim -yR     Like "evim" in read-only mode                  eview
vimdiff vim -d      Start in diff mode  diff-mode
```

gvimdiff vim -gd   Start in diff mode diff-mode

Additional characters may follow, they are ignored. For example, you can have "gvim-5" to start the GUI. You must have an executable by that name then, of course.

On Unix, you would normally have one executable called Vim, and links from the different startup-names to that executable. If your system does not support links and you do not want to have several copies of the executable, you could use an alias instead. For example:

```
alias view   vim -R
alias gvim   vim -g
```

startup-options

The option arguments may be given in any order. Single-letter options can be combined after one dash. There can be no option arguments after the "--" argument.

On VMS all option arguments are assumed to be lowercase, unless preceded with a slash. Thus "-R" means recovery and "-/R" readonly.

--help -h --help -?

-?

-h Give usage (help) message and exit. {not in Vi}
See info-message about capturing the text.

--version

--version Print version information and exit. Same output as for :version command. {not in Vi}
See info-message about capturing the text.

--noplugin

--noplugin Skip loading plugins. Resets the 'loadplugins' option.
{not in Vi}
Note that the -u argument may also disable loading plugins:

argument	load: vimrc files	plugins	defaults.vim
(nothing)	yes	yes	yes
-u NONE	no	no	no
-u DEFAULTS	no	no	yes
-u NORC	no	yes	no
--noplugin	yes	no	yes

--startuptime {fname} --startuptime

During startup write timing messages to the file {fname}.
This can be used to find out where time is spent while loading your .vimrc, plugins and opening the first file.
When {fname} already exists new messages are appended.
(Only available when compiled with the +startuptime feature).

--literal

--literal Take file names literally, don't expand wildcards. Not needed for Unix, because Vim always takes file names literally (the shell expands wildcards).

Applies to all the names, also the ones that come before this argument.

-+

+[num] The cursor will be positioned on line "num" for the first file being edited. If "num" is missing, the cursor will be positioned on the last line.

-+/

+/{pat} The cursor will be positioned on the first line containing "pat" in the first file being edited (see pattern for the available search patterns). The search starts at the cursor position, which can be the first line or the cursor position last used from viminfo . To force a search from the first line use "+1 +/pat".

+{command} -+c -c

-c {command} {command} will be executed after the first file has been read (and after autocommands and modelines for that file have been processed). "command" is interpreted as an Ex command. If the "command" contains spaces, it must be enclosed in double quotes (this depends on the shell that is used). Example:

```
vim "+set si" main.c
vim "+find stdio.h"
vim -c "set ff=dos" -c wq mine.mak
```

Note: You can use up to 10 "+" or "-c" arguments in a Vim command. They are executed in the order given. A "-S" argument counts as a "-c" argument as well. {Vi only allows one command}

--cmd {command} --cmd

{command} will be executed before processing any vimrc file. Otherwise it acts like -c {command}. You can use up to 10 of these commands, independently from "-c" commands. {not in Vi}

-S

-S {file} The {file} will be sourced after the first file has been read. This is an easy way to do the equivalent of:

```
-c "source {file}"
```

It can be mixed with "-c" arguments and repeated like "-c". The limit of 10 "-c" arguments applies here as well. {file} cannot start with a "-". {not in Vi}

-S Works like "-S Session.vim". Only when used as the last argument or when another "-" option follows.

-r

-r Recovery mode. Without a file name argument, a list of existing swap files is given. With a file name, a swap file is read to recover a crashed editing session. See

crash-recovery .

-L

-L Same as -r. {only in some versions of Vi: "List recoverable edit sessions"}

-R

-R Readonly mode. The 'readonly' option will be set for all the files being edited. You can still edit the buffer, but will be prevented from accidentally overwriting a file. If you forgot that you are in View mode and did make some changes, you can overwrite a file by adding an exclamation mark to the Ex command, as in ":w!". The 'readonly' option can be reset with ":set noro" (see the options chapter, options). Subsequent edits will not be done in readonly mode. Calling the executable "view" has the same effect as the -R argument. The 'updatecount' option will be set to 10000, meaning that the swap file will not be updated automatically very often. See -M for disallowing modifications.

-m

-m Modifications not allowed to be written. The 'write' option will be reset, so that writing files is disabled. However, the 'write' option can be set to enable writing again. {not in Vi}

-M

-M Modifications not allowed. The 'modifiable' option will be reset, so that changes are not allowed. The 'write' option will be reset, so that writing files is disabled. However, the 'modifiable' and 'write' options can be set to enable changes and writing. {not in Vi}

-Z restricted-mode E145

-Z Restricted mode. All commands that make use of an external shell are disabled. This includes suspending with CTRL-Z, ":sh", filtering, the system() function, backtick expansion, delete(), rename(), mkdir(), writefile(), libcall(), job_start(), etc. {not in Vi}

-g

-g Start Vim in GUI mode. See gui . For the opposite see -v . {not in Vi}

-v

-v Start Ex in Vi mode. Only makes a difference when the executable is called "ex" or "gvim". For gvim the GUI is not started if possible.

-e

-e Start Vim in Ex mode Q . Only makes a difference when the executable is not called "ex".

-E

-E Start Vim in improved Ex mode gQ . Only makes a difference when the executable is not called "exim". {not in Vi}

-s-ex

-s Silent or batch mode. Only when Vim was started as "ex" or when preceded with the "-e" argument. Otherwise see -s , which does take an argument while this use of "-s" doesn't. To be used when Vim is used to execute Ex commands from a file instead of a terminal. Switches off most prompts and informative messages. Also warnings and error messages. The output of these commands is displayed (to stdout):

```
:print
:list
:number
:set      to display option values.
```

When 'verbose' is non-zero messages are printed (for debugging, to stderr). 'term' and $TERM are not used. If Vim appears to be stuck try typing "qa!<Enter>". You don't get a prompt thus you can't see Vim is waiting for you to type something. Initializations are skipped (except the ones given with the "-u" argument). Example:

```
vim -e -s  < thefilter  thefile
```

-b

-b Binary mode. File I/O will only recognize <NL> to separate lines. The 'expandtab' option will be reset. The 'textwidth' option is set to 0. 'modeline' is reset. The 'binary' option is set. This is done after reading the vimrc/exrc files but before reading any file in the arglist. See also edit-binary . {not in Vi}

-l

-l Lisp mode. Sets the 'lisp' and 'showmatch' options on.

-A

-A Arabic mode. Sets the 'arabic' option on. (Only when compiled with the +arabic features (which include +rightleft), otherwise Vim gives an error message and exits.) {not in Vi}

-F

-F Farsi mode. Sets the 'fkmap' and 'rightleft' options on. (Only when compiled with +rightleft and +farsi features, otherwise Vim gives an error message and exits.) {not in Vi}

-H

-H Hebrew mode. Sets the 'hkmap' and 'rightleft' options on. (Only when compiled with the +rightleft feature, otherwise

Vim gives an error message and exits.) {not in Vi}

-V verbose

-V[N] Verbose. Sets the 'verbose' option to [N] (default: 10). Messages will be given for each file that is ":source"d and for reading or writing a viminfo file. Can be used to find out what is happening upon startup and exit. {not in Vi}
Example:
```
vim -V8 foobar
```

-V[N]{filename}
Like -V and set 'verbosefile' to {filename}. The result is that messages are not displayed but written to the file {filename}. {filename} must not start with a digit.
Example:
```
vim -V20vimlog foobar
```

-D

-D Debugging. Go to debugging mode when executing the first command from a script. debug-mode
{not available when compiled without the |+eval| feature}
{not in Vi}

-C

-C Compatible mode. Sets the 'compatible' option. You can use this to get 'compatible', even though a .vimrc file exists. Keep in mind that the command ":set nocompatible" in some plugin or startup script overrules this, so you may end up with 'nocompatible' anyway. To find out, use:
```
:verbose set compatible?
```
Several plugins won't work with 'compatible' set. You may want to set it after startup this way:
```
vim "+set cp" filename
```
Also see compatible-default . {not in Vi}

-N

-N Not compatible mode. Resets the 'compatible' option. You can use this to get 'nocompatible', when there is no .vimrc file or when using "-u NONE".
Also see compatible-default . {not in Vi}

-y easy

-y Easy mode. Implied for evim and eview . Starts with 'insertmode' set and behaves like a click-and-type editor. This sources the script $VIMRUNTIME/evim.vim. Mappings are set up to work like most click-and-type editors, see evim-keys . The GUI is started when available.
{not in Vi}

-n

-n No swap file will be used. Recovery after a crash will be impossible. Handy if you want to view or edit a file on a very slow medium (e.g., a floppy).
Can also be done with ":set updatecount=0". You can switch it

on again by setting the 'updatecount' option to some value,
e.g., ":set uc=100".
NOTE: Don't combine -n with -b, making -nb, because that has a
different meaning: -nb .
'updatecount' is set to 0 AFTER executing commands from a
vimrc file, but before the GUI initializations. Thus it
overrides a setting for 'updatecount' in a vimrc file, but not
in a gvimrc file. See startup .
When you want to reduce accesses to the disk (e.g., for a
laptop), don't use "-n", but set 'updatetime' and
'updatecount' to very big numbers, and type ":preserve" when
you want to save your work. This way you keep the possibility
for crash recovery.
{not in Vi}

-o

-o[N] Open N windows, split horizontally. If [N] is not given,
one window is opened for every file given as argument. If
there is not enough room, only the first few files get a
window. If there are more windows than arguments, the last
few windows will be editing an empty file.
{not in Vi}

-O

-O[N] Open N windows, split vertically. Otherwise it's like -o.
If both the -o and the -O option are given, the last one on
the command line determines how the windows will be split.
{not in Vi}

-p

-p[N] Open N tab pages. If [N] is not given, one tab page is opened
for every file given as argument. The maximum is set with
'tabpagemax' pages (default 10). If there are more tab pages
than arguments, the last few tab pages will be editing an
empty file. Also see tabpage .
{not in Vi}

-T

-T {terminal} Set the terminal type to "terminal". This influences the
codes that Vim will send to your terminal. This is normally
not needed, because Vim will be able to find out what type
of terminal you are using. (See terminal-info .) {not in Vi}

--not-a-term

--not-a-term Tells Vim that the user knows that the input and/or output is
not connected to a terminal. This will avoid the warning and
the two second delay that would happen.
Also avoids the "Reading from stdin..." message.
{not in Vi}

--ttyfail

--ttyfail When the stdin or stdout is not a terminal (tty) then exit
right away.

-d

-d Start in diff mode, like vimdiff .
{not in Vi} {not available when compiled without the +diff
feature}

-d {device} Only on the Amiga and when not compiled with the +diff
feature. Works like "-dev".

-dev

-dev {device} Only on the Amiga: The {device} is opened to be used for
editing.
Normally you would use this to set the window position and
size: "-d con:x/y/width/height", e.g.,
"-d con:30/10/600/150". But you can also use it to start
editing on another device, e.g., AUX:. {not in Vi}

-f

-f GUI: Do not disconnect from the program that started Vim.
'f' stands for "foreground". If omitted, the GUI forks a new
process and exits the current one. "-f" should be used when
gvim is started by a program that will wait for the edit
session to finish (e.g., mail or readnews). If you want gvim
never to fork, include 'f' in 'guioptions' in your gvimrc .
Careful: You can use "-gf" to start the GUI in the foreground,
but "-fg" is used to specify the foreground color. gui-fork

Amiga: Do not restart Vim to open a new window. This
option should be used when Vim is started by a program that
will wait for the edit session to finish (e.g., mail or
readnews). See amiga-window .

MS-Windows: This option is not supported. However, when
running Vim with an installed vim.bat or gvim.bat file it
works.
{not in Vi}

--nofork

--nofork GUI: Do not fork. Same as -f .

-u E282

-u {vimrc} The file {vimrc} is read for initializations. Most other
initializations are skipped; see initialization .

This can be used to start Vim in a special mode, with special
mappings and settings. A shell alias can be used to make
this easy to use. For example:

```
alias vimc vim -u ~/.c_vimrc !*
```

Also consider using autocommands; see autocommand .

When {vimrc} is equal to "NONE" (all uppercase), all
initializations from files and environment variables are
skipped, including reading the gvimrc file when the GUI
starts. Loading plugins is also skipped.

When {vimrc} is equal to "NORC" (all uppercase), this has the
same effect as "NONE", but loading plugins is not skipped.

When {vimrc} is equal to "DEFAULTS" (all uppercase), this has
the same effect as "NONE", but the defaults.vim script is
loaded, which will also set 'nocompatible'.

Using the "-u" argument with another argument than DEFAULTS
has the side effect that the 'compatible' option will be on by
default. This can have unexpected effects. See
 'compatible' .
{not in Vi}

                                                -U E230
-U {gvimrc}   The file {gvimrc} is read for initializations when the GUI
starts. Other GUI initializations are skipped. When {gvimrc}
is equal to "NONE", no file is read for GUI initializations at
all. gui-init
Exception: Reading the system-wide menu file is always done.
{not in Vi}

                                                -i
-i {viminfo}   The file "viminfo" is used instead of the default viminfo
file. If the name "NONE" is used (all uppercase), no viminfo
file is read or written, even if 'viminfo' is set or when
":rv" or ":wv" are used. See also viminfo-file .
{not in Vi}

                                                --clean
--clean   Similar to "-u DEFAULTS -U NONE -i NONE":
- initializations from files and environment variables is
  skipped
-'runtimepath'and 'packpath' are set to exclude home
  directory entries (does not happen with -u DEFAULTS).
- the defaults.vim script is loaded, which implies
  'nocompatible': use Vim defaults
- no gvimrc script is loaded
- no viminfo file is read or written
- the home directory is excluded from 'runtimepath'
                                                -x
-x   Use encryption to read/write files. Will prompt for a key,
which is then stored in the 'key' option. All writes will
then use this key to encrypt the text. The '-x' argument is
not needed when reading a file, because there is a check if
the file that is being read has been encrypted, and Vim asks
for a key automatically. encryption

                                                -X
-X   Do not try connecting to the X server to get the current
window title and copy/paste using the X clipboard. This
avoids a long startup time when running Vim in a terminal
emulator and the connection to the X server is slow.
See --startuptime to find out if affects you.
Only makes a difference on Unix or VMS, when compiled with the
 +X11 feature. Otherwise it's ignored.
To disable the connection only for specific terminals, see the

'clipboard' option.
When the X11 Session Management Protocol (XSMP) handler has been built in, the -X option also disables that connection as it, too, may have undesirable delays.
When the connection is desired later anyway (e.g., for client-server messages), call the serverlist() function. This does not enable the XSMP handler though.
{not in Vi}

-s

-s {scriptin} The script file "scriptin" is read. The characters in the file are interpreted as if you had typed them. The same can be done with the command ":source! {scriptin}". If the end of the file is reached before the editor exits, further characters are read from the keyboard. Only works when not started in Ex mode, see -s-ex . See also complex-repeat .
{not in Vi}

-w_nr

-w {number}
-w{number} Set the 'window' option to {number}.

-w

-w {scriptout} All the characters that you type are recorded in the file "scriptout", until you exit Vim. This is useful if you want to create a script file to be used with "vim -s" or ":source!". When the "scriptout" file already exists, new characters are appended. See also complex-repeat .
{scriptout} cannot start with a digit.
{not in Vi}

-W

-W {scriptout} Like -w, but do not append, overwrite an existing file.
{not in Vi}

--remote [+{cmd}] {file} ...
Open the {file} in another Vim that functions as a server.
Any non-file arguments must come before this.
See --remote . {not in Vi}

--remote-silent [+{cmd}] {file} ...
Like --remote, but don't complain if there is no server.
See --remote-silent . {not in Vi}

--remote-wait [+{cmd}] {file} ...
Like --remote, but wait for the server to finish editing the file(s).
See --remote-wait . {not in Vi}

--remote-wait-silent [+{cmd}] {file} ...
Like --remote-wait, but don't complain if there is no server.
See --remote-wait-silent . {not in Vi}

--servername {name}

Specify the name of the Vim server to send to or to become.
See --servername . {not in Vi}

--remote-send {keys}
Send {keys} to a Vim server and exit.
See --remote-send . {not in Vi}

--remote-expr {expr}
Evaluate {expr} in another Vim that functions as a server.
The result is printed on stdout.
See --remote-expr . {not in Vi}

--serverlist Output a list of Vim server names and exit. See
--serverlist . {not in Vi}

--socketid {id} --socketid
GTK+ GUI Vim only. Make gvim try to use GtkPlug mechanism, so
that it runs inside another window. See gui-gtk-socketid
for details. {not in Vi}

--windowid {id} --windowid
Win32 GUI Vim only. Make gvim try to use the window {id} as a
parent, so that it runs inside that window. See
gui-w32-windowid for details. {not in Vi}

--echo-wid --echo-wid
GTK+ GUI Vim only. Make gvim echo the Window ID on stdout,
which can be used to run gvim in a kpart widget. The format
of the output is:
WID: 12345\n
{not in Vi}

--role {role} --role
GTK+ 2 GUI only. Set the role of the main window to {role}.
The window role can be used by a window manager to uniquely
identify a window, in order to restore window placement and
such. The --role argument is passed automatically when
restoring the session on login. See gui-gnome-session
{not in Vi}

-P {parent-title} -P MDI E671 E672
Win32 only: Specify the title of the parent application. When
possible, Vim will run in an MDI window inside the
application.
{parent-title} must appear in the window title of the parent
application. Make sure that it is specific enough.
Note that the implementation is still primitive. It won't
work with all applications and the menu doesn't work.

-nb -nb
-nb={fname}
-nb:{hostname}:{addr}:{password}
Attempt connecting to Netbeans and become an editor server for
it. The second form specifies a file to read connection info

from. The third form specifies the hostname, address and
password for connecting to Netbeans. netbeans-run
{only available when compiled with the +netbeans_intg
feature; if not then -nb will make Vim exit}

If the executable is called "view", Vim will start in Readonly mode. This is useful if you can make a hard or symbolic link from "view" to "vim". Starting in Readonly mode can also be done with "vim -R".

If the executable is called "ex", Vim will start in "Ex" mode. This means it will accept only ":" commands. But when the "-v" argument is given, Vim will start in Normal mode anyway.

Additional arguments are available on unix like systems when compiled with X11 GUI support. See gui-resources .

==
2. Vim on the Amiga starting-amiga

Starting Vim from the Workbench workbench

Vim can be started from the Workbench by clicking on its icon twice. It will then start with an empty buffer.

Vim can be started to edit one or more files by using a "Project" icon. The "Default Tool" of the icon must be the full pathname of the Vim executable. The name of the ".info" file must be the same as the name of the text file. By clicking on this icon twice, Vim will be started with the file name as current file name, which will be read into the buffer (if it exists). You can edit multiple files by pressing the shift key while clicking on icons, and clicking twice on the last one. The "Default Tool" for all these icons must be the same.

It is not possible to give arguments to Vim, other than file names, from the workbench.

Vim window amiga-window

Vim will run in the CLI window where it was started. If Vim was started with the "run" or "runback" command, or if Vim was started from the workbench, it will open a window of its own.

Technical detail:
        To open the new window a little trick is used. As soon as Vim recognizes that it does not run in a normal CLI window, it will create a script file in "t:". This script file contains the same command as the one Vim was started with, and an "endcli" command. This script file is then executed with a "newcli" command (the "c:run" and "c:newcli" commands are required for this to work). The script file will hang around until reboot, or until you delete it. This method is required to get the ":sh" and ":!" commands to work correctly. But when Vim was started with the -f option (foreground

mode), this method is not used. The reason for this is that
when a program starts Vim with the -f option it will wait for Vim to
exit. With the script trick, the calling program does not know when
Vim exits. The -f option can be used when Vim is started by a mail
program which also waits for the edit session to finish. As a
consequence, the ":sh" and ":!" commands are not available when the
-f option is used.

Vim will automatically recognize the window size and react to window
resizing. Under Amiga DOS 1.3, it is advised to use the fastfonts program,
"FF", to speed up display redrawing.

==
3. Running eVim evim-keys

EVim runs Vim as click-and-type editor. This is very unlike the original Vi
idea. But it helps for people that don't use Vim often enough to learn the
commands. Hopefully they will find out that learning to use Normal mode
commands will make their editing much more effective.

In Evim these options are changed from their default value:

```
:set nocompatible       Use Vim improvements
:set insertmode         Remain in Insert mode most of the time
:set hidden             Keep invisible buffers loaded
:set backup             Keep backup files (not for VMS)
:set backspace=2        Backspace over everything
:set autoindent         auto-indent new lines
:set history=50         keep 50 lines of Ex commands
:set ruler              show the cursor position
:set incsearch          show matches halfway typing a pattern
:set mouse=a            use the mouse in all modes
:set hlsearch           highlight all matches for a search pattern
:set whichwrap+=<,>,[,]  <Left> and <Right> wrap around line breaks
:set guioptions-=a      non-Unix only: don't do auto-select
```

Key mappings:

```
<Down>          moves by screen lines rather than file lines
<Up>            idem
Q               does "gq", formatting, instead of Ex mode
<BS>            in Visual mode: deletes the selection
CTRL-X          in Visual mode: Cut to clipboard
<S-Del>         idem
CTRL-C          in Visual mode: Copy to clipboard
<C-Insert>      idem
CTRL-V          Pastes from the clipboard (in any mode)
<S-Insert>      idem
CTRL-Q          do what CTRL-V used to do
CTRL-Z          undo
CTRL-Y          redo
<M-Space>       system menu
CTRL-A          select all
<C-Tab>         next window, CTRL-W w
<C-F4>          close window, CTRL-W c
```

Additionally:
- ":behave mswin" is used :behave
- syntax highlighting is enabled
- filetype detection is enabled, filetype plugins and indenting is enabled
- in a text file 'textwidth' is set to 78

One hint: If you want to go to Normal mode to be able to type a sequence of commands, use CTRL-L. i_CTRL-L

==
4. Initialization   initialization   startup

This section is about the non-GUI version of Vim. See gui-fork for additional initialization when starting the GUI.

At startup, Vim checks environment variables and files and sets values accordingly. Vim proceeds in this order:

1. Set the 'shell' and 'term' option   SHELL   COMSPEC   TERM
        The environment variable SHELL, if it exists, is used to set the
        'shell' option. On MS-DOS and Win32, the COMSPEC variable is used
        if SHELL is not set.
        The environment variable TERM, if it exists, is used to set the 'term'
        option. However, 'term' will change later when starting the GUI (step
        8 below).

2. Process the arguments
        The options and file names from the command that start Vim are
        inspected. Buffers are created for all files (but not loaded yet).
        The -V argument can be used to display or log what happens next,
        useful for debugging the initializations.

3. Execute Ex commands, from environment variables and/or files
        An environment variable is read as one Ex command line, where multiple
        commands must be separated with '|' or "<NL>".
                                                                  vimrc   exrc
        A file that contains initialization commands is called a "vimrc" file.
        Each line in a vimrc file is executed as an Ex command line. It is
        sometimes also referred to as "exrc" file. They are the same type of
        file, but "exrc" is what Vi always used, "vimrc" is a Vim specific
        name. Also see vimrc-intro .

        Places for your personal initializations:
                Unix $HOME/.vimrc or $HOME/.vim/vimrc
                OS/2 $HOME/.vimrc, $HOME/vimfiles/vimrc
                                or $VIM/.vimrc (or _vimrc)
                MS-Windows $HOME/_vimrc, $HOME/vimfiles/vimrc
                                or $VIM/_vimrc
                Amiga   s:.vimrc, home:.vimrc, home:vimfiles:vimrc
                                or $VIM/.vimrc

        The files are searched in the order specified above and only the first
        one that is found is read.

RECOMMENDATION: Put all your Vim configuration stuff in the
$HOME/.vim/ directory ($HOME/vimfiles/ for MS-Windows). That makes it
easy to copy it to another system.

If Vim was started with "-u filename", the file "filename" is used.
All following initializations until 4. are skipped. $MYVIMRC is not
set.
"vim -u NORC" can be used to skip these initializations without
reading a file. "vim -u NONE" also skips loading plugins. -u

If Vim was started in Ex mode with the "-s" argument, all following
initializations until 4. are skipped. Only the "-u" option is
interpreted.

evim.vim

a. If vim was started as evim or eview or with the -y argument, the
script $VIMRUNTIME/evim.vim will be loaded.

system-vimrc

b. For Unix, MS-DOS, MS-Windows, OS/2, VMS, Macintosh, RISC-OS and Amiga
the system vimrc file is read for initializations. The path of this
file is shown with the ":version" command. Mostly it's "$VIM/vimrc".
Note that this file is ALWAYS read in 'compatible' mode, since the
automatic resetting of 'compatible' is only done later. Add a ":set
nocp" command if you like.
For the Macintosh the $VIMRUNTIME/macmap.vim is read.

VIMINIT .vimrc _vimrc EXINIT .exrc _exrc $MYVIMRC

c. Five places are searched for initializations. The first that exists
is used, the others are ignored. The $MYVIMRC environment variable is
set to the file that was first found, unless $MYVIMRC was already set
and when using VIMINIT.
I The environment variable VIMINIT (see also compatible-default) (*)
The value of $VIMINIT is used as an Ex command line.
II The user vimrc file(s):
"$HOME/.vimrc" (for Unix and OS/2) (*)
"$HOME/.vim/vimrc" (for Unix and OS/2) (*)
"s:.vimrc" (for Amiga) (*)
"home:.vimrc" (for Amiga) (*)
"home:vimfiles:vimrc" (for Amiga) (*)
"$VIM/.vimrc" (for OS/2 and Amiga) (*)
"$HOME/_vimrc" (for MS-DOS and Win32) (*)
"$HOME/vimfiles/vimrc" (for MS-DOS and Win32) (*)
"$VIM/_vimrc" (for MS-DOS and Win32) (*)
Note: For Unix, OS/2 and Amiga, when ".vimrc" does not exist,
"_vimrc" is also tried, in case an MS-DOS compatible file
system is used. For MS-DOS and Win32 ".vimrc" is checked
after "_vimrc", in case long file names are used.
Note: For MS-DOS and Win32, "$HOME" is checked first. If no
"_vimrc" or ".vimrc" is found there, "$VIM" is tried.
See $VIM for when $VIM is not set.
III The environment variable EXINIT.
The value of $EXINIT is used as an Ex command line.
IV The user exrc file(s). Same as for the user vimrc file, but with
"vimrc" replaced by "exrc". But only one of ".exrc" and "_exrc" is

used, depending on the system. And without the (*)!
V The default vimrc file, $VIMRUNTIME/defaults.vim. This sets up options values and has "syntax on" and "filetype on" commands, which is what most new users will want. See defaults.vim .

d. If the 'exrc' option is on (which is NOT the default), the current directory is searched for three files. The first that exists is used, the others are ignored.
- The file ".vimrc" (for Unix, Amiga and OS/2) (*)
"_vimrc" (for MS-DOS and Win32) (*)
- The file "_vimrc" (for Unix, Amiga and OS/2) (*)
".vimrc" (for MS-DOS and Win32) (*)
- The file ".exrc" (for Unix, Amiga and OS/2)
"_exrc" (for MS-DOS and Win32)

(*) Using this file or environment variable will cause 'compatible' to be off by default. See compatible-default .

Note: When using the mzscheme interface, it is initialized after loading the vimrc file. Changing 'mzschemedll' later has no effect.

4. Load the plugin scripts. load-plugins
This does the same as the command:
:runtime! plugin/**/*.vim
The result is that all directories in the 'runtimepath' option will be searched for the "plugin" sub-directory and all files ending in ".vim" will be sourced (in alphabetical order per directory), also in subdirectories.
However, directories in 'runtimepath' ending in "after" are skipped here and only loaded after packages, see below.
Loading plugins won't be done when:
- The 'loadplugins' option was reset in a vimrc file.
- The --noplugin command line argument is used.
- The --clean command line argument is used.
- The "-u NONE" command line argument is used -u .
- When Vim was compiled without the +eval feature.
Note that using "-c 'set noloadplugins'" doesn't work, because the commands from the command line have not been executed yet. You can use "--cmd 'set noloadplugins'" or "--cmd 'set loadplugins'" --cmd .

Packages are loaded. These are plugins, as above, but found in the "start" directory of each entry in 'packpath'. Every plugin directory found is added in 'runtimepath' and then the plugins are sourced. See packages .

The plugins scripts are loaded, as above, but now only the directories ending in "after" are used. Note that 'runtimepath' will have changed if packages have been found, but that should not add a directory ending in "after".

5. Set 'shellpipe' and 'shellredir'
The 'shellpipe' and 'shellredir' options are set according to the value of the 'shell' option, unless they have been set before.
This means that Vim will figure out the values of 'shellpipe' and

'shellredir' for you, unless you have set them yourself.

6. Set 'updatecount' to zero, if "-n" command argument used

7. Set binary options
   If the "-b" flag was given to Vim, the options for binary editing will
   be set now. See -b .

8. Perform GUI initializations
   Only when starting "gvim", the GUI initializations will be done. See
    gui-init .

9. Read the viminfo file
   If the 'viminfo' option is not empty, the viminfo file is read. See
    viminfo-file .

10. Read the quickfix file
   If the "-q" flag was given to Vim, the quickfix file is read. If this
   fails, Vim exits.

11. Open all windows
   When the -o flag was given, windows will be opened (but not
   displayed yet).
   When the -p flag was given, tab pages will be created (but not
   displayed yet).
   When switching screens, it happens now. Redrawing starts.
   If the "-q" flag was given to Vim, the first error is jumped to.
   Buffers for all windows will be loaded.

12. Execute startup commands
   If a "-t" flag was given to Vim, the tag is jumped to.
   The commands given with the -c and +cmd arguments are executed.
   If the 'insertmode' option is set, Insert mode is entered.
   The starting flag is reset, has("vim_starting") will now return zero.
   The v:vim_did_enter variable is set to 1.
   The VimEnter autocommands are executed.

The $MYVIMRC or $MYGVIMRC file will be set to the first found vimrc and/or
gvimrc file.

Some hints on using initializations

Standard setup:
Create a vimrc file to set the default settings and mappings for all your edit
sessions. Put it in a place so that it will be found by 3b:
```
   ~/.vimrc        (Unix and OS/2)
   s:.vimrc        (Amiga)
   $VIM\_vimrc     (MS-DOS and Win32)
```
Note that creating a vimrc file will cause the 'compatible' option to be off
by default. See compatible-default .

Local setup:
Put all commands that you need for editing a specific directory only into a

vimrc file and place it in that directory under the name ".vimrc" ("_vimrc" for MS-DOS and Win32). NOTE: To make Vim look for these special files you have to turn on the option 'exrc'. See trojan-horse too.

System setup:
This only applies if you are managing a Unix system with several users and want to set the defaults for all users. Create a vimrc file with commands for default settings and mappings and put it in the place that is given with the ":version" command.

Saving the current state of Vim to a file

Whenever you have changed values of options or when you have created a mapping, then you may want to save them in a vimrc file for later use. See save-settings about saving the current state of settings to a file.

Avoiding setup problems for Vi users

Vi uses the variable EXINIT and the file "~/.exrc". So if you do not want to interfere with Vi, then use the variable VIMINIT and the file "vimrc" instead.

Amiga environment variables

On the Amiga, two types of environment variables exist. The ones set with the DOS 1.3 (or later) setenv command are recognized. See the AmigaDos 1.3 manual. The environment variables set with the old Manx Set command (before version 5.0) are not recognized.

MS-DOS line separators

On MS-DOS-like systems (MS-DOS itself, Win32, and OS/2), Vim assumes that all the vimrc files have <CR> <NL> pairs as line separators. This will give problems if you have a file with only <NL>s and have a line like ":map xx yy^M". The trailing ^M will be ignored.

Vi compatible default value

compatible-default

When Vim starts, the 'compatible' option is on. This will be used when Vim starts its initializations. But as soon as:
- a user vimrc file is found, or
- a vimrc file in the current directory is found, or
- the "VIMINIT" environment variable is set, or
- the "-N" command line argument is given, or
- the "--clean" command line argument is given, or
- the defaults.vim script is loaded, or
- a gvimrc file was found,

then the option will be set to 'nocompatible'.

Note that this does NOT happen when a system-wide vimrc file was found.

This has the side effect of setting or resetting other options (see 'compatible'). But only the options that have not been set or reset will be changed. This has the same effect like the value of 'compatible' had this value when starting Vim.

'compatible' is NOT reset, and defaults.vim is not loaded:
- when Vim was started with the -u command line argument, especially with "-u NONE", or
- when started with the -C command line argument, or
- when the name of the executable ends in "ex". (This has been done to make Vim behave like "ex", when it is started as "ex")

But there is a side effect of setting or resetting 'compatible' at the moment a .vimrc file is found: Mappings are interpreted the moment they are encountered. This makes a difference when using things like "<CR>". If the mappings depend on a certain value of 'compatible', set or reset it before giving the mapping.

Defaults without a .vimrc file

defaults.vim

If Vim is started normally and no user vimrc file is found, the $VIMRUNTIME/defaults.vim script is loaded. This will set 'compatible' off, switch on syntax highlighting and a few more things. See the script for details. NOTE: this is done since Vim 8.0, not in Vim 7.4. (it was added in patch 7.4.2111 to be exact).

This should work well for new Vim users. If you create your own .vimrc, it is recommended to add these lines somewhere near the top:

```
unlet! skip_defaults_vim
source $VIMRUNTIME/defaults.vim
```

Then Vim works like before you had a .vimrc. Copying $VIMRUNTIME/vimrc_example is way to do this. Alternatively, you can copy defaults.vim to your .vimrc and modify it (but then you won't get updates when it changes).

If you don't like some of the defaults, you can still source defaults.vim and revert individual settings. See the defaults.vim file for hints on how to revert each item.

skip_defaults_vim

If you use a system-wide vimrc and don't want defaults.vim to change settings, set the "skip_defaults_vim" variable. If this was set and you want to load defaults.vim from your .vimrc, first unlet skip_defaults_vim, as in the example above.

Avoiding trojan horses

trojan-horse

While reading the "vimrc" or the "exrc" file in the current directory, some commands can be disabled for security reasons by setting the 'secure' option. This is always done when executing the command from a tags file. Otherwise it would be possible that you accidentally use a vimrc or tags file that somebody else created and contains nasty commands. The disabled commands are the ones that start a shell, the ones that write to a file, and ":autocmd". The ":map"

commands are echoed, so you can see which keys are being mapped.
	If you want Vim to execute all commands in a local vimrc file, you can reset the 'secure' option in the EXINIT or VIMINIT environment variable or in the global "exrc" or "vimrc" file. This is not possible in "vimrc" or "exrc" in the current directory, for obvious reasons.
	On Unix systems, this only happens if you are not the owner of the vimrc file. Warning: If you unpack an archive that contains a vimrc or exrc file, it will be owned by you. You won't have the security protection. Check the vimrc file before you start Vim in that directory, or reset the 'exrc' option. Some Unix systems allow a user to do "chown" on a file. This makes it possible for another user to create a nasty vimrc and make you the owner. Be careful!
	When using tag search commands, executing the search command (the last part of the line in the tags file) is always done in secure mode. This works just like executing a command from a vimrc/exrc in the current directory.

If Vim startup is slow

slow-start

If Vim takes a long time to start up, use the --startuptime argument to find out what happens. There are a few common causes:
- If the Unix version was compiled with the GUI and/or X11 (check the output of ":version" for "+GUI" and "+X11"), it may need to load shared libraries and connect to the X11 server. Try compiling a version with GUI and X11 disabled. This also should make the executable smaller.
  Use the -X command line argument to avoid connecting to the X server when running in a terminal.
- If you have "viminfo" enabled, the loading of the viminfo file may take a while. You can find out if this is the problem by disabling viminfo for a moment (use the Vim argument "-i NONE", -i). Try reducing the number of lines stored in a register with ":set viminfo='20,<50,s10". viminfo-file .

Intro message

:intro

When Vim starts without a file name, an introductory message is displayed (for those who don't know what Vim is). It is removed as soon as the display is redrawn in any way. To see the message again, use the ":intro" command (if there is not enough room, you will see only part of it).
	To avoid the intro message on startup, add the 'I' flag to 'shortmess'.

info-message

The --help and --version arguments cause Vim to print a message and then exit. Normally the message is sent to stdout, thus can be redirected to a file with:

```
vim --help >file
```

From inside Vim:

```
:read !vim --help
```

When using gvim, it detects that it might have been started from the desktop, without a terminal to show messages on. This is detected when both stdout and

stderr are not a tty. This breaks the ":read" command, as used in the example above. To make it work again, set 'shellredir' to ">" instead of the default ">&":

```
:set shellredir=>
:read !gvim --help
```

This still won't work for systems where gvim does not use stdout at all though.

==
5. $VIM and $VIMRUNTIME

$VIM

The environment variable "$VIM" is used to locate various user files for Vim, such as the user startup script ".vimrc". This depends on the system, see startup .

To avoid the need for every user to set the $VIM environment variable, Vim will try to get the value for $VIM in this order:
1. The value defined by the $VIM environment variable. You can use this to make Vim look in a specific directory for its support files. Example:
```
setenv VIM /home/paul/vim
```
2. The path from 'helpfile' is used, unless it contains some environment variable too (the default is "$VIMRUNTIME/doc/help.txt": chicken-egg problem). The file name ("help.txt" or any other) is removed. Then trailing directory names are removed, in this order: "doc", "runtime" and "vim{version}" (e.g., "vim54").
3. For MSDOS, Win32 and OS/2 Vim tries to use the directory name of the executable. If it ends in "/src", this is removed. This is useful if you unpacked the .zip file in some directory, and adjusted the search path to find the vim executable. Trailing directory names are removed, in this order: "runtime" and "vim{version}" (e.g., "vim54").
4. For Unix the compile-time defined installation directory is used (see the output of ":version").

Once Vim has done this once, it will set the $VIM environment variable. To change it later, use a ":let" command like this:
```
:let $VIM = "/home/paul/vim/"
```

$VIMRUNTIME

The environment variable "$VIMRUNTIME" is used to locate various support files, such as the on-line documentation and files used for syntax highlighting. For example, the main help file is normally "$VIMRUNTIME/doc/help.txt".
You don't normally set $VIMRUNTIME yourself, but let Vim figure it out. This is the order used to find the value of $VIMRUNTIME:
1. If the environment variable $VIMRUNTIME is set, it is used. You can use this when the runtime files are in an unusual location.
2. If "$VIM/vim{version}" exists, it is used. {version} is the version number of Vim, without any '-' or '.'. For example: "$VIM/vim54". This is the normal value for $VIMRUNTIME.
3. If "$VIM/runtime" exists, it is used.
4. The value of $VIM is used. This is for backwards compatibility with older versions.

5. When the 'helpfile' option is set and doesn't contain a '$', its value is
   used, with "doc/help.txt" removed from the end.

For Unix, when there is a compiled-in default for $VIMRUNTIME (check the
output of ":version"), steps 2, 3 and 4 are skipped, and the compiled-in
default is used after step 5. This means that the compiled-in default
overrules the value of $VIM. This is useful if $VIM is "/etc" and the runtime
files are in "/usr/share/vim/vim54".

Once Vim has done this once, it will set the $VIMRUNTIME environment variable.
To change it later, use a ":let" command like this:

```
:let $VIMRUNTIME = "/home/piet/vim/vim54"
```

In case you need the value of $VIMRUNTIME in a shell (e.g., for a script that
greps in the help files) you might be able to use this:

```
VIMRUNTIME=`vim -e -T dumb --cmd 'exe "set t_cm=\<C-M>"|echo $VIMRUNTIME|quit' | t
```

==
6. Suspending   suspend

                                        iconize iconise CTRL-Z v_CTRL-Z
CTRL-Z   Suspend Vim, like ":stop".
                        Works in Normal and in Visual mode. In Insert and
                        Command-line mode, the CTRL-Z is inserted as a normal
                        character. In Visual mode Vim goes back to Normal
                        mode.
                        Note: if CTRL-Z undoes a change see mswin.vim .

:sus[pend][!]   or   :sus :suspend :st :stop
:st[op][!]   Suspend Vim.
                        If the '!' is not given and 'autowrite' is set, every
                        buffer with changes and a file name is written out.
                        If the '!' is given or 'autowrite' is not set, changed
                        buffers are not written, don't forget to bring Vim
                        back to the foreground later!

In the GUI, suspending is implemented as iconising gvim. In Windows 95/NT,
gvim is minimized.

On many Unix systems, it is possible to suspend Vim with CTRL-Z. This is only
possible in Normal and Visual mode (see next chapter, vim-modes). Vim will
continue if you make it the foreground job again. On other systems, CTRL-Z
will start a new shell. This is the same as the ":sh" command. Vim will
continue if you exit from the shell.

In X-windows the selection is disowned when Vim suspends. this means you
can't paste it in another application (since Vim is going to sleep an attempt
to get the selection would make the program hang).

==
7. Exiting   exiting

There are several ways to exit Vim:
- Close the last window with `:quit`. Only when there are no changes.
- Close the last window with `:quit!`. Also when there are changes.
- Close all windows with `:qall`. Only when there are no changes.
- Close all windows with `:qall!`. Also when there are changes.
- Use `:cquit`. Also when there are changes.

When using `:cquit` or when there was an error message Vim exits with exit code 1. Errors can be avoided by using `:silent!` or with `:catch`.

==
8. Saving settings   save-settings

Mostly you will edit your vimrc files manually. This gives you the greatest flexibility. There are a few commands to generate a vimrc file automatically. You can use these files as they are, or copy/paste lines to include in another vimrc file.

                                                          :mk :mkexrc
:mk[exrc] [file]   Write current key mappings and changed options to [file] (default ".exrc" in the current directory), unless it already exists. {not in Vi}

:mk[exrc]! [file]   Always write current key mappings and changed options to [file] (default ".exrc" in the current directory). {not in Vi}

                                                          :mkv :mkvimrc
:mkv[imrc][!] [file]   Like ":mkexrc", but the default is ".vimrc" in the current directory. The ":version" command is also written to the file. {not in Vi}

These commands will write ":map" and ":set" commands to a file, in such a way that when these commands are executed, the current key mappings and options will be set to the same values. The options 'columns', 'endofline', 'fileformat', 'key', 'lines', 'modified', 'scroll', 'term', 'textmode', 'ttyfast' and 'ttymouse' are not included, because these are terminal or file dependent. Note that the options 'binary', 'paste' and 'readonly' are included, this might not always be what you want.

When special keys are used in mappings, The 'cpoptions' option will be temporarily set to its Vim default, to avoid the mappings to be misinterpreted. This makes the file incompatible with Vi, but makes sure it can be used with different terminals.

Only global mappings are stored, not mappings local to a buffer.

A common method is to use a default ".vimrc" file, make some modifications with ":map" and ":set" commands and write the modified file. First read the default ".vimrc" in with a command like ":source ~piet/.vimrc.Cprogs", change the settings and then save them in the current directory with ":mkvimrc!". If you want to make this file your default .vimrc, move it to your home directory (on Unix), s: (Amiga) or $VIM directory (MS-DOS). You could also use autocommands autocommand and/or modelines modeline .

vimrc-option-example
If you only want to add a single option setting to your vimrc, you can use these steps:
1. Edit your vimrc file with Vim.
2. Play with the option until it's right. E.g., try out different values for 'guifont'.
3. Append a line to set the value of the option, using the expression register '=' to enter the value. E.g., for the 'guifont' option:
   o:set guifont=<C-R>=&guifont<CR><Esc>
  [<C-R> is a CTRL-R, <CR> is a return, <Esc> is the escape key]
   You need to escape special characters, esp. spaces.

Note that when you create a .vimrc file, this can influence the 'compatible' option, which has several side effects. See 'compatible' .
":mkvimrc", ":mkexrc" and ":mksession" write the command to set or reset the 'compatible' option to the output file first, because of these side effects.

==
9. Views and Sessions views-sessions

This is introduced in sections 21.4 and 21.5 of the user manual.

View view-file
A View is a collection of settings that apply to one window. You can save a View and when you restore it later, the text is displayed in the same way. The options and mappings in this window will also be restored, so that you can continue editing like when the View was saved.

Session session-file
A Session keeps the Views for all windows, plus the global settings. You can save a Session and when you restore it later the window layout looks the same. You can use a Session to quickly switch between different projects, automatically loading the files you were last working on in that project.

Views and Sessions are a nice addition to viminfo-files, which are used to remember information for all Views and Sessions together viminfo-file .

You can quickly start editing with a previously saved View or Session with the -S argument:
        vim -S Session.vim

All this is {not in Vi} and {not available when compiled without the +mksession feature}.

:mks :mksession
:mks[ession][!] [file] Write a Vim script that restores the current editing
                       session.
                       When [!] is included an existing file is overwritten.
                       When [file] is omitted "Session.vim" is used.

The output of ":mksession" is like ":mkvimrc", but additional commands are added to the file. Which ones depends on the 'sessionoptions' option. The resulting file, when executed with a ":source" command:

1. Restores global mappings and options, if 'sessionoptions' contains
   "options". Script-local mappings will not be written.
2. Restores global variables that start with an uppercase letter and contain
   at least one lowercase letter, if 'sessionoptions' contains "globals".
3. Unloads all currently loaded buffers.
4. Restores the current directory if 'sessionoptions' contains "curdir", or
   sets the current directory to where the Session file is if 'sessionoptions'
   contains "sesdir".
5. Restores GUI Vim window position, if 'sessionoptions' contains "winpos".
6. Restores screen size, if 'sessionoptions' contains "resize".
7. Reloads the buffer list, with the last cursor positions. If
   'sessionoptions' contains "buffers" then all buffers are restored,
   including hidden and unloaded buffers. Otherwise only buffers in windows
   are restored.
8. Restores all windows with the same layout. If 'sessionoptions' contains
   "help", help windows are restored. If 'sessionoptions' contains "blank",
   windows editing a buffer without a name will be restored.
   If 'sessionoptions' contains "winsize" and no (help/blank) windows were
   left out, the window sizes are restored (relative to the screen size).
   Otherwise, the windows are just given sensible sizes.
9. Restores the Views for all the windows, as with :mkview . But
   'sessionoptions' is used instead of 'viewoptions'.
10. If a file exists with the same name as the Session file, but ending in
    "x.vim" (for eXtra), executes that as well. You can use *x.vim files to
    specify additional settings and actions associated with a given Session,
    such as creating menu items in the GUI version.

After restoring the Session, the full filename of your current Session is
available in the internal variable "v:this_session" this_session-variable .
An example mapping:
  :nmap <F2> :wa<Bar>exe "mksession! " . v:this_session<CR>:so ~/sessions/
This saves the current Session, and starts off the command to load another.

A session includes all tab pages, unless "tabpages" was removed from
'sessionoptions'. tab-page

The SessionLoadPost autocmd event is triggered after a session file is
loaded/sourced.

                                                        SessionLoad-variable
While the session file is loading the SessionLoad global variable is set to 1.
Plugins can use this to postpone some work until the SessionLoadPost event is
triggered.

                                                        :mkvie :mkview
:mkvie[w][!] [file]   Write a Vim script that restores the contents of the
                        current window.
                        When [!] is included an existing file is overwritten.
                        When [file] is omitted or is a number from 1 to 9, a
                        name is generated and 'viewdir' prepended. When the
                        last path part of 'viewdir' does not exist, this
                        directory is created. E.g., when 'viewdir' is
                        "$VIM/vimfiles/view" then "view" is created in
                        "$VIM/vimfiles".
                        An existing file is always overwritten then. Use

:loadview to load this view again.
When [file] is the name of a file ('viewdir' is not used), a command to edit the file is added to the generated file.

The output of ":mkview" contains these items:
1. The argument list used in the window. When the global argument list is used it is reset to the global list.
   The index in the argument list is also restored.
2. The file being edited in the window. If there is no file, the window is made empty.
3. Restore mappings, abbreviations and options local to the window if 'viewoptions' contains "options" or "localoptions". For the options it restores only values that are local to the current buffer and values local to the window.
   When storing the view as part of a session and "options" is in 'sessionoptions', global values for local options will be stored too.
4. Restore folds when using manual folding and 'viewoptions' contains "folds". Restore manually opened and closed folds.
5. The scroll position and the cursor position in the file. Doesn't work very well when there are closed folds.
6. The local current directory, if it is different from the global current directory and 'viewoptions' contains "curdir".

Note that Views and Sessions are not perfect:
- They don't restore everything. For example, defined functions, autocommands and ":syntax on" are not included. Things like register contents and command line history are in viminfo, not in Sessions or Views.
- Global option values are only set when they differ from the default value. When the current value is not the default value, loading a Session will not set it back to the default value. Local options will be set back to the default value though.
- Existing mappings will be overwritten without warning. An existing mapping may cause an error for ambiguity.
- When storing manual folds and when storing manually opened/closed folds, changes in the file between saving and loading the view will mess it up.
- The Vim script is not very efficient. But still faster than typing the commands yourself!

:lo :loadview
:lo[adview] [nr] Load the view for the current file. When [nr] is omitted, the view stored with ":mkview" is loaded.
When [nr] is specified, the view stored with ":mkview [nr]" is loaded.

The combination of ":mkview" and ":loadview" can be used to store up to ten different views of a file. These are remembered in the directory specified with the 'viewdir' option. The views are stored using the file name. If a file is renamed or accessed through a (symbolic) link the view will not be found.

You might want to clean up your 'viewdir' directory now and then.

To automatically save and restore views for *.c files:

```
	au BufWinLeave *.c mkview
	au BufWinEnter *.c silent loadview
```

==========

10. The viminfo file

viminfo viminfo-file E136 E575 E576 E577

If you exit Vim and later start it again, you would normally lose a lot of information. The viminfo file can be used to remember that information, which enables you to continue where you left off.

This is introduced in section 21.3 of the user manual.

The viminfo file is used to store:
- The command line history.
- The search string history.
- The input-line history.
- Contents of non-empty registers.
- Marks for several files.
- File marks, pointing to locations in files.
- Last search/substitute pattern (for 'n' and '&').
- The buffer list.
- Global variables.

The viminfo file is not supported when the +viminfo feature has been disabled at compile time.

You could also use a Session file. The difference is that the viminfo file does not depend on what you are working on. There normally is only one viminfo file. Session files are used to save the state of a specific editing Session. You could have several Session files, one for each project you are working on. Viminfo and Session files together can be used to effectively enter Vim and directly start working in your desired setup. session-file

viminfo-read

When Vim is started and the 'viminfo' option is non-empty, the contents of the viminfo file are read and the info can be used in the appropriate places. The v:oldfiles variable is filled. The marks are not read in at startup (but file marks are). See initialization for how to set the 'viminfo' option upon startup.

viminfo-write

When Vim exits and 'viminfo' is non-empty, the info is stored in the viminfo file (it's actually merged with the existing one, if one exists). The 'viminfo' option is a string containing information about what info should be stored, and contains limits on how much should be stored (see 'viminfo').

Merging happens in two ways. Most items that have been changed or set in the current Vim session are stored, and what was not changed is filled from what is currently in the viminfo file. For example:
- Vim session A reads the viminfo, which contains variable START.
- Vim session B does the same
- Vim session A sets the variables AAA and BOTH and exits
- Vim session B sets the variables BBB and BOTH and exits

Now the viminfo will have:

```
   START - it was in the viminfo and wasn't changed in session A or B
   AAA   - value from session A, session B kept it
   BBB   - value from session B
   BOTH  - value from session B, value from session A is lost
```

viminfo-timestamp

For some items a timestamp is used to keep the last changed version. Here it doesn't matter in which sequence Vim sessions exit, the newest item(s) are always kept. This is used for:
- The command line history.
- The search string history.
- The input-line history.
- Contents of non-empty registers.
- The jump list
- File marks

The timestamp feature was added before Vim 8.0. Older versions of Vim, starting with 7.4.1131, will keep the items with timestamp, but not use them. Thus when using both an older and a newer version of Vim the most recent data will be kept.

Notes for Unix:
- The file protection for the viminfo file will be set to prevent other users from being able to read it, because it may contain any text or commands that you have worked with.
- If you want to share the viminfo file with other users (e.g. when you "su" to another user), you can make the file writable for the group or everybody. Vim will preserve this when replacing the viminfo file. Be careful, don't allow just anybody to read and write your viminfo file!
- Vim will not overwrite a viminfo file that is not writable by the current "real" user. This helps for when you did "su" to become root, but your $HOME is still set to a normal user's home directory. Otherwise Vim would create a viminfo file owned by root that nobody else can read.
- The viminfo file cannot be a symbolic link. This is to avoid security issues.

Marks are stored for each file separately. When a file is read and 'viminfo' is non-empty, the marks for that file are read from the viminfo file. NOTE: The marks are only written when exiting Vim, which is fine because marks are remembered for all the files you have opened in the current editing session, unless ":bdel" is used. If you want to save the marks for a file that you are about to abandon with ":bdel", use ":wv". The '[' and ']' marks are not stored, but the '"' mark is. The '"' mark is very useful for jumping to the cursor position when the file was last exited. No marks are saved for files that start with any string given with the "r" flag in 'viminfo'. This can be used to avoid saving marks for files on removable media (for MS-DOS you would use "ra:,rb:", for Amiga "rdf0:,rdf1:,rdf2:").
The v:oldfiles variable is filled with the file names that the viminfo file has marks for.

viminfo-file-marks

Uppercase marks ('A to 'Z) are stored when writing the viminfo file. The numbered marks ('0 to '9) are a bit special. When the viminfo file is written (when exiting or with the ":wviminfo" command), '0 is set to the current cursor position and file. The old '0 is moved to '1, '1 to '2, etc. This

resembles what happens with the "1 to "9 delete registers. If the current cursor position is already present in '0 to '9, it is moved to '0, to avoid having the same position twice. The result is that with "'0", you can jump back to the file and line where you exited Vim. To do that right away, try using this command:

```
vim -c "normal '0"
```

In a csh compatible shell you could make an alias for it:

```
alias lvim vim -c '"'normal "'"0'"'
```

For a bash-like shell:

```
alias lvim='vim -c "normal '\''0"'
```

Use the "r" flag in 'viminfo' to specify for which files no marks should be remembered.

VIMINFO FILE NAME viminfo-file-name

- The default name of the viminfo file is "$HOME/.viminfo" for Unix and OS/2, "s:.viminfo" for Amiga, "$HOME_viminfo" for MS-DOS and Win32. For the last two, when $HOME is not set, "$VIM_viminfo" is used. When $VIM is also not set, "c:_viminfo" is used. For OS/2 "$VIM/.viminfo" is used when $HOME is not set and $VIM is set.
- The 'n' flag in the 'viminfo' option can be used to specify another viminfo file name 'viminfo' .
- The "-i" Vim argument can be used to set another file name, -i . When the file name given is "NONE" (all uppercase), no viminfo file is ever read or written. Also not for the commands below!
- The 'viminfofile' option can be used like the "-i" argument. In fact, the value form the "-i" argument is stored in the 'viminfofile' option.
- For the commands below, another file name can be given, overriding the default and the name given with 'viminfo' or "-i" (unless it's NONE).

CHARACTER ENCODING viminfo-encoding

The text in the viminfo file is encoded as specified with the 'encoding' option. Normally you will always work with the same 'encoding' value, and this works just fine. However, if you read the viminfo file with another value for 'encoding' than what it was written with, some of the text (non-ASCII characters) may be invalid. If this is unacceptable, add the 'c' flag to the 'viminfo' option:

```
:set viminfo+=c
```

Vim will then attempt to convert the text in the viminfo file from the 'encoding' value it was written with to the current 'encoding' value. This requires Vim to be compiled with the +iconv feature. Filenames are not converted.

MANUALLY READING AND WRITING viminfo-read-write

Two commands can be used to read and write the viminfo file manually. This can be used to exchange registers between two running Vim programs: First type ":wv" in one and then ":rv" in the other. Note that if the register already contained something, then ":rv!" would be required. Also note however that this means everything will be overwritten with information from the first Vim, including the command line history, etc.

The viminfo file itself can be edited by hand too, although we suggest you start with an existing one to get the format right. It is reasonably self-explanatory once you're in there. This can be useful in order to create a second file, say "~/.my_viminfo" which could contain certain settings that you always want when you first start Vim. For example, you can preload registers with particular data, or put certain commands in the command line history. A line in your .vimrc file like

```
:rviminfo! ~/.my_viminfo
```

can be used to load this information. You could even have different viminfos for different types of files (e.g., C code) and load them based on the file name, using the ":autocmd" command (see :autocmd).

viminfo-errors

When Vim detects an error while reading a viminfo file, it will not overwrite that file. If there are more than 10 errors, Vim stops reading the viminfo file. This was done to avoid accidentally destroying a file when the file name of the viminfo file is wrong. This could happen when accidentally typing "vim -i file" when you wanted "vim -R file" (yes, somebody accidentally did that!). If you want to overwrite a viminfo file with an error in it, you will either have to fix the error, or delete the file (while Vim is running, so most of the information will be restored).

:rv :rviminfo E195

:rv[iminfo][!] [file] Read from viminfo file [file] (default: see above). If [!] is given, then any information that is already set (registers, marks, v:oldfiles , etc.) will be overwritten {not in Vi}

:wv :wviminfo E137 E138 E574 E886 E929

:wv[iminfo][!] [file] Write to viminfo file [file] (default: see above). The information in the file is first read in to make a merge between old and new info. When [!] is used, the old information is not read first, only the internal info is written. If 'viminfo' is empty, marks for up to 100 files will be written.
When you get error "E929: Too many viminfo temp files" check that no old temp files were left behind (e.g. ~/.viminf*) and that you can write in the directory of the .viminfo file.
{not in Vi}

:ol :oldfiles

:ol[dfiles] List the files that have marks stored in the viminfo file. This list is read on startup and only changes afterwards with `:rviminfo!`. Also see v:oldfiles . The number can be used with c_#< .

The output can be filtered with :filter , e.g.:
filter /\.vim/ oldfiles
The filtering happens on the file name.
{not in Vi, only when compiled with the +eval feature}

:bro[wse] ol[dfiles][!]
List file names as with :oldfiles , and then prompt for a number. When the number is valid that file from the list is edited.
If you get the press-enter prompt you can press "q" and still get the prompt to enter a file number.
Use ! to abandon a modified buffer. abandon
{not when compiled with tiny or small features}

editing.txt For Vim version 8.1. Last change: 2018 Mar 29

VIM REFERENCE MANUAL by Bram Moolenaar

Editing files edit-files

==========

1. Introduction edit-intro

Editing a file with Vim means:

1. reading the file into a buffer
2. changing the buffer with editor commands
3. writing the buffer into a file

current-file

As long as you don't write the buffer, the original file remains unchanged.
If you start editing a file (read a file into the buffer), the file name is
remembered as the "current file name". This is also known as the name of the
current buffer. It can be used with "%" on the command line :_% .

alternate-file

If there already was a current file name, then that one becomes the alternate
file name. It can be used with "#" on the command line :_# and you can use
the CTRL-^ command to toggle between the current and the alternate file.
However, the alternate file name is not changed when :keepalt is used.
An alternate file name is remembered for each window.

:keepalt :keepa

:keepalt {cmd} Execute {cmd} while keeping the current alternate file
name. Note that commands invoked indirectly (e.g.,
with a function) may still set the alternate file
name. {not in Vi}

All file names are remembered in the buffer list. When you enter a file name,
for editing (e.g., with ":e filename") or writing (e.g., with ":w filename"),
the file name is added to the list. You can use the buffer list to remember
which files you edited and to quickly switch from one file to another (e.g.,
to copy text) with the CTRL-^ command. First type the number of the file
and then hit CTRL-^. {Vi: only one alternate file name is remembered}

CTRL-G or CTRL-G :f :fi :file

:f[ile] Prints the current file name (as typed, unless ":cd" was used), the cursor position (unless the 'ruler' option is set), and the file status (readonly, modified, read errors, new file). See the 'shortmess' option about how to make this message shorter. {Vi does not include column number}

:f[ile]! like :file , but don't truncate the name even when 'shortmess' indicates this.

{count}CTRL-G Like CTRL-G, but prints the current file name with full path. If the count is higher than 1 the current buffer number is also given. {not in Vi}

g_CTRL-G word-count byte-count

g CTRL-G Prints the current position of the cursor in five ways: Column, Line, Word, Character and Byte. If the number of Characters and Bytes is the same then the Character position is omitted.
If there are characters in the line that take more than one position on the screen (<Tab> or special character), both the "real" column and the screen column are shown, separated with a dash.
Also see the 'ruler' option and the wordcount() function.
{not in Vi}

v_g_CTRL-G

{Visual}g CTRL-G Similar to "g CTRL-G", but Word, Character, Line, and Byte counts for the visually selected region are displayed.
In Blockwise mode, Column count is also shown. (For {Visual} see Visual-mode .)
{not in VI}

:file_f

:f[ile][!] {name} Sets the current file name to {name}. The optional ! avoids truncating the message, as with :file .
If the buffer did have a name, that name becomes the alternate-file name. An unlisted buffer is created to hold the old name.

:0file

:0f[ile][!] Remove the name of the current buffer. The optional ! avoids truncating the message, as with :file . {not in Vi}

:buffers
:files
:ls List all the currently known file names. See 'windows.txt' :files :buffers :ls . {not in Vi}

Vim will remember the full path name of a file name that you enter. In most cases when the file name is displayed only the name you typed is shown, but the full path name is being used if you used the ":cd" command :cd .

home-replace
If the environment variable $HOME is set, and the file name starts with that string, it is often displayed with HOME replaced with "~". This was done to keep file names short. When reading or writing files the full name is still used, the "~" is only used when displaying file names. When replacing the file name would result in just "~", "~/" is used instead (to avoid confusion between options set to $HOME with 'backupext' set to "~").

When writing the buffer, the default is to use the current file name. Thus when you give the "ZZ" or ":wq" command, the original file will be overwritten. If you do not want this, the buffer can be written into another file by giving a file name argument to the ":write" command. For example:

```
vim testfile
[change the buffer with editor commands]
:w newfile
:q
```

This will create a file "newfile", that is a modified copy of "testfile". The file "testfile" will remain unchanged. Anyway, if the 'backup' option is set, Vim renames or copies the original file before it will be overwritten. You can use this file if you discover that you need the original file. See also the 'patchmode' option. The name of the backup file is normally the same as the original file with 'backupext' appended. The default "~" is a bit strange to avoid accidentally overwriting existing files. If you prefer ".bak" change the 'backupext' option. Extra dots are replaced with '_' on MS-DOS machines, when Vim has detected that an MS-DOS-like filesystem is being used (e.g., messydos or crossdos) or when the 'shortname' option is on. The backup file can be placed in another directory by setting 'backupdir'.

auto-shortname
Technical: On the Amiga you can use 30 characters for a file name. But on an MS-DOS-compatible filesystem only 8 plus 3 characters are available. Vim tries to detect the type of filesystem when it is creating the .swp file. If an MS-DOS-like filesystem is suspected, a flag is set that has the same effect as setting the 'shortname' option. This flag will be reset as soon as you start editing a new file. The flag will be used when making the file name for the ".swp" and ".~" files for the current file. But when you are editing a file in a normal filesystem and write to an MS-DOS-like filesystem the flag will not have been set. In that case the creation of the ".~" file may fail and you will get an error message. Use the 'shortname' option in this case.

When you started editing without giving a file name, "No File" is displayed in messages. If the ":write" command is used with a file name argument, the file name for the current file is set to that file name. This only happens when the 'F' flag is included in 'cpoptions' (by default it is included) cpo-F . This is useful when entering text in an empty buffer and then writing it to a

file. If 'cpoptions' contains the 'f' flag (by default it is NOT included)
 cpo-f the file name is set for the ":read file" command. This is useful
when starting Vim without an argument and then doing ":read file" to start
editing a file.
When the file name was set and 'filetype' is empty the filetype detection
autocommands will be triggered.
                                                        not-edited
Because the file name was set without really starting to edit that file, you
are protected from overwriting that file. This is done by setting the
"notedited" flag. You can see if this flag is set with the CTRL-G or ":file"
command. It will include "[Not edited]" when the "notedited" flag is set.
When writing the buffer to the current file name (with ":w!"), the "notedited"
flag is reset.

                                                        abandon
Vim remembers whether you have changed the buffer. You are protected from
losing the changes you made. If you try to quit without writing, or want to
start editing another file, Vim will refuse this. In order to overrule this
protection, add a '!' to the command. The changes will then be lost. For
example: ":q" will not work if the buffer was changed, but ":q!" will. To see
whether the buffer was changed use the "CTRL-G" command. The message includes
the string "[Modified]" if the buffer has been changed, or "+" if the 'm' flag
is in 'shortmess'.

If you want to automatically save the changes without asking, switch on the
'autowriteall' option. 'autowrite' is the associated Vi-compatible option
that does not work for all commands.

If you want to keep the changed buffer without saving it, switch on the
'hidden' option. See hidden-buffer . Some commands work like this even when
'hidden' is not set, check the help for the command.

==
2. Editing a file   edit-a-file

                                                        :e :edit reload
:e[dit] [++opt] [+cmd] Edit the current file. This is useful to re-edit the
                        current file, when it has been changed outside of Vim.
                        This fails when changes have been made to the current
                        buffer and 'autowriteall' isn't set or the file can't
                        be written.
                        Also see ++opt and +cmd .
                        {Vi: no ++opt}

                                                        :edit! discard
:e[dit]! [++opt] [+cmd]
                        Edit the current file always. Discard any changes to
                        the current buffer. This is useful if you want to
                        start all over again.
                        Also see ++opt and +cmd .
                        {Vi: no ++opt}

                                                        :edit_f
:e[dit] [++opt] [+cmd] {file}

Edit {file}.
This fails when changes have been made to the current buffer, unless 'hidden' is set or 'autowriteall' is set and the file can be written.
Also see ++opt and +cmd .
{Vi: no ++opt}

:edit!_f

:e[dit]! [++opt] [+cmd] {file}
Edit {file} always. Discard any changes to the current buffer.
Also see ++opt and +cmd .
{Vi: no ++opt}

:e[dit] [++opt] [+cmd] #[count]
Edit the [count]th buffer (as shown by :files).
This command does the same as [count] CTRL-^. But ":e #" doesn't work if the alternate buffer doesn't have a file name, while CTRL-^ still works then.
Also see ++opt and +cmd .
{Vi: no ++opt}

:ene :enew

:ene[w]
Edit a new, unnamed buffer. This fails when changes have been made to the current buffer, unless 'hidden' is set or 'autowriteall' is set and the file can be written.
If 'fileformats' is not empty, the first format given will be used for the new buffer. If 'fileformats' is empty, the 'fileformat' of the current buffer is used.
{not in Vi}

:ene! :enew!

:ene[w]!
Edit a new, unnamed buffer. Discard any changes to the current buffer.
Set 'fileformat' like :enew .
{not in Vi}

:fin :find

:fin[d][!] [++opt] [+cmd] {file}
Find {file} in 'path' and then :edit it.
{not in Vi} {not available when the +file_in_path feature was disabled at compile time}

:{count}fin[d][!] [++opt] [+cmd] {file}
Just like ":find", but use the {count} match in 'path'. Thus ":2find file" will find the second "file" found in 'path'. When there are fewer matches for the file in 'path' than asked for, you get an error message.

:ex

:ex [++opt] [+cmd] [file]
Same as :edit .

:vi[sual][!] [++opt] [+cmd] [file] :vi :visual
When used in Ex mode: Leave Ex-mode , go back to Normal mode. Otherwise same as :edit .

:vie[w][!] [++opt] [+cmd] file :vie :view
When used in Ex mode: Leave Ex-mode , go back to Normal mode. Otherwise same as :edit , but set 'readonly' option for this buffer. {not in Vi}

CTRL-^ CTRL-^ CTRL-6
Edit the alternate file. Mostly the alternate file is the previously edited file. This is a quick way to toggle between two files. It is equivalent to ":e #", except that it also works when there is no file name.

If the 'autowrite' or 'autowriteall' option is on and the buffer was changed, write it.
Mostly the ^ character is positioned on the 6 key, pressing CTRL and 6 then gets you what we call CTRL-^. But on some non-US keyboards CTRL-^ is produced in another way.

{count}CTRL-^
Edit [count]th file in the buffer list (equivalent to ":e #[count]"). This is a quick way to switch between files.
See CTRL-^ above for further details.
{not in Vi}

[count]]f]f [f
[count][f
Same as "gf". Deprecated.

[count]gf gf E446 E447
Edit the file whose name is under or after the cursor. Mnemonic: "goto file".
Uses the 'isfname' option to find out which characters are supposed to be in a file name. Trailing punctuation characters ".,:;!" are ignored. Escaped spaces "\ " are reduced to a single space.
Uses the 'path' option as a list of directory names to look for the file. See the 'path' option for details about relative directories and wildcards.
Uses the 'suffixesadd' option to check for file names with a suffix added.
If the file can't be found, 'includeexpr' is used to modify the name and another attempt is done.
If a [count] is given, the count'th file that is found in the 'path' is edited.
This command fails if Vim refuses to abandon the current file.
If you want to edit the file in a new window use CTRL-W_CTRL-F .

If you do want to edit a new file, use:
		:e <cfile>
To make gf always work like that:
		:map gf :e <cfile><CR>
If the name is a hypertext link, that looks like
"type://machine/path", you need the netrw plugin.
For Unix the '~' character is expanded, like in
"~user/file". Environment variables are expanded too
expand-env .
{not in Vi}
{not available when the +file_in_path feature was
disabled at compile time}

v_gf
{Visual}[count]gf	Same as "gf", but the highlighted text is used as the
name of the file to edit. 'isfname' is ignored.
Leading blanks are skipped, otherwise all blanks and
special characters are included in the file name.
(For {Visual} see Visual-mode .)
{not in VI}

gF
[count]gF		Same as "gf", except if a number follows the file
name, then the cursor is positioned on that line in
the file. The file name and the number must be
separated by a non-filename (see 'isfname') and
non-numeric character. White space between the
filename, the separator and the number are ignored.
Examples:
		eval.c:10
		eval.c @ 20
		eval.c (30)
		eval.c 40

v_gF
{Visual}[count]gF	Same as "v_gf".

These commands are used to start editing a single file. This means that the file is read into the buffer and the current file name is set. The file that is opened depends on the current directory, see :cd .

See read-messages for an explanation of the message that is given after the file has been read.

You can use the ":e!" command if you messed up the buffer and want to start all over again. The ":e" command is only useful if you have changed the current file name.

:filename {file}
Besides the things mentioned here, more special items for where a filename is expected are mentioned at cmdline-special .

Note for systems other than Unix: When using a command that accepts a single file name (like ":edit file") spaces in the file name are allowed, but

trailing spaces are ignored. This is useful on systems that regularly embed spaces in file names (like MS-Windows and the Amiga). Example: The command ":e   Long File Name " will edit the file "Long File Name". When using a command that accepts more than one file name (like ":next file1 file2") embedded spaces must be escaped with a backslash.

                                                    wildcard   wildcards
Wildcards in {file} are expanded, but as with file completion, 'wildignore' and 'suffixes' apply. Which wildcards are supported depends on the system. These are the common ones:

```
        ?       matches one character
        *       matches anything, including nothing
        **      matches anything, including nothing, recurses into directories
        [abc]   match 'a', 'b' or 'c'
```

To avoid the special meaning of the wildcards prepend a backslash. However, on MS-Windows the backslash is a path separator and "path\[abc]" is still seen as a wildcard when "[" is in the 'isfname' option. A simple way to avoid this is to use "path\[[]abc]", this matches the file "path\[abc]".

                                                starstar-wildcard
Expanding "**" is possible on Unix, Win32, Mac OS/X and a few other systems. This allows searching a directory tree. This goes up to 100 directories deep. Note there are some commands where this works slightly differently, see file-searching .
Example:

```
        :n **/*.txt
```

Finds files:

```
        aaa.txt
        subdir/bbb.txt
        a/b/c/d/ccc.txt
```

When non-wildcard characters are used right before or after "**" these are only matched in the top directory. They are not used for directories further down in the tree. For example:

```
        :n /usr/inc**/types.h
```

Finds files:

```
        /usr/include/types.h
        /usr/include/sys/types.h
        /usr/inc/old/types.h
```

Note that the path with "/sys" is included because it does not need to match "/inc". Thus it's like matching "/usr/inc*/*/*...", not "/usr/inc*/inc*/inc*".

                                                backtick-expansion   `-expansion
On Unix and a few other systems you can also use backticks for the file name argument, for example:

```
        :next `find . -name ver\\*.c -print`
        :view `ls -t *.patch  \| head -n1`
```

Vim will run the command in backticks using the 'shell' and use the standard output as argument for the given Vim command (error messages from the shell command will be discarded).
To see what shell command Vim is running, set the 'verbose' option to 4. When the shell command returns a non-zero exit code, an error message will be displayed and the Vim command will be aborted. To avoid this make the shell

always return zero like so:
	:next `find . -name ver\\*.c -print \|\| true`

The backslashes before the star are required to prevent the shell from
expanding "ver*.c" prior to execution of the find program. The backslash
before the shell pipe symbol "|" prevents Vim from parsing it as command
termination.
This also works for most other systems, with the restriction that the
backticks must be around the whole item. It is not possible to have text
directly before the first or just after the last backtick.

`=
You can have the backticks expanded as a Vim expression, instead of as an
external command, by putting an equal sign right after the first backtick,
e.g.:
	:e `=tempname()`
The expression can contain just about anything, thus this can also be used to
avoid the special meaning of '"', '|', '%' and '#'. However, 'wildignore'
does apply like to other wildcards.

Environment variables in the expression are expanded when evaluating the
expression, thus this works:
	:e `=$HOME . '/.vimrc'`
This does not work, $HOME is inside a string and used literally:
	:e `='$HOME' . '/.vimrc'`

If the expression returns a string then names are to be separated with line
breaks. When the result is a List then each item is used as a name. Line
breaks also separate names.
Note that such expressions are only supported in places where a filename is
expected as an argument to an Ex-command.

++opt	[++opt]
The [++opt] argument can be used to force the value of 'fileformat',
'fileencoding' or 'binary' to a value for one command, and to specify the
behavior for bad characters. The form is:
	++{optname}
Or:
	++{optname}={value}

Where {optname} is one of:	++ff	++enc	++bin	++nobin	++edit
    ff   or fileformat   overrides 'fileformat'
    enc   or encoding   overrides 'fileencoding'
    bin   or binary   sets 'binary'
    nobin or nobinary   resets 'binary'
    bad   specifies behavior for bad characters
    edit   for :read only: keep option values as if editing
                            a file

{value} cannot contain white space. It can be any valid value for these
options. Examples:
	:e ++ff=unix
This edits the same file again with 'fileformat' set to "unix".

```
        :w ++enc=latin1 newfile
```
This writes the current buffer to "newfile" in latin1 format.

There may be several ++opt arguments, separated by white space. They must all appear before any +cmd argument.

++bad

The argument of "++bad=" specifies what happens with characters that can't be converted and illegal bytes. It can be one of three things:

++bad=X	A single-byte character that replaces each bad character.
++bad=keep	Keep bad characters without conversion. Note that this may result in illegal bytes in your text!
++bad=drop	Remove the bad characters.

The default is like "++bad=?": Replace each bad character with a question mark. In some places an inverted question mark is used (0xBF).

Note that not all commands use the ++bad argument, even though they do not give an error when you add it. E.g. :write .

Note that when reading, the 'fileformat' and 'fileencoding' options will be set to the used format. When writing this doesn't happen, thus a next write will use the old value of the option. Same for the 'binary' option.

+cmd [+cmd]

The [+cmd] argument can be used to position the cursor in the newly opened file, or execute any other command:

+	Start at the last line.
+{num}	Start at line {num}.
+/{pat}	Start at first line containing {pat}.
+{command}	Execute {command} after opening the new file. {command} is any Ex command.

To include a white space in the {pat} or {command}, precede it with a backslash. Double the number of backslashes.

```
        :edit  +/The\ book           file
        :edit  +/dir\ dirname\\      file
        :edit  +set\ dir=c:\\\\temp  file
```
Note that in the last example the number of backslashes is halved twice: Once for the "+cmd" argument and once for the ":set" command.

file-formats

The 'fileformat' option sets the <EOL> style for a file:

'fileformat'	characters	name	
"dos"	<CR><NL> or <NL>	DOS format	DOS-format
"unix"	<NL>	Unix format	Unix-format
"mac"	<CR>	Mac format	Mac-format

Previously 'textmode' was used. It is obsolete now.

When reading a file, the mentioned characters are interpreted as the <EOL>. In DOS format (default for MS-DOS, OS/2 and Win32), <CR><NL> and <NL> are both interpreted as the <EOL>. Note that when writing the file in DOS format, <CR> characters will be added for each single <NL>. Also see file-read .

When writing a file, the mentioned characters are used for <EOL>. For DOS format <CR><NL> is used. Also see DOS-format-write .

You can read a file in DOS format and write it in Unix format. This will replace all <CR><NL> pairs by <NL> (assuming 'fileformats' includes "dos"):

```
:e file
:set fileformat=unix
:w
```

If you read a file in Unix format and write with DOS format, all <NL> characters will be replaced with <CR><NL> (assuming 'fileformats' includes "unix"):

```
:e file
:set fileformat=dos
:w
```

If you start editing a new file and the 'fileformats' option is not empty (which is the default), Vim will try to detect whether the lines in the file are separated by the specified formats. When set to "unix,dos", Vim will check for lines with a single <NL> (as used on Unix and Amiga) or by a <CR> <NL> pair (MS-DOS). Only when ALL lines end in <CR><NL>, 'fileformat' is set to "dos", otherwise it is set to "unix". When 'fileformats' includes "mac", and no <NL> characters are found in the file, 'fileformat' is set to "mac".

If the 'fileformat' option is set to "dos" on non-MS-DOS systems the message "[dos format]" is shown to remind you that something unusual is happening. On MS-DOS systems you get the message "[unix format]" if 'fileformat' is set to "unix". On all systems but the Macintosh you get the message "[mac format]" if 'fileformat' is set to "mac".

If the 'fileformats' option is empty and DOS format is used, but while reading a file some lines did not end in <CR><NL>, "[CR missing]" will be included in the file message.
If the 'fileformats' option is empty and Mac format is used, but while reading a file a <NL> was found, "[NL missing]" will be included in the file message.

If the new file does not exist, the 'fileformat' of the current buffer is used when 'fileformats' is empty. Otherwise the first format from 'fileformats' is used for the new file.

Before editing binary, executable or Vim script files you should set the 'binary' option. A simple way to do this is by starting Vim with the "-b" option. This will avoid the use of 'fileformat'. Without this you risk that single <NL> characters are unexpectedly replaced with <CR><NL>.

You can encrypt files that are written by setting the 'key' option. This provides some security against others reading your files. encryption

==
3. The argument list   argument-list arglist

If you give more than one file name when starting Vim, this list is remembered as the argument list. You can jump to each file in this list.

Do not confuse this with the buffer list, which you can see with the :buffers command. The argument list was already present in Vi, the buffer list is new in Vim. Every file name in the argument list will also be present in the buffer list (unless it was deleted with :bdel or :bwipe). But it's common that names in the buffer list are not in the argument list.

This subject is introduced in section 07.2 of the user manual.

There is one global argument list, which is used for all windows by default. It is possible to create a new argument list local to a window, see :arglocal .

You can use the argument list with the following commands, and with the expression functions argc() and argv() . These all work on the argument list of the current window.

:ar :args

:ar[gs] Print the argument list, with the current file in square brackets.

:ar[gs] [++opt] [+cmd] {arglist} :args_f

Define {arglist} as the new argument list and edit the first one. This fails when changes have been made and Vim does not want to abandon the current buffer. Also see ++opt and +cmd . {Vi: no ++opt}

:ar[gs]! [++opt] [+cmd] {arglist} :args_f!

Define {arglist} as the new argument list and edit the first one. Discard any changes to the current buffer. Also see ++opt and +cmd . {Vi: no ++opt}

:[count]arge[dit][!] [++opt] [+cmd] {name} .. :arge :argedit

Add {name}s to the argument list and edit it. When {name} already exists in the argument list, this entry is edited. This is like using :argadd and then :edit . Spaces in filenames have to be escaped with "\". [count] is used like with :argadd . If the current file cannot be abandon ed {name}s will still be added to the argument list, but won't be edited. No check for duplicates is done. Also see ++opt and +cmd . {not in Vi}

:[count]arga[dd] {name} .. :arga :argadd E479

:[count]arga[dd]

Add the {name}s to the argument list. When {name} is omitted add the current buffer name to the argument list. If [count] is omitted, the {name}s are added just after the current entry in the argument list.

Otherwise they are added after the [count]'th file.
If the argument list is "a b c", and "b" is the
current argument, then these commands result in:

command	new argument list
:argadd x	a b x c
:0argadd x	x a b c
:1argadd x	a x b c
:$argadd x	a b c x

And after the last one:

:+2argadd y	a b c x y

There is no check for duplicates, it is possible to
add a file to the argument list twice.
The currently edited file is not changed.
{not in Vi}
Note: you can also use this method:

```
:args ## x
```

This will add the "x" item and sort the new list.

:argd[elete] {pattern} .. :argd :argdelete E480

Delete files from the argument list that match the
{pattern}s. {pattern} is used like a file pattern,
see file-pattern . "%" can be used to delete the
current entry.
This command keeps the currently edited file, also
when it's deleted from the argument list.
Example:

```
:argdel *.obj
```

{not in Vi}

:[range]argd[elete]

Delete the {range} files from the argument list.
Example:

```
:10,$argdel
```

Deletes arguments 10 and further, keeping 1-9.

```
:$argd
```

Deletes just the last one.

```
:argd
:.argd
```

Deletes the current argument.

```
:%argd
```

Removes all the files from the arglist.
When the last number in the range is too high, up to
the last argument is deleted.
{not in Vi}

:argu :argument

:[count]argu[ment] [count] [++opt] [+cmd]

Edit file [count] in the argument list. When [count]
is omitted the current entry is used. This fails
when changes have been made and Vim does not want to
 abandon the current buffer.
Also see ++opt and +cmd .
{not in Vi}

:[count]argu[ment]! [count] [++opt] [+cmd]

Edit file [count] in the argument list, discard any changes to the current buffer. When [count] is omitted the current entry is used.
Also see ++opt and +cmd .
{not in Vi}

:[count]n[ext] [++opt] [+cmd] :n :ne :next E165 E163
Edit [count] next file. This fails when changes have been made and Vim does not want to abandon the current buffer. Also see ++opt and +cmd . {Vi: no count or ++opt}.

:[count]n[ext]! [++opt] [+cmd]
Edit [count] next file, discard any changes to the buffer. Also see ++opt and +cmd . {Vi: no count or ++opt}.

:n[ext] [++opt] [+cmd] {arglist} :next_f
Same as :args_f .

:n[ext]! [++opt] [+cmd] {arglist}
Same as :args_f! .

:[count]N[ext] [count] [++opt] [+cmd] :Next :N E164
Edit [count] previous file in argument list. This fails when changes have been made and Vim does not want to abandon the current buffer.
Also see ++opt and +cmd . {Vi: no count or ++opt}.

:[count]N[ext]! [count] [++opt] [+cmd]
Edit [count] previous file in argument list. Discard any changes to the buffer. Also see ++opt and +cmd . {Vi: no count or ++opt}.

:[count]prev[ious] [count] [++opt] [+cmd] :prev :previous
Same as :Next. Also see ++opt and +cmd . {Vi: only in some versions}

:rew :rewind
:rew[ind] [++opt] [+cmd]
Start editing the first file in the argument list. This fails when changes have been made and Vim does not want to abandon the current buffer.
Also see ++opt and +cmd . {Vi: no ++opt}

:rew[ind]! [++opt] [+cmd]
Start editing the first file in the argument list. Discard any changes to the buffer. Also see ++opt and +cmd . {Vi: no ++opt}

:fir :first
:fir[st][!] [++opt] [+cmd]
Other name for ":rewind". {not in Vi}

:la[st] [++opt] [+cmd] :la :last
Start editing the last file in the argument list. This fails when changes have been made and Vim does not want to abandon the current buffer. Also see ++opt and +cmd . {not in Vi}

:la[st]! [++opt] [+cmd]
Start editing the last file in the argument list. Discard any changes to the buffer. Also see ++opt and +cmd . {not in Vi}

:[count]wn[ext] [++opt] :wn :wnext
Write current file and start editing the [count] next file. Also see ++opt and +cmd . {not in Vi}

:[count]wn[ext] [++opt] {file}
Write current file to {file} and start editing the [count] next file, unless {file} already exists and the 'writeany' option is off. Also see ++opt and +cmd . {not in Vi}

:[count]wn[ext]! [++opt] {file}
Write current file to {file} and start editing the [count] next file. Also see ++opt and +cmd . {not in Vi}

:[count]wN[ext][!] [++opt] [file] :wN :wNext
:[count]wp[revious][!] [++opt] [file] :wp :wprevious
Same as :wnext, but go to previous file instead of next. {not in Vi}

The [count] in the commands above defaults to one. For some commands it is possible to use two counts. The last one (rightmost one) is used.

If no [+cmd] argument is present, the cursor is positioned at the last known cursor position for the file. If 'startofline' is set, the cursor will be positioned at the first non-blank in the line, otherwise the last know column is used. If there is no last known cursor position the cursor will be in the first line (the last line in Ex mode).

{arglist}
The wildcards in the argument list are expanded and the file names are sorted. Thus you can use the command "vim *.c" to edit all the C files. From within Vim the command ":n *.c" does the same.

White space is used to separate file names. Put a backslash before a space or tab to include it in a file name. E.g., to edit the single file "foo bar":
```
:next foo\ bar
```

On Unix and a few other systems you can also use backticks, for example:
```
:next `find . -name \\*.c -print`
```
The backslashes before the star are required to prevent "*.c" to be expanded

by the shell before executing the find program.

arglist-position
When there is an argument list you can see which file you are editing in the title of the window (if there is one and 'title' is on) and with the file message you get with the "CTRL-G" command. You will see something like
        (file 4 of 11)
If 'shortmess' contains 'f' it will be
        (4 of 11)
If you are not really editing the file at the current position in the argument list it will be
        (file (4) of 11)
This means that you are position 4 in the argument list, but not editing the fourth file in the argument list. This happens when you do ":e file".

LOCAL ARGUMENT LIST

{not in Vi}

:arglocal
:argl[ocal] Make a local copy of the global argument list. Doesn't start editing another file.

:argl[ocal][!] [++opt] [+cmd] {arglist}
Define a new argument list, which is local to the current window. Works like :args_f otherwise.

:argglobal
:argg[lobal] Use the global argument list for the current window. Doesn't start editing another file.

:argg[lobal][!] [++opt] [+cmd] {arglist}
Use the global argument list for the current window. Define a new global argument list like :args_f . All windows using the global argument list will see this new list.

There can be several argument lists. They can be shared between windows. When they are shared, changing the argument list in one window will also change it in the other window.

When a window is split the new window inherits the argument list from the current window. The two windows then share this list, until one of them uses :arglocal or :argglobal to use another argument list.

USING THE ARGUMENT LIST

:argdo
:[range]argdo[!] {cmd} Execute {cmd} for each file in the argument list or if [range] is specified only for arguments in that range. It works like doing this:
        :rewind

```
                        :{cmd}
                        :next
                        :{cmd}
                        etc.
                    When the current file can't be  abandon ed and the [!]
                     is not present, the command fails.
                     When an error is detected on one file, further files
                     in the argument list will not be visited.
                     The last file in the argument list (or where an error
                     occurred) becomes the current file.
                     {cmd} can contain '|' to concatenate several commands.
                     {cmd} must not change the argument list.
                     Note: While this command is executing, the Syntax
                     autocommand event is disabled by adding it to
                     'eventignore'.  This considerably speeds up editing
                     each file.
                     {not in Vi}
                     Also see  :windo ,  :tabdo ,  :bufdo ,  :cdo ,  :ldo ,
                      :cfdo  and  :lfdo

Example:
        :args *.c
        :argdo set ff=unix | update
This sets the 'fileformat' option to "unix" and writes the file if it is now
changed.  This is done for all *.c files.

Example:
        :args *.[ch]
        :argdo %s/\<my_foo\>/My_Foo/ge | update
This changes the word "my_foo" to "My_Foo" in all *.c and *.h files.  The "e"
flag is used for the ":substitute" command to avoid an error for files where
"my_foo" isn't used.  ":update" writes the file only if changes were made.

==============================================================================
4. Writing                                              writing   save-file

Note: When the 'write' option is off, you are not able to write any file.

                                                          :w   :write
                                        E502   E503   E504   E505
                                        E512   E514   E667   E796   E949
:w[rite] [++opt]        Write the whole buffer to the current file.  This is
                        the normal way to save changes to a file.  It fails
                        when the 'readonly' option is set or when there is
                        another reason why the file can't be written.
                        For ++opt see  ++opt , but only ++bin, ++nobin, ++ff
                        and ++enc are effective.

:w[rite]! [++opt]       Like ":write", but forcefully write when 'readonly' is
                        set or there is another reason why writing was
                        refused.
                        Note: This may change the permission and ownership of
                        the file and break (symbolic) links.  Add the 'W' flag
                        to 'cpoptions' to avoid this.
```

:[range]w[rite][!] [++opt]
                        Write the specified lines to the current file. This
                        is unusual, because the file will not contain all
                        lines in the buffer.

                                                                :w_f   :write_f
:[range]w[rite] [++opt] {file}
                        Write the specified lines to {file}, unless it
                        already exists and the 'writeany' option is off.

                                                                :w!
:[range]w[rite]! [++opt] {file}
                        Write the specified lines to {file}. Overwrite an
                        existing file.

                                                        :w_a   :write_a   E494
:[range]w[rite][!] [++opt] >>
                        Append the specified lines to the current file.

:[range]w[rite][!] [++opt] >> {file}
                        Append the specified lines to {file}. '!' forces the
                        write even if file does not exist.

                                                                :w_c   :write_c
:[range]w[rite] [++opt] !{cmd}
                        Execute {cmd} with [range] lines as standard input
                        (note the space in front of the '!'). {cmd} is
                        executed like with ":!{cmd}", any '!' is replaced with
                        the previous command :! .

The default [range] for the ":w" command is the whole buffer (1,$). If you
write the whole buffer, it is no longer considered changed. When you
write it to a different file with ":w somefile" it depends on the "+" flag in
'cpoptions'. When included, the write command will reset the 'modified' flag,
even though the buffer itself may still be different from its file.

If a file name is given with ":w" it becomes the alternate file. This can be
used, for example, when the write fails and you want to try again later with
":w #". This can be switched off by removing the 'A' flag from the
'cpoptions' option.

Note that the 'fsync' option matters here. If it's set it may make writes
slower (but safer).

                                                                :sav   :saveas
:sav[eas][!] [++opt] {file}
                        Save the current buffer under the name {file} and set
                        the filename of the current buffer to {file}. The
                        previous name is used for the alternate file name.
                        The [!] is needed to overwrite an existing file.
                        When 'filetype' is empty filetype detection is done
                        with the new name, before the file is written.
                        When the write was successful 'readonly' is reset.

{not in Vi}

:up :update

:[range]up[date][!] [++opt] [>>] [file]
Like ":write", but only write when the buffer has been modified. {not in Vi}

WRITING WITH MULTIPLE BUFFERS buffer-write

:wa :wall

:wa[ll] Write all changed buffers. Buffers without a file name cause an error message. Buffers which are readonly are not written. {not in Vi}

:wa[ll]! Write all changed buffers, even the ones that are readonly. Buffers without a file name are not written and cause an error message. {not in Vi}

Vim will warn you if you try to overwrite a file that has been changed elsewhere. See timestamp .

backup E207 E506 E507 E508 E509 E510
If you write to an existing file (but do not append) while the 'backup', 'writebackup' or 'patchmode' option is on, a backup of the original file is made. The file is either copied or renamed (see 'backupcopy'). After the file has been successfully written and when the 'writebackup' option is on and the 'backup' option is off, the backup file is deleted. When the 'patchmode' option is on the backup file may be renamed.

backup-table

'backup'	'writebackup'	action
off	off	no backup made
off	on	backup current file, deleted afterwards (default)
on	off	delete old backup, backup current file
on	on	delete old backup, backup current file

When the 'backupskip' pattern matches with the name of the file which is written, no backup file is made. The values of 'backup' and 'writebackup' are ignored then.

When the 'backup' option is on, an old backup file (with the same name as the new backup file) will be deleted. If 'backup' is not set, but 'writebackup' is set, an existing backup file will not be deleted. The backup file that is made while the file is being written will have a different name.

On some filesystems it's possible that in a crash you lose both the backup and the newly written file (it might be there but contain bogus data). In that case try recovery, because the swap file is synced to disk and might still be there. :recover

The directories given with the 'backupdir' option are used to put the backup file in. (default: same directory as the written file).

Whether the backup is a new file, which is a copy of the original file, or the original file renamed depends on the 'backupcopy' option. See there for an explanation of when the copy is made and when the file is renamed.

If the creation of a backup file fails, the write is not done. If you want to write anyway add a '!' to the command.

write-permissions

When writing a new file the permissions are read-write. For unix the mask is 0666 with additionally umask applied. When writing a file that was read Vim will preserve the permissions, but clear the s-bit.

write-readonly

When the 'cpoptions' option contains 'W', Vim will refuse to overwrite a readonly file. When 'W' is not present, ":w!" will overwrite a readonly file, if the system allows it (the directory must be writable).

write-fail

If the writing of the new file fails, you have to be careful not to lose your changes AND the original file. If there is no backup file and writing the new file failed, you have already lost the original file! DON'T EXIT VIM UNTIL YOU WRITE OUT THE FILE! If a backup was made, it is put back in place of the original file (if possible). If you exit Vim, and lose the changes you made, the original file will mostly still be there. If putting back the original file fails, there will be an error message telling you that you lost the original file.

DOS-format-write

If the 'fileformat' is "dos", <CR> <NL> is used for <EOL>. This is default for MS-DOS, Win32 and OS/2. On other systems the message "[dos format]" is shown to remind you that an unusual <EOL> was used.

Unix-format-write

If the 'fileformat' is "unix", <NL> is used for <EOL>. On MS-DOS, Win32 and OS/2 the message "[unix format]" is shown.

Mac-format-write

If the 'fileformat' is "mac", <CR> is used for <EOL>. On non-Mac systems the message "[mac format]" is shown.

See also file-formats and the 'fileformat' and 'fileformats' options.

ACL

ACL stands for Access Control List. It is an advanced way to control access rights for a file. It is used on new MS-Windows and Unix systems, but only when the filesystem supports it.

Vim attempts to preserve the ACL info when writing a file. The backup file will get the ACL info of the original file.

The ACL info is also used to check if a file is read-only (when opening the file).

read-only-share

When MS-Windows shares a drive on the network it can be marked as read-only. This means that even if the file read-only attribute is absent, and the ACL settings on NT network shared drives allow writing to the file, you can still

not write to the file. Vim on Win32 platforms will detect read-only network drives and will mark the file as read-only. You will not be able to override it with :write .

write-device

When the file name is actually a device name, Vim will not make a backup (that would be impossible). You need to use "!", since the device already exists.
Example for Unix:
```
:w! /dev/lpt0
```
and for MS-DOS or MS-Windows:
```
:w! lpt0
```
For Unix a device is detected when the name doesn't refer to a normal file or a directory. A fifo or named pipe also looks like a device to Vim.
For MS-DOS and MS-Windows the device is detected by its name:
```
AUX
CON
CLOCK$
NUL
PRN
COMn    n=1,2,3... etc
LPTn    n=1,2,3... etc
```
The names can be in upper- or lowercase.

==========

5. Writing and quitting write-quit

:q :quit

:q[uit] Quit the current window. Quit Vim if this is the last window. This fails when changes have been made and Vim refuses to abandon the current buffer, and when the last file in the argument list has not been edited.
If there are other tab pages and quitting the last window in the current tab page the current tab page is closed tab-page .
Triggers the QuitPre autocommand event.
See CTRL-W_q for quitting another window.

:conf[irm] q[uit] Quit, but give prompt when changes have been made, or the last file in the argument list has not been edited. See :confirm and 'confirm'. {not in Vi}

:q[uit]! Quit without writing, also when the current buffer has changes. The buffer is unloaded, also when it has 'hidden' set.
If this is the last window and there is a modified hidden buffer, the current buffer is abandoned and the first changed hidden buffer becomes the current buffer.
Use ":qall!" to exit always.

:cq[uit] Quit always, without writing, and return an error code. See :cq . Used for Manx's QuickFix mode (see quickfix). {not in Vi}

:wq

:wq [++opt] Write the current file and quit. Writing fails when the file is read-only or the buffer does not have a name. Quitting fails when the last file in the argument list has not been edited.

:wq! [++opt] Write the current file and quit. Writing fails when the current buffer does not have a name.

:wq [++opt] {file} Write to {file} and quit. Quitting fails when the last file in the argument list has not been edited.

:wq! [++opt] {file} Write to {file} and quit.

:[range]wq[!] [++opt] [file]
Same as above, but only write the lines in [range].

:x :xit

:[range]x[it][!] [++opt] [file]
Like ":wq", but write only when changes have been made.
When 'hidden' is set and there are more windows, the current buffer becomes hidden, after writing the file.

:exi :exit

:[range]exi[t][!] [++opt] [file]
Same as :xit.

ZZ

ZZ Write current file, if modified, and quit (same as ":x"). (Note: If there are several windows for the current file, the file is written if it was modified and the window is closed).

ZQ

ZQ Quit without checking for changes (same as ":q!"). {not in Vi}

MULTIPLE WINDOWS AND BUFFERS window-exit

:qa :qall

:qa[ll] Exit Vim, unless there are some buffers which have been changed. (Use ":bmod" to go to the next modified buffer). When 'autowriteall' is set all changed buffers will be written, like :wqall . {not in Vi}

:conf[irm] qa[ll]
Exit Vim. Bring up a prompt when some buffers have been changed. See :confirm . {not in Vi}

:qa[ll]! Exit Vim. Any changes to buffers are lost. {not in Vi}
Also see :cquit , it does the same but exits with a non-zero value.

:quita   :quitall
:quita[ll][!]   Same as ":qall". {not in Vi}

:wqa[ll] [++opt]   :wqa   :wqall   :xa   :xall
:xa[ll] Write all changed buffers and exit Vim. If there are buffers
         without a file name, which are readonly or which cannot be
         written for another reason, Vim will not quit. {not in Vi}

:conf[irm] wqa[ll] [++opt]
:conf[irm] xa[ll]
         Write all changed buffers and exit Vim. Bring up a prompt
         when some buffers are readonly or cannot be written for
         another reason. See :confirm . {not in Vi}

:wqa[ll]! [++opt]
:xa[ll]! Write all changed buffers, even the ones that are readonly,
         and exit Vim. If there are buffers without a file name or
         which cannot be written for another reason, or there is a
         terminal with a running job, Vim will not quit.
         {not in Vi}

==
6. Dialogs   edit-dialogs

:confirm   :conf
:conf[irm] {command}   Execute {command}, and use a dialog when an
                        operation has to be confirmed. Can be used on the
                         :q , :qa and :w commands (the latter to override
                        a read-only setting), and any other command that can
                        fail in such a way, such as :only , :buffer ,
                         :bdelete , etc.

Examples:
  :confirm w foo
       Will ask for confirmation when "foo" already exists.
  :confirm q
       Will ask for confirmation when there are changes.
  :confirm qa
       If any modified, unsaved buffers exist, you will be prompted to save
        or abandon each one. There are also choices to "save all" or "abandon
        all".

If you want to always use ":confirm", set the 'confirm' option.

                         :browse   :bro   E338   E614   E615   E616
:bro[wse] {command}   Open a file selection dialog for an argument to
                        {command}. At present this works for :e , :w ,
                         :wall , :wq , :wqall , :x , :xall , :exit ,
                         :view , :sview , :r , :saveas , :sp , :mkexrc ,
                         :mkvimrc , :mksession , :mkview , :split ,
                         :vsplit , :tabe , :tabnew , :cfile , :cgetfile ,
                         :caddfile , :lfile , :lgetfile , :laddfile ,
                         :diffsplit , :diffpatch , :open , :pedit ,

:redir , :source , :update , :visual , :vsplit , and :qall if 'confirm' is set.
{only in Win32, Athena, Motif, GTK and Mac GUI}
When ":browse" is not possible you get an error message. If the +browse feature is missing or the {command} doesn't support browsing, the {command} is executed without a dialog.
":browse set" works like :options .
See also :oldfiles for ":browse oldfiles".

The syntax is best shown via some examples:

```
:browse e $vim/foo
```
Open the browser in the $vim/foo directory, and edit the file chosen.

```
:browse e
```
Open the browser in the directory specified with 'browsedir', and edit the file chosen.

```
:browse w
```
Open the browser in the directory of the current buffer, with the current buffer filename as default, and save the buffer under the filename chosen.

```
:browse w C:/bar
```
Open the browser in the C:/bar directory, with the current buffer filename as default, and save the buffer under the filename chosen.

Also see the 'browsedir' option.
For versions of Vim where browsing is not supported, the command is executed unmodified.

browsefilter

For MS Windows and GTK, you can modify the filters that are used in the browse dialog. By setting the g:browsefilter or b:browsefilter variables, you can change the filters globally or locally to the buffer. The variable is set to a string in the format "{filter label}\t{pattern};{pattern}\n" where {filter label} is the text that appears in the "Files of Type" comboBox, and {pattern} is the pattern which filters the filenames. Several patterns can be given, separated by ';'.

For Motif the same format is used, but only the very first pattern is actually used (Motif only offers one pattern, but you can edit it).

For example, to have only Vim files in the dialog, you could use the following command:

```
let g:browsefilter = "Vim Scripts\t*.vim\nVim Startup Files\t*vimrc\n"
```

You can override the filter setting on a per-buffer basis by setting the b:browsefilter variable. You would most likely set b:browsefilter in a filetype plugin, so that the browse dialog would contain entries related to the type of file you are currently editing. Disadvantage: This makes it difficult to start editing a file of a different type. To overcome this, you may want to add "All Files\t*.*\n" as the final filter, so that the user can still access any desired file.

To avoid setting browsefilter when Vim does not actually support it, you can use has("browsefilter"):

```
if has("browsefilter")
   let g:browsefilter = "whatever"
endif
```

==
7. The current directory current-directory

You may use the :cd and :lcd commands to change to another directory, so you will not have to type that directory name in front of the file names. It also makes a difference for executing external commands, e.g. ":!ls".

Changing directory fails when the current buffer is modified, the '.' flag is present in 'cpoptions' and "!" is not used in the command.

:cd E747 E472

:cd[!] On non-Unix systems: Print the current directory name. On Unix systems: Change the current directory to the home directory. Use :pwd to print the current directory on all systems.

:cd[!] {path} Change the current directory to {path}. If {path} is relative, it is searched for in the directories listed in 'cdpath'. Does not change the meaning of an already opened file, because its full path name is remembered. Files from the arglist may change though! On MS-DOS this also changes the active drive. To change to the directory of the current file:

```
:cd %:h
```

:cd- E186

:cd[!] - Change to the previous current directory (before the previous ":cd {path}" command). {not in Vi}

:chd :chdir

:chd[ir][!] [path] Same as :cd.

:lc :lcd

:lc[d][!] {path} Like :cd, but only set the current directory when the cursor is in the current window. The current directory for other windows is not changed, switching to another window will stop using {path}. {not in Vi}

:lch :lchdir

:lch[dir][!] Same as :lcd. {not in Vi}

:pw :pwd E187

:pw[d] Print the current directory name. {Vi: no pwd} Also see getcwd().

So long as no :lcd command has been used, all windows share the same current directory. Using a command to jump to another window doesn't change anything for the current directory.
When a :lcd command has been used for a window, the specified directory becomes the current directory for that window. Windows where the :lcd command has not been used stick to the global current directory. When jumping to another window the current directory will become the last specified local current directory. If none was specified, the global current directory is used.
When a :cd command is used, the current window will lose his local current directory and will use the global current directory from now on.

After using :cd the full path name will be used for reading and writing files. On some networked file systems this may cause problems. The result of using the full path name is that the file names currently in use will remain referring to the same file. Example: If you have a file a:test and a directory a:vim the commands ":e test" ":cd vim" ":w" will overwrite the file a:test and not write a:vim/test. But if you do ":w test" the file a:vim/test will be written, because you gave a new file name and did not refer to a filename before the ":cd".

==
8. Editing binary files edit-binary

Although Vim was made to edit text files, it is possible to edit binary files. The -b Vim argument (b for binary) makes Vim do file I/O in binary mode, and sets some options for editing binary files ('binary' on, 'textwidth' to 0, 'modeline' off, 'expandtab' off). Setting the 'binary' option has the same effect. Don't forget to do this before reading the file.

There are a few things to remember when editing binary files:
- When editing executable files the number of characters must not change. Use only the "R" or "r" command to change text. Do not delete characters with "x" or by backspacing.
- Set the 'textwidth' option to 0. Otherwise lines will unexpectedly be split in two.
- When there are not many <EOL>s, the lines will become very long. If you want to edit a line that does not fit on the screen reset the 'wrap' option. Horizontal scrolling is used then. If a line becomes too long (more than about 32767 characters on the Amiga, much more on 32-bit systems, see limits) you cannot edit that line. The line will be split when reading the file. It is also possible that you get an "out of memory" error when reading the file.
- Make sure the 'binary' option is set BEFORE loading the file. Otherwise both <CR> <NL> and <NL> are considered to end a line and when the file is written the <NL> will be replaced with <CR> <NL>.
- <Nul> characters are shown on the screen as ^@. You can enter them with "CTRL-V CTRL-@" or "CTRL-V 000" {Vi cannot handle <Nul> characters in the file}
- To insert a <NL> character in the file split a line. When writing the buffer to a file a <NL> will be written for the <EOL>.
- Vim normally appends an <EOL> at the end of the file if there is none. Setting the 'binary' option prevents this. If you want to add the final <EOL>, set the 'endofline' option. You can also read the value of this

option to see if there was an <EOL> for the last line (you cannot see this in the text).

==
9. Encryption   encryption

Vim is able to write files encrypted, and read them back. The encrypted text cannot be read without the right key.
{only available when compiled with the |+cryptv| feature} E833

The text in the swap file and the undo file is also encrypted. E843
However, this is done block-by-block and may reduce the time needed to crack a password. You can disable the swap file, but then a crash will cause you to lose your work. The undo file can be disabled without much disadvantage.

```
:set noundofile
:noswapfile edit secrets
```

Note: The text in memory is not encrypted. A system administrator may be able to see your text while you are editing it. When filtering text with ":!filter" or using ":w !command" the text is also not encrypted, this may reveal it to others. The 'viminfo' file is not encrypted.

You could do this to edit very secret text:

```
:set noundofile viminfo=
:noswapfile edit secrets.txt
```

Keep in mind that without a swap file you risk losing your work in the event of a crash or a power failure.

WARNING: If you make a typo when entering the key and then write the file and exit, the text will be lost!

The normal way to work with encryption, is to use the ":X" command, which will ask you to enter a key. A following write command will use that key to encrypt the file. If you later edit the same file, Vim will ask you to enter a key. If you type the same key as that was used for writing, the text will be readable again. If you use a wrong key, it will be a mess.

                                                              :X
:X   Prompt for an encryption key. The typing is done without showing the actual text, so that someone looking at the display won't see it. The typed key is stored in the 'key' option, which is used to encrypt the file when it is written. The file will remain unchanged until you write it. See also -x .

The value of the 'key' options is used when text is written. When the option is not empty, the written file will be encrypted, using the value as the encryption key. A magic number is prepended, so that Vim can recognize that the file is encrypted.

To disable the encryption, reset the 'key' option to an empty value:

```
:set key=
```

You can use the 'cryptmethod' option to select the type of encryption, use one of these:

```
	:setlocal cm=zip	" weak method, backwards compatible
	:setlocal cm=blowfish	" method with flaws
	:setlocal cm=blowfish2	" medium strong method
```

Do this before writing the file. When reading an encrypted file it will be set automatically to the method used when that file was written. You can change 'cryptmethod' before writing that file to change the method.

To set the default method, used for new files, use this in your vimrc file:

```
	set cm=blowfish2
```

Using "blowfish2" is highly recommended. Only use another method if you must use an older Vim version that does not support it.

The message given for reading and writing a file will show "[crypted]" when using zip, "[blowfish]" when using blowfish, etc.

When writing an undo file, the same key and method will be used for the text in the undo file. persistent-undo .

To test for blowfish support you can use these conditions:

```
	has('crypt-blowfish')
	has('crypt-blowfish2')
```

This works since Vim 7.4.1099 while blowfish support was added earlier. Thus the condition failing doesn't mean blowfish is not supported. You can test for blowfish with:

```
	v:version >= 703
```

And for blowfish2 with:

```
	v:version > 704 || (v:version == 704 && has('patch401'))
```

If you are sure Vim includes patch 7.4.237 a simpler check is:

```
	has('patch-7.4.401')
```

E817 E818 E819 E820

When encryption does not work properly, you would be able to write your text to a file and never be able to read it back. Therefore a test is performed to check if the encryption works as expected. If you get one of these errors don't write the file encrypted! You need to rebuild the Vim binary to fix this.

E831 This is an internal error, "cannot happen". If you can reproduce it, please report to the developers.

When reading a file that has been encrypted and the 'key' option is not empty, it will be used for decryption. If the value is empty, you will be prompted to enter the key. If you don't enter a key, or you enter the wrong key, the file is edited without being decrypted. There is no warning about using the wrong key (this makes brute force methods to find the key more difficult).

If want to start reading a file that uses a different key, set the 'key' option to an empty string, so that Vim will prompt for a new one. Don't use the ":set" command to enter the value, other people can read the command over your shoulder.

Since the value of the 'key' option is supposed to be a secret, its value can

never be viewed. You should not set this option in a vimrc file.

An encrypted file can be recognized by the "file" command, if you add these
lines to "/etc/magic", "/usr/share/misc/magic" or wherever your system has the
"magic" file:

```
0  string  VimCrypt~       Vim encrypted file
>9 string  01      - "zip" cryptmethod
>9 string  02      - "blowfish" cryptmethod
>9 string  03      - "blowfish2" cryptmethod
```

Notes:
- Encryption is not possible when doing conversion with 'charconvert'.
- Text you copy or delete goes to the numbered registers. The registers can
  be saved in the .viminfo file, where they could be read. Change your
  'viminfo' option to be safe.
- Someone can type commands in Vim when you walk away for a moment, he should
  not be able to get the key.
- If you make a typing mistake when entering the key, you might not be able to
  get your text back!
- If you type the key with a ":set key=value" command, it can be kept in the
  history, showing the 'key' value in a viminfo file.
- There is never 100% safety. The encryption in Vim has not been tested for
  robustness.
- The algorithm used for 'cryptmethod' "zip" is breakable. A 4 character key
  in about one hour, a 6 character key in one day (on a Pentium 133 PC). This
  requires that you know some text that must appear in the file. An expert
  can break it for any key. When the text has been decrypted, this also means
  that the key can be revealed, and other files encrypted with the same key
  can be decrypted.
- Pkzip uses the same encryption as 'cryptmethod' "zip", and US Govt has no
  objection to its export. Pkzip's public file APPNOTE.TXT describes this
  algorithm in detail.
- The implementation of 'cryptmethod' "blowfish" has a flaw. It is possible
  to crack the first 64 bytes of a file and in some circumstances more of the
  file. Use of it is not recommended, but it's still the strongest method
  supported by Vim 7.3 and 7.4. The "zip" method is even weaker.
- Vim originates from the Netherlands. That is where the sources come from.
  Thus the encryption code is not exported from the USA.

==
10. Timestamps timestamp timestamps

Vim remembers the modification timestamp, mode and size of a file when you
begin editing it. This is used to avoid that you have two different versions
of the same file (without you knowing this).

After a shell command is run (:!cmd suspend :read! K) timestamps,
file modes and file sizes are compared for all buffers in a window. Vim will
run any associated FileChangedShell autocommands or display a warning for
any files that have changed. In the GUI this happens when Vim regains input
focus.

E321 E462
If you want to automatically reload a file when it has been changed outside of

Vim, set the 'autoread' option. This doesn't work at the moment you write the file though, only when the file wasn't changed inside of Vim.

If you do not want to be asked or automatically reload the file, you can use this:
```
	set buftype=nofile
```

Or, when starting gvim from a shell:
```
	gvim file.log -c "set buftype=nofile"
```

Note that if a FileChangedShell autocommand is defined you will not get a warning message or prompt. The autocommand is expected to handle this.

There is no warning for a directory (e.g., with netrw-browse). But you do get warned if you started editing a new file and it was created as a directory later.

When Vim notices the timestamp of a file has changed, and the file is being edited in a buffer but has not changed, Vim checks if the contents of the file is equal. This is done by reading the file again (into a hidden buffer, which is immediately deleted again) and comparing the text. If the text is equal, you will get no warning.

If you don't get warned often enough you can use the following command.

:checkt :checktime

:checkt[ime]		Check if any buffers were changed outside of Vim.
			This checks and warns you if you would end up with two
			versions of a file.
			If this is called from an autocommand, a ":global"
			command or is not typed the actual check is postponed
			until a moment the side effects (reloading the file)
			would be harmless.
			Each loaded buffer is checked for its associated file
			being changed. If the file was changed Vim will take
			action. If there are no changes in the buffer and
			'autoread' is set, the buffer is reloaded. Otherwise,
			you are offered the choice of reloading the file. If
			the file was deleted you get an error message.
			If the file previously didn't exist you get a warning
			if it exists now.
			Once a file has been checked the timestamp is reset,
			you will not be warned again.

:[N]checkt[ime] {filename}
:[N]checkt[ime] [N]
			Check the timestamp of a specific buffer. The buffer
			may be specified by name, number or with a pattern.

E813 E814

Vim will reload the buffer if you chose to. If a window is visible that contains this buffer, the reloading will happen in the context of this window. Otherwise a special window is used, so that most autocommands will work. You

can't close this window. A few other restrictions apply. Best is to make sure nothing happens outside of the current buffer. E.g., setting window-local options may end up in the wrong window. Splitting the window, doing something there and closing it should be OK (if there are no side effects from other autocommands). Closing unrelated windows and buffers will get you into trouble.

Before writing a file the timestamp is checked. If it has changed, Vim will ask if you really want to overwrite the file:

```
        WARNING: The file has been changed since reading it!!!
        Do you really want to write to it (y/n)?
```

If you hit 'y' Vim will continue writing the file. If you hit 'n' the write is aborted. If you used ":wq" or "ZZ" Vim will not exit, you will get another chance to write the file.

The message would normally mean that somebody has written to the file after the edit session started. This could be another person, in which case you probably want to check if your changes to the file and the changes from the other person should be merged. Write the file under another name and check for differences (the "diff" program can be used for this).

It is also possible that you modified the file yourself, from another edit session or with another command (e.g., a filter command). Then you will know which version of the file you want to keep.

There is one situation where you get the message while there is nothing wrong: On a Win32 system on the day daylight saving time starts. There is something in the Win32 libraries that confuses Vim about the hour time difference. The problem goes away the next day.

==
11. File Searching file-searching

{not available when compiled without the |+path_extra| feature}

The file searching is currently used for the 'path', 'cdpath' and 'tags' options, for finddir() and findfile() . Other commands use wildcards which is slightly different.

There are three different types of searching:

1) Downward search: starstar
   Downward search uses the wildcards '*', '**' and possibly others supported by your operating system. '*' and '**' are handled inside Vim, so they work on all operating systems. Note that "**" only acts as a special wildcard when it is at the start of a name.

   The usage of '*' is quite simple: It matches 0 or more characters. In a search pattern this would be ".*". Note that the "." is not used for file searching.

   '**' is more sophisticated:

```
      - It ONLY matches directories.
      - It matches up to 30 directories deep by default, so you can use it to
        search an entire directory tree
      - The maximum number of levels matched can be given by appending a number
        to '**'.
        Thus '/usr/**2' can match:
                /usr
                /usr/include
                /usr/include/sys
                /usr/include/g++
                /usr/lib
                /usr/lib/X11
                ....
       It does NOT match '/usr/include/g++/std' as this would be three
        levels.
        The allowed number range is 0 ('**0' is removed) to 100
        If the given number is smaller than 0 it defaults to 30, if it's
        bigger than 100 then 100 is used.  The system also has a limit on the
        path length, usually 256 or 1024 bytes.
      - '**' can only be at the end of the path or be followed by a path
        separator or by a number and a path separator.

   You can combine '*' and '**' in any order:
        /usr/**/sys/*
        /usr/*tory/sys/**
        /usr/**2/sys/*

2) Upward search:
   Here you can give a directory and then search the directory tree upward for
   a file.  You could give stop-directories to limit the upward search.  The
   stop-directories are appended to the path (for the 'path' option) or to
   the filename (for the 'tags' option) with a ';'.  If you want several
   stop-directories separate them with ';'.  If you want no stop-directory
   ("search upward till the root directory) just use ';'.
        /usr/include/sys;/usr
   will search in:
           /usr/include/sys
           /usr/include
           /usr

   If you use a relative path the upward search is started in Vim's current
   directory or in the directory of the current file (if the relative path
   starts with './' and 'd' is not included in 'cpoptions').

   If Vim's current path is /u/user_x/work/release and you do
        :set path=include;/u/user_x
  and then search for a file with  gf  the file is searched in:
        /u/user_x/work/release/include
        /u/user_x/work/include
        /u/user_x/include

3) Combined up/downward search:
   If Vim's current path is /u/user_x/work/release and you do
        set path=**;/u/user_x
```

```
 and then search for a file with  gf  the file is searched in:
       /u/user_x/work/release/**
       /u/user_x/work/**
       /u/user_x/**

  BE CAREFUL!  This might consume a lot of time, as the search of
  '/u/user_x/**' includes '/u/user_x/work/**' and
  '/u/user_x/work/release/**'.  So '/u/user_x/work/release/**' is searched
  three times and '/u/user_x/work/**' is searched twice.

  In the above example you might want to set path to:
       :set path=**,/u/user_x/**
 This searches:
       /u/user_x/work/release/**
       /u/user_x/**
  This searches the same directories, but in a different order.

  Note that completion for ":find", ":sfind", and ":tabfind" commands do not
  currently work with 'path' items that contain a URL or use the double star
  with depth limiter (/usr/**2) or upward search (;) notations.

```

motion.txt For Vim version 8.1. Last change: 2017 Oct 15

VIM REFERENCE MANUAL by Bram Moolenaar

Cursor motions cursor-motions navigation

These commands move the cursor position. If the new position is off of the screen, the screen is scrolled to show the cursor (see also 'scrolljump' and 'scrolloff' options).

General remarks:

If you want to know where you are in the file use the "CTRL-G" command CTRL-G or the "g CTRL-G" command g_CTRL-G . If you set the 'ruler' option, the cursor position is continuously shown in the status line (which slows down Vim a little).

Experienced users prefer the hjkl keys because they are always right under their fingers. Beginners often prefer the arrow keys, because they do not know what the hjkl keys do. The mnemonic value of hjkl is clear from looking at the keyboard. Think of j as an arrow pointing downwards.

The 'virtualedit' option can be set to make it possible to move the cursor to positions where there is no character or halfway a character.

==========

1. Motions and operators operator

The motion commands can be used after an operator command, to have the command operate on the text that was moved over. That is the text between the cursor position before and after the motion. Operators are generally used to delete or change text. The following operators are available:

c	c	change
d	d	delete
y	y	yank into register (does not change the text)
~	~	swap case (only if 'tildeop' is set)
g~	g~	swap case
gu	gu	make lowercase
gU	gU	make uppercase
!	!	filter through an external program
=	=	filter through 'equalprg' or C-indenting if empty

```
gq      gq      text formatting
g?      g?      ROT13 encoding
>       >       shift right
<       <       shift left
zf      zf      define a fold
g@      g@      call function set with the 'operatorfunc' option
```

If the motion includes a count and the operator also had a count before it,
the two counts are multiplied. For example: "2d3w" deletes six words.

After applying the operator the cursor is mostly left at the start of the text
that was operated upon. For example, "yfe" doesn't move the cursor, but "yFe"
moves the cursor leftwards to the "e" where the yank started.

linewise characterwise

The operator either affects whole lines, or the characters between the start
and end position. Generally, motions that move between lines affect lines
(are linewise), and motions that move within a line affect characters (are
characterwise). However, there are some exceptions.

exclusive inclusive

A character motion is either inclusive or exclusive. When inclusive, the
start and end position of the motion are included in the operation. When
exclusive, the last character towards the end of the buffer is not included.
Linewise motions always include the start and end position.

Which motions are linewise, inclusive or exclusive is mentioned with the
command. There are however, two general exceptions:

1. If the motion is exclusive and the end of the motion is in column 1, the
   end of the motion is moved to the end of the previous line and the motion
   becomes inclusive. Example: "}" moves to the first line after a paragraph,
   but "d}" will not include that line.

   exclusive-linewise

2. If the motion is exclusive, the end of the motion is in column 1 and the
   start of the motion was at or before the first non-blank in the line, the
   motion becomes linewise. Example: If a paragraph begins with some blanks
   and you do "d}" while standing on the first non-blank, all the lines of
   the paragraph are deleted, including the blanks. If you do a put now, the
   deleted lines will be inserted below the cursor position.

Note that when the operator is pending (the operator command is typed, but the
motion isn't yet), a special set of mappings can be used. See :omap .

Instead of first giving the operator and then a motion you can use Visual
mode: mark the start of the text with "v", move the cursor to the end of the
text that is to be affected and then hit the operator. The text between the
start and the cursor position is highlighted, so you can see what text will
be operated upon. This allows much more freedom, but requires more key
strokes and has limited redo functionality. See the chapter on Visual mode
Visual-mode .

You can use a ":" command for a motion. For example "d:call FindEnd()".
But this can't be repeated with "." if the command is more than one line.
This can be repeated:

```
        d:call search("f")<CR>
This cannot be repeated:
        d:if 1<CR>
           call search("f")<CR>
        endif<CR>
Note that when using ":" any motion becomes characterwise exclusive.
```

FORCING A MOTION TO BE LINEWISE, CHARACTERWISE OR BLOCKWISE

When a motion is not of the type you would like to use, you can force another type by using "v", "V" or CTRL-V just after the operator.
Example:

```
        dj
```

deletes two lines

```
        dvj
```

deletes from the cursor position until the character below the cursor

```
        d<C-V>j
```

deletes the character under the cursor and the character below the cursor.

Be careful with forcing a linewise movement to be used characterwise or blockwise, the column may not always be defined.

		o_v
v	When used after an operator, before the motion command: Force the operator to work characterwise, also when the motion is linewise. If the motion was linewise, it will become exclusive . If the motion already was characterwise, toggle inclusive/exclusive. This can be used to make an exclusive motion inclusive and an inclusive motion exclusive.	
		o_V
V	When used after an operator, before the motion command: Force the operator to work linewise, also when the motion is characterwise.	
		o_CTRL-V
CTRL-V	When used after an operator, before the motion command: Force the operator to work blockwise. This works like Visual block mode selection, with the corners defined by the cursor position before and after the motion.	

==========

2. Left-right motions left-right-motions

These commands move the cursor to the specified column in the current line. They stop at the first column and at the end of the line, except "$", which may move to one of the next lines. See 'whichwrap' option to make some of the commands move across line boundaries.

h	or	h
<Left>	or	<Left>
CTRL-H	or	CTRL-H <BS>

<BS> [count] characters to the left. exclusive motion.
Note: If you prefer <BS> to delete a character, use
the mapping:
        :map CTRL-V<BS> X
(to enter "CTRL-V<BS>" type the CTRL-V key, followed
by the <BS> key)
See :fixdel if the <BS> key does not do what you
want.

l or l
<Right> or <Right> <Space>
<Space> [count] characters to the right. exclusive motion.
See the 'whichwrap' option for adjusting the behavior
at end of line

0 To the first character of the line. exclusive
motion.

<Home> <kHome>
<Home> To the first character of the line. exclusive
motion. When moving up or down next, stay in same
TEXT column (if possible). Most other commands stay
in the same SCREEN column. <Home> works like "1|",
which differs from "0" when the line starts with a
<Tab>. {not in Vi}

^ To the first non-blank character of the line.
 exclusive motion.

$ <End> <kEnd>
$ or <End> To the end of the line. When a count is given also go
[count - 1] lines downward. inclusive motion.
In Visual mode the cursor goes to just after the last
character in the line.
When 'virtualedit' is active, "$" may move the cursor
back from past the end of the line to the last
character in the line.

g_
g_ To the last non-blank character of the line and
[count - 1] lines downward inclusive . {not in Vi}

g0 g<Home>
g0 or g<Home> When lines wrap ('wrap' on): To the first character of
the screen line. exclusive motion. Differs from
"0" when a line is wider than the screen.
When lines don't wrap ('wrap' off): To the leftmost
character of the current line that is on the screen.
Differs from "0" when the first character of the line
is not on the screen. {not in Vi}

g^

g^ When lines wrap ('wrap' on): To the first non-blank character of the screen line. exclusive motion. Differs from "^" when a line is wider than the screen. When lines don't wrap ('wrap' off): To the leftmost non-blank character of the current line that is on the screen. Differs from "^" when the first non-blank character of the line is not on the screen. {not in Vi}

gm

gm Like "g0", but half a screenwidth to the right (or as much as possible). {not in Vi}

g$ g<End>

g$ or g<End> When lines wrap ('wrap' on): To the last character of the screen line and [count - 1] screen lines downward inclusive . Differs from "$" when a line is wider than the screen.
When lines don't wrap ('wrap' off): To the rightmost character of the current line that is visible on the screen. Differs from "$" when the last character of the line is not on the screen or when a count is used. Additionally, vertical movements keep the column, instead of going to the end of the line.
When 'virtualedit' is enabled moves to the end of the screen line.
{not in Vi}

bar

| To screen column [count] in the current line. exclusive motion. Ceci n'est pas une pipe.

f

f{char} To [count]'th occurrence of {char} to the right. The cursor is placed on {char} inclusive .
{char} can be entered as a digraph digraph-arg .
When 'encoding' is set to Unicode, composing characters may be used, see utf-8-char-arg .
:lmap mappings apply to {char}. The CTRL-^ command in Insert mode can be used to switch this on/off i_CTRL-^ .

F

F{char} To the [count]'th occurrence of {char} to the left. The cursor is placed on {char} exclusive .
{char} can be entered like with the f command.

t

t{char} Till before [count]'th occurrence of {char} to the right. The cursor is placed on the character left of {char} inclusive .
{char} can be entered like with the f command.

T

```
T{char}                 Till after [count]'th occurrence of {char} to the
                        left.  The cursor is placed on the character right of
                        {char}  exclusive .
                        {char} can be entered like with the  f  command.

                                                                        ;
;                       Repeat latest f, t, F or T [count] times. See  cpo-;

                                                                        ,
,                       Repeat latest f, t, F or T in opposite direction
                        [count] times. See also  cpo-;

==============================================================================
3. Up-down motions                                      up-down-motions

k               or                                      k
<Up>            or                                      <Up>   CTRL-P
CTRL-P                  [count] lines upward  linewise .

j               or                                      j
<Down>          or                                      <Down>
CTRL-J          or                                      CTRL-J
<NL>            or                                      <NL>   CTRL-N
CTRL-N                  [count] lines downward  linewise .

gk              or                                      gk   g<Up>
g<Up>                   [count] display lines upward.   exclusive  motion.
                        Differs from 'k' when lines wrap, and when used with
                        an operator, because it's not linewise.  {not in Vi}

gj              or                                      gj   g<Down>
g<Down>                 [count] display lines downward.   exclusive  motion.
                        Differs from 'j' when lines wrap, and when used with
                        an operator, because it's not linewise.  {not in Vi}

                                                                        -
-  <minus>              [count] lines upward, on the first non-blank
                        character  linewise .

+               or                                      +
CTRL-M          or                                      CTRL-M   <CR>
<CR>                    [count] lines downward, on the first non-blank
                        character  linewise .

                                                                        _
_  <underscore>         [count] - 1 lines downward, on the first non-blank
                        character  linewise .

                                                                        G
G                       Goto line [count], default last line, on the first
                        non-blank character  linewise .  If 'startofline' not
                        set, keep the same column.
                        G is a one of  jump-motions .
```

<C-End>
<C-End> Goto line [count], default last line, on the last
character inclusive . {not in Vi}

<C-Home> or gg <C-Home>
gg Goto line [count], default first line, on the first
non-blank character linewise . If 'startofline' not
set, keep the same column.

:[range]
:[range] Set the cursor on the last line number in [range].
[range] can also be just one line number, e.g., ":1"
or ":'m".
In contrast with G this command does not modify the
 jumplist .

N%
{count}% Go to {count} percentage in the file, on the first
non-blank in the line linewise . To compute the new
line number this formula is used:
    ({count} * number-of-lines + 99) / 100
See also 'startofline' option. {not in Vi}

:[range]go[to] [count] :go :goto go
[count]go Go to [count] byte in the buffer. Default [count] is
one, start of the file. When giving [range], the
last number in it used as the byte count. End-of-line
characters are counted depending on the current
'fileformat' setting.
Also see the line2byte() function, and the 'o'
option in 'statusline'.
{not in Vi}
{not available when compiled without the
 +byte_offset feature}

These commands move to the specified line. They stop when reaching the first
or the last line. The first two commands put the cursor in the same column
(if possible) as it was after the last command that changed the column,
except after the "$" command, then the cursor will be put on the last
character of the line.

If "k", "-" or CTRL-P is used with a [count] and there are less than [count]
lines above the cursor and the 'cpo' option includes the "-" flag it is an
error. cpo-- .

==
4. Word motions word-motions

<S-Right> or <S-Right> w
w [count] words forward. exclusive motion.

<C-Right> or <C-Right> W
W [count] WORDS forward. exclusive motion.

e

e   Forward to the end of word [count] inclusive .
                        Does not stop in an empty line.

                                                            E
E   Forward to the end of WORD [count] inclusive .
                        Does not stop in an empty line.

<S-Left>   or   <S-Left>   b
b   [count] words backward.   exclusive motion.

<C-Left>   or   <C-Left>   B
B   [count] WORDS backward.   exclusive motion.

                                                            ge
ge   Backward to the end of word [count] inclusive .

                                                            gE
gE   Backward to the end of WORD [count] inclusive .

These commands move over words or WORDS.
                                                            word
A word consists of a sequence of letters, digits and underscores, or a
sequence of other non-blank characters, separated with white space (spaces,
tabs, <EOL>). This can be changed with the 'iskeyword' option. An empty line
is also considered to be a word.
                                                            WORD
A WORD consists of a sequence of non-blank characters, separated with white
space. An empty line is also considered to be a WORD.

A sequence of folded lines is counted for one word of a single character.
"w" and "W", "e" and "E" move to the start/end of the first word or WORD after
a range of folded lines. "b" and "B" move to the start of the first word or
WORD before the fold.

Special case: "cw" and "cW" are treated like "ce" and "cE" if the cursor is
on a non-blank. This is because "cw" is interpreted as change-word, and a
word does not include the following white space. {Vi: "cw" when on a blank
followed by other blanks changes only the first blank; this is probably a
bug, because "dw" deletes all the blanks}

Another special case: When using the "w" motion in combination with an
operator and the last word moved over is at the end of a line, the end of
that word becomes the end of the operated text, not the first word in the
next line.

The original Vi implementation of "e" is buggy. For example, the "e" command
will stop on the first character of a line if the previous line was empty.
But when you use "2e" this does not happen. In Vim "ee" and "2e" are the
same, which is more logical. However, this causes a small incompatibility
between Vi and Vim.

==
5. Text object motions   object-motions

(
([count] sentences backward.   exclusive motion.

)
)   [count] sentences forward.   exclusive motion.

{
{   [count] paragraphs backward.   exclusive motion.

}
}   [count] paragraphs forward.   exclusive motion.

]]
]]   [count] sections forward or to the next '{' in the
                        first column. When used after an operator, then also
                        stops below a '}' in the first column.   exclusive
                        Note that exclusive-linewise often applies.

][
][[count] sections forward or to the next '}' in the
                        first column.   exclusive
                        Note that exclusive-linewise often applies.

[[
[[[count] sections backward or to the previous '{' in
                        the first column.   exclusive
                        Note that exclusive-linewise often applies.

[]
[]   [count] sections backward or to the previous '}' in
                        the first column.   exclusive
                        Note that exclusive-linewise often applies.

These commands move over three kinds of text objects.

sentence
A sentence is defined as ending at a '.', '!' or '?' followed by either the
end of a line, or by a space or tab. Any number of closing ')', ']', '"'
and ''' characters may appear after the '.', '!' or '?' before the spaces,
tabs or end of line. A paragraph and section boundary is also a sentence
boundary.
If the 'J' flag is present in 'cpoptions', at least two spaces have to
follow the punctuation mark; <Tab>s are not recognized as white space.
The definition of a sentence cannot be changed.

paragraph
A paragraph begins after each empty line, and also at each of a set of
paragraph macros, specified by the pairs of characters in the 'paragraphs'
option. The default is "IPLPPPQPP TPHPLIPpLpItpplpipbp", which corresponds to
the macros ".IP", ".LP", etc. (These are nroff macros, so the dot must be in
the first column). A section boundary is also a paragraph boundary.
Note that a blank line (only containing white space) is NOT a paragraph
boundary.
Also note that this does not include a '{' or '}' in the first column. When

the '{' flag is in 'cpoptions' then '{' in the first column is used as a paragraph boundary posix .

section
A section begins after a form-feed (<C-L>) in the first column and at each of a set of section macros, specified by the pairs of characters in the 'sections' option. The default is "SHNHH HUnhsh", which defines a section to start at the nroff macros ".SH", ".NH", ".H", ".HU", ".nh" and ".sh".

The "]" and "[" commands stop at the '{' or '}' in the first column. This is useful to find the start or end of a function in a C program. Note that the first character of the command determines the search direction and the second character the type of brace found.

If your '{' or '}' are not in the first column, and you would like to use "[[" and "]]" anyway, try these mappings:
```
:map [[ ?{<CR>w99[{
:map ][ /}<CR>b99]}
:map ]] j0[[%/{<CR>
:map [] k$][%?}<CR>
```
[type these literally, see <>]

==========
6. Text object selection object-select text-objects v_a v_i

This is a series of commands that can only be used while in Visual mode or after an operator. The commands that start with "a" select "a"n object including white space, the commands starting with "i" select an "inner" object without white space, or just the white space. Thus the "inner" commands always select less text than the "a" commands.

These commands are {not in Vi}.
These commands are not available when the +textobjects feature has been disabled at compile time.
Also see `gn` and `gN`, operating on the last search pattern.

v_aw aw
aw "a word", select [count] words (see word).
Leading or trailing white space is included, but not counted.
When used in Visual linewise mode "aw" switches to Visual characterwise mode.

v_iw iw
iw "inner word", select [count] words (see word).
White space between words is counted too.
When used in Visual linewise mode "iw" switches to Visual characterwise mode.

v_aW aW
aW "a WORD", select [count] WORDs (see WORD).
Leading or trailing white space is included, but not counted.

When used in Visual linewise mode "aW" switches to
Visual characterwise mode.

v_iW iW

iW "inner WORD", select [count] WORDs (see WORD).
White space between words is counted too.
When used in Visual linewise mode "iW" switches to
Visual characterwise mode.

v_as as

as "a sentence", select [count] sentences (see
sentence).
When used in Visual mode it is made characterwise.

v_is is

is "inner sentence", select [count] sentences (see
sentence).
When used in Visual mode it is made characterwise.

v_ap ap

ap "a paragraph", select [count] paragraphs (see
paragraph).
Exception: a blank line (only containing white space)
is also a paragraph boundary.
When used in Visual mode it is made linewise.

v_ip ip

ip "inner paragraph", select [count] paragraphs (see
paragraph).
Exception: a blank line (only containing white space)
is also a paragraph boundary.
When used in Visual mode it is made linewise.

v_a] v_a[a] a[

a]
a["a [] block", select [count] '[' ']' blocks. This
goes backwards to the [count] unclosed '[', and finds
the matching ']'. The enclosed text is selected,
including the '[' and ']'.
When used in Visual mode it is made characterwise.

v_i] v_i[i] i[

i]
i["inner [] block", select [count] '[' ']' blocks. This
goes backwards to the [count] unclosed '[', and finds
the matching ']'. The enclosed text is selected,
excluding the '[' and ']'.
When used in Visual mode it is made characterwise.

v_a) a) a(

a)
a(vab v_ab v_a(ab
ab "a block", select [count] blocks, from "[count] [(" to
the matching ')', including the '(' and ')' (see
[( ). Does not include white space outside of the
parenthesis.
When used in Visual mode it is made characterwise.

i) v_i) i) i(
i(vib v_ib v_i(ib
ib "inner block", select [count] blocks, from "[count] [(" to the matching ')', excluding the '(' and ')' (see [( ).
When used in Visual mode it is made characterwise.

a> v_a> v_a< a> a<
a< "a <> block", select [count] <> blocks, from the [count]'th unmatched '<' backwards to the matching '>', including the '<' and '>'.
When used in Visual mode it is made characterwise.

i> v_i> v_i< i> i<
i< "inner <> block", select [count] <> blocks, from the [count]'th unmatched '<' backwards to the matching '>', excluding the '<' and '>'.
When used in Visual mode it is made characterwise.

v_at at
at "a tag block", select [count] tag blocks, from the [count]'th unmatched "<aaa>" backwards to the matching "</aaa>", including the "<aaa>" and "</aaa>".
See tag-blocks about the details.
When used in Visual mode it is made characterwise.

v_it it
it "inner tag block", select [count] tag blocks, from the [count]'th unmatched "<aaa>" backwards to the matching "</aaa>", excluding the "<aaa>" and "</aaa>".
See tag-blocks about the details.
When used in Visual mode it is made characterwise.

a} v_a} a} a{
a{ v_aB v_a{ aB
aB "a Block", select [count] Blocks, from "[count] [{" to the matching '}', including the '{' and '}' (see [{).
When used in Visual mode it is made characterwise.

i} v_i} i} i{
i{ v_iB v_i{ iB
iB "inner Block", select [count] Blocks, from "[count] [{" to the matching '}', excluding the '{' and '}' (see [{).
When used in Visual mode it is made characterwise.

a" v_aquote aquote
a' v_a' a'
a`  v_a` a`
"a quoted string". Selects the text from the previous quote until the next quote. The 'quoteescape' option is used to skip escaped quotes.

Only works within one line.
When the cursor starts on a quote, Vim will figure out
which quote pairs form a string by searching from the
start of the line.
Any trailing white space is included, unless there is
none, then leading white space is included.
When used in Visual mode it is made characterwise.
Repeating this object in Visual mode another string is
included. A count is currently not used.

i" v_iquote iquote
i' v_i' i'
i`  v_i` i`
Like a", a' and a`, but exclude the quotes and
repeating won't extend the Visual selection.
Special case: With a count of 2 the quotes are
included, but no extra white space as with a"/a'/a`.

When used after an operator:
For non-block objects:
For the "a" commands: The operator applies to the object and the white space after the object. If there is no white space after the object or when the cursor was in the white space before the object, the white space before the object is included.
For the "inner" commands: If the cursor was on the object, the operator applies to the object. If the cursor was on white space, the operator applies to the white space.
For a block object:
The operator applies to the block where the cursor is in, or the block on which the cursor is on one of the braces. For the "inner" commands the surrounding braces are excluded. For the "a" commands, the braces are included.

When used in Visual mode:
When start and end of the Visual area are the same (just after typing "v"):
One object is selected, the same as for using an operator.
When start and end of the Visual area are not the same:
For non-block objects the area is extended by one object or the white space up to the next object, or both for the "a" objects. The direction in which this happens depends on which side of the Visual area the cursor is. For the block objects the block is extended one level outwards.

For illustration, here is a list of delete commands, grouped from small to big objects. Note that for a single character and a whole line the existing vi movement commands are used.

"dl"	delete character (alias: "x")	dl
"diw"	delete inner word	diw
"daw"	delete a word	daw
"diW"	delete inner WORD (see WORD)	diW
"daW"	delete a WORD (see WORD)	daW
"dgn"	delete the next search pattern match	dgn
"dd"	delete one line	dd
"dis"	delete inner sentence	dis

```
        "das"   delete a sentence                       das
        "dib"   delete inner '(' ')' block              dib
        "dab"   delete a '(' ')' block                  dab
        "dip"   delete inner paragraph                  dip
        "dap"   delete a paragraph                      dap
        "diB"   delete inner '{' '}' block              diB
        "daB"   delete a '{' '}' block                  daB
```

Note the difference between using a movement command and an object. The movement command operates from here (cursor position) to where the movement takes us. When using an object the whole object is operated upon, no matter where on the object the cursor is. For example, compare "dw" and "daw": "dw" deletes from the cursor position to the start of the next word, "daw" deletes the word under the cursor and the space after or before it.

Tag blocks tag-blocks

For the "it" and "at" text objects an attempt is done to select blocks between matching tags for HTML and XML. But since these are not completely compatible there are a few restrictions.

The normal method is to select a <tag> until the matching </tag>. For "at" the tags are included, for "it" they are excluded. But when "it" is repeated the tags will be included (otherwise nothing would change). Also, "it" used on a tag block with no contents will select the leading tag.

"<aaa/>" items are skipped. Case is ignored, also for XML where case does matter.

In HTML it is possible to have a tag like <br> or <meta ...> without a matching end tag. These are ignored.

The text objects are tolerant about mistakes. Stray end tags are ignored.

==
7. Marks mark-motions E20 E78

Jumping to a mark can be done in two ways:
1. With ` (backtick): The cursor is positioned at the specified location and the motion is exclusive .
2. With ' (single quote): The cursor is positioned on the first non-blank character in the line of the specified location and the motion is linewise.

m m mark Mark
m{a-zA-Z} Set mark {a-zA-Z} at cursor position (does not move the cursor, this is not a motion command).

m' m`
m' or m` Set the previous context mark. This can be jumped to with the "''" or "``" command (does not move the cursor, this is not a motion command).

m[or m] Set the '[or '] mark. Useful when an operator is to be simulated by multiple commands. (does not move the cursor, this is not a motion command).

m< or m> Set the '< or '> mark. Useful to change what the `gv` command selects. (does not move the cursor, this is not a motion command).
Note that the Visual mode cannot be set, only the start and end position.

:[range]ma[rk] {a-zA-Z'} Set mark {a-zA-Z'} at last line number in [range], column 0. Default is cursor line.

:[range]k{a-zA-Z'} Same as :mark, but the space before the mark name can be omitted.

'{a-z} `{a-z} Jump to the mark {a-z} in the current buffer.

'{A-Z0-9} `{A-Z0-9} To the mark {A-Z0-9} in the file where it was set (not a motion command when in another file). {not in Vi}

g'{mark} g`{mark} Jump to the {mark}, but don't change the jumplist when jumping within the current buffer. Example:
```
g`"
```
jumps to the last known position in a file. See $VIMRUNTIME/vimrc_example.vim.
Also see :keepjumps .
{not in Vi}

:marks List all the current marks (not a motion command).
The '(, ') , '{ and '} marks are not listed.
The first column has number zero.
{not in Vi}

:marks {arg} List the marks that are mentioned in {arg} (not a motion command). For example:
```
:marks aB
```
to list marks 'a' and 'B'. {not in Vi}

:delm[arks] {marks} Delete the specified marks. Marks that can be deleted include A-Z and 0-9. You cannot delete the ' mark. They can be specified by giving the list of mark names, or with a range, separated with a dash. Spaces

are ignored. Examples:
:delmarks a	deletes mark a
:delmarks a b 1	deletes marks a, b and 1
:delmarks Aa	deletes marks A and a
:delmarks p-z	deletes marks in the range p to z
:delmarks ^.[]	deletes marks ^ . [ ]
:delmarks \"	deletes mark "
{not in Vi}

:delm[arks]!	Delete all marks for the current buffer, but not marks A-Z or 0-9.
{not in Vi}

A mark is not visible in any way. It is just a position in the file that is remembered. Do not confuse marks with named registers, they are totally unrelated.

'a - 'z	lowercase marks, valid within one file
'A - 'Z	uppercase marks, also called file marks, valid between files
'0 - '9	numbered marks, set from .viminfo file

Lowercase marks 'a to 'z are remembered as long as the file remains in the buffer list. If you remove the file from the buffer list, all its marks are lost. If you delete a line that contains a mark, that mark is erased.

Lowercase marks can be used in combination with operators. For example: "d't" deletes the lines from the cursor position to mark 't'. Hint: Use mark 't' for Top, 'b' for Bottom, etc.. Lowercase marks are restored when using undo and redo.

Uppercase marks 'A to 'Z include the file name. {Vi: no uppercase marks} You can use them to jump from file to file. You can only use an uppercase mark with an operator if the mark is in the current file. The line number of the mark remains correct, even if you insert/delete lines or edit another file for a moment. When the 'viminfo' option is not empty, uppercase marks are kept in the .viminfo file. See viminfo-file-marks .

Numbered marks '0 to '9 are quite different. They can not be set directly. They are only present when using a viminfo file viminfo-file . Basically '0 is the location of the cursor when you last exited Vim, '1 the last but one time, etc. Use the "r" flag in 'viminfo' to specify files for which no Numbered mark should be stored. See viminfo-file-marks .

'[`[
'[`[	To the first character of the previously changed or yanked text. {not in Vi}

'] `]
'] `]	To the last character of the previously changed or yanked text. {not in Vi}

After executing an operator the Cursor is put at the beginning of the text that was operated upon. After a put command ("p" or "P") the cursor is

sometimes placed at the first inserted line and sometimes on the last inserted character. The four commands above put the cursor at either end. Example: After yanking 10 lines you want to go to the last one of them: "10Y']". After inserting several lines with the "p" command you want to jump to the lowest inserted line: "p']". This also works for text that has been inserted.

Note: After deleting text, the start and end positions are the same, except when using blockwise Visual mode. These commands do not work when no change was made yet in the current file.

'< `<
'< `< To the first line or character of the last selected Visual area in the current buffer. For block mode it may also be the last character in the first line (to be able to define the block). {not in Vi}.

'> `>
'> `> To the last line or character of the last selected Visual area in the current buffer. For block mode it may also be the first character of the last line (to be able to define the block). Note that 'selection' applies, the position may be just after the Visual area. {not in Vi}.

'' ``
'' `` To the position before the latest jump, or where the last "m'" or "m`" command was given. Not set when the :keepjumps command modifier was used.
Also see restore-position .

'quote `quote
'" `" To the cursor position when last exiting the current buffer. Defaults to the first character of the first line. See last-position-jump for how to use this for each opened file.
Only one position is remembered per buffer, not one for each window. As long as the buffer is visible in a window the position won't be changed.
{not in Vi}.

'^ `^
'^ `^ To the position where the cursor was the last time when Insert mode was stopped. This is used by the gi command. Not set when the :keepjumps command modifier was used. {not in Vi}

'. `.
'. `. To the position where the last change was made. The position is at or near where the change started. Sometimes a command is executed as several changes, then the position can be near the end of what the command changed. For example when inserting a word, the position will be on the last character.
To jump to older changes use g; .

{not in Vi}

'(`(To the start of the current sentence, like the (command. {not in Vi}

') `) To the end of the current sentence, like the) command. {not in Vi}

'{ `{ To the start of the current paragraph, like the { command. {not in Vi}

'} `} To the end of the current paragraph, like the } command. {not in Vi}

These commands are not marks themselves, but jump to a mark:

]' [count] times to next line with a lowercase mark below the cursor, on the first non-blank character in the line. {not in Vi}

]` [count] times to lowercase mark after the cursor. {not in Vi}

[' [count] times to previous line with a lowercase mark before the cursor, on the first non-blank character in the line. {not in Vi}

[` [count] times to lowercase mark before the cursor. {not in Vi}

:loc[kmarks] {command} Execute {command} without adjusting marks. This is useful when changing text in a way that the line count will be the same when the change has completed.
WARNING: When the line count does change, marks below the change will keep their line number, thus move to another text line.
These items will not be adjusted for deleted/inserted lines:
- lower case letter marks 'a - 'z
- upper case letter marks 'A - 'Z
- numbered marks '0 - '9
- last insert position '^
- last change position '.
- the Visual area '< and '>

- line numbers in placed signs
- line numbers in quickfix positions
- positions in the jumplist
- positions in the tagstack
These items will still be adjusted:
- previous context mark ''
- the cursor position
- the view of a window on a buffer
- folds
- diffs

:kee[pmarks] {command} :kee :keepmarks
Currently only has effect for the filter command :range! :
- When the number of lines after filtering is equal to or larger than before, all marks are kept at the same line number.
- When the number of lines decreases, the marks in the lines that disappeared are deleted.
In any case the marks below the filtered text have their line numbers adjusted, thus stick to the text, as usual.
When the 'R' flag is missing from 'cpoptions' this has the same effect as using ":keepmarks".

:keepj :keepjumps
:keepj[umps] {command}
Moving around in {command} does not change the '' , '. and '^ marks, the jumplist or the changelist .
Useful when making a change or inserting text automatically and the user doesn't want to go to this position. E.g., when updating a "Last change" timestamp in the first line:

```
:let lnum = line(".")
:keepjumps normal gg
:call SetLastChange()
:keepjumps exe "normal " . lnum . "G"
```

Note that ":keepjumps" must be used for every command. When invoking a function the commands in that function can still change the jumplist. Also, for ":keepjumps exe 'command '" the "command" won't keep jumps. Instead use: ":exe 'keepjumps command'"

==
8. Jumps jump-motions

A "jump" is a command that normally moves the cursor several lines away. If you make the cursor "jump" the position of the cursor before the jump is remembered. You can return to that position with the "''" and "``" command, unless the line containing that position was changed or deleted. The following commands are "jump" commands: "'", "`", "G", "/", "?", "n", "N",

"%", "(", ")", "[[", "]]", "{", "}", ":s", ":tag", "L", "M", "H" and the commands that start editing a new file.

CTRL-O

CTRL-O Go to [count] Older cursor position in jump list (not a motion command). {not in Vi} {not available without the |+jumplist| feature}

<Tab> or CTRL-I <Tab>

CTRL-I Go to [count] newer cursor position in jump list (not a motion command). {not in Vi} {not available without the |+jumplist| feature}

:ju :jumps

:ju[mps] Print the jump list (not a motion command). {not in Vi} {not available without the |+jumplist| feature}

:cle :clearjumps

:cle[arjumps] Clear the jump list of the current window. {not in Vi} {not available without the |+jumplist| feature}

jumplist

Jumps are remembered in a jump list. With the CTRL-O and CTRL-I command you can go to cursor positions before older jumps, and back again. Thus you can move up and down the list. There is a separate jump list for each window. The maximum number of entries is fixed at 100.
{not available without the |+jumplist| feature}

For example, after three jump commands you have this jump list:

```
  jump line  col file/text
    3     1    0 some text
    2    70    0 another line
    1  1154   23 end.
 >
```

The "file/text" column shows the file name, or the text at the jump if it is in the current file (an indent is removed and a long line is truncated to fit in the window).

You are currently in line 1167. If you then use the CTRL-O command, the cursor is put in line 1154. This results in:

```
  jump line  col file/text
    2     1    0 some text
    1    70    0 another line
 >  0  1154   23 end.
    1  1167    0 foo bar
```

The pointer will be set at the last used jump position. The next CTRL-O

command will use the entry above it, the next CTRL-I command will use the entry below it. If the pointer is below the last entry, this indicates that you did not use a CTRL-I or CTRL-O before. In this case the CTRL-O command will cause the cursor position to be added to the jump list, so you can get back to the position before the CTRL-O. In this case this is line 1167.

With more CTRL-O commands you will go to lines 70 and 1. If you use CTRL-I you can go back to 1154 and 1167 again. Note that the number in the "jump" column indicates the count for the CTRL-O or CTRL-I command that takes you to this position.

If you use a jump command, the current line number is inserted at the end of the jump list. If the same line was already in the jump list, it is removed. The result is that when repeating CTRL-O you will get back to old positions only once.

When the :keepjumps command modifier is used, jumps are not stored in the jumplist. Jumps are also not stored in other cases, e.g., in a :global command. You can explicitly add a jump by setting the ' mark with "m'". Note that calling setpos() does not do this.

After the CTRL-O command that got you into line 1154 you could give another jump command (e.g., "G"). The jump list would then become:

```
  jump line  col file/text
    4     1    0 some text
    3    70    0 another line
    2  1167    0 foo bar
    1  1154   23 end.
 >
```

The line numbers will be adjusted for deleted and inserted lines. This fails if you stop editing a file without writing, like with ":n!".

When you split a window, the jumplist will be copied to the new window.

If you have included the ' item in the 'viminfo' option the jumplist will be stored in the viminfo file and restored when starting Vim.

CHANGE LIST JUMPS changelist change-list-jumps E664

When making a change the cursor position is remembered. One position is remembered for every change that can be undone, unless it is close to a previous change. Two commands can be used to jump to positions of changes, also those that have been undone:

g; E662

g; Go to [count] older position in change list.
If [count] is larger than the number of older change positions go to the oldest change.
If there is no older change an error message is given.
(not a motion command)
{not in Vi}

{not available without the |+jumplist| feature}

g, E663

g, Go to [count] newer cursor position in change list. Just like g; but in the opposite direction. (not a motion command)
{not in Vi}
{not available without the |+jumplist| feature}

When using a count you jump as far back or forward as possible. Thus you can use "999g;" to go to the first change for which the position is still remembered. The number of entries in the change list is fixed and is the same as for the jumplist .

When two undo-able changes are in the same line and at a column position less than 'textwidth' apart only the last one is remembered. This avoids that a sequence of small changes in a line, for example "xxxxx", adds many positions to the change list. When 'textwidth' is zero 'wrapmargin' is used. When that also isn't set a fixed number of 79 is used. Detail: For the computations bytes are used, not characters, to avoid a speed penalty (this only matters for multi-byte encodings).

Note that when text has been inserted or deleted the cursor position might be a bit different from the position of the change. Especially when lines have been deleted.

When the :keepjumps command modifier is used the position of a change is not remembered.

:changes

:changes Print the change list. A ">" character indicates the current position. Just after a change it is below the newest entry, indicating that `g;` takes you to the newest entry position. The first column indicates the count needed to take you to this position. Example:

```
change line  col text
    3     9    8 bla bla bla
    2    11   57 foo is a bar
    1    14   54 the latest changed line
>
```

The `3g;` command takes you to line 9. Then the output of `:changes` is:

```
change line  col text
>   0     9    8 bla bla bla
    1    11   57 foo is a bar
    2    14   54 the latest changed line
```

Now you can use "g," to go to line 11 and "2g," to go to line 14.

==========

9. Various motions various-motions

% Find the next item in this line after or under the cursor and jump to its match. inclusive motion. Items can be:
([{}]) parenthesis or (curly/square) brackets (this can be changed with the 'matchpairs' option)
/* */ start or end of C-style comment
#if, #ifdef, #else, #elif, #endif C preprocessor conditionals (when the cursor is on the # or no ([{ following)
For other items the matchit plugin can be used, see matchit-install . This plugin also helps to skip matches in comments.

When 'cpoptions' contains "M" cpo-M backslashes before parens and braces are ignored. Without "M" the number of backslashes matters: an even number doesn't match with an odd number. Thus in "(\))" and "\((\)" the first and last parenthesis match.

When the '%' character is not present in 'cpoptions' cpo-% , parens and braces inside double quotes are ignored, unless the number of parens/braces in a line is uneven and this line and the previous one does not end in a backslash. '(', '{', '[', ']', '}' and ')' are also ignored (parens and braces inside single quotes). Note that this works fine for C, but not for Perl, where single quotes are used for strings.

Nothing special is done for matches in comments. You can either use the matchit plugin matchit-install or put quotes around matches.

No count is allowed, {count}% jumps to a line {count} percentage down the file N% . Using '%' on #if/#else/#endif makes the movement linewise.

[(go to [count] previous unmatched '('. exclusive motion. {not in Vi}

[{ go to [count] previous unmatched '{'. exclusive motion. {not in Vi}

]) go to [count] next unmatched ')'. exclusive motion. {not in Vi}

]}

]}   go to [count] next unmatched '}'.
                         exclusive motion. {not in Vi}

The above four commands can be used to go to the start or end of the current code block. It is like doing "%" on the '(', ')', '{' or '}' at the other end of the code block, but you can do this from anywhere in the code block. Very useful for C programs. Example: When standing on "case x:", "[{" will bring you back to the switch statement.

                                                ]m
]m   Go to [count] next start of a method (for Java or similar structured language). When not before the start of a method, jump to the start or end of the class. When no '{' is found after the cursor, this is an error.   exclusive motion. {not in Vi}
                                                ]M
]M   Go to [count] next end of a method (for Java or similar structured language). When not before the end of a method, jump to the start or end of the class. When no '}' is found after the cursor, this is an error. exclusive motion. {not in Vi}
                                                [m
[m   Go to [count] previous start of a method (for Java or similar structured language). When not after the start of a method, jump to the start or end of the class. When no '{' is found before the cursor this is an error. exclusive motion. {not in Vi}
                                                [M
[M   Go to [count] previous end of a method (for Java or similar structured language). When not after the end of a method, jump to the start or end of the class. When no '}' is found before the cursor this is an error. exclusive motion. {not in Vi}

The above two commands assume that the file contains a class with methods. The class definition is surrounded in '{' and '}'. Each method in the class is also surrounded with '{' and '}'. This applies to the Java language. The file looks like this:

```
        // comment
        class foo {
                int method_one() {
                        body_one();
                }
                int method_two() {
                        body_two();
                }
        }
```

Starting with the cursor on "body_two()", using "[m" will jump to the '{' at the start of "method_two()" (obviously this is much more useful when the method is long!). Using "2[m" will jump to the start of "method_one()". Using "3[m" will jump to the start of the class.

                                                [#

[#   go to [count] previous unmatched "#if" or "#else".
                        exclusive motion. {not in Vi}

                                                ]#
]#   go to [count] next unmatched "#else" or "#endif".
                        exclusive motion. {not in Vi}

These two commands work in C programs that contain #if/#else/#endif
constructs. It brings you to the start or end of the #if/#else/#endif where
the current line is included. You can then use "%" to go to the matching line.

                                                [star [/
[* or [/   go to [count] previous start of a C comment "/*".
                        exclusive motion. {not in Vi}

                                                ]star]/
]* or]/   go to [count] next end of a C comment "*/".
                        exclusive motion. {not in Vi}

                                                H
H   To line [count] from top (Home) of window (default:
                        first line on the window) on the first non-blank
                        character linewise . See also 'startofline' option.
                        Cursor is adjusted for 'scrolloff' option, unless an
                        operator is pending, in which case the text may
                        scroll. E.g. "yH" yanks from the first visible line
                        until the cursor line (inclusive).

                                                M
M   To Middle line of window, on the first non-blank
                        character linewise . See also 'startofline' option.

                                                L
L   To line [count] from bottom of window (default: Last
                        line on the window) on the first non-blank character
                        linewise . See also 'startofline' option.
                        Cursor is adjusted for 'scrolloff' option, unless an
                        operator is pending, in which case the text may
                        scroll. E.g. "yL" yanks from the cursor to the last
                        visible line.

<LeftMouse>   Moves to the position on the screen where the mouse
                        click is exclusive . See also <LeftMouse> . If the
                        position is in a status line, that window is made the
                        active window and the cursor is not moved. {not in Vi}

 vim:tw=78:ts=8:noet:ft=help:norl:

scroll.txt For Vim version 8.1. Last change: 2018 Apr 26

VIM REFERENCE MANUAL by Bram Moolenaar

Scrolling scrolling

These commands move the contents of the window. If the cursor position is moved off of the window, the cursor is moved onto the window (with 'scrolloff' screen lines around it). A page is the number of lines in the window minus two. The mnemonics for these commands may be a bit confusing. Remember that the commands refer to moving the window (the part of the buffer that you see) upwards or downwards in the buffer. When the window moves upwards in the buffer, the text in the window moves downwards on your screen.

See section 03.7 of the user manual for an introduction.

==========

1. Scrolling downwards scroll-down

The following commands move the edit window (the part of the buffer that you see) downwards (this means that more lines downwards in the text buffer can be seen):

CTRL-E

CTRL-E Scroll window [count] lines downwards in the buffer. The text moves upwards on the screen. Mnemonic: Extra lines.

CTRL-D

CTRL-D Scroll window Downwards in the buffer. The number of lines comes from the 'scroll' option (default: half a screen). If [count] given, first set 'scroll' option to [count]. The cursor is moved the same number of lines down in the file (if possible; when lines wrap and when hitting the end of the file there may be a difference). When the cursor is on the last line of the buffer nothing happens and a beep is produced. See also 'startofline' option. {difference from vi: Vim scrolls 'scroll' screen lines, instead of file lines; makes a difference when lines wrap}

<S-Down> or <S-Down> <kPageDown>
<PageDown> or <PageDown> CTRL-F
CTRL-F Scroll window [count] pages Forwards (downwards) in

the buffer. See also 'startofline' option.
When there is only one window the 'window' option
might be used.

z+ Without [count]: Redraw with the line just below the window at the top of the window. Put the cursor in that line, at the first non-blank in the line. With [count]: just like "z<CR>".

==========

2. Scrolling upwards scroll-up

The following commands move the edit window (the part of the buffer that you see) upwards (this means that more lines upwards in the text buffer can be seen):

CTRL-Y Scroll window [count] lines upwards in the buffer. The text moves downwards on the screen.
Note: When using the MS-Windows key bindings CTRL-Y is remapped to redo.

CTRL-U Scroll window Upwards in the buffer. The number of lines comes from the 'scroll' option (default: half a screen). If [count] given, first set the 'scroll' option to [count]. The cursor is moved the same number of lines up in the file (if possible; when lines wrap and when hitting the end of the file there may be a difference). When the cursor is on the first line of the buffer nothing happens and a beep is produced. See also 'startofline' option.
{difference from vi: Vim scrolls 'scroll' screen lines, instead of file lines; makes a difference when lines wrap}

<S-Up> or <PageUp> or CTRL-B Scroll window [count] pages Backwards (upwards) in the buffer. See also 'startofline' option.
When there is only one window the 'window' option might be used.

z^ Without [count]: Redraw with the line just above the window at the bottom of the window. Put the cursor in that line, at the first non-blank in the line.
With [count]: First scroll the text to put the [count] line at the bottom of the window, then redraw with the line which is now at the top of the window at the bottom of the window. Put the cursor in that line, at the first non-blank in the line.

==
3. Scrolling relative to cursor   scroll-cursor

The following commands reposition the edit window (the part of the buffer that you see) while keeping the cursor on the same line. Note that the 'scrolloff' option may cause context lines to show above and below the cursor.

                                                                z<CR>
z<CR>   Redraw, line [count] at top of window (default
                        cursor line). Put cursor at first non-blank in the
                        line.

                                                                zt
zt   Like "z<CR>", but leave the cursor in the same
                        column. {not in Vi}

                                                                zN<CR>
z{height}<CR>   Redraw, make window {height} lines tall. This is
                        useful to make the number of lines small when screen
                        updating is very slow. Cannot make the height more
                        than the physical screen height.

                                                                z.
z.   Redraw, line [count] at center of window (default
                        cursor line). Put cursor at first non-blank in the
                        line.

                                                                zz
zz   Like "z.", but leave the cursor in the same column.
                        Careful: If caps-lock is on, this command becomes
                        "ZZ": write buffer and exit! {not in Vi}

                                                                z-
z-   Redraw, line [count] at bottom of window (default
                        cursor line). Put cursor at first non-blank in the
                        line.

                                                                zb
zb   Like "z-", but leave the cursor in the same column.
                        {not in Vi}

==
4. Scrolling horizontally   scroll-horizontal

For the following four commands the cursor follows the screen. If the character that the cursor is on is moved off the screen, the cursor is moved to the closest character that is on the screen. The value of 'sidescroll' is not used.

z<Right>   or   zl   z<Right>
zl   Move the view on the text [count] characters to the
                        right, thus scroll the text [count] characters to the
                        left. This only works when 'wrap' is off. {not in
                        Vi}

z<Left>	or	zh	z<Left>

zh	Move the view on the text [count] characters to the left, thus scroll the text [count] characters to the right. This only works when 'wrap' is off. {not in Vi}

zL

zL	Move the view on the text half a screenwidth to the right, thus scroll the text half a screenwidth to the left. This only works when 'wrap' is off. {not in Vi}

zH

zH	Move the view on the text half a screenwidth to the left, thus scroll the text half a screenwidth to the right. This only works when 'wrap' is off. {not in Vi}

For the following two commands the cursor is not moved in the text, only the text scrolls on the screen.

zs

zs	Scroll the text horizontally to position the cursor at the start (left side) of the screen. This only works when 'wrap' is off. {not in Vi}

ze

ze	Scroll the text horizontally to position the cursor at the end (right side) of the screen. This only works when 'wrap' is off. {not in Vi}

==========

## 5. Scrolling synchronously	scroll-binding

Occasionally, it is desirable to bind two or more windows together such that when one window is scrolled, the other windows are also scrolled. In Vim, windows can be given this behavior by setting the (window-specific) 'scrollbind' option. When a window that has 'scrollbind' set is scrolled, all other 'scrollbind' windows are scrolled the same amount, if possible. The behavior of 'scrollbind' can be modified by the 'scrollopt' option.

When using the scrollbars, the binding only happens when scrolling the window with focus (where the cursor is). You can use this to avoid scroll-binding for a moment without resetting options.

When a window also has the 'diff' option set, the scroll-binding uses the differences between the two buffers to synchronize the position precisely. Otherwise the following method is used.

scrollbind-relative

Each 'scrollbind' window keeps track of its "relative offset," which can be thought of as the difference between the current window's vertical scroll position and the other window's vertical scroll position. When one of the

'scrollbind' windows is asked to vertically scroll past the beginning or end limit of its text, the window no longer scrolls, but remembers how far past the limit it wishes to be. The window keeps this information so that it can maintain the same relative offset, regardless of its being asked to scroll past its buffer's limits.

However, if a 'scrollbind' window that has a relative offset that is past its buffer's limits is given the cursor focus, the other 'scrollbind' windows must jump to a location where the current window's relative offset is valid. This behavior can be changed by clearing the "jump" flag from the 'scrollopt' option.

syncbind :syncbind :sync

:syncbind Force all 'scrollbind' windows to have the same relative offset. I.e., when any of the 'scrollbind' windows is scrolled to the top of its buffer, all of the 'scrollbind' windows will also be at the top of their buffers.

scrollbind-quickadj

The 'scrollbind' flag is meaningful when using keyboard commands to vertically scroll a window, and also meaningful when using the vertical scrollbar of the window which has the cursor focus. However, when using the vertical scrollbar of a window which doesn't have the cursor focus, 'scrollbind' is ignored. This allows quick adjustment of the relative offset of 'scrollbind' windows.

==========

6. Scrolling with a mouse wheel scroll-mouse-wheel

When your mouse has a scroll wheel, it should work with Vim in the GUI. How it works depends on your system. It might also work in an xterm xterm-mouse-wheel . By default only vertical scroll wheels are supported, but some GUIs also support horizontal scroll wheels.

For the Win32 GUI the scroll action is hard coded. It works just like dragging the scrollbar of the current window. How many lines are scrolled depends on your mouse driver. If the scroll action causes input focus problems, see intellimouse-wheel-problems .

For the X11 GUIs (Motif, Athena and GTK) scrolling the wheel generates key presses <ScrollWheelUp>, <ScrollWheelDown>, <ScrollWheelLeft> and <ScrollWheelRight>. For example, if you push the scroll wheel upwards a <ScrollWheelUp> key press is generated causing the window to scroll upwards (while the text is actually moving downwards). The default action for these keys are:

<ScrollWheelUp>	scroll three lines up	<ScrollWheelUp>
<S-ScrollWheelUp>	scroll one page up	<S-ScrollWheelUp>
<C-ScrollWheelUp>	scroll one page up	<C-ScrollWheelUp>
<ScrollWheelDown>	scroll three lines down	<ScrollWheelDown>
<S-ScrollWheelDown>	scroll one page down	<S-ScrollWheelDown>
<C-ScrollWheelDown>	scroll one page down	<C-ScrollWheelDown>
<ScrollWheelLeft>	scroll six columns left	<ScrollWheelLeft>
<S-ScrollWheelLeft>	scroll one page left	<S-ScrollWheelLeft>
<C-ScrollWheelLeft>	scroll one page left	<C-ScrollWheelLeft>

```
    <ScrollWheelRight>      scroll six columns right     <ScrollWheelRight>
    <S-ScrollWheelRight>    scroll one page right        <S-ScrollWheelRight>
    <C-ScrollWheelRight>    scroll one page right        <C-ScrollWheelRight>
```
This should work in all modes, except when editing the command line.

Note that horizontal scrolling only works if 'nowrap' is set. Also, unless the "h" flag in 'guioptions' is set, the cursor moves to the longest visible line if the cursor line is about to be scrolled off the screen (similarly to how the horizontal scrollbar works).

You can modify the default behavior by mapping the keys. For example, to make the scroll wheel move one line or half a page in Normal mode:
```
   :map <ScrollWheelUp> <C-Y>
   :map <S-ScrollWheelUp> <C-U>
   :map <ScrollWheelDown> <C-E>
   :map <S-ScrollWheelDown> <C-D>
```
You can also use Alt and Ctrl modifiers.

This only works when Vim gets the scroll wheel events, of course. You can check if this works with the "xev" program.

When using XFree86, the /etc/XF86Config file should have the correct entry for your mouse. For FreeBSD, this entry works for a Logitech scrollmouse:
```
    Protocol     "MouseMan"
    Device       "/dev/psm0"
    ZAxisMapping 4 5
```
See the XFree86 documentation for information.

<MouseDown> <MouseUp>

The keys <MouseDown> and <MouseUp> have been deprecated. Use <ScrollWheelUp> instead of <MouseDown> and use <ScrollWheelDown> instead of <MouseUp>.

xterm-mouse-wheel

To use the mouse wheel in a new xterm you only have to make the scroll wheel work in your Xserver, as mentioned above.

To use the mouse wheel in an older xterm you must do this:
1. Make it work in your Xserver, as mentioned above.
2. Add translations for the xterm, so that the xterm will pass a scroll event to Vim as an escape sequence.
3. Add mappings in Vim, to interpret the escape sequences as <ScrollWheelDown> or <ScrollWheelUp> keys.

You can do the translations by adding this to your ~.Xdefaults file (or other file where your X resources are kept):

```
  XTerm*VT100.Translations:            #override \n\
                s<Btn4Down>: string("0x9b") string("[64~") \n\
                s<Btn5Down>: string("0x9b") string("[65~") \n\
                <Btn4Down>: string("0x9b") string("[62~") \n\
                <Btn5Down>: string("0x9b") string("[63~") \n\
                <Btn4Up>: \n\
                <Btn5Up>:
```

Add these mappings to your vimrc file:

```
:map <M-Esc>[62~ <ScrollWheelUp>
:map! <M-Esc>[62~ <ScrollWheelUp>
:map <M-Esc>[63~ <ScrollWheelDown>
:map! <M-Esc>[63~ <ScrollWheelDown>
:map <M-Esc>[64~ <S-ScrollWheelUp>
:map! <M-Esc>[64~ <S-ScrollWheelUp>
:map <M-Esc>[65~ <S-ScrollWheelDown>
:map! <M-Esc>[65~ <S-ScrollWheelDown>
```

vim:tw=78:ts=8:noet:ft=help:norl:

insert.txt For Vim version 8.1. Last change: 2018 Feb 10

VIM REFERENCE MANUAL by Bram Moolenaar

Inserting and replacing text Insert Insert-mode mode-ins-repl

Most of this file is about Insert and Replace mode. At the end are a few commands for inserting text in other ways.

An overview of the most often used commands can be found in chapter 24 of the user manual usr_24.txt .

Also see 'virtualedit', for moving the cursor to positions where there is no character. Useful for editing a table.

==
1. Special keys ins-special-keys

In Insert and Replace mode, the following characters have a special meaning; other characters are inserted directly. To insert one of these special characters into the buffer, precede it with CTRL-V. To insert a <Nul> character use "CTRL-V CTRL-@" or "CTRL-V 000". On some systems, you have to use "CTRL-V 003" to insert a CTRL-C. Note: When CTRL-V is mapped you can often use CTRL-Q instead i_CTRL-Q .

If you are working in a special language mode when inserting text, see the 'langmap' option, 'langmap' , on how to avoid switching this mode on and off all the time.

If you have 'insertmode' set, <Esc> and a few other keys get another meaning. See 'insertmode' .

char	action
<Esc> or CTRL-[i_CTRL-[i_<Esc>	End insert or Replace mode, go back to Normal mode. Finish abbreviation. Note: If your <Esc> key is hard to hit on your keyboard, train yourself to use CTRL-[. If Esc doesn't work and you are using a Mac, try CTRL-Esc.

Or disable Listening under Accessibility preferences.

i_CTRL-C
CTRL-C Quit insert mode, go back to Normal mode. Do not check for abbreviations. Does not trigger the InsertLeave autocommand event.

i_CTRL-@
CTRL-@ Insert previously inserted text and stop insert. {Vi: only when typed as first char, only up to 128 chars}

i_CTRL-A
CTRL-A Insert previously inserted text. {not in Vi}

i_CTRL-H i_<BS> i_BS
<BS> or CTRL-H Delete the character before the cursor (see i_backspacing about joining lines).
See :fixdel if your <BS> key does not do what you want.
{Vi: does not delete autoindents}

i_<Del> i_DEL
<Del> Delete the character under the cursor. If the cursor is at the end of the line, and the 'backspace' option includes "eol", delete the <EOL>; the next line is appended after the current one.
See :fixdel if your <Del> key does not do what you want.
{not in Vi}

i_CTRL-W
CTRL-W Delete the word before the cursor (see i_backspacing about joining lines). See the section "word motions", word-motions , for the definition of a word.

i_CTRL-U
CTRL-U Delete all entered characters before the cursor in the current line. If there are no newly entered characters and 'backspace' is not empty, delete all characters before the cursor in the current line.
See i_backspacing about joining lines.

i_CTRL-I i_<Tab> i_Tab
<Tab> or CTRL-I Insert a tab. If the 'expandtab' option is on, the equivalent number of spaces is inserted (use CTRL-V <Tab> to avoid the expansion; use CTRL-Q <Tab> if CTRL-V is mapped i_CTRL-Q). See also the 'smarttab' option and ins-expandtab .

i_CTRL-J i_<NL>
<NL> or CTRL-J Begin new line.

i_CTRL-M i_<CR>
<CR> or CTRL-M Begin new line.

i_CTRL-K
CTRL-K {char1} [char2]
Enter digraph (see digraphs). When {char1} is a special key, the code for that key is inserted in <> form. For example, the string "<S-Space>" can be entered by typing <C-K><S-Space> (two keys). Neither char is considered for mapping. {not in Vi}

CTRL-N Find next keyword (see i_CTRL-N). {not in Vi}
CTRL-P Find previous keyword (see i_CTRL-P). {not in Vi}

```
CTRL-R {0-9a-z"%#*+:.-=}                                        i_CTRL-R
                Insert the contents of a register.  Between typing CTRL-R and
                the second character, '"' will be displayed to indicate that
                you are expected to enter the name of a register.
                The text is inserted as if you typed it, but mappings and
                abbreviations are not used.  If you have options like
                'textwidth', 'formatoptions', or 'autoindent' set, this will
                influence what will be inserted.  This is different from what
                happens with the "p" command and pasting with the mouse.
                Special registers:
                        '""'    the unnamed register, containing the text of
                                the last delete or yank
                        '%'     the current file name
                        '#'     the alternate file name
                        '*'     the clipboard contents (X11: primary selection)
                        '+'     the clipboard contents
                        '/'     the last search pattern
                        ':'     the last command-line
                        '.'     the last inserted text
                        '-'     the last small (less than a line) delete
                                                        i_CTRL-R_=
                        '='     the expression register: you are prompted to
                                enter an expression (see  expression )
                                Note that 0x80 (128 decimal) is used for
                                special keys.  E.g., you can use this to move
                                the cursor up:
                                        CTRL-R ="\<Up>"
                                Use CTRL-R CTRL-R to insert text literally.
                                When the result is a  List  the items are used
                                as lines.  They can have line breaks inside
                                too.
                                When the result is a Float it's automatically
                                converted to a String.
                                When append() or setline() is invoked the undo
                                sequence will be broken.
                See  registers  about registers.  {not in Vi}

CTRL-R CTRL-R {0-9a-z"%#*+/:.-=}                        i_CTRL-R_CTRL-R
                Insert the contents of a register.  Works like using a single
                CTRL-R, but the text is inserted literally, not as if typed.
                This differs when the register contains characters like <BS>.
                Example, where register a contains "ab^Hc":
                CTRL-R a                results in "ac".
                CTRL-R CTRL-R a         results in "ab^Hc".
                Options 'textwidth', 'formatoptions', etc. still apply.  If
                you also want to avoid these, use CTRL-R CTRL-O, see below.
                The '.' register (last inserted text) is still inserted as
                typed.  {not in Vi}

CTRL-R CTRL-O {0-9a-z"%#*+/:.-=}                        i_CTRL-R_CTRL-O
                Insert the contents of a register literally and don't
                auto-indent.  Does the same as pasting with the mouse
                 <MiddleMouse> . When the register is linewise this will
```

insert the text above the current line, like with `P`.
Does not replace characters!
The '.' register (last inserted text) is still inserted as
typed. {not in Vi}

CTRL-R CTRL-P {0-9a-z"%#*+/:.-=} i_CTRL-R_CTRL-P
Insert the contents of a register literally and fix the
indent, like [<MiddleMouse> .
Does not replace characters!
The '.' register (last inserted text) is still inserted as
typed. {not in Vi}

i_CTRL-T
CTRL-T Insert one shiftwidth of indent at the start of the current
line. The indent is always rounded to a 'shiftwidth' (this is
vi compatible). {Vi: only when in indent}
i_CTRL-D
CTRL-D Delete one shiftwidth of indent at the start of the current
line. The indent is always rounded to a 'shiftwidth' (this is
vi compatible). {Vi: CTRL-D works only when used after
autoindent}
i_0_CTRL-D
0 CTRL-D Delete all indent in the current line. {Vi: CTRL-D works
only when used after autoindent}
i_^_CTRL-D
^ CTRL-D Delete all indent in the current line. The indent is
restored in the next line. This is useful when inserting a
label. {Vi: CTRL-D works only when used after autoindent}

i_CTRL-V
CTRL-V Insert next non-digit literally. For special keys, the
terminal code is inserted. It's also possible to enter the
decimal, octal or hexadecimal value of a character
 i_CTRL-V_digit .
The characters typed right after CTRL-V are not considered for
mapping. {Vi: no decimal byte entry}
Note: When CTRL-V is mapped (e.g., to paste text) you can
often use CTRL-Q instead i_CTRL-Q .

i_CTRL-Q
CTRL-Q Same as CTRL-V.
Note: Some terminal connections may eat CTRL-Q, it doesn't
work then. It does work in the GUI.

CTRL-X Enter CTRL-X mode. This is a sub-mode where commands can
be given to complete words or scroll the window. See
 i_CTRL-X and ins-completion . {not in Vi}

i_CTRL-E
CTRL-E Insert the character which is below the cursor. {not in Vi}
i_CTRL-Y
CTRL-Y Insert the character which is above the cursor. {not in Vi}
Note that for CTRL-E and CTRL-Y 'textwidth' is not used, to be
able to copy characters from a long line.

```
                                                        i_CTRL-_
CTRL-_          Switch between languages, as follows:
                -  When in a rightleft window, revins and nohkmap are toggled,
                   since English will likely be inserted in this case.
                -  When in a norightleft window, revins and hkmap are toggled,
                   since Hebrew will likely be inserted in this case.

                CTRL-_ moves the cursor to the end of the typed text.

                This command is only available when the 'allowrevins' option
                is set.
                Please refer to  rileft.txt  for more information about
                right-to-left mode.
                {not in Vi}
                Only if compiled with the  +rightleft  feature.

                                                        i_CTRL-^
CTRL-^          Toggle the use of typing language characters.
                When language  :lmap  mappings are defined:
                - If 'iminsert' is 1 (langmap mappings used) it becomes 0 (no
                  langmap mappings used).
                - If 'iminsert' has another value it becomes 1, thus langmap
                  mappings are enabled.
                When no language mappings are defined:
                - If 'iminsert' is 2 (Input Method used) it becomes 0 (no
                  Input Method used).
                - If 'iminsert' has another value it becomes 2, thus the Input
                  Method is enabled.
                When set to 1, the value of the "b:keymap_name" variable, the
                'keymap' option or "<lang>" appears in the status line.
                The language mappings are normally used to type characters
                that are different from what the keyboard produces.  The
                'keymap' option can be used to install a whole number of them.
                {not in Vi}

                                                        i_CTRL-]
CTRL-]          Trigger abbreviation, without inserting a character.  {not in
                Vi}

                                                        i_<Insert>
<Insert>        Toggle between Insert and Replace mode.  {not in Vi}
-------------------------------------------------------------------------------

                                                        i_backspacing
The effect of the <BS>, CTRL-W, and CTRL-U depend on the 'backspace' option
(unless 'revins' is set).  This is a comma separated list of items:

item        action
indent      allow backspacing over autoindent
eol         allow backspacing over end-of-line (join lines)
start       allow backspacing over the start position of insert; CTRL-W and
            CTRL-U stop once at the start position
```

When 'backspace' is empty, Vi compatible backspacing is used. You cannot backspace over autoindent, before column 1 or before where insert started.

For backwards compatibility the values "0", "1" and "2" are also allowed, see 'backspace' .

If the 'backspace' option does contain "eol" and the cursor is in column 1 when one of the three keys is used, the current line is joined with the previous line. This effectively deletes the <EOL> in front of the cursor. {Vi: does not cross lines, does not delete past start position of insert}

i_CTRL-V_digit

With CTRL-V the decimal, octal or hexadecimal value of a character can be entered directly. This way you can enter any character, except a line break (<NL>, value 10). There are five ways to enter the character value:

first char	mode	max nr of chars	max value	
(none)	decimal	3	255	
o or O	octal	3	377	(255)
x or X	hexadecimal	2	ff	(255)
u	hexadecimal	4	ffff	(65535)
U	hexadecimal	8	7fffffff	(2147483647)

Normally you would type the maximum number of characters. Thus to enter a space (value 32) you would type <C-V>032. You can omit the leading zero, in which case the character typed after the number must be a non-digit. This happens for the other modes as well: As soon as you type a character that is invalid for the mode, the value before it will be used and the "invalid" character is dealt with in the normal way.

If you enter a value of 10, it will end up in the file as a 0. The 10 is a <NL>, which is used internally to represent the <Nul> character. When writing the buffer to a file, the <NL> character is translated into <Nul>. The <NL> character is written at the end of each line. Thus if you want to insert a <NL> character in a file you will have to make a line break.

i_CTRL-X insert_expand

CTRL-X enters a sub-mode where several commands can be used. Most of these commands do keyword completion; see ins-completion . These are not available when Vim was compiled without the +insert_expand feature.

Two commands can be used to scroll the window up or down, without exiting insert mode:

i_CTRL-X_CTRL-E

CTRL-X CTRL-E scroll window one line up.
When doing completion look here: complete_CTRL-E

i_CTRL-X_CTRL-Y

CTRL-X CTRL-Y scroll window one line down.
When doing completion look here: complete_CTRL-Y

After CTRL-X is pressed, each CTRL-E (CTRL-Y) scrolls the window up (down) by one line unless that would cause the cursor to move from its current position

in the file. As soon as another key is pressed, CTRL-X mode is exited and that key is interpreted as in Insert mode.

==
2. Special special keys ins-special-special

The following keys are special. They stop the current insert, do something, and then restart insertion. This means you can do something without getting out of Insert mode. This is very handy if you prefer to use the Insert mode all the time, just like editors that don't have a separate Normal mode. You may also want to set the 'backspace' option to "indent,eol,start" and set the 'insertmode' option. You can use CTRL-O if you want to map a function key to a command.

The changes (inserted or deleted characters) before and after these keys can be undone separately. Only the last change can be redone and always behaves like an "i" command.

char	action	
<Up>	cursor one line up	i_<Up>
<Down>	cursor one line down	i_<Down>
CTRL-G <Up>	cursor one line up, insert start column	i_CTRL-G_<Up>
CTRL-G k	cursor one line up, insert start column	i_CTRL-G_k
CTRL-G CTRL-K	cursor one line up, insert start column	i_CTRL-G_CTRL-K
CTRL-G <Down>	cursor one line down, insert start column	i_CTRL-G_<Down>
CTRL-G j	cursor one line down, insert start column	i_CTRL-G_j
CTRL-G CTRL-J	cursor one line down, insert start column	i_CTRL-G_CTRL-J
<Left>	cursor one character left	i_<Left>
<Right>	cursor one character right	i_<Right>
<S-Left>	cursor one word back (like "b" command)	i_<S-Left>
<C-Left>	cursor one word back (like "b" command)	i_<C-Left>
<S-Right>	cursor one word forward (like "w" command)	i_<S-Right>
<C-Right>	cursor one word forward (like "w" command)	i_<C-Right>
<Home>	cursor to first char in the line	i_<Home>
<End>	cursor to after last char in the line	i_<End>
<C-Home>	cursor to first char in the file	i_<C-Home>
<C-End>	cursor to after last char in the file	i_<C-End>
<LeftMouse>	cursor to position of mouse click	i_<LeftMouse>
<S-Up>	move window one page up	i_<S-Up>
<PageUp>	move window one page up	i_<PageUp>
<S-Down>	move window one page down	i_<S-Down>
<PageDown>	move window one page down	i_<PageDown>
<ScrollWheelDown>	move window three lines down	i_<ScrollWheelDown>
<S-ScrollWheelDown>	move window one page down	i_<S-ScrollWheelDown>
<ScrollWheelUp>	move window three lines up	i_<ScrollWheelUp>
<S-ScrollWheelUp>	move window one page up	i_<S-ScrollWheelUp>
<ScrollWheelLeft>	move window six columns left	i_<ScrollWheelLeft>
<S-ScrollWheelLeft>	move window one page left	i_<S-ScrollWheelLeft>
<ScrollWheelRight>	move window six columns right	i_<ScrollWheelRight>
<S-ScrollWheelRight>	move window one page right	i_<S-ScrollWheelRight>
CTRL-O	execute one command, return to Insert mode	i_CTRL-O
CTRL-\ CTRL-O	like CTRL-O but don't move the cursor	i_CTRL-_CTRL-O

```
CTRL-L          when 'insertmode' is set: go to Normal mode   i_CTRL-L
CTRL-G u        break undo sequence, start new change         i_CTRL-G_u
CTRL-G U        don't break undo with next left/right cursor  i_CTRL-G_U
                movement (but only if the cursor stays
                within same the line)
-------------------------------------------------------------------------
```

Note: If the cursor keys take you out of Insert mode, check the 'noesckeys' option.

The CTRL-O command sometimes has a side effect: If the cursor was beyond the end of the line, it will be put on the last character in the line. In mappings it's often better to use <Esc> (first put an "x" in the text, <Esc> will then always put the cursor on it). Or use CTRL-\ CTRL-O, but then beware of the cursor possibly being beyond the end of the line. Note that the command following CTRL-\ CTRL-O can still move the cursor, it is not restored to its original position.

The CTRL-O command takes you to Normal mode. If you then use a command enter Insert mode again it normally doesn't nest. Thus when typing "a<C-O>a" and then <Esc> takes you back to Normal mode, you do not need to type <Esc> twice. An exception is when not typing the command, e.g. when executing a mapping or sourcing a script. This makes mappings work that briefly switch to Insert mode.

The shifted cursor keys are not available on all terminals.

Another side effect is that a count specified before the "i" or "a" command is ignored. That is because repeating the effect of the command after CTRL-O is too complicated.

An example for using CTRL-G u:

```
:inoremap <C-H> <C-G>u<C-H>
```

This redefines the backspace key to start a new undo sequence. You can now undo the effect of the backspace key, without changing what you typed before that, with CTRL-O u. Another example:

```
:inoremap <CR> <C-]><C-G>u<CR>
```

This breaks undo at each line break. It also expands abbreviations before this.

An example for using CTRL-G U:

```
inoremap <Left>  <C-G>U<Left>
inoremap <Right> <C-G>U<Right>
inoremap <expr> <Home> col('.') == match(getline('.'), '\S') + 1 ?
 \ repeat('<C-G>U<Left>', col('.') - 1) :
 \ (col('.') < match(getline('.'), '\S') ?
 \     repeat('<C-G>U<Right>', match(getline('.'), '\S') + 0) :
 \     repeat('<C-G>U<Left>', col('.') - 1 - match(getline('.'), '\S')))
inoremap <expr> <End> repeat('<C-G>U<Right>', col('$') - col('.'))
```

```
        inoremap ( ()<C-G>U<Left>
```

This makes it possible to use the cursor keys in Insert mode, without breaking the undo sequence and therefore using . (redo) will work as expected. Also entering a text like (with the "(" mapping from above):

```
   Lorem ipsum (dolor
```

will be repeatable by using . to the expected

```
   Lorem ipsum (dolor)
```

Using CTRL-O splits undo: the text typed before and after it is undone separately. If you want to avoid this (e.g., in a mapping) you might be able to use CTRL-R = i_CTRL-R . E.g., to call a function:

```
        :imap <F2> <C-R>=MyFunc()<CR>
```

When the 'whichwrap' option is set appropriately, the <Left> and <Right> keys on the first/last character in the line make the cursor wrap to the previous/next line.

The CTRL-G j and CTRL-G k commands can be used to insert text in front of a column. Example:

```
   int i;
   int j;
```

Position the cursor on the first "int", type "istatic <C-G>j ". The result is:

```
   static int i;
          int j;
```

When inserting the same text in front of the column in every line, use the Visual blockwise command "I" v_b_I .

==========

3. 'textwidth' and 'wrapmargin' options ins-textwidth

The 'textwidth' option can be used to automatically break a line before it gets too long. Set the 'textwidth' option to the desired maximum line length. If you then type more characters (not spaces or tabs), the last word will be put on a new line (unless it is the only word on the line). If you set 'textwidth' to 0, this feature is disabled.

The 'wrapmargin' option does almost the same. The difference is that 'textwidth' has a fixed width while 'wrapmargin' depends on the width of the screen. When using 'wrapmargin' this is equal to using 'textwidth' with a value equal to (columns - 'wrapmargin'), where columns is the width of the screen.

When 'textwidth' and 'wrapmargin' are both set, 'textwidth' is used.

If you don't really want to break the line, but view the line wrapped at a convenient place, see the 'linebreak' option.

The line is only broken automatically when using Insert mode, or when appending to a line. When in replace mode and the line length is not

changed, the line will not be broken.

Long lines are broken if you enter a non-white character after the margin.
The situations where a line will be broken can be restricted by adding
characters to the 'formatoptions' option:
"l" Only break a line if it was not longer than 'textwidth' when the insert
     started.
"v" Only break at a white character that has been entered during the
     current insert command. This is mostly Vi-compatible.
"lv" Only break if the line was not longer than 'textwidth' when the insert
     started and only at a white character that has been entered during the
     current insert command. Only differs from "l" when entering non-white
     characters while crossing the 'textwidth' boundary.

Normally an internal function will be used to decide where to break the line.
If you want to do it in a different way set the 'formatexpr' option to an
expression that will take care of the line break.

If you want to format a block of text, you can use the "gq" operator. Type
"gq" and a movement command to move the cursor to the end of the block. In
many cases, the command "gq}" will do what you want (format until the end of
paragraph). Alternatively, you can use "gqap", which will format the whole
paragraph, no matter where the cursor currently is. Or you can use Visual
mode: hit "v", move to the end of the block, and type "gq". See also gq .

==
4. 'expandtab', 'smarttab' and 'softtabstop' options   ins-expandtab

If the 'expandtab' option is on, spaces will be used to fill the amount of
whitespace of the tab. If you want to enter a real <Tab>, type CTRL-V first
(use CTRL-Q when CTRL-V is mapped i_CTRL-Q).
The 'expandtab' option is off by default. Note that in Replace mode, a single
character is replaced with several spaces. The result of this is that the
number of characters in the line increases. Backspacing will delete one
space at a time. The original character will be put back for only one space
that you backspace over (the last one). {Vi does not have the 'expandtab'
option}

                                                        ins-smarttab
When the 'smarttab' option is on, a <Tab> inserts 'shiftwidth' positions at
the beginning of a line and 'tabstop' positions in other places. This means
that often spaces instead of a <Tab> character are inserted. When 'smarttab'
is off, a <Tab> always inserts 'tabstop' positions, and 'shiftwidth' is only
used for ">>" and the like. {not in Vi}

                                                        ins-softtabstop
When the 'softtabstop' option is non-zero, a <Tab> inserts 'softtabstop'
positions, and a <BS> used to delete white space, will delete 'softtabstop'
positions. This feels like 'tabstop' was set to 'softtabstop', but a real
<Tab> character still takes 'tabstop' positions, so your file will still look
correct when used by other applications.

If 'softtabstop' is non-zero, a <BS> will try to delete as much white space to
move to the previous 'softtabstop' position, except when the previously

inserted character is a space, then it will only delete the character before the cursor. Otherwise you cannot always delete a single character before the cursor. You will have to delete 'softtabstop' characters first, and then type extra spaces to get where you want to be.

==
5. Replace mode   Replace   Replace-mode   mode-replace

Enter Replace mode with the "R" command in normal mode.

In Replace mode, one character in the line is deleted for every character you type. If there is no character to delete (at the end of the line), the typed character is appended (as in Insert mode). Thus the number of characters in a line stays the same until you get to the end of the line. If a <NL> is typed, a line break is inserted and no character is deleted.

Be careful with <Tab> characters. If you type a normal printing character in its place, the number of characters is still the same, but the number of columns will become smaller.

If you delete characters in Replace mode (with <BS>, CTRL-W, or CTRL-U), what happens is that you delete the changes. The characters that were replaced are restored. If you had typed past the existing text, the characters you added are deleted. This is effectively a character-at-a-time undo.

If the 'expandtab' option is on, a <Tab> will replace one character with several spaces. The result of this is that the number of characters in the line increases. Backspacing will delete one space at a time. The original character will be put back for only one space that you backspace over (the last one). {Vi does not have the 'expandtab' option}

==
6. Virtual Replace mode   vreplace-mode   Virtual-Replace-mode

Enter Virtual Replace mode with the "gR" command in normal mode.
{not available when compiled without the |+vreplace| feature}
{Vi does not have Virtual Replace mode}

Virtual Replace mode is similar to Replace mode, but instead of replacing actual characters in the file, you are replacing screen real estate, so that characters further on in the file never appear to move.

So if you type a <Tab> it may replace several normal characters, and if you type a letter on top of a <Tab> it may not replace anything at all, since the <Tab> will still line up to the same place as before.

Typing a <NL> still doesn't cause characters later in the file to appear to move. The rest of the current line will be replaced by the <NL> (that is, they are deleted), and replacing continues on the next line. A new line is NOT inserted unless you go past the end of the file.

Interesting effects are seen when using CTRL-T and CTRL-D. The characters before the cursor are shifted sideways as normal, but characters later in the line still remain still. CTRL-T will hide some of the old line under the

shifted characters, but CTRL-D will reveal them again.

As with Replace mode, using <BS> etc will bring back the characters that were replaced. This still works in conjunction with 'smartindent', CTRL-T and CTRL-D, 'expandtab', 'smarttab', 'softtabstop', etc.

In 'list' mode, Virtual Replace mode acts as if it was not in 'list' mode, unless "L" is in 'cpoptions'.

Note that the only situations for which characters beyond the cursor should appear to move are in List mode 'list' , and occasionally when 'wrap' is set (and the line changes length to become shorter or wider than the width of the screen). In other cases spaces may be inserted to avoid following characters to move.

This mode is very useful for editing <Tab> separated columns in tables, for entering new data while keeping all the columns aligned.

==
7. Insert mode completion   ins-completion

In Insert and Replace mode, there are several commands to complete part of a keyword or line that has been typed. This is useful if you are using complicated keywords (e.g., function names with capitals and underscores).

These commands are not available when the +insert_expand feature was disabled at compile time.

Completion can be done for:

1. Whole lines   i_CTRL-X_CTRL-L
2. keywords in the current file   i_CTRL-X_CTRL-N
3. keywords in 'dictionary'   i_CTRL-X_CTRL-K
4. keywords in 'thesaurus', thesaurus-style   i_CTRL-X_CTRL-T
5. keywords in the current and included files   i_CTRL-X_CTRL-I
6. tags   i_CTRL-X_CTRL-]
7. file names   i_CTRL-X_CTRL-F
8. definitions or macros   i_CTRL-X_CTRL-D
9. Vim command-line   i_CTRL-X_CTRL-V
10. User defined completion   i_CTRL-X_CTRL-U
11. omni completion   i_CTRL-X_CTRL-O
12. Spelling suggestions   i_CTRL-X_s
13. keywords in 'complete'   i_CTRL-N   i_CTRL-P

All these, except CTRL-N and CTRL-P, are done in CTRL-X mode. This is a sub-mode of Insert and Replace modes. You enter CTRL-X mode by typing CTRL-X and one of the CTRL-X commands. You exit CTRL-X mode by typing a key that is not a valid CTRL-X mode command. Valid keys are the CTRL-X command itself, CTRL-N (next), and CTRL-P (previous).

Also see the 'infercase' option if you want to adjust the case of the match.

                                                             complete_CTRL-E
When completion is active you can use CTRL-E to stop it and go back to the

originally typed text. The CTRL-E will not be inserted.

complete_CTRL-Y

When the popup menu is displayed you can use CTRL-Y to stop completion and accept the currently selected entry. The CTRL-Y is not inserted. Typing a space, Enter, or some other unprintable character will leave completion mode and insert that typed character.

When the popup menu is displayed there are a few more special keys, see popupmenu-keys .

Note: The keys that are valid in CTRL-X mode are not mapped. This allows for ":map ^F ^X^F" to work (where ^F is CTRL-F and ^X is CTRL-X). The key that ends CTRL-X mode (any key that is not a valid CTRL-X mode command) is mapped. Also, when doing completion with 'complete' mappings apply as usual.

Note: While completion is active Insert mode can't be used recursively. Mappings that somehow invoke ":normal i.." will generate an E523 error.

The following mappings are suggested to make typing the completion commands a bit easier (although they will hide other commands):

```
:inoremap ^] ^X^]
:inoremap ^F ^X^F
:inoremap ^D ^X^D
:inoremap ^L ^X^L
```

As a special case, typing CTRL-R to perform register insertion (see i_CTRL-R) will not exit CTRL-X mode. This is primarily to allow the use of the '=' register to call some function to determine the next operation. If the contents of the register (or result of the '=' register evaluation) are not valid CTRL-X mode keys, then CTRL-X mode will be exited as if those keys had been typed.

For example, the following will map <Tab> to either actually insert a <Tab> if the current line is currently only whitespace, or start/continue a CTRL-N completion operation:

```
function! CleverTab()
   if strpart( getline('.'), 0, col('.')-1 ) =~ '^\s*$'
      return "\<Tab>"
   else
      return "\<C-N>"
   endif
endfunction
inoremap <Tab> <C-R>=CleverTab()<CR>
```

Completing whole lines compl-whole-line

i_CTRL-X_CTRL-L

CTRL-X CTRL-L Search backwards for a line that starts with the same characters as those in the current line before the cursor. Indent is ignored. The matching line is

inserted in front of the cursor.
The 'complete' option is used to decide which buffers are searched for a match. Both loaded and unloaded buffers are used.

CTRL-L or CTRL-P — Search backwards for next matching line. This line replaces the previous matching line.

CTRL-N — Search forward for next matching line. This line replaces the previous matching line.

CTRL-X CTRL-L — After expanding a line you can additionally get the line next to it by typing CTRL-X CTRL-L again, unless a double CTRL-X is used. Only works for loaded buffers.

Completing keywords in current file compl-current

i_CTRL-X_CTRL-P
i_CTRL-X_CTRL-N

CTRL-X CTRL-N — Search forwards for words that start with the keyword in front of the cursor. The found keyword is inserted in front of the cursor.

CTRL-X CTRL-P — Search backwards for words that start with the keyword in front of the cursor. The found keyword is inserted in front of the cursor.

CTRL-N — Search forward for next matching keyword. This keyword replaces the previous matching keyword.

CTRL-P — Search backwards for next matching keyword. This keyword replaces the previous matching keyword.

CTRL-X CTRL-N or CTRL-X CTRL-P — Further use of CTRL-X CTRL-N or CTRL-X CTRL-P will copy the words following the previous expansion in other contexts unless a double CTRL-X is used.

If there is a keyword in front of the cursor (a name made out of alphabetic characters and characters in 'iskeyword'), it is used as the search pattern, with "\<" prepended (meaning: start of a word). Otherwise "\<\k\k" is used as search pattern (start of any keyword of at least two characters).

In Replace mode, the number of characters that are replaced depends on the length of the matched string. This works like typing the characters of the matched string in Replace mode.

If there is not a valid keyword character before the cursor, any keyword of at least two characters is matched.

```
e.g., to get:
    printf("(%g, %g, %g)", vector[0], vector[1], vector[2]);
just type:
    printf("(%g, %g, %g)", vector[0], ^P[1], ^P[2]);
```

The search wraps around the end of the file, the value of 'wrapscan' is not used here.

Multiple repeats of the same completion are skipped; thus a different match will be inserted at each CTRL-N and CTRL-P (unless there is only one matching keyword).

Single character matches are never included, as they usually just get in the way of what you were really after.
```
        e.g., to get:
                printf("name = %s\n", name);
        just type:
                printf("name = %s\n", n^P);
        or even:
                printf("name = %s\n", ^P);
```
The 'n' in '\n' is skipped.

After expanding a word, you can use CTRL-X CTRL-P or CTRL-X CTRL-N to get the word following the expansion in other contexts. These sequences search for the text just expanded and further expand by getting an extra word. This is useful if you need to repeat a sequence of complicated words. Although CTRL-P and CTRL-N look just for strings of at least two characters, CTRL-X CTRL-P and CTRL-X CTRL-N can be used to expand words of just one character.
```
        e.g., to get:
                M&eacute;xico
        you can type:
                M^N^P^X^P^X^P
```
CTRL-N starts the expansion and then CTRL-P takes back the single character "M", the next two CTRL-X CTRL-P's get the words "&eacute" and ";xico".

If the previous expansion was split, because it got longer than 'textwidth', then just the text in the current line will be used.

If the match found is at the end of a line, then the first word in the next line will be inserted and the message "word from next line" displayed, if this word is accepted the next CTRL-X CTRL-P or CTRL-X CTRL-N will search for those lines starting with this word.

Completing keywords in 'dictionary' compl-dictionary

i_CTRL-X_CTRL-K

CTRL-X CTRL-K Search the files given with the 'dictionary' option for words that start with the keyword in front of the cursor. This is like CTRL-N, but only the dictionary files are searched, not the current file. The found keyword is inserted in front of the cursor. This could potentially be pretty slow, since all matches are found before the first match is used. By default, the 'dictionary' option is empty.
For suggestions where to find a list of words, see the 'dictionary' option.

CTRL-K or
CTRL-N		Search forward for next matching keyword. This
		keyword replaces the previous matching keyword.

CTRL-P		Search backwards for next matching keyword. This
		keyword replaces the previous matching keyword.

i_CTRL-X_CTRL-T
CTRL-X CTRL-T		Works as CTRL-X CTRL-K, but in a special way. It uses
		the 'thesaurus' option instead of 'dictionary'. If a
		match is found in the thesaurus file, all the
		remaining words on the same line are included as
		matches, even though they don't complete the word.
		Thus a word can be completely replaced.

		For an example, imagine the 'thesaurus' file has a
		line like this:
			angry furious mad enraged
		Placing the cursor after the letters "ang" and typing
		CTRL-X CTRL-T would complete the word "angry";
		subsequent presses would change the word to "furious",
		"mad" etc.
		Other uses include translation between two languages,
		or grouping API functions by keyword.

CTRL-T or
CTRL-N		Search forward for next matching keyword. This
		keyword replaces the previous matching keyword.

CTRL-P		Search backwards for next matching keyword. This
		keyword replaces the previous matching keyword.

Completing keywords in the current and included files	compl-keyword

The 'include' option is used to specify a line that contains an include file
name. The 'path' option is used to search for include files.

i_CTRL-X_CTRL-I
CTRL-X CTRL-I		Search for the first keyword in the current and
		included files that starts with the same characters
		as those before the cursor. The matched keyword is
		inserted in front of the cursor.

CTRL-N		Search forwards for next matching keyword. This
		keyword replaces the previous matching keyword.
		Note: CTRL-I is the same as <Tab>, which is likely to
		be typed after a successful completion, therefore
		CTRL-I is not used for searching for the next match.

CTRL-P		Search backward for previous matching keyword. This
		keyword replaces the previous matching keyword.

CTRL-X CTRL-I	Further use of CTRL-X CTRL-I will copy the words

following the previous expansion in other contexts
unless a double CTRL-X is used.

Completing tags compl-tag
i_CTRL-X_CTRL-]

CTRL-X CTRL-] Search for the first tag that starts with the same characters as before the cursor. The matching tag is inserted in front of the cursor. Alphabetic characters and characters in 'iskeyword' are used to decide which characters are included in the tag name (same as for a keyword). See also CTRL-] . The 'showfulltag' option can be used to add context from around the tag definition.

CTRL-] or
CTRL-N Search forwards for next matching tag. This tag replaces the previous matching tag.

CTRL-P Search backward for previous matching tag. This tag replaces the previous matching tag.

Completing file names compl-filename
i_CTRL-X_CTRL-F

CTRL-X CTRL-F Search for the first file name that starts with the same characters as before the cursor. The matching file name is inserted in front of the cursor. Alphabetic characters and characters in 'isfname' are used to decide which characters are included in the file name. Note: the 'path' option is not used here (yet).

CTRL-F or
CTRL-N Search forwards for next matching file name. This file name replaces the previous matching file name.

CTRL-P Search backward for previous matching file name. This file name replaces the previous matching file name.

Completing definitions or macros compl-define

The 'define' option is used to specify a line that contains a definition. The 'include' option is used to specify a line that contains an include file name. The 'path' option is used to search for include files.

i_CTRL-X_CTRL-D

CTRL-X CTRL-D Search in the current and included files for the first definition (or macro) name that starts with the same characters as before the cursor. The found definition name is inserted in front of the cursor.

CTRL-D or
CTRL-N Search forwards for next matching macro name. This macro name replaces the previous matching macro name.

CTRL-P		Search backward for previous matching macro name.
		This macro name replaces the previous matching macro
		name.

CTRL-X CTRL-D	Further use of CTRL-X CTRL-D will copy the words
		following the previous expansion in other contexts
		unless a double CTRL-X is used.

Completing Vim commands		compl-vim

Completion is context-sensitive. It works like on the Command-line. It completes an Ex command as well as its arguments. This is useful when writing a Vim script.

		i_CTRL-X_CTRL-V
CTRL-X CTRL-V		Guess what kind of item is in front of the cursor and find the first match for it.
		Note: When CTRL-V is mapped you can often use CTRL-Q instead of i_CTRL-Q .
	CTRL-V or
	CTRL-N		Search forwards for next match. This match replaces the previous one.

	CTRL-P		Search backwards for previous match. This match replaces the previous one.

	CTRL-X CTRL-V	Further use of CTRL-X CTRL-V will do the same as CTRL-V. This allows mapping a key to do Vim command completion, for example:
			:imap <Tab> <C-X><C-V>

User defined completion		compl-function

Completion is done by a function that can be defined by the user with the 'completefunc' option. See below for how the function is called and an example complete-functions .

		i_CTRL-X_CTRL-U
CTRL-X CTRL-U		Guess what kind of item is in front of the cursor and find the first match for it.
	CTRL-U or
	CTRL-N		Use the next match. This match replaces the previous one.

	CTRL-P		Use the previous match. This match replaces the previous one.

Omni completion		compl-omni

Completion is done by a function that can be defined by the user with the 'omnifunc' option. This is to be used for filetype-specific completion.

See below for how the function is called and an example complete-functions .
For remarks about specific filetypes see compl-omni-filetypes .
More completion scripts will appear, check www.vim.org. Currently there is a
first version for C++.

                                                                i_CTRL-X_CTRL-O
CTRL-X CTRL-O   Guess what kind of item is in front of the cursor and
                        find the first match for it.
        CTRL-O or
        CTRL-N   Use the next match. This match replaces the previous
                        one.

        CTRL-P   Use the previous match. This match replaces the
                        previous one.

Spelling suggestions   compl-spelling

A word before or at the cursor is located and correctly spelled words are
suggested to replace it. If there is a badly spelled word in the line, before
or under the cursor, the cursor is moved to after it. Otherwise the word just
before the cursor is used for suggestions, even though it isn't badly spelled.

NOTE: CTRL-S suspends display in many Unix terminals. Use 's' instead. Type
CTRL-Q to resume displaying.

                                                  i_CTRL-X_CTRL-S   i_CTRL-X_s
CTRL-X CTRL-S   or
CTRL-X s   Locate the word in front of the cursor and find the
                        first spell suggestion for it.
        CTRL-S or
        CTRL-N   Use the next suggestion. This replaces the previous
                        one. Note that you can't use 's' here.

        CTRL-P   Use the previous suggestion. This replaces the
                        previous one.

Completing keywords from different sources   compl-generic

                                                                i_CTRL-N
CTRL-N   Find next match for words that start with the
                        keyword in front of the cursor, looking in places
                        specified with the 'complete' option. The found
                        keyword is inserted in front of the cursor.

                                                                i_CTRL-P
CTRL-P   Find previous match for words that start with the
                        keyword in front of the cursor, looking in places
                        specified with the 'complete' option. The found
                        keyword is inserted in front of the cursor.

        CTRL-N   Search forward for next matching keyword. This

keyword replaces the previous matching keyword.

CTRL-P Search backwards for next matching keyword. This keyword replaces the previous matching keyword.

CTRL-X CTRL-N or
CTRL-X CTRL-P Further use of CTRL-X CTRL-N or CTRL-X CTRL-P will copy the words following the previous expansion in other contexts unless a double CTRL-X is used.

FUNCTIONS FOR FINDING COMPLETIONS complete-functions

This applies to 'completefunc' and 'omnifunc'.

The function is called in two different ways:
- First the function is called to find the start of the text to be completed.
- Later the function is called to actually find the matches.

On the first invocation the arguments are:
   a:findstart 1
   a:base   empty

The function must return the column where the completion starts. It must be a number between zero and the cursor column "col('.')". This involves looking at the characters just before the cursor and including those characters that could be part of the completed item. The text between this column and the cursor column will be replaced with the matches.

Special return values:
   -1 If no completion can be done, the completion will be cancelled with an error message.
   -2 To cancel silently and stay in completion mode.
   -3 To cancel silently and leave completion mode.

On the second invocation the arguments are:
   a:findstart 0
   a:base   the text with which matches should match; the text that was located in the first call (can be empty)

The function must return a List with the matching words. These matches usually include the "a:base" text. When there are no matches return an empty List.

In order to return more information than the matching words, return a Dict that contains the List. The Dict can have these items:
   words   The List of matching words (mandatory).
   refresh A string to control re-invocation of the function (optional).
            The only value currently recognized is "always", the effect is that the function is called whenever the leading text is changed.
Other items are ignored.

For acting upon end of completion, see the CompleteDone autocommand event.

For example, the function can contain this:
```
	let matches = ... list of words ...
	return {'words': matches, 'refresh': 'always'}
```

complete-items

Each list item can either be a string or a Dictionary. When it is a string it is used as the completion. When it is a Dictionary it can contain these items:

word	the text that will be inserted, mandatory
abbr	abbreviation of "word"; when not empty it is used in the menu instead of "word"
menu	extra text for the popup menu, displayed after "word" or "abbr"
info	more information about the item, can be displayed in a preview window
kind	single letter indicating the type of completion
icase	when non-zero case is to be ignored when comparing items to be equal; when omitted zero is used, thus items that only differ in case are added
dup	when non-zero this match will be added even when an item with the same word is already present.
empty	when non-zero this match will be added even when it is an empty string
user_data	custom data which is associated with the item and available in v:completed_item

All of these except "icase", "dup" and "empty" must be a string. If an item does not meet these requirements then an error message is given and further items in the list are not used. You can mix string and Dictionary items in the returned list.

The "menu" item is used in the popup menu and may be truncated, thus it should be relatively short. The "info" item can be longer, it will be displayed in the preview window when "preview" appears in 'completeopt'. The "info" item will also remain displayed after the popup menu has been removed. This is useful for function arguments. Use a single space for "info" to remove existing text in the preview window. The size of the preview window is three lines, but 'previewheight' is used when it has a value of 1 or 2.

The "kind" item uses a single letter to indicate the kind of completion. This may be used to show the completion differently (different color or icon). Currently these types can be used:

v	variable
f	function or method
m	member of a struct or class
t	typedef
d	#define or macro

When searching for matches takes some time call complete_add() to add each match to the total list. These matches should then not appear in the returned list! Call complete_check() now and then to allow the user to press a key while still searching for matches. Stop searching when it returns non-zero.

E839 E840

The function is allowed to move the cursor, it is restored afterwards.
The function is not allowed to move to another window or delete text.

An example that completes the names of the months:

```
fun! CompleteMonths(findstart, base)
  if a:findstart
    " locate the start of the word
    let line = getline('.')
    let start = col('.') - 1
    while start > 0 && line[start - 1] =~ '\a'
      let start -= 1
    endwhile
    return start
  else
    " find months matching with "a:base"
    let res = []
    for m in split("Jan Feb Mar Apr May Jun Jul Aug Sep Oct Nov Dec")
      if m =~ '^' . a:base
        call add(res, m)
      endif
    endfor
    return res
  endif
endfun
set completefunc=CompleteMonths
```

The same, but now pretending searching for matches is slow:

```
fun! CompleteMonths(findstart, base)
  if a:findstart
    " locate the start of the word
    let line = getline('.')
    let start = col('.') - 1
    while start > 0 && line[start - 1] =~ '\a'
      let start -= 1
    endwhile
    return start
  else
    " find months matching with "a:base"
    for m in split("Jan Feb Mar Apr May Jun Jul Aug Sep Oct Nov Dec")
      if m =~ '^' . a:base
        call complete_add(m)
      endif
      sleep 300m        " simulate searching for next match
      if complete_check()
        break
      endif
    endfor
    return []
  endif
endfun
set completefunc=CompleteMonths
```

INSERT COMPLETION POPUP MENU

ins-completion-menu
popupmenu-completion

Vim can display the matches in a simplistic popup menu.

The menu is used when:
- The 'completeopt' option contains "menu" or "menuone".
- The terminal supports at least 8 colors.
- There are at least two matches. One if "menuone" is used.

The 'pumheight' option can be used to set a maximum height. The default is to use all space available.
The 'pumwidth' option can be used to set a minimum width. The default is 15 characters.

There are three states:
1. A complete match has been inserted, e.g., after using CTRL-N or CTRL-P.
2. A cursor key has been used to select another match. The match was not inserted then, only the entry in the popup menu is highlighted.
3. Only part of a match has been inserted and characters were typed or the backspace key was used. The list of matches was then adjusted for what is in front of the cursor.

You normally start in the first state, with the first match being inserted.
When "longest" is in 'completeopt' and there is more than one match you start in the third state.

If you select another match, e.g., with CTRL-N or CTRL-P, you go to the first state. This doesn't change the list of matches.

When you are back at the original text then you are in the third state. To get there right away you can use a mapping that uses CTRL-P right after starting the completion:

```
:imap <F7> <C-N><C-P>
```

popupmenu-keys

In the first state these keys have a special meaning:

<BS> and CTRL-H — Delete one character, find the matches for the word before the cursor. This reduces the list of matches, often to one entry, and switches to the second state.

Any non-special character: Stop completion without changing the match and insert the typed character.

In the second and third state these keys have a special meaning:

<BS> and CTRL-H — Delete one character, find the matches for the shorter word before the cursor. This may find more matches.

CTRL-L — Add one character from the current match, may reduce the number of matches.

any printable, non-white character: Add this character and reduce the number of matches.

In all three states these can be used:

CTRL-Y — Yes: Accept the currently selected match and stop completion.

CTRL-E End completion, go back to what was there before selecting a match (what was typed or longest common string).
<PageUp> Select a match several entries back, but don't insert it.
<PageDown> Select a match several entries further, but don't insert it.
<Up> Select the previous match, as if CTRL-P was used, but don't insert it.
<Down> Select the next match, as if CTRL-N was used, but don't insert it.
<Space> or <Tab> Stop completion without changing the match and insert the typed character.

The behavior of the <Enter> key depends on the state you are in:
first state: Use the text as it is and insert a line break.
second state: Insert the currently selected match.
third state: Use the text as it is and insert a line break.

In other words: If you used the cursor keys to select another entry in the list of matches then the <Enter> key inserts that match. If you typed something else then <Enter> inserts a line break.

The colors of the menu can be changed with these highlight groups:
Pmenu normal item hl-Pmenu
PmenuSel selected item hl-PmenuSel
PmenuSbar scrollbar hl-PmenuSbar
PmenuThumb thumb of the scrollbar hl-PmenuThumb

There are no special mappings for when the popup menu is visible. However, you can use an Insert mode mapping that checks the pumvisible() function to do something different. Example:
```
:inoremap <Down> <C-R>=pumvisible() ? "\<lt>C-N>" : "\<lt>Down>"<CR>
```

You can use of <expr> in mapping to have the popup menu used when typing a character and some condition is met. For example, for typing a dot:
```
inoremap <expr> . MayComplete()
func MayComplete()
    if (can complete)
      return ".\<C-X>\<C-O>"
    endif
    return '.'
endfunc
```

See :map-<expr> for more info.

FILETYPE-SPECIFIC REMARKS FOR OMNI COMPLETION compl-omni-filetypes

The file used for {filetype} should be autoload/{filetype}complete.vim in 'runtimepath'. Thus for "java" it is autoload/javacomplete.vim.

C ft-c-omni

Completion of C code requires a tags file. You should use Exuberant ctags,

because it adds extra information that is needed for completion. You can find
it here: http://ctags.sourceforge.net/ Version 5.6 or later is recommended.

For version 5.5.4 you should add a patch that adds the "typename:" field:
	ftp://ftp.vim.org/pub/vim/unstable/patches/ctags-5.5.4.patch
A compiled .exe for MS-Windows can be found at:
	http://ctags.sourceforge.net/
	https://github.com/universal-ctags/ctags-win32

If you want to complete system functions you can do something like this. Use
ctags to generate a tags file for all the system header files:
	% ctags -R -f ~/.vim/systags /usr/include /usr/local/include
In your vimrc file add this tags file to the 'tags' option:
	set tags+=~/.vim/systags

When using CTRL-X CTRL-O after a name without any "." or "->" it is completed
from the tags file directly. This works for any identifier, also function
names. If you want to complete a local variable name, which does not appear
in the tags file, use CTRL-P instead.

When using CTRL-X CTRL-O after something that has "." or "->" Vim will attempt
to recognize the type of the variable and figure out what members it has.
This means only members valid for the variable will be listed.

When a member name already was complete, CTRL-X CTRL-O will add a "." or
"->" for composite types.

Vim doesn't include a C compiler, only the most obviously formatted
declarations are recognized. Preprocessor stuff may cause confusion.
When the same structure name appears in multiple places all possible members
are included.

CSS	ft-css-omni

Complete properties and their appropriate values according to CSS 2.1
specification.

HTML	ft-html-omni
XHTML	ft-xhtml-omni

CTRL-X CTRL-O provides completion of various elements of (X)HTML files. It is
designed to support writing of XHTML 1.0 Strict files but will also work for
other versions of HTML. Features:

- after "<" complete tag name depending on context (no div suggestion inside
  of an a tag); '/>' indicates empty tags
- inside of tag complete proper attributes (no width attribute for an a tag);
  show also type of attribute; '*' indicates required attributes
- when attribute has limited number of possible values help to complete them
- complete names of entities
- complete values of "class" and "id" attributes with data obtained from
  <style> tag and included CSS files

- when completing value of "style" attribute or working inside of "style" tag switch to ft-css-omni completion
- when completing values of events attributes or working inside of "script" tag switch to ft-javascript-omni completion
- when used after "</" CTRL-X CTRL-O will close the last opened tag

Note: When used first time completion menu will be shown with little delay - this is time needed for loading of data file.
Note: Completion may fail in badly formatted documents. In such case try to run :make command to detect formatting problems.

HTML flavor html-flavor

The default HTML completion depends on the filetype. For HTML files it is HTML 4.01 Transitional ('filetype' is "html"), for XHTML it is XHTML 1.0 Strict ('filetype' is "xhtml").

When doing completion outside of any other tag you will have possibility to choose DOCTYPE and the appropriate data file will be loaded and used for all next completions.

More about format of data file in xml-omni-datafile . Some of the data files may be found on the Vim website (www).

Note that b:html_omni_flavor may point to a file with any XML data. This makes possible to mix PHP (ft-php-omni) completion with any XML dialect (assuming you have data file for it). Without setting that variable XHTML 1.0 Strict will be used.

JAVASCRIPT ft-javascript-omni

Completion of most elements of JavaScript language and DOM elements.

Complete:

- variables
- function name; show function arguments
- function arguments
- properties of variables trying to detect type of variable
- complete DOM objects and properties depending on context
- keywords of language

Completion works in separate JavaScript files (&ft==javascript), inside of <script> tag of (X)HTML and in values of event attributes (including scanning of external files).

DOM compatibility

At the moment (beginning of 2006) there are two main browsers - MS Internet Explorer and Mozilla Firefox. These two applications are covering over 90% of market. Theoretically standards are created by W3C organisation (http://www.w3c.org) but they are not always followed/implemented.

```
IE      FF      W3C  Omni completion
+/-     +/-     +    +
+       +       -    +
+       -       -    -
-       +       -    -
```

Regardless from state of implementation in browsers but if element is defined in standards, completion plugin will place element in suggestion list. When both major engines implemented element, even if this is not in standards it will be suggested. All other elements are not placed in suggestion list.

PHP ft-php-omni

Completion of PHP code requires a tags file for completion of data from external files and for class aware completion. You should use Exuberant ctags version 5.5.4 or newer. You can find it here: http://ctags.sourceforge.net/

Script completes:

- after $ variables name
  - if variable was declared as object add "->", if tags file is available show name of class
  - after "->" complete only function and variable names specific for given class. To find class location and contents tags file is required. Because PHP isn't strongly typed language user can use @var tag to declare class:

```
/* @var $myVar myClass */
$myVar->
```

    Still, to find myClass contents tags file is required.

- function names with additional info:
  - in case of built-in functions list of possible arguments and after | type data returned by function
  - in case of user function arguments and name of file where function was defined (if it is not current file)

- constants names
- class names after "new" declaration

Note: when doing completion first time Vim will load all necessary data into memory. It may take several seconds. After next use of completion delay should not be noticeable.

Script detects if cursor is inside <?php ?> tags. If it is outside it will automatically switch to HTML/CSS/JavaScript completion. Note: contrary to original HTML files completion of tags (and only tags) isn't context aware.

RUBY ft-ruby-omni

Completion of Ruby code requires that vim be built with `+ruby`.

Ruby completion will parse your buffer on demand in order to provide a list of completions. These completions will be drawn from modules loaded by 'require' and modules defined in the current buffer.

The completions provided by CTRL-X CTRL-O are sensitive to the context:

	CONTEXT	COMPLETIONS PROVIDED
1.	Not inside a class definition	Classes, constants and globals
2.	Inside a class definition	Methods or constants defined in the class
3.	After '.', '::' or ':'	Methods applicable to the object being dereferenced
4.	After ':' or ':foo'	Symbol name (beginning with 'foo')

Notes:
- Vim will load/evaluate code in order to provide completions. This may cause some code execution, which may be a concern. This is no longer enabled by default, to enable this feature add
  `let g:rubycomplete_buffer_loading = 1`
- In context 1 above, Vim can parse the entire buffer to add a list of classes to the completion results. This feature is turned off by default, to enable it add
  `let g:rubycomplete_classes_in_global = 1`
  to your vimrc
- In context 2 above, anonymous classes are not supported.
- In context 3 above, Vim will attempt to determine the methods supported by the object.
- Vim can detect and load the Rails environment for files within a rails project. The feature is disabled by default, to enable it add
  `let g:rubycomplete_rails = 1`
  to your vimrc

SYNTAX ft-syntax-omni

Vim has the ability to color syntax highlight nearly 500 languages. Part of this highlighting includes knowing what keywords are part of a language. Many filetypes already have custom completion scripts written for them, the syntaxcomplete plugin provides basic completion for all other filetypes. It does this by populating the omni completion list with the text Vim already knows how to color highlight. It can be used for any filetype and provides a minimal language-sensitive completion.

To enable syntax code completion you can run:
```
setlocal omnifunc=syntaxcomplete#Complete
```

You can automate this by placing the following in your `.vimrc` (after any ":filetype" command):
```
if has("autocmd") && exists("+omnifunc")
```

```
        autocmd Filetype *
                    \   if &omnifunc == "" |
                    \           setlocal omnifunc=syntaxcomplete#Complete |
                    \   endif
    endif
```

The above will set completion to this script only if a specific plugin does
not already exist for that filetype.

Each filetype can have a wide range of syntax items. The plugin allows you to
customize which syntax groups to include or exclude from the list. Let's have
a look at the PHP filetype to see how this works.

If you edit a file called, index.php, run the following command:

```
    syntax list
```

The first thing you will notice is that there are many different syntax groups.
The PHP language can include elements from different languages like HTML,
JavaScript and many more. The syntax plugin will only include syntax groups
that begin with the filetype, "php", in this case. For example these syntax
groups are included by default with the PHP: phpEnvVar, phpIntVar,
phpFunctions.

If you wish non-filetype syntax items to also be included, you can use a
regular expression syntax (added in version 13.0 of
autoload/syntaxcomplete.vim) to add items. Looking at the output from
":syntax list" while editing a PHP file I can see some of these entries:

```
    htmlArg,htmlTag,htmlTagName,javaScriptStatement,javaScriptGlobalObjects
```

To pick up any JavaScript and HTML keyword syntax groups while editing a PHP
file, you can use 3 different regexs, one for each language. Or you can
simply restrict the include groups to a particular value, without using
a regex string:

```
    let g:omni_syntax_group_include_php = 'php\w\+,javaScript\w\+,html\w\+'
    let g:omni_syntax_group_include_php = 'phpFunctions,phpMethods'
```

The basic form of this variable is:

```
    let g:omni_syntax_group_include_{filetype} = 'regex,comma,separated'
```

The PHP language has an enormous number of items which it knows how to syntax
highlight. These items will be available within the omni completion list.

Some people may find this list unwieldy or are only interested in certain
items. There are two ways to prune this list (if necessary). If you find
certain syntax groups you do not wish displayed you can use two different
methods to identify these groups. The first specifically lists the syntax
groups by name. The second uses a regular expression to identify both
syntax groups. Simply add one the following to your vimrc:

```
    let g:omni_syntax_group_exclude_php = 'phpCoreConstant,phpConstant'
    let g:omni_syntax_group_exclude_php = 'php\w*Constant'
```

Add as many syntax groups to this list by comma separating them. The basic
form of this variable is:

```
    let g:omni_syntax_group_exclude_{filetype} = 'regex,comma,separated'
```

You can create as many of these variables as you need, varying only the
filetype at the end of the variable name.

The plugin uses the isKeyword option to determine where word boundaries are
for the syntax items. For example, in the Scheme language completion should
include the "-", call-with-output-file. Depending on your filetype, this may
not provide the words you are expecting. Setting the
g:omni_syntax_use_iskeyword option to 0 will force the syntax plugin to break
on word characters. This can be controlled adding the following to your
vimrc:

```
    let g:omni_syntax_use_iskeyword = 0
```

For plugin developers, the plugin exposes a public function OmniSyntaxList.
This function can be used to request a List of syntax items. When editing a
SQL file (:e syntax.sql) you can use the ":syntax list" command to see the
various groups and syntax items. For example:

```
    syntax list
```

Yields data similar to this:

```
    sqlOperator    xxx some prior all like and any escape exists in is not
                       or intersect minus between distinct
                       links to Operator
    sqlType        xxx varbit varchar nvarchar bigint int uniqueidentifier
                       date money long tinyint unsigned xml text smalldate
                       double datetime nchar smallint numeric time bit char
                       varbinary binary smallmoney
                       image float integer timestamp real decimal
```

There are two syntax groups listed here: sqlOperator and sqlType. To retrieve
a List of syntax items you can call OmniSyntaxList a number of different
ways. To retrieve all syntax items regardless of syntax group:

```
    echo OmniSyntaxList( [] )
```

To retrieve only the syntax items for the sqlOperator syntax group:

```
    echo OmniSyntaxList( ['sqlOperator'] )
```

To retrieve all syntax items for both the sqlOperator and sqlType groups:

```
    echo OmniSyntaxList( ['sqlOperator', 'sqlType'] )
```

A regular expression can also be used:

```
    echo OmniSyntaxList( ['sql\w\+'] )
```

From within a plugin, you would typically assign the output to a List:

```
    let myKeywords = []
    let myKeywords = OmniSyntaxList( ['sqlKeyword'] )
```

SQL ft-sql-omni

Completion for the SQL language includes statements, functions, keywords.
It will also dynamically complete tables, procedures, views and column lists
with data pulled directly from within a database. For detailed instructions
and a tutorial see omni-sql-completion .

The SQL completion plugin can be used in conjunction with other completion plugins. For example, the PHP filetype has its own completion plugin. Since PHP is often used to generate dynamic website by accessing a database, the SQL completion plugin can also be enabled. This allows you to complete PHP code and SQL code at the same time.

XML ft-xml-omni

Vim 7 provides a mechanism for context aware completion of XML files. It depends on a special xml-omni-datafile and two commands: :XMLns and :XMLent . Features are:

- after "<" complete the tag name, depending on context
- inside of a tag complete proper attributes
- when an attribute has a limited number of possible values help to complete them
- complete names of entities (defined in xml-omni-datafile and in the current file with "<!ENTITY" declarations)
- when used after "</" CTRL-X CTRL-O will close the last opened tag

Format of XML data file xml-omni-datafile

XML data files are stored in the "autoload/xml" directory in 'runtimepath'. Vim distribution provides examples of data files in the "$VIMRUNTIME/autoload/xml" directory. They have a meaningful name which will be used in commands. It should be a unique name which will not create conflicts. For example, the name xhtml10s.vim means it is the data file for XHTML 1.0 Strict.

Each file contains a variable with a name like g:xmldata_xhtml10s . It is a compound from two parts:

1. "g:xmldata_" general prefix, constant for all data files
2. "xhtml10s" the name of the file and the name of the described XML dialect; it will be used as an argument for the :XMLns command

Part two must be exactly the same as name of file.

The variable is a Dictionary . Keys are tag names and each value is a two element List . The first element of the List is also a List with the names of possible children. The second element is a Dictionary with the names of attributes as keys and the possible values of attributes as values. Example:

```
let g:xmldata_crippled = {
\ "vimxmlentities": ["amp", "lt", "gt", "apos", "quot"],
\ 'vimxmlroot': ['tag1'],
\ 'tag1':
\ [ ['childoftag1a', 'childoftag1b'], {'attroftag1a': [],
\ 'attroftag1b': ['valueofattr1', 'valueofattr2']}],
\ 'childoftag1a':
\ [ [], {'attrofchild': ['attrofchild']}],
```

```
    \ 'childoftag1b':
    \ [ ['childoftag1a'], {'attrofchild': []}],
    \ "vimxmltaginfo": {
    \ 'tag1': ['Menu info', 'Long information visible in preview window']},
    \ 'vimxmlattrinfo': {
    \ 'attrofchild': ['Menu info', 'Long information visible in preview window']}}
```

This example would be put in the "autoload/xml/crippled.vim" file and could help to write this file:

```
    <tag1 attroftag1b="valueofattr1">
        <childoftag1a attrofchild>
                &amp; &lt;
        </childoftag1a>
        <childoftag1b attrofchild="5">
            <childoftag1a>
                &gt; &apos; &quot;
            </childoftag1a>
        </childoftag1b>
    </tag1>
```

In the example four special elements are visible:

1. "vimxmlentities" - a special key with List containing entities of this XML dialect.
2. If the list containing possible values of attributes has one element and this element is equal to the name of the attribute this attribute will be treated as boolean and inserted as 'attrname' and not as 'attrname="'
3. "vimxmltaginfo" - a special key with a Dictionary containing tag names as keys and two element List as values, for additional menu info and the long description.
4. "vimxmlattrinfo" - special key with Dictionary containing attribute names as keys and two element List as values, for additional menu info and long description.

Note: Tag names in the data file MUST not contain a namespace description. Check xsl.vim for an example.
Note: All data and functions are publicly available as global variables/functions and can be used for personal editing functions.

DTD -> Vim dtd2vim

On www is the script dtd2vim which parses DTD and creates an XML data file for Vim XML omni completion.

    dtd2vim: http://www.vim.org/scripts/script.php?script_id=1462

Check the beginning of that file for usage details.
The script requires perl and:

    perlSGML: http://savannah.nongnu.org/projects/perlsgml

Commands

:XMLns {name} [{namespace}] :XMLns

Vim has to know which data file should be used and with which namespace. For loading of the data file and connecting data with the proper namespace use :XMLns command. The first (obligatory) argument is the name of the data (xhtml10s, xsl). The second argument is the code of namespace (h, xsl). When used without a second argument the dialect will be used as default - without namespace declaration. For example to use XML completion in .xsl files:

```
:XMLns xhtml10s
:XMLns xsl xsl
```

:XMLent {name} :XMLent

By default entities will be completed from the data file of the default namespace. The XMLent command should be used in case when there is no default namespace:

```
:XMLent xhtml10s
```

Usage

While used in this situation (after declarations from previous part, | is cursor position):

```
<|
```

Will complete to an appropriate XHTML tag, and in this situation:

```
<xsl:|
```

Will complete to an appropriate XSL tag.

The script xmlcomplete.vim, provided through the autoload mechanism, has the xmlcomplete#GetLastOpenTag() function which can be used in XML files to get the name of the last open tag (b:unaryTagsStack has to be defined):

```
:echo xmlcomplete#GetLastOpenTag("b:unaryTagsStack")
```

==

8. Insert mode commands inserting

The following commands can be used to insert new text into the buffer. They can all be undone and repeated with the "." command.

a a

a Append text after the cursor [count] times. If the cursor is in the first column of an empty line Insert

starts there. But not when 'virtualedit' is set!

A
A   Append text at the end of the line [count] times.

<insert>   or   i   insert   <Insert>
i   Insert text before the cursor [count] times.
When using CTRL-O in Insert mode i_CTRL-O the count
is not supported.

I
I   Insert text before the first non-blank in the line
[count] times.
When the 'H' flag is present in 'cpoptions' and the
line only contains blanks, insert start just before
the last blank.

gI
gI   Insert text in column 1 [count] times. {not in Vi}

gi
gi   Insert text in the same position as where Insert mode
was stopped last time in the current buffer.
This uses the '^ mark. It's different from "`^i"
when the mark is past the end of the line.
The position is corrected for inserted/deleted lines,
but NOT for inserted/deleted characters.
When the :keepjumps command modifier is used the '^
mark won't be changed.
{not in Vi}

o
o   Begin a new line below the cursor and insert text,
repeat [count] times. {Vi: blank [count] screen
lines}
When the '#' flag is in 'cpoptions' the count is
ignored.

O
O   Begin a new line above the cursor and insert text,
repeat [count] times. {Vi: blank [count] screen
lines}
When the '#' flag is in 'cpoptions' the count is
ignored.

These commands are used to start inserting text. You can end insert mode with
<Esc>. See mode-ins-repl for the other special characters in Insert mode.
The effect of [count] takes place after Insert mode is exited.

When 'autoindent' is on, the indent for a new line is obtained from the
previous line. When 'smartindent' or 'cindent' is on, the indent for a line
is automatically adjusted for C programs.

'textwidth' can be set to the maximum width for a line. When a line becomes

too long when appending characters a line break is automatically inserted.

==
9. Ex insert commands   inserting-ex

                                                        :a :append
:{range}a[ppend][!]   Insert several lines of text below the specified
                        line. If the {range} is missing, the text will be
                        inserted after the current line.
                        Adding [!] toggles 'autoindent' for the time this
                        command is executed.

                                                        :i :in :insert
:{range}i[nsert][!]   Insert several lines of text above the specified
                        line. If the {range} is missing, the text will be
                        inserted before the current line.
                        Adding [!] toggles 'autoindent' for the time this
                        command is executed.

These two commands will keep on asking for lines, until you type a line
containing only a ".". Watch out for lines starting with a backslash, see
 line-continuation .

When in Ex mode (see -e) a backslash at the end of the line can be used to
insert a NUL character. To be able to have a line ending in a backslash use
two backslashes. This means that the number of backslashes is halved, but
only at the end of the line.

NOTE: These commands cannot be used with :global or :vglobal .
":append" and ":insert" don't work properly in between ":if" and
":endif", ":for" and ":endfor", ":while" and ":endwhile".

                                                        :start :startinsert
:star[tinsert][!]   Start Insert mode just after executing this command.
                        Works like typing "i" in Normal mode. When the ! is
                        included it works like "A", append to the line.
                        Otherwise insertion starts at the cursor position.
                        Note that when using this command in a function or
                        script, the insertion only starts after the function
                        or script is finished.
                        This command does not work from :normal .
                        {not in Vi}

                                                        :stopi :stopinsert
:stopi[nsert]   Stop Insert mode as soon as possible. Works like
                        typing <Esc> in Insert mode.
                        Can be used in an autocommand, example:
                                :au BufEnter scratch stopinsert

                                                replacing-ex :startreplace
:startr[eplace][!]   Start Replace mode just after executing this command.
                        Works just like typing "R" in Normal mode. When the
                        ! is included it acts just like "$R" had been typed

(ie. begin replace mode at the end-of-line). Otherwise replacement begins at the cursor position. Note that when using this command in a function or script that the replacement will only start after the function or script is finished. {not in Vi}

:startgreplace

:startg[replace][!] Just like :startreplace , but use Virtual Replace mode, like with gR . {not in Vi}

==========

10. Inserting a file inserting-file

:r :re :read

:r[ead] [++opt] [name]
Insert the file [name] (default: current file) below the cursor.
See ++opt for the possible values of [++opt].

:{range}r[ead] [++opt] [name]
Insert the file [name] (default: current file) below the specified line.
See ++opt for the possible values of [++opt].

:r! :read!

:[range]r[ead] [++opt] !{cmd}
Execute {cmd} and insert its standard output below the cursor or the specified line. A temporary file is used to store the output of the command which is then read into the buffer. 'shellredir' is used to save the output of the command, which can be set to include stderr or not. {cmd} is executed like with ":!{cmd}", any '!' is replaced with the previous command :! .
See ++opt for the possible values of [++opt].

These commands insert the contents of a file, or the output of a command, into the buffer. They can be undone. They cannot be repeated with the "." command. They work on a line basis, insertion starts below the line in which the cursor is, or below the specified line. To insert text above the first line use the command ":0r {name}".

After the ":read" command, the cursor is left on the first non-blank in the first new line. Unless in Ex mode, then the cursor is left on the last new line (sorry, this is Vi compatible).

If a file name is given with ":r", it becomes the alternate file. This can be used, for example, when you want to edit that file instead: ":e! #". This can be switched off by removing the 'a' flag from the 'cpoptions' option.

Of the [++opt] arguments one is specifically for ":read", the ++edit argument. This is useful when the ":read" command is actually used to read a file into the buffer as if editing that file. Use this command in an empty buffer:

```
        :read ++edit filename
```
The effect is that the 'fileformat', 'fileencoding', 'bomb', etc. options are set to what has been detected for "filename". Note that a single empty line remains, you may want to delete it.

file-read

The 'fileformat' option sets the <EOL> style for a file:

'fileformat'	characters	name
"dos"	<CR><NL> or <NL>	DOS format
"unix"	<NL>	Unix format
"mac"	<CR>	Mac format

Previously 'textmode' was used. It is obsolete now.

If 'fileformat' is "dos", a <CR> in front of an <NL> is ignored and a CTRL-Z at the end of the file is ignored.

If 'fileformat' is "mac", a <NL> in the file is internally represented by a <CR>. This is to avoid confusion with a <NL> which is used to represent a <NUL>. See CR-used-for-NL .

If the 'fileformats' option is not empty Vim tries to recognize the type of <EOL> (see file-formats). However, the 'fileformat' option will not be changed, the detected format is only used while reading the file.
A similar thing happens with 'fileencodings'.

On non-MS-DOS, Win32, and OS/2 systems the message "[dos format]" is shown if a file is read in DOS format, to remind you that something unusual is done.
On Macintosh, MS-DOS, Win32, and OS/2 the message "[unix format]" is shown if a file is read in Unix format.
On non-Macintosh systems, the message "[Mac format]" is shown if a file is read in Mac format.

An example on how to use ":r !":
```
        :r !uuencode binfile binfile
```
This command reads "binfile", uuencodes it and reads it into the current buffer. Useful when you are editing e-mail and want to include a binary file.

read-messages

When reading a file Vim will display a message with information about the read file. In the table is an explanation for some of the items. The others are self explanatory. Using the long or the short version depends on the 'shortmess' option.

long	short	meaning
[readonly]	{RO}	the file is write protected
[fifo/socket]		using a stream
[fifo]		using a fifo stream
[socket]		using a socket stream
[CR missing]		reading with "dos" 'fileformat' and a NL without a preceding CR was found.
[NL found]		reading with "mac" 'fileformat' and a NL was found (could be "unix" format)
[long lines split]		at least one line was split in two

[NOT converted]	conversion from 'fileencoding' to 'encoding' was desired but not possible
[converted]	conversion from 'fileencoding' to 'encoding' done
[crypted]	file was decrypted
[READ ERRORS]	not all of the file could be read

vim:tw=78:ts=8:noet:ft=help:norl:

VIM REFERENCE MANUAL by Bram Moolenaar

This file describes commands that delete or change text. In this context, changing text means deleting the text and replacing it with other text using one command. You can undo all of these commands. You can repeat the non-Ex commands with the "." command.

For inserting text see insert.txt .

==========

1. Deleting text deleting E470

["x]<Del> or <Del> x dl

["x]x Delete [count] characters under and after the cursor [into register x] (not linewise). Does the same as "dl".
The <Del> key does not take a [count]. Instead, it deletes the last character of the count.
See :fixdel if the <Del> key does not do what you want. See 'whichwrap' for deleting a line break (join lines). {Vi does not support <Del>}

X dh

["x]X Delete [count] characters before the cursor [into register x] (not linewise). Does the same as "dh".
Also see 'whichwrap' .

d

["x]d{motion} Delete text that {motion} moves over [into register x]. See below for exceptions.

dd

["x]dd Delete [count] lines [into register x] linewise .

D

["x]D Delete the characters under the cursor until the end of the line and [count]-1 more lines [into register x]; synonym for "d$".

(not linewise)
When the '#' flag is in 'cpoptions' the count is
ignored.

{Visual}["x]x or v_x v_d v_<Del>
{Visual}["x]d or
{Visual}["x]<Del> Delete the highlighted text [into register x] (for
{Visual} see Visual-mode). {not in Vi}

{Visual}["x]CTRL-H or v_CTRL-H v_<BS>
{Visual}["x]<BS> When in Select mode: Delete the highlighted text [into
register x].

{Visual}["x]X or v_X v_D v_b_D
{Visual}["x]D Delete the highlighted lines [into register x] (for
{Visual} see Visual-mode). In Visual block mode,
"D" deletes the highlighted text plus all text until
the end of the line. {not in Vi}

:d :de :del :delete :dl :dp
:[range]d[elete] [x] Delete [range] lines (default: current line) [into
register x].
Note these weird abbreviations:

:dl	delete and list
:dell	idem
:delel	idem
:deletl	idem
:deletel	idem
:dp	delete and print
:dep	idem
:delp	idem
:delep	idem
:deletp	idem
:deletep	idem

:[range]d[elete] [x] {count}
Delete {count} lines, starting with [range]
(default: current line cmdline-ranges) [into
register x].

These commands delete text. You can repeat them with the `.` command
(except `:d`) and undo them. Use Visual mode to delete blocks of text. See
registers for an explanation of registers.

An exception for the d{motion} command: If the motion is not linewise, the
start and end of the motion are not in the same line, and there are only
blanks before the start and there are no non-blanks after the end of the
motion, the delete becomes linewise. This means that the delete also removes
the line of blanks that you might expect to remain. Use the o_v operator to
force the motion to be characterwise.

Trying to delete an empty region of text (e.g., "d0" in the first column)
is an error when 'cpoptions' includes the 'E' flag.

J

J   Join [count] lines, with a minimum of two lines.
                        Remove the indent and insert up to two spaces (see
                        below). Fails when on the last line of the buffer.
                        If [count] is too big it is reduced to the number of
                        lines available.

v_J

{Visual}J   Join the highlighted lines, with a minimum of two
                        lines. Remove the indent and insert up to two spaces
                        (see below). {not in Vi}

gJ

gJ   Join [count] lines, with a minimum of two lines.
                        Don't insert or remove any spaces. {not in Vi}

v_gJ

{Visual}gJ   Join the highlighted lines, with a minimum of two
                        lines. Don't insert or remove any spaces. {not in
                        Vi}

:j :join

:[range]j[oin][!] [flags]
                        Join [range] lines. Same as "J", except with [!]
                        the join does not insert or delete any spaces.
                        If a [range] has equal start and end values, this
                        command does nothing. The default behavior is to
                        join the current line with the line below it.
                        {not in Vi: !}
                        See ex-flags for [flags].

:[range]j[oin][!] {count} [flags]
                        Join {count} lines, starting with [range] (default:
                        current line cmdline-ranges). Same as "J", except
                        with [!] the join does not insert or delete any
                        spaces.
                        {not in Vi: !}
                        See ex-flags for [flags].

These commands delete the <EOL> between lines. This has the effect of joining multiple lines into one line. You can repeat these commands (except `:j`) and undo them.

These commands, except "gJ", insert one space in place of the <EOL> unless there is trailing white space or the next line starts with a ')'. These commands, except "gJ", delete any leading white space on the next line. If the 'joinspaces' option is on, these commands insert two spaces after a '.', '!' or '?' (but if 'cpoptions' includes the 'j' flag, they insert two spaces only after a '.').
The 'B' and 'M' flags in 'formatoptions' change the behavior for inserting spaces before and after a multi-byte character fo-table .

The '[mark is set at the end of the first line that was joined, '] at the end of the resulting line.

==
2. Delete and insert   delete-insert   replacing

                                                                        R
R   Enter Replace mode: Each character you type replaces
                        an existing character, starting with the character
                        under the cursor. Repeat the entered text [count]-1
                        times. See Replace-mode for more details.

                                                                        gR
gR   Enter Virtual Replace mode: Each character you type
                        replaces existing characters in screen space. So a
                        <Tab> may replace several characters at once.
                        Repeat the entered text [count]-1 times. See
                         Virtual-Replace-mode for more details.

                                                                        c
["x]c{motion}   Delete {motion} text [into register x] and start
                        insert. When 'cpoptions' includes the 'E' flag and
                        there is no text to delete (e.g., with "cTx" when the
                        cursor is just after an 'x'), an error occurs and
                        insert mode does not start (this is Vi compatible).
                        When 'cpoptions' does not include the 'E' flag, the
                        "c" command always starts insert mode, even if there
                        is no text to delete.

                                                                        cc
["x]cc   Delete [count] lines [into register x] and start
                        insert linewise . If 'autoindent' is on, preserve
                        the indent of the first line.

                                                                        C
["x]C   Delete from the cursor position to the end of the
                        line and [count]-1 more lines [into register x], and
                        start insert. Synonym for c$ (not linewise).

                                                                        s
["x]s   Delete [count] characters [into register x] and start
                        insert (s stands for Substitute). Synonym for "cl"
                        (not linewise).

                                                                        S
["x]S   Delete [count] lines [into register x] and start
                        insert. Synonym for "cc" linewise .

{Visual}["x]c   or   v_c   v_s
{Visual}["x]s   Delete the highlighted text [into register x] and
                        start insert (for {Visual} see Visual-mode). {not
                        in Vi}

                                                                        v_r
{Visual}["x]r{char}   Replace all selected characters by {char}.

v_C
{Visual}["x]C Delete the highlighted lines [into register x] and start insert. In Visual block mode it works differently v_b_C . {not in Vi}

v_S
{Visual}["x]S Delete the highlighted lines [into register x] and start insert (for {Visual} see Visual-mode). {not in Vi}

v_R
{Visual}["x]R Currently just like {Visual}["x]S. In a next version it might work differently. {not in Vi}

Notes:
- You can end Insert and Replace mode with <Esc>.
- See the section "Insert and Replace mode" mode-ins-repl for the other special characters in these modes.
- The effect of [count] takes place after Vim exits Insert or Replace mode.
- When the 'cpoptions' option contains '$' and the change is within one line, Vim continues to show the text to be deleted and puts a '$' at the last deleted character.

See registers for an explanation of registers.

Replace mode is just like Insert mode, except that every character you enter deletes one character. If you reach the end of a line, Vim appends any further characters (just like Insert mode). In Replace mode, the backspace key restores the original text (if there was any). (See section "Insert and Replace mode" mode-ins-repl).

cw cW
Special case: When the cursor is in a word, "cw" and "cW" do not include the white space after a word, they only change up to the end of the word. This is because Vim interprets "cw" as change-word, and a word does not include the following white space.
{Vi: "cw" when on a blank followed by other blanks changes only the first blank; this is probably a bug, because "dw" deletes all the blanks; use the 'w' flag in 'cpoptions' to make it work like Vi anyway}

If you prefer "cw" to include the space after a word, use this mapping:
```
:map cw dwi
```
Or use "caw" (see aw).

:c :ch :change
:{range}c[hange][!] Replace lines of text with some different text. Type a line containing only "." to stop replacing. Without {range}, this command changes only the current line.
Adding [!] toggles 'autoindent' for the time this command is executed.

==========
3. Simple changes simple-change

r

r{char} Replace the character under the cursor with {char}. If {char} is a <CR> or <NL>, a line break replaces the character. To replace with a real <CR>, use CTRL-V <CR>. CTRL-V <NL> replaces with a <Nul>. {Vi: CTRL-V <CR> still replaces with a line break, cannot replace something with a <CR>}

If {char} is CTRL-E or CTRL-Y the character from the line below or above is used, just like with i_CTRL-E and i_CTRL-Y . This also works with a count, thus `10r<C-E>` copies 10 characters from the line below.

If you give a [count], Vim replaces [count] characters with [count] {char}s. When {char} is a <CR> or <NL>, however, Vim inserts only one <CR>: "5r<CR>" replaces five characters with a single line break. When {char} is a <CR> or <NL>, Vim performs autoindenting. This works just like deleting the characters that are replaced and then doing "i<CR><Esc>". {char} can be entered as a digraph digraph-arg . :lmap mappings apply to {char}. The CTRL-^ command in Insert mode can be used to switch this on/off i_CTRL-^ . See utf-8-char-arg about using composing characters when 'encoding' is Unicode.

gr

gr{char} Replace the virtual characters under the cursor with {char}. This replaces in screen space, not file space. See gR and Virtual-Replace-mode for more details. As with r a count may be given. {char} can be entered like with r .

digraph-arg

The argument for Normal mode commands like r and t is a single character. When 'cpo' doesn't contain the 'D' flag, this character can also be entered like digraphs . First type CTRL-K and then the two digraph characters. {not available when compiled without the |+digraphs| feature}

case

The following commands change the case of letters. The currently active locale is used. See :language . The LC_CTYPE value matters here.

~

~ 'notildeop' option: Switch case of the character under the cursor and move the cursor to the right. If a [count] is given, do that many characters. {Vi: no count}

~{motion} 'tildeop' option: switch case of {motion} text. {Vi: tilde cannot be used as an operator}

g~

g~{motion}		Switch case of {motion} text. {not in Vi}

g~g~ g~g~ g~~
g~~		Switch case of current line. {not in Vi}.

v_~
{Visual}~		Switch case of highlighted text (for {Visual} see Visual-mode). {not in Vi}

v_U
{Visual}U		Make highlighted text uppercase (for {Visual} see Visual-mode). {not in Vi}

gU uppercase
gU{motion}		Make {motion} text uppercase. {not in Vi}
Example:
```
:map! <C-F> <Esc>gUiw`]a
```
This works in Insert mode: press CTRL-F to make the word before the cursor uppercase. Handy to type words in lowercase and then make them uppercase.

gUgU gUgU gUU
gUU		Make current line uppercase. {not in Vi}.

v_u
{Visual}u		Make highlighted text lowercase (for {Visual} see Visual-mode). {not in Vi}

gu lowercase
gu{motion}		Make {motion} text lowercase. {not in Vi}

gugu gugu guu
guu		Make current line lowercase. {not in Vi}.

g? rot13
g?{motion}		Rot13 encode {motion} text. {not in Vi}

v_g?
{Visual}g?		Rot13 encode the highlighted text (for {Visual} see Visual-mode). {not in Vi}

g?g? g?g? g??
g??		Rot13 encode current line. {not in Vi}.

To turn one line into title caps, make every first letter of a word uppercase:
```
:s/\v<(.)(\w*)/\u\1\L\2/g
```

Adding and subtracting

CTRL-A
CTRL-A		Add [count] to the number or alphabetic character at or after the cursor. {not in Vi}

v_CTRL-A
{Visual}CTRL-A Add [count] to the number or alphabetic character in the highlighted text. {not in Vi}

v_g_CTRL-A
{Visual}g CTRL-A Add [count] to the number or alphabetic character in the highlighted text. If several lines are highlighted, each one will be incremented by an additional [count] (so effectively creating a [count] incrementing sequence). {not in Vi}
For Example, if you have this list of numbers:

```
1.
1.
1.
1.
```

Move to the second "1." and Visually select three lines, pressing g CTRL-A results in:

```
1.
2.
3.
4.
```

CTRL-X
CTRL-X Subtract [count] from the number or alphabetic character at or after the cursor. {not in Vi}

v_CTRL-X
{Visual}CTRL-X Subtract [count] from the number or alphabetic character in the highlighted text. {not in Vi}

On MS-Windows, this is mapped to cut Visual text dos-standard-mappings . If you want to disable the mapping, use this:

```
silent! vunmap <C-X>
```

v_g_CTRL-X
{Visual}g CTRL-X Subtract [count] from the number or alphabetic character in the highlighted text. If several lines are highlighted, each value will be decremented by an additional [count] (so effectively creating a [count] decrementing sequence). {not in Vi}

The CTRL-A and CTRL-X commands can work for:
- signed and unsigned decimal numbers
- unsigned binary, octal and hexadecimal numbers
- alphabetic characters

This depends on the 'nrformats' option:
- When 'nrformats' includes "bin", Vim assumes numbers starting with '0b' or '0B' are binary.
- When 'nrformats' includes "octal", Vim considers numbers starting with a '0' to be octal, unless the number includes a '8' or '9'. Other numbers are decimal and may have a preceding minus sign.

  If the cursor is on a number, the commands apply to that number; otherwise
  Vim uses the number to the right of the cursor.
- When 'nrformats' includes "hex", Vim assumes numbers starting with '0x' or
  '0X' are hexadecimal. The case of the rightmost letter in the number
  determines the case of the resulting hexadecimal number. If there is no
  letter in the current number, Vim uses the previously detected case.
- When 'nrformats' includes "alpha", Vim will change the alphabetic character
  under or after the cursor. This is useful to make lists with an alphabetic
  index.

For decimals a leading negative sign is considered for incrementing/
decrementing, for binary, octal and hex values, it won't be considered. To
ignore the sign Visually select the number before using CTRL-A or CTRL-X.

For numbers with leading zeros (including all octal and hexadecimal numbers),
Vim preserves the number of characters in the number when possible. CTRL-A on
"0077" results in "0100", CTRL-X on "0x100" results in "0x0ff".
There is one exception: When a number that starts with a zero is found not to
be octal (it contains a '8' or '9'), but 'nrformats' does include "octal",
leading zeros are removed to avoid that the result may be recognized as an
octal number.

Note that when 'nrformats' includes "octal", decimal numbers with leading
zeros cause mistakes, because they can be confused with octal numbers.

Note similarly, when 'nrformats' includes "bin", binary numbers with a leading
'0x' or '0X' can be interpreted as hexadecimal rather than binary since '0b'
are valid hexadecimal digits.

The CTRL-A command is very useful in a macro. Example: Use the following
steps to make a numbered list.

1. Create the first list entry, make sure it starts with a number.
2. qa   - start recording into register 'a'
3. Y   - yank the entry
4. p   - put a copy of the entry below the first one
5. CTRL-A   - increment the number
6. q   - stop recording
7. <count>@a - repeat the yank, put and increment <count> times

SHIFTING LINES LEFT OR RIGHT shift-left-right

<{motion} Shift {motion} lines one 'shiftwidth' leftwards. <

<< Shift [count] lines one 'shiftwidth' leftwards. <<

{Visual}[count]< Shift the highlighted lines [count] 'shiftwidth' leftwards (for {Visual} see Visual-mode). {not in Vi} v_<

>

>{motion} Shift {motion} lines one 'shiftwidth' rightwards.

>>

>> Shift [count] lines one 'shiftwidth' rightwards.

v_>

{Visual}[count]> Shift the highlighted lines [count] 'shiftwidth' rightwards (for {Visual} see Visual-mode). {not in Vi}

:<

:[range]< Shift [range] lines one 'shiftwidth' left. Repeat '<' for shifting multiple 'shiftwidth's.

:[range]< {count} Shift {count} lines one 'shiftwidth' left, starting with [range] (default current line cmdline-ranges). Repeat '<' for shifting multiple 'shiftwidth's.

:[range]le[ft] [indent] left align lines in [range]. Sets the indent in the lines to [indent] (default 0). {not in Vi}

:>

:[range]> [flags] Shift {count} [range] lines one 'shiftwidth' right. Repeat '>' for shifting multiple 'shiftwidth's. See ex-flags for [flags].

:[range]> {count} [flags]
  Shift {count} lines one 'shiftwidth' right, starting with [range] (default current line cmdline-ranges). Repeat '>' for shifting multiple 'shiftwidth's. See ex-flags for [flags].

The ">" and "<" commands are handy for changing the indentation within programs. Use the 'shiftwidth' option to set the size of the white space which these commands insert or delete. Normally the 'shiftwidth' option is 8, but you can set it to, say, 3 to make smaller indents. The shift leftwards stops when there is no indent. The shift right does not affect empty lines.

If the 'shiftround' option is on, the indent is rounded to a multiple of 'shiftwidth'.

If the 'smartindent' option is on, or 'cindent' is on and 'cinkeys' contains '#' with a zero value, shift right does not affect lines starting with '#' (these are supposed to be C preprocessor lines that must stay in column 1). This can be changed with the 'cino' option, see cino-# .

When the 'expandtab' option is off (this is the default) Vim uses <Tab>s as much as possible to make the indent. You can use ">><<" to replace an indent made out of spaces with the same indent made out of <Tab>s (and a few spaces if necessary). If the 'expandtab' option is on, Vim uses only spaces. Then you can use ">><<" to replace <Tab>s in the indent by spaces (or use `:retab!`).

To move a line several 'shiftwidth's, use Visual mode or the `:` commands.
For example:

```
        Vjj4>           move three lines 4 indents to the right
        :<<<            move current line 3 indents to the left
        :>> 5           move 5 lines 2 indents to the right
        :5>>            move line 5 2 indents to the right
```

==
4. Complex changes   complex-change

4.1 Filter commands   filter

A filter is a program that accepts text at standard input, changes it in some way, and sends it to standard output. You can use the commands below to send some text through a filter, so that it is replaced by the filter output. Examples of filters are "sort", which sorts lines alphabetically, and "indent", which formats C program files (you need a version of indent that works like a filter; not all versions do). The 'shell' option specifies the shell Vim uses to execute the filter command (See also the 'shelltype' option). You can repeat filter commands with ".". Vim does not recognize a comment (starting with '"') after the `:!` command.

                                                                !
!{motion}{filter}   Filter {motion} text lines through the external
                        program {filter}.

                                                                !!
!!{filter}   Filter [count] lines through the external program
                        {filter}.

                                                                v_!
{Visual}!{filter}   Filter the highlighted lines through the external
                        program {filter} (for {Visual} see Visual-mode).
                        {not in Vi}

:{range}![!]{filter} [!][arg]   :range!
                        Filter {range} lines through the external program
                        {filter}. Vim replaces the optional bangs with the
                        latest given command and appends the optional [arg].
                        Vim saves the output of the filter command in a
                        temporary file and then reads the file into the buffer
                         tempfile . Vim uses the 'shellredir' option to
                        redirect the filter output to the temporary file.
                        However, if the 'shelltemp' option is off then pipes
                        are used when possible (on Unix).
                        When the 'R' flag is included in 'cpoptions' marks in
                        the filtered lines are deleted, unless the
                         :keepmarks command is used. Example:
                                :keepmarks '<,'>!sort
                       When the number of lines after filtering is less than
                        before, marks in the missing lines are deleted anyway.

                                                                =
={motion}   Filter {motion} lines through the external program

given with the 'equalprg' option. When the 'equalprg' option is empty (this is the default), use the internal formatting function C-indenting and 'lisp'. But when 'indentexpr' is not empty, it will be used instead indent-expression. When Vim was compiled without internal formatting then the "indent" program is used as a last resort.

== Filter [count] lines like with ={motion}.

{Visual}= Filter the highlighted lines like with ={motion}. {not in Vi}

tempfile setuid

Vim uses temporary files for filtering, generating diffs and also for tempname(). For Unix, the file will be in a private directory (only accessible by the current user) to avoid security problems (e.g., a symlink attack or other people reading your file). When Vim exits the directory and all files in it are deleted. When Vim has the setuid bit set this may cause problems, the temp file is owned by the setuid user but the filter command probably runs as the original user.
On MS-DOS and OS/2 the first of these directories that works is used: $TMP, $TEMP, c:\TMP, c:\TEMP.
For Unix the list of directories is: $TMPDIR, /tmp, current-dir, $HOME.
For MS-Windows the GetTempFileName() system function is used.
For other systems the tmpnam() library function is used.

4.2 Substitute

:substitute :s :su

:[range]s[ubstitute]/{pattern}/{string}/[flags] [count]
For each line in [range] replace a match of {pattern} with {string}.
For the {pattern} see pattern.
{string} can be a literal string, or something special; see sub-replace-special.
E939
When [range] and [count] are omitted, replace in the current line only. When [count] is given, replace in [count] lines, starting with the last line in [range]. When [range] is omitted start in the current line. [count] must be a positive number. Also see cmdline-ranges.

See :s_flags for [flags].

:[range]s[ubstitute] [flags] [count]
:[range]&[&][flags] [count] :&
Repeat last :substitute with same search pattern and substitute string, but without the same flags. You

may add [flags], see :s_flags .
Note that after `:substitute` the '&' flag can't be
used, it's recognized as a pattern separator.
The space between `:substitute` and the 'c', 'g',
'i', 'I' and 'r' flags isn't required, but in scripts
it's a good idea to keep it to avoid confusion.

:[range]~[&][flags] [count] :~
Repeat last substitute with same substitute string
but with last used search pattern. This is like
`:&r`. See :s_flags for [flags].

&
& Synonym for `:s` (repeat last substitute). Note
that the flags are not remembered, thus it might
actually work differently. You can use `:&&` to keep
the flags.

g&
g& Synonym for `:%s//~/&` (repeat last substitute with
last search pattern on all lines with the same flags).
For example, when you first do a substitution with
`:s/pattern/repl/flags` and then `/search` for
something else, `g&` will do `:%s/search/repl/flags`.
Mnemonic: global substitute. {not in Vi}

:snomagic :sno
:[range]sno[magic] ... Same as `:substitute`, but always use 'nomagic'.
{not in Vi}

:smagic :sm
:[range]sm[agic] ... Same as `:substitute`, but always use 'magic'.
{not in Vi}

:s_flags
The flags that you can use for the substitute commands:

:&&
[&] Must be the first one: Keep the flags from the previous substitute
command. Examples:
:&&
:s/this/that/&
Note that `:s` and `:&` don't keep the flags.
{not in Vi}

[c] Confirm each substitution. Vim highlights the matching string (with
hl-IncSearch). You can type: :s_c
'y' to substitute this match
'l' to substitute this match and then quit ("last")
'n' to skip this match
<Esc> to quit substituting
'a' to substitute this and all remaining matches {not in Vi}
'q' to quit substituting {not in Vi}
CTRL-E to scroll the screen up {not in Vi, not available when

compiled without the +insert_expand feature}
CTRL-Y to scroll the screen down {not in Vi, not available when
compiled without the +insert_expand feature}
If the 'edcompatible' option is on, Vim remembers the [c] flag and
toggles it each time you use it, but resets it when you give a new
search pattern.
{not in Vi: highlighting of the match, other responses than 'y' or 'n'}

[e] When the search pattern fails, do not issue an error message and, in
particular, continue in maps as if no error occurred. This is most
useful to prevent the "No match" error from breaking a mapping. Vim
does not suppress the following error messages, however:
Regular expressions can't be delimited by letters
\ should be followed by /, ? or &
No previous substitute regular expression
Trailing characters
Interrupted
{not in Vi}

[g] Replace all occurrences in the line. Without this argument,
replacement occurs only for the first occurrence in each line. If
the 'edcompatible' option is on, Vim remembers this flag and toggles
it each time you use it, but resets it when you give a new search
pattern. If the 'gdefault' option is on, this flag is on by default
and the [g] argument switches it off.

[i] Ignore case for the pattern. The 'ignorecase' and 'smartcase' options
are not used.
{not in Vi}

[I] Don't ignore case for the pattern. The 'ignorecase' and 'smartcase'
options are not used.
{not in Vi}

[n] Report the number of matches, do not actually substitute. The [c]
flag is ignored. The matches are reported as if 'report' is zero.
Useful to count-items .
If \= sub-replace-expression is used, the expression will be
evaluated in the sandbox at every match.

[p] Print the line containing the last substitute.

[#] Like [p] and prepend the line number.

[l] Like [p] but print the text like :list .

[r] Only useful in combination with `:&` or `:s` without arguments. `:&r`
works the same way as `:~`: When the search pattern is empty, use the
previously used search pattern instead of the search pattern from the
last substitute or `:global`. If the last command that did a search
was a substitute or `:global`, there is no effect. If the last
command was a search command such as "/", use the pattern from that
command.
For `:s` with an argument this already happens:

```
		:s/blue/red/
		/green
		:s//red/   or  :~   or  :&r
	The last commands will replace "green" with "red".
		:s/blue/red/
		/green
		:&
	The last command will replace "blue" with "red".
	 {not in Vi}
```

Note that there is no flag to change the "magicness" of the pattern. A different command is used instead, or you can use /\v and friends. The reason is that the flags can only be found by skipping the pattern, and in order to skip the pattern the "magicness" must be known. Catch 22!

If the {pattern} for the substitute command is empty, the command uses the pattern from the last substitute or `:global` command. If there is none, but there is a previous search pattern, that one is used. With the [r] flag, the command uses the pattern from the last substitute, `:global`, or search command.

If the {string} is omitted the substitute is done as if it's empty. Thus the matched pattern is deleted. The separator after {pattern} can also be left out then. Example:

```
	:%s/TESTING
```

This deletes "TESTING" from all lines, but only one per line.

For compatibility with Vi these two exceptions are allowed:
"\/{string}/" and "\?{string}?" do the same as "//{string}/r".
"\&{string}&" does the same as "//{string}/".

E146

Instead of the '/' which surrounds the pattern and replacement string, you can use any other single-byte character, but not an alphanumeric character, '\', '"' or '|'. This is useful if you want to include a '/' in the search pattern or replacement string. Example:

```
	:s+/+//+
```

For the definition of a pattern, see pattern . In Visual block mode, use /\%V in the pattern to have the substitute work in the block only. Otherwise it works on whole lines anyway.

sub-replace-special :s\=

When the {string} starts with "\=" it is evaluated as an expression, see sub-replace-expression . You can use that for complex replacement or special characters.

Otherwise these characters in {string} have a special meaning:

:s%

When {string} is equal to "%" and '/' is included with the 'cpoptions' option, then the {string} of the previous substitute command is used, see cpo-/

magic	nomagic	action	
&	\&	replaced with the whole matched pattern	s/\&
\&	&	replaced with &	

```
      \0          replaced with the whole matched pattern           \0   s/\0
      \1          replaced with the matched pattern in the first
                  pair of ()                                          s/\1
      \2          replaced with the matched pattern in the second
                  pair of ()                                          s/\2
      ..          ..                                                  s/\3
      \9          replaced with the matched pattern in the ninth
                  pair of ()                                          s/\9
  ~       \~      replaced with the {string} of the previous
                  substitute                                          s~
 \~        ~      replaced with ~                                     s/\~
      \u          next character made uppercase                       s/\u
      \U          following characters made uppercase, until \E       s/\U
      \l          next character made lowercase                       s/\l
      \L          following characters made lowercase, until \E       s/\L
      \e          end of \u, \U, \l and \L (NOTE: not <Esc>!)         s/\e
      \E          end of \u, \U, \l and \L                            s/\E
      <CR>        split line in two at this point
                  (Type the <CR> as CTRL-V <Enter>)                   s<CR>
      \r          idem                                                s/\r
      \<CR>       insert a carriage-return (CTRL-M)
                  (Type the <CR> as CTRL-V <Enter>)                   s/\<CR>
      \n          insert a <NL> (<NUL> in the file)
                  (does NOT break the line)                           s/\n
      \b          insert a <BS>                                       s/\b
      \t          insert a <Tab>                                      s/\t
      \\          insert a single backslash                           s/\\
      \x          where x is any character not mentioned above:
                  Reserved for future expansion
```

The special meaning is also used inside the third argument {sub} of the substitute() function with the following exceptions:
- A % inserts a percent literally without regard to 'cpoptions'.
- magic is always set without regard to 'magic'.
- A ~ inserts a tilde literally.
- <CR> and \r inserts a carriage-return (CTRL-M).
- \<CR> does not have a special meaning. it's just one of \x.

Examples:

```
:s/a\|b/xxx\0xxx/g             modifies "a b"      to "xxxaxxx xxxbxxx"
:s/\([abc]\)\([efg]\)/\2\1/g   modifies "af fa bg" to "fa fa gb"
:s/abcde/abc^Mde/              modifies "abcde"    to "abc", "de" (two lines)
:s/$/\^M/                      modifies "abcde"    to "abcde^M"
:s/\w\+/\u\0/g                 modifies "bla bla"  to "Bla Bla"
:s/\w\+/\L\u\0/g               modifies "BLA bla"  to "Bla Bla"
```

Note: "\L\u" can be used to capitalize the first letter of a word. This is not compatible with Vi and older versions of Vim, where the "\u" would cancel out the "\L". Same for "\U\l".

Note: In previous versions CTRL-V was handled in a special way. Since this is not Vi compatible, this was removed. Use a backslash instead.

```
command         text    result
```

```
:s/aa/a^Ma/     aa      a<line-break>a
:s/aa/a\^Ma/    aa      a^Ma
:s/aa/a\\^Ma/   aa      a\<line-break>a
```

(you need to type CTRL-V <CR> to get a ^M here)

The numbering of "\1", "\2" etc. is done based on which "\(" comes first in the pattern (going left to right). When a parentheses group matches several times, the last one will be used for "\1", "\2", etc. Example:

```
  :s/\(\(a[a-d] \)*\)/\2/      modifies "aa ab x" to "ab x"
```

The "\2" is for "\(a[a-d] \)". At first it matches "aa ", secondly "ab ".

When using parentheses in combination with '|', like in \([ab]\)\|\([cd]\), either the first or second pattern in parentheses did not match, so either \1 or \2 is empty. Example:

```
  :s/\([ab]\)\|\([cd]\)/\1x/g   modifies "a b c d"  to "ax bx x x"
```

:sc :sce :scg :sci :scI :scl :scp :sg :sgc

2-letter and 3-letter :substitute commands

List of :substitute commands

	c	e	g	i	I	n	p	l	r
c	:sc	:sce	:scg	:sci	:scI	:scn	:scp	:scl	---
e									
g	:sgc	:sge	:sg	:sgi	:sgI	:sgn	:sgp	:sgl	:sgr
i	:sic	:sie	---	:si	:siI	:sin	:sip	---	:sir
I	:sIc	:sIe	:sIg	:sIi	:sI	:sIn	:sIp	:sIl	:sIr
n									
p									
l									
r	:src	---	:srg	:sri	:srI	:srn	:srp	:srl	:sr

Exceptions:

```
     :scr  is  `:scriptnames`
     :se   is  `:set`
     :sig  is  `:sign`
     :sil  is  `:silent`
     :sn   is  `:snext`
     :sp   is  `:split`
     :sl   is  `:sleep`
     :sre  is  `:srewind`
```

Substitute with an expression sub-replace-expression
sub-replace-\= s/\=

When the substitute string starts with "\=" the remainder is interpreted as an expression.

The special meaning for characters as mentioned at sub-replace-special does

not apply except for "<CR>". A <NL> character is used as a line break, you can get one with a double-quote string: "\n". Prepend a backslash to get a real <NL> character (which will be a NUL in the file).

The "\=" notation can also be used inside the third argument {sub} of substitute() function. In this case, the special meaning for characters as mentioned at sub-replace-special does not apply at all. Especially, <CR> and <NL> are interpreted not as a line break but as a carriage-return and a new-line respectively.

When the result is a List then the items are joined with separating line breaks. Thus each item becomes a line, except that they can contain line breaks themselves.

The whole matched text can be accessed with "submatch(0)". The text matched with the first pair of () with "submatch(1)". Likewise for further sub-matches in ().

Be careful: The separation character must not appear in the expression! Consider using a character like "@" or ":". There is no problem if the result of the expression contains the separation character.

Examples:

```
:s@\n@\="\r" . expand("$HOME") . "\r"@
```

This replaces an end-of-line with a new line containing the value of $HOME.

```
s/E/\="\<Char-0x20ac>"/g
```

This replaces each 'E' character with a euro sign. Read more in <Char-> .

4.3 Search and replace

search-replace

:pro :promptfind

:promptf[ind] [string]

Put up a Search dialog. When [string] is given, it is used as the initial search string.
{only for Win32, Motif and GTK GUI}

:promptr :promptrepl

:promptr[epl] [string]

Put up a Search/Replace dialog. When [string] is given, it is used as the initial search string.
{only for Win32, Motif and GTK GUI}

4.4 Changing tabs

change-tabs

:ret :retab :retab!

:[range]ret[ab][!] [new_tabstop]

Replace all sequences of white-space containing a <Tab> with new strings of white-space using the new tabstop value given. If you do not specify a new tabstop size or it is zero, Vim uses the current value of 'tabstop'.
The current value of 'tabstop' is always used to

compute the width of existing tabs.
With !, Vim also replaces strings of only normal
spaces with tabs where appropriate.
With 'expandtab' on, Vim replaces all tabs with the
appropriate number of spaces.
This command sets 'tabstop' to the new value given,
and if performed on the whole file, which is default,
should not make any visible change.
Careful: This command modifies any <Tab> characters
inside of strings in a C program. Use "\t" to avoid
this (that's a good habit anyway).
`:retab!` may also change a sequence of spaces by
<Tab> characters, which can mess up a printf().
If the +vartabs feature is enabled then a list of
tab widths separated by commas may be used in place of
a single tabstop. Each value in the list represents
the width of one tabstop, except the final value which
applies to all following tabstops.
{not in Vi}

retab-example
Example for using autocommands and ":retab" to edit a file which is stored
with tabstops at 8 but edited with tabstops set at 4. Warning: white space
inside of strings can change! Also see 'softtabstop' option.

```
:auto BufReadPost     *.xx    retab! 4
:auto BufWritePre     *.xx    retab! 8
:auto BufWritePost    *.xx    retab! 4
:auto BufNewFile      *.xx    set ts=4
```

==========
5. Copying and moving text   copy-move

quote
"{a-zA-Z0-9.%#:-"}   Use register {a-zA-Z0-9.%#:-"} for next delete, yank
or put (use uppercase character to append with
delete and yank) ({.%#:} only work with put).

:reg   :registers
:reg[isters]   Display the contents of all numbered and named
registers. If a register is written to for :redir
it will not be listed.
{not in Vi}

:reg[isters] {arg}   Display the contents of the numbered and named
registers that are mentioned in {arg}. For example:
:reg 1a
to display registers '1' and 'a'. Spaces are allowed
in {arg}. {not in Vi}

:di   :display
:di[splay] [arg]   Same as :registers. {not in Vi}

y yank

["x]y{motion} Yank {motion} text [into register x]. When no characters are to be yanked (e.g., "y0" in column 1), this is an error when 'cpoptions' includes the 'E' flag.

yy

["x]yy Yank [count] lines [into register x] linewise .

Y

["x]Y yank [count] lines [into register x] (synonym for yy, linewise). If you like "Y" to work from the cursor to the end of line (which is more logical, but not Vi-compatible) use ":map Y y$".

v_y

{Visual}["x]y Yank the highlighted text [into register x] (for {Visual} see Visual-mode). {not in Vi}

v_Y

{Visual}["x]Y Yank the highlighted lines [into register x] (for {Visual} see Visual-mode). {not in Vi}

:y :yank E850

:[range]y[ank] [x] Yank [range] lines [into register x]. Yanking to the "* or "+ registers is possible only when the +clipboard feature is included.

:[range]y[ank] [x] {count}
Yank {count} lines, starting with last line number in [range] (default: current line cmdline-ranges), [into register x].

p put E353

["x]p Put the text [from register x] after the cursor [count] times. {Vi: no count}

P

["x]P Put the text [from register x] before the cursor [count] times. {Vi: no count}

<MiddleMouse>

["x]<MiddleMouse> Put the text from a register before the cursor [count] times. Uses the "* register, unless another is specified.
Leaves the cursor at the end of the new text.
Using the mouse only works when 'mouse' contains 'n' or 'a'.
{not in Vi}
If you have a scrollwheel and often accidentally paste text, you can use these mappings to disable the pasting with the middle mouse button:

```
:map <MiddleMouse> <Nop>
:imap <MiddleMouse> <Nop>
```

You might want to disable the multi-click versions
too, see double-click .

gp
["x]gp Just like "p", but leave the cursor just after the new
text. {not in Vi}

gP
["x]gP Just like "P", but leave the cursor just after the new
text. {not in Vi}

:pu :put
:[line]pu[t] [x] Put the text [from register x] after [line] (default
current line). This always works linewise , thus
this command can be used to put a yanked block as new
lines.
If no register is specified, it depends on the 'cb'
option: If 'cb' contains "unnamedplus", paste from the
+ register quoteplus . Otherwise, if 'cb' contains
"unnamed", paste from the * register quotestar .
Otherwise, paste from the unnamed register
quote_quote .
The register can also be '=' followed by an optional
expression. The expression continues until the end of
the command. You need to escape the '|' and '"'
characters to prevent them from terminating the
command. Example:
:put ='path' . \",/test\"
If there is no expression after '=', Vim uses the
previous expression. You can see it with ":dis =".

:[line]pu[t]! [x] Put the text [from register x] before [line] (default
current line).

]p]<MiddleMouse>
["x]p or
["x]]p or
["x]<MiddleMouse> Like "p", but adjust the indent to the current line.
Using the mouse only works when 'mouse' contains 'n'
or 'a'. {not in Vi}

[P
["x][P or
]P
["x]]P or
[p [<MiddleMouse>
["x][p or
["x][<MiddleMouse> Like "P", but adjust the indent to the current line.
Using the mouse only works when 'mouse' contains 'n'
or 'a'. {not in Vi}

You can use these commands to copy text from one place to another. Do this
by first getting the text into a register with a yank, delete or change
command, then inserting the register contents with a put command. You can
also use these commands to move text from one file to another, because Vim
preserves all registers when changing buffers (the CTRL-^ command is a quick
way to toggle between two files).

linewise-register characterwise-register

You can repeat the put commands with "." (except for :put) and undo them. If the command that was used to get the text into the register was linewise , Vim inserts the text below ("p") or above ("P") the line where the cursor is. Otherwise Vim inserts the text after ("p") or before ("P") the cursor. With the ":put" command, Vim always inserts the text in the next line. You can exchange two characters with the command sequence "xp". You can exchange two lines with the command sequence "ddp". You can exchange two words with the command sequence "deep" (start with the cursor in the blank space before the first word). You can use the "']" or "`]" command after the put command to move the cursor to the end of the inserted text, or use "'[" or "`[" to move the cursor to the start.

put-Visual-mode v_p v_P
When using a put command like p or P in Visual mode, Vim will try to replace the selected text with the contents of the register. Whether this works well depends on the type of selection and the type of the text in the register. With blockwise selection it also depends on the size of the block and whether the corners are on an existing character. (Implementation detail: it actually works by first putting the register after the selection and then deleting the selection.)
The previously selected text is put in the unnamed register. If you want to put the same text into a Visual selection several times you need to use another register. E.g., yank the text to copy, Visually select the text to replace and use "0p . You can repeat this as many times as you like, the unnamed register will be changed each time.

When you use a blockwise Visual mode command and yank only a single line into a register, a paste on a visual selected area will paste that single line on each of the selected lines (thus replacing the blockwise selected region by a block of the pasted line).

blockwise-register
If you use a blockwise Visual mode command to get the text into the register, the block of text will be inserted before ("P") or after ("p") the cursor column in the current and next lines. Vim makes the whole block of text start in the same column. Thus the inserted text looks the same as when it was yanked or deleted. Vim may replace some <Tab> characters with spaces to make this happen. However, if the width of the block is not a multiple of a <Tab> width and the text after the inserted block contains <Tab>s, that text may be misaligned.

Note that after a characterwise yank command, Vim leaves the cursor on the first yanked character that is closest to the start of the buffer. This means that "yl" doesn't move the cursor, but "yh" moves the cursor one character left.
Rationale: In Vi the "y" command followed by a backwards motion would sometimes not move the cursor to the first yanked character, because redisplaying was skipped. In Vim it always moves to the first character, as specified by Posix.
With a linewise yank command the cursor is put in the first line, but the column is unmodified, thus it may not be on the first yanked character.

There are ten types of registers: registers E354
1. The unnamed register ""

2. 10 numbered registers "0 to "9
3. The small delete register "-
4. 26 named registers "a to "z or "A to "Z
5. three read-only registers ":, "., "%
6. alternate buffer register "#
7. the expression register "=
8. The selection and drop registers "*, "+ and "~
9. The black hole register "_
10. Last search pattern register "/

1. Unnamed register ""   quote_quote   quotequote
Vim fills this register with text deleted with the "d", "c", "s", "x" commands
or copied with the yank "y" command, regardless of whether or not a specific
register was used (e.g. "xdd). This is like the unnamed register is pointing
to the last used register. Thus when appending using an uppercase register
name, the unnamed register contains the same text as the named register.
An exception is the '_' register: "_dd does not store the deleted text in any
register.
Vim uses the contents of the unnamed register for any put command (p or P)
which does not specify a register. Additionally you can access it with the
name '""'. This means you have to type two double quotes. Writing to the ""
register writes to register "0.
{Vi: register contents are lost when changing files, no '""'}

2. Numbered registers "0 to "9   quote_number   quote0   quote1
                                        quote2   quote3   quote4   quote9
Vim fills these registers with text from yank and delete commands.
   Numbered register 0 contains the text from the most recent yank command,
unless the command specified another register with ["x].
   Numbered register 1 contains the text deleted by the most recent delete or
change command, unless the command specified another register or the text is
less than one line (the small delete register is used then). An exception is
made for the delete operator with these movement commands: % , (,) , `
 / , ? , n , N , { and } . Register "1 is always used then (this is Vi
compatible). The "- register is used as well if the delete is within a line.
Note that these characters may be mapped. E.g. % is mapped by the matchit
plugin.
   With each successive deletion or change, Vim shifts the previous contents
of register 1 into register 2, 2 into 3, and so forth, losing the previous
contents of register 9.
{Vi: numbered register contents are lost when changing files; register 0 does
not exist}

3. Small delete register "-   quote_-   quote-
This register contains text from commands that delete less than one line,
except when the command specifies a register with ["x].
{not in Vi}

4. Named registers "a to "z or "A to "Z   quote_alpha   quotea
Vim fills these registers only when you say so. Specify them as lowercase
letters to replace their previous contents or as uppercase letters to append
to their previous contents. When the '>' flag is present in 'cpoptions' then
a line break is inserted before the appended text.

5. Read-only registers ":, ". and "%
These are '%', '#', ':' and '.'. You can use them only with the "p", "P",
and ":put" commands and with CTRL-R. {not in Vi}
                                                quote_. quote. E29
        ".   Contains the last inserted text (the same as what is inserted
                with the insert mode commands CTRL-A and CTRL-@). Note: this
                doesn't work with CTRL-R on the command-line. It works a bit
                differently, like inserting the text instead of putting it
                ('textwidth' and other options affect what is inserted).
                                                        quote_% quote%
        "%   Contains the name of the current file.
                                                quote_: quote: E30
        ":   Contains the most recent executed command-line. Example: Use
                "@:" to repeat the previous command-line command.
                The command-line is only stored in this register when at least
                one character of it was typed. Thus it remains unchanged if
                the command was completely from a mapping.
                {not available when compiled without the +cmdline_hist
                feature}
                                                        quote_# quote#
6. Alternate file register "#
Contains the name of the alternate file for the current window. It will
change how the CTRL-^ command works.
This register is writable, mainly to allow for restoring it after a plugin has
changed it. It accepts buffer number:
    let altbuf = bufnr(@#)
    ...
    let @# = altbuf
It will give error E86 if you pass buffer number and this buffer does not
exist.
It can also accept a match with an existing buffer name:
    let @# = 'buffer_name'
Error E93 if there is more than one buffer matching the given name or E94
if none of buffers matches the given name.

7. Expression register "=   quote_= quote= @=
This is not really a register that stores text, but is a way to use an
expression in commands which use a register. The expression register is
read-write.

When typing the '=' after " or CTRL-R the cursor moves to the command-line,
where you can enter any expression (see expression). All normal
command-line editing commands are available, including a special history for
expressions. When you end the command-line by typing <CR>, Vim computes the
result of the expression. If you end it with <Esc>, Vim abandons the
expression. If you do not enter an expression, Vim uses the previous
expression (like with the "/" command).

The expression must evaluate to a String. A Number is always automatically
converted to a String. For the "p" and ":put" command, if the result is a
Float it's converted into a String. If the result is a List each element is
turned into a String and used as a line. A Dictionary or FuncRef results in
an error message (use string() to convert).

If the "= register is used for the "p" command, the String is split up at <NL> characters. If the String ends in a <NL>, it is regarded as a linewise register. {not in Vi}

8. Selection and drop registers "*, "+ and "~
Use these registers for storing and retrieving the selected text for the GUI. See quotestar and quoteplus . When the clipboard is not available or not working, the unnamed register is used instead. For Unix systems the clipboard is only available when the +xterm_clipboard feature is present. {not in Vi}

Note that there is only a distinction between "* and "+ for X11 systems. For an explanation of the difference, see x11-selection . Under MS-Windows, use of "* and "+ is actually synonymous and refers to the gui-clipboard .

quote_~ quote~ <Drop>
The read-only "~ register stores the dropped text from the last drag'n'drop operation. When something has been dropped onto Vim, the "~ register is filled in and the <Drop> pseudo key is sent for notification. You can remap this key if you want; the default action (for all modes) is to insert the contents of the "~ register at the cursor position. {not in Vi}
{only available when compiled with the +dnd feature, currently only with the GTK GUI}

Note: The "~ register is only used when dropping plain text onto Vim.
Drag'n'drop of URI lists is handled internally.

9. Black hole register "_ quote_
When writing to this register, nothing happens. This can be used to delete text without affecting the normal registers. When reading from this register, nothing is returned. {not in Vi}

10. Last search pattern register "/ quote_/ quote/
Contains the most recent search-pattern. This is used for "n" and 'hlsearch'. It is writable with `:let`, you can change it to have 'hlsearch' highlight other matches without actually searching. You can't yank or delete into this register. The search direction is available in v:searchforward .
Note that the value is restored when returning from a function
function-search-undo .
{not in Vi}

@/
You can write to a register with a `:let` command :let-@ . Example:
```
:let @/ = "the"
```

If you use a put command without specifying a register, Vim uses the register that was last filled (this is also the contents of the unnamed register). If you are confused, use the `:dis` command to find out what Vim will put (this command displays all named and numbered registers; the unnamed register is labelled '""').

The next three commands always work on whole lines.

:[range]co[py] {address} :co :copy
Copy the lines given by [range] to below the line

given by {address}.

:t
:t Synonym for copy.

:[range]m[ove] {address} :m :mo :move E134
Move the lines given by [range] to below the line
given by {address}.

==========
6. Formatting text formatting

:[range]ce[nter] [width] :ce :center
Center lines in [range] between [width] columns
(default 'textwidth' or 80 when 'textwidth' is 0).
{not in Vi}

:[range]ri[ght] [width] :ri :right
Right-align lines in [range] at [width] columns
(default 'textwidth' or 80 when 'textwidth' is 0).
{not in Vi}

:le :left
:[range]le[ft] [indent]
Left-align lines in [range]. Sets the indent in the
lines to [indent] (default 0). {not in Vi}

gq
gq{motion} Format the lines that {motion} moves over.
Formatting is done with one of three methods:
1. If 'formatexpr' is not empty the expression is
evaluated. This can differ for each buffer.
2. If 'formatprg' is not empty an external program
is used.
3. Otherwise formatting is done internally.

In the third case the 'textwidth' option controls the
length of each formatted line (see below).
If the 'textwidth' option is 0, the formatted line
length is the screen width (with a maximum width of
79).
The 'formatoptions' option controls the type of
formatting fo-table .
The cursor is left on the first non-blank of the last
formatted line.
NOTE: The "Q" command formerly performed this
function. If you still want to use "Q" for
formatting, use this mapping:
:nnoremap Q gq

gqgq gqgq gqq
gqq Format the current line. With a count format that
many lines. {not in Vi}

v_gq
{Visual}gq Format the highlighted text. (for {Visual} see Visual-mode). {not in Vi}

gw
gw{motion} Format the lines that {motion} moves over. Similar to gq but puts the cursor back at the same position in the text. However, 'formatprg' and 'formatexpr' are not used. {not in Vi}

gwgw gwgw gww
gww Format the current line as with "gw". {not in Vi}

v_gw
{Visual}gw Format the highlighted text as with "gw". (for {Visual} see Visual-mode). {not in Vi}

Example: To format the current paragraph use: gqap
gqap

The "gq" command leaves the cursor in the line where the motion command takes the cursor. This allows you to repeat formatting repeated with ".". This works well with "gqj" (format current and next line) and "gq}" (format until end of paragraph). Note: When 'formatprg' is set, "gq" leaves the cursor on the first formatted line (as with using a filter command).

If you want to format the current paragraph and continue where you were, use:
gwap
If you always want to keep paragraphs formatted you may want to add the 'a' flag to 'formatoptions'. See auto-format .

If the 'autoindent' option is on, Vim uses the indent of the first line for the following lines.

Formatting does not change empty lines (but it does change lines with only white space!).

The 'joinspaces' option is used when lines are joined together.

You can set the 'formatexpr' option to an expression or the 'formatprg' option to the name of an external program for Vim to use for text formatting. The 'textwidth' and other options have no effect on formatting by an external program.

format-formatexpr
The 'formatexpr' option can be set to a Vim Script function that performs reformatting of the buffer. This should usually happen in an ftplugin , since formatting is highly dependent on the type of file. It makes sense to use an autoload script, so the corresponding script is only loaded when actually needed and the script should be called <filetype>format.vim.

For example, the XML filetype plugin distributed with Vim in the $VIMRUNTIME directory, sets the 'formatexpr' option to:

```
   setlocal formatexpr=xmlformat#Format()
```

That means, you will find the corresponding script, defining the
xmlformat#Format() function, in the directory:
`$VIMRUNTIME/autoload/xmlformat.vim`

Here is an example script that removes trailing whitespace from the selected
text. Put it in your autoload directory, e.g. ~/.vim/autoload/format.vim:

```
  func! format#Format()
    " only reformat on explicit gq command
    if mode() != 'n'
      " fall back to Vims internal reformatting
      return 1
    endif
    let lines = getline(v:lnum, v:lnum + v:count - 1)
    call map(lines, {key, val -> substitute(val, '\s\+$', '', 'g')})
    call setline('.', lines)

    " do not run internal formatter!
    return 0
  endfunc
```

You can then enable the formatting by executing:
```
  setlocal formatexpr=format#Format()
```

Note: this function explicitly returns non-zero when called from insert mode
(which basically means, text is inserted beyond the 'textwidth' limit). This
causes Vim to fall back to reformat the text by using the internal formatter.

However, if the gq command is used to reformat the text, the function
will receive the selected lines, trim trailing whitespace from those lines and
put them back in place. If you are going to split single lines into multiple
lines, be careful not to overwrite anything.

If you want to allow reformatting of text from insert or replace mode, one has
to be very careful, because the function might be called recursively. For
debugging it helps to set the 'debug' option.

                                                        right-justify
There is no command in Vim to right justify text. You can do it with
an external command, like "par" (e.g.: "!}par" to format until the end of the
paragraph) or set 'formatprg' to "par".

                                                        format-comments
An overview of comment formatting is in section 30.6 of the user manual.

Vim can automatically insert and format comments in a special way. Vim
recognizes a comment by a specific string at the start of the line (ignoring
white space). Three types of comments can be used:

- A comment string that repeats at the start of each line. An example is the
  type of comment used in shell scripts, starting with "#".
- A comment string that occurs only in the first line, not in the following

  lines. An example is this list with dashes.
- Three-piece comments that have a start string, an end string, and optional
  lines in between. The strings for the start, middle and end are different.
  An example is the C style comment:
        /*
         * this is a C comment
         */

The 'comments' option is a comma-separated list of parts. Each part defines a
type of comment string. A part consists of:
        {flags}:{string}

{string} is the literal text that must appear.

{flags}:
  n   Nested comment. Nesting with mixed parts is allowed. If 'comments'
        is "n:),n:>" a line starting with ">) >" is a comment.

  b   Blank (<Space>, <Tab> or <EOL>) required after {string}.

  f   Only the first line has the comment string. Do not repeat comment on
        the next line, but preserve indentation (e.g., a bullet-list).

  s   Start of three-piece comment

  m   Middle of a three-piece comment

  e   End of a three-piece comment

  l   Left align. Used together with 's' or 'e', the leftmost character of
        start or end will line up with the leftmost character from the middle.
        This is the default and can be omitted. See below for more details.

  r   Right align. Same as above but rightmost instead of leftmost. See
        below for more details.

  O   Don't consider this comment for the "O" command.

  x   Allows three-piece comments to be ended by just typing the last
        character of the end-comment string as the first action on a new
        line when the middle-comment string has been inserted automatically.
        See below for more details.

  {digits}
        When together with 's' or 'e': add {digit} amount of offset to an
        automatically inserted middle or end comment leader. The offset begins
        from a left alignment. See below for more details.

  -{digits}
        Like {digits} but reduce the indent. This only works when there is
        some indent for the start or end part that can be removed.

When a string has none of the 'f', 's', 'm' or 'e' flags, Vim assumes the
comment string repeats at the start of each line. The flags field may be

empty.

Any blank space in the text before and after the {string} is part of the {string}, so do not include leading or trailing blanks unless the blanks are a required part of the comment string.

When one comment leader is part of another, specify the part after the whole. For example, to include both "-" and "->", use
	:set comments=f:->,f:-

A three-piece comment must always be given as start,middle,end, with no other parts in between. An example of a three-piece comment is
	sr:/*,mb:*,ex:*/
for C-comments. To avoid recognizing "*ptr" as a comment, the middle string includes the 'b' flag. For three-piece comments, Vim checks the text after the start and middle strings for the end string. If Vim finds the end string, the comment does not continue on the next line. Three-piece comments must have a middle string because otherwise Vim can't recognize the middle lines.

Notice the use of the "x" flag in the above three-piece comment definition. When you hit Return in a C-comment, Vim will insert the middle comment leader for the new line: " * ". To close this comment you just have to type "/" before typing anything else on the new line. This will replace the middle-comment leader with the end-comment leader and apply any specified alignment, leaving just " */". There is no need to hit Backspace first.

When there is a match with a middle part, but there also is a matching end part which is longer, the end part is used. This makes a C style comment work without requiring the middle part to end with a space.

Here is an example of alignment flags at work to make a comment stand out (kind of looks like a 1 too). Consider comment string:
	:set comments=sr:/***,m:**,ex-2:******/

```
                                /***
                                  **<--right aligned from "r" flag
                                  **
offset 2 spaces for the "-2" flag--->**
                                ******/
```

In this case, the first comment was typed, then return was pressed 4 times, then "/" was pressed to end the comment.

Here are some finer points of three part comments. There are three times when alignment and offset flags are taken into consideration: opening a new line after a start-comment, opening a new line before an end-comment, and automatically ending a three-piece comment. The end alignment flag has a backwards perspective; the result is that the same alignment flag used with "s" and "e" will result in the same indent for the starting and ending pieces. Only one alignment per comment part is meant to be used, but an offset number will override the "r" and "l" flag.

Enabling 'cindent' will override the alignment flags in many cases. Reindenting using a different method like gq or = will not consult alignment flags either. The same behaviour can be defined in those other

formatting options. One consideration is that 'cindent' has additional options for context based indenting of comments but cannot replicate many three piece indent alignments. However, 'indentexpr' has the ability to work better with three piece comments.

Other examples:
```
   "b:*"        Includes lines starting with "*", but not if the "*" is
                followed by a non-blank.  This avoids a pointer dereference
                like "*str" to be recognized as a comment.
   "n:>"        Includes a line starting with ">", ">>", ">>>", etc.
   "fb:-"       Format a list that starts with "- ".
```

By default, "b:#" is included. This means that a line that starts with "#include" is not recognized as a comment line. But a line that starts with "# define" is recognized. This is a compromise.

{not available when compiled without the |+comments| feature}

fo-table

You can use the 'formatoptions' option to influence how Vim formats text. 'formatoptions' is a string that can contain any of the letters below. The default setting is "tcq". You can separate the option letters with commas for readability.

letter meaning when present in 'formatoptions'

t Auto-wrap text using textwidth

c Auto-wrap comments using textwidth, inserting the current comment leader automatically.

r Automatically insert the current comment leader after hitting <Enter> in Insert mode.

o Automatically insert the current comment leader after hitting 'o' or 'O' in Normal mode.

q Allow formatting of comments with "gq". Note that formatting will not change blank lines or lines containing only the comment leader. A new paragraph starts after such a line, or when the comment leader changes.

w Trailing white space indicates a paragraph continues in the next line. A line that ends in a non-white character ends a paragraph.

a Automatic formatting of paragraphs. Every time text is inserted or deleted the paragraph will be reformatted. See auto-format . When the 'c' flag is present this only happens for recognized comments.

n When formatting text, recognize numbered lists. This actually uses the 'formatlistpat' option, thus any kind of list can be used. The indent of the text after the number is used for the next line. The default is to find a number, optionally followed by '.', ':', ')', ']' or '}'. Note that 'autoindent' must be set too. Doesn't work well together with "2". Example:

```
        1. the first item
           wraps
        2. the second item
```

2 When formatting text, use the indent of the second line of a paragraph

```
        for the rest of the paragraph, instead of the indent of the first
        line.  This supports paragraphs in which the first line has a
        different indent than the rest.  Note that 'autoindent' must be set
        too.  Example:
                        first line of a paragraph
                second line of the same paragraph
                third line.
       This also works inside comments, ignoring the comment leader.
v       Vi-compatible auto-wrapping in insert mode: Only break a line at a
        blank that you have entered during the current insert command.  (Note:
        this is not 100% Vi compatible.  Vi has some "unexpected features" or
        bugs in this area.  It uses the screen column instead of the line
        column.)
b       Like 'v', but only auto-wrap if you enter a blank at or before
        the wrap margin.  If the line was longer than 'textwidth' when you
        started the insert, or you do not enter a blank in the insert before
        reaching 'textwidth', Vim does not perform auto-wrapping.
l       Long lines are not broken in insert mode: When a line was longer than
        'textwidth' when the insert command started, Vim does not
        automatically format it.
m       Also break at a multi-byte character above 255.  This is useful for
        Asian text where every character is a word on its own.
M       When joining lines, don't insert a space before or after a multi-byte
        character.  Overrules the 'B' flag.
B       When joining lines, don't insert a space between two multi-byte
        characters.  Overruled by the 'M' flag.
1       Don't break a line after a one-letter word.  It's broken before it
        instead (if possible).
j       Where it makes sense, remove a comment leader when joining lines.  For
        example, joining:
                int i;   // the index
                         // in the list
        Becomes:
                int i;   // the index in the list

With 't' and 'c' you can specify when Vim performs auto-wrapping:
value   action
""      no automatic formatting (you can use "gq" for manual formatting)
"t"     automatic formatting of text, but not comments
"c"     automatic formatting for comments, but not text (good for C code)
"tc"    automatic formatting for text and comments

Note that when 'textwidth' is 0, Vim does no automatic formatting anyway (but
does insert comment leaders according to the 'comments' option).  An exception
is when the 'a' flag is present.  auto-format

Note that when 'paste' is on, Vim does no formatting at all.

Note that 'textwidth' can be non-zero even if Vim never performs auto-wrapping;
'textwidth' is still useful for formatting with "gq".

If the 'comments' option includes "/*", "*" and/or "*/", then Vim has some
built in stuff to treat these types of comments a bit more cleverly.
```

Opening a new line before or after "/*" or "*/" (with 'r' or 'o' present in 'formatoptions') gives the correct start of the line automatically. The same happens with formatting and auto-wrapping. Opening a line after a line starting with "/*" or "*" and containing "*/", will cause no comment leader to be inserted, and the indent of the new line is taken from the line containing the start of the comment.
E.g.:

```
    /*
     * Your typical comment.
     */
    The indent on this line is the same as the start of the above
    comment.
```

All of this should be really cool, especially in conjunction with the new :autocmd command to prepare different settings for different types of file.

Some examples:

```
  for C code (only format comments):
        :set fo=croq
 for Mail/news (format all, don't start comment with "o" command):
        :set fo=tcrq
```

Automatic formatting auto-format autoformat

When the 'a' flag is present in 'formatoptions' text is formatted automatically when inserting text or deleting text. This works nice for editing text paragraphs. A few hints on how to use this:

- You need to properly define paragraphs. The simplest is paragraphs that are separated by a blank line. When there is no separating blank line, consider using the 'w' flag and adding a space at the end of each line in the paragraphs except the last one.

- You can set the 'formatoptions' based on the type of file filetype or specifically for one file with a modeline .

- Set 'formatoptions' to "aw2tq" to make text with indents like this:

```
            bla bla foobar bla
        bla foobar bla foobar bla
            bla bla foobar bla
        bla foobar bla bla foobar
```

- Add the 'c' flag to only auto-format comments. Useful in source code.

- Set 'textwidth' to the desired width. If it is zero then 79 is used, or the width of the screen if this is smaller.

And a few warnings:

- When part of the text is not properly separated in paragraphs, making changes in this text will cause it to be formatted anyway. Consider doing

```
        :set fo-=a
```

- When using the 'w' flag (trailing space means paragraph continues) and deleting the last line of a paragraph with dd , the paragraph will be joined with the next one.

- Changed text is saved for undo. Formatting is also a change. Thus each format action saves text for undo. This may consume quite a lot of memory.

- Formatting a long paragraph and/or with complicated indenting may be slow.

==
7. Sorting text   sorting

Vim has a sorting function and a sorting command. The sorting function can be found here: sort() , uniq() .

                                                                :sor   :sort
:[range]sor[t][!] [b][f][i][n][o][r][u][x] [/{pattern}/]
                        Sort lines in [range]. When no range is given all
                        lines are sorted.

                        With [!] the order is reversed.

                        With [i] case is ignored.

                        Options [n][f][x][o][b] are mutually exclusive.

                        With [n] sorting is done on the first decimal number
                        in the line (after or inside a {pattern} match).
                        One leading '-' is included in the number.

                        With [f] sorting is done on the Float in the line.
                        The value of Float is determined similar to passing
                        the text (after or inside a {pattern} match) to
                        str2float() function. This option is available only
                        if Vim was compiled with Floating point support.

                        With [x] sorting is done on the first hexadecimal
                        number in the line (after or inside a {pattern}
                        match). A leading "0x" or "0X" is ignored.
                        One leading '-' is included in the number.

                        With [o] sorting is done on the first octal number in
                        the line (after or inside a {pattern} match).

                        With [b] sorting is done on the first binary number in
                        the line (after or inside a {pattern} match).

                        With [u] (u stands for unique) only keep the first of
                        a sequence of identical lines (ignoring case when [i]
                        is used). Without this flag, a sequence of identical
                        lines will be kept in their original order.
                        Note that leading and trailing white space may cause

lines to be different.

When /{pattern}/ is specified and there is no [r] flag the text matched with {pattern} is skipped, so that you sort on what comes after the match.
Instead of the slash any non-letter can be used.
For example, to sort on the second comma-separated field:

```
:sort /[^,]*,/
```

To sort on the text at virtual column 10 (thus ignoring the difference between tabs and spaces):

```
:sort /.*\%10v/
```

To sort on the first number in the line, no matter what is in front of it:

```
:sort /.\{-}\ze\d/
```

(Explanation: ".\{-}" matches any text, "\ze" sets the end of the match and \d matches a digit.)
With [r] sorting is done on the matching {pattern} instead of skipping past it as described above.
For example, to sort on only the first three letters of each line:

```
:sort /\a\a\a/ r
```

If a {pattern} is used, any lines which don't have a match for {pattern} are kept in their current order, but separate from the lines which do match {pattern}.
If you sorted in reverse, they will be in reverse order after the sorted lines, otherwise they will be in their original order, right before the sorted lines.

If {pattern} is empty (e.g. // is specified), the last search pattern is used. This allows trying out a pattern first.

Note that using `:sort` with `:global` doesn't sort the matching lines, it's quite useless.

The details about sorting depend on the library function used. There is no guarantee that sorting obeys the current locale. You will have to try it out. Vim does do a "stable" sort.

The sorting can be interrupted, but if you interrupt it too late in the process you may end up with duplicated lines. This also depends on the system library function used.

indent.txt For Vim version 8.1. Last change: 2018 Apr 04

VIM REFERENCE MANUAL by Bram Moolenaar

This file is about indenting C programs and other files.

==========

1. Indenting C style programs C-indenting

The basics for C style indenting are explained in section 30.2 of the user manual.

Vim has options for automatically indenting C style program files. Many programming languages including Java and C++ follow very closely the formatting conventions established with C. These options affect only the indent and do not perform other formatting. There are additional options that affect other kinds of formatting as well as indenting, see format-comments , fo-table , gq and formatting for the main ones.

Note that this will not work when the +smartindent or +cindent features have been disabled at compile time.

There are in fact four main methods available for indentation, each one overrides the previous if it is enabled, or non-empty for 'indentexpr':

'autoindent' uses the indent from the previous line.
'smartindent' is like 'autoindent' but also recognizes some C syntax to increase/reduce the indent where appropriate.
'cindent' Works more cleverly than the other two and is configurable to different indenting styles.
'indentexpr' The most flexible of all: Evaluates an expression to compute the indent of a line. When non-empty this method overrides the other ones. See indent-expression .

The rest of this section describes the 'cindent' option.

Note that 'cindent' indenting does not work for every code scenario. Vim is not a C compiler: it does not recognize all syntax. One requirement is that toplevel functions have a '{' in the first column. Otherwise they are easily confused with declarations.

These four options control C program indenting:

'cindent' Enables Vim to perform C program indenting automatically.
'cinkeys' Specifies which keys trigger reindenting in insert mode.
'cinoptions' Sets your preferred indent style.
'cinwords' Defines keywords that start an extra indent in the next line.

If 'lisp' is not on and 'equalprg' is empty, the "=" operator indents using Vim's built-in algorithm rather than calling an external program.

See autocommand for how to set the 'cindent' option automatically for C code

files and reset it for others.

cinkeys-format indentkeys-format

The 'cinkeys' option is a string that controls Vim's indenting in response to typing certain characters or commands in certain contexts. Note that this not only triggers C-indenting. When 'indentexpr' is not empty 'indentkeys' is used instead. The format of 'cinkeys' and 'indentkeys' is equal.

The default is "0{,0},0),:,0#,!^F,o,O,e" which specifies that indenting occurs as follows:

```
        "0{"    if you type '{' as the first character in a line
        "0}"    if you type '}' as the first character in a line
        "0)"    if you type ')' as the first character in a line
        ":"     if you type ':' after a label or case statement
        "0#"    if you type '#' as the first character in a line
        "!^F"   if you type CTRL-F (which is not inserted)
        "o"     if you type a <CR> anywhere or use the "o" command (not in
                insert mode!)
        "O"     if you use the "O" command (not in insert mode!)
        "e"     if you type the second 'e' for an "else" at the start of a
                line
```

Characters that can precede each key: i_CTRL-F

```
!       When a '!' precedes the key, Vim will not insert the key but will
        instead reindent the current line.  This allows you to define a
        command key for reindenting the current line.  CTRL-F is the default
        key for this.  Be careful if you define CTRL-I for this because CTRL-I
        is the ASCII code for <Tab>.
*       When a '*' precedes the key, Vim will reindent the line before
        inserting the key.  If 'cinkeys' contains "*<Return>", Vim reindents
        the current line before opening a new line.
0       When a zero precedes the key (but appears after '!' or '*') Vim will
        reindent the line only if the key is the first character you type in
        the line.  When used before "=" Vim will only reindent the line if
        there is only white space before the word.
```

When neither '!' nor '*' precedes the key, Vim reindents the line after you type the key. So ';' sets the indentation of a line which includes the ';'.

Special key names:

```
<>      Angle brackets mean spelled-out names of keys.  For example: "<Up>",
        "<Ins>" (see  key-notation ).
^       Letters preceded by a caret (^) are control characters.  For example:
        "^F" is CTRL-F.
o       Reindent a line when you use the "o" command or when Vim opens a new
        line below the current one (e.g., when you type <Enter> in insert
        mode).
O       Reindent a line when you use the "O" command.
e       Reindent a line that starts with "else" when you type the second 'e'.
:       Reindent a line when a ':' is typed which is after a label or case
        statement.  Don't reindent for a ":" in "class::method" for C++.  To
        Reindent for any ":", use "<:>".
=word   Reindent when typing the last character of "word".  "word" may
```

actually be part of another word. Thus "=end" would cause reindenting when typing the "d" in "endif" or "endwhile". But not when typing "bend". Also reindent when completion produces a word that starts with "word". "0=word" reindents when there is only white space before the word.

=~word Like =word, but ignore case.

If you really want to reindent when you type 'o', 'O', 'e', '0', '<', '>', '*', ':' or '!', use "<o>", "<O>", "<e>", "<0>", "<<>", "<>>", "<*>", "<:>" or "<!>", respectively, for those keys.

For an emacs-style indent mode where lines aren't indented every time you press <Enter> but only if you press <Tab>, I suggest:

```
:set cinkeys=0{,0},:,0#,!<Tab>,!^F
```

You might also want to switch off 'autoindent' then.

Note: If you change the current line's indentation manually, Vim ignores the cindent settings for that line. This prevents vim from reindenting after you have changed the indent by typing <BS>, <Tab>, or <Space> in the indent or used CTRL-T or CTRL-D.

cinoptions-values

The 'cinoptions' option sets how Vim performs indentation. The value after the option character can be one of these (N is any number):

N	indent N spaces
-N	indent N spaces to the left
Ns	N times 'shiftwidth' spaces
-Ns	N times 'shiftwidth' spaces to the left

In the list below,
"N" represents a number of your choice (the number can be negative). When there is an 's' after the number, Vim multiplies the number by 'shiftwidth': "1s" is 'shiftwidth', "2s" is two times 'shiftwidth', etc. You can use a decimal point, too: "-0.5s" is minus half a 'shiftwidth'.
The examples below assume a 'shiftwidth' of 4.

cino->

>N Amount added for "normal" indent. Used after a line that should increase the indent (lines starting with "if", an opening brace, etc.). (default 'shiftwidth').

```
cino=                cino=>2              cino=>2s
  if (cond)            if (cond)            if (cond)
  {                    {                    {
      foo;                 foo;                 foo;
  }                    }                    }
```

cino-e

eN Add N to the prevailing indent inside a set of braces if the opening brace at the End of the line (more precise: is not the first character in a line). This is useful if you want a different indent when the '{' is at the start of the line from when '{' is at the end of the line. (default 0).

```
cino=                cino=e2              cino=e-2
```

```
if (cond) {         if (cond) {         if (cond) {
    foo;                foo;              foo;
}                   }                   }
else                else                else
{                   {                   {
    bar;                bar;                bar;
}                   }                   }
```

cino-n

nN Add N to the prevailing indent for a statement after an "if", "while", etc., if it is NOT inside a set of braces. This is useful if you want a different indent when there is no '{' before the statement from when there is a '{' before it. (default 0).

```
cino=               cino=n2             cino=n-2
  if (cond)           if (cond)           if (cond)
      foo;                foo;              foo;
  else                else                else
  {                   {                   {
      bar;                bar;                bar;
  }                   }                   }
```

cino-f

fN Place the first opening brace of a function or other block in column N. This applies only for an opening brace that is not inside other braces and is at the start of the line. What comes after the brace is put relative to this brace. (default 0).

```
cino=               cino=f.5s           cino=f1s
  func()              func()              func()
  {                   {                   {
      int foo;            int foo;            int foo;
```

cino-{

{N Place opening braces N characters from the prevailing indent. This applies only for opening braces that are inside other braces. (default 0).

```
cino=               cino={.5s           cino={1s
  if (cond)           if (cond)           if (cond)
  {                   {                   {
      foo;                foo;                foo;
```

cino-}

}N Place closing braces N characters from the matching opening brace. (default 0).

```
cino=               cino={2,}-0.5s      cino=}2
  if (cond)           if (cond)           if (cond)
  {                   {                   {
      foo;                foo;                foo;
  }                   }                   }
```

cino-^

^N Add N to the prevailing indent inside a set of braces if the opening brace is in column 0. This can specify a different indent for whole of a function (some may like to set it to a negative number). (default 0).

```
cino=                cino=^-2             cino=^-s
  func()               func()               func()
  {                    {                    {
      if (cond)          if (cond)            if (cond)
      {                  {                    {
          a = b;             a = b;               a = b;
      }                  }                    }
  }                    }                    }
```

cino-L

LN Controls placement of jump labels. If N is negative, the label will be placed at column 1. If N is non-negative, the indent of the label will be the prevailing indent minus N. (default -1).

```
cino=                cino=L2              cino=Ls
  func()               func()               func()
  {                    {                    {
      {                    {                    {
          stmt;                stmt;                stmt;
  LABEL:               LABEL:               LABEL:
      }                    }                    }
  }                    }                    }
```

cino-:

:N Place case labels N characters from the indent of the switch(). (default 'shiftwidth').

```
cino=                cino=:0
  switch (x)           switch(x)
  {                    {
      case 1:          case 1:
          a = b;           a = b;
      default:         default:
  }                    }
```

cino-=

=N Place statements occurring after a case label N characters from the indent of the label. (default 'shiftwidth').

```
cino=                cino==10
   case 11:              case 11:  a = a + 1;
       a = a + 1;                  b = b + 1;
```

cino-l

lN If N != 0 Vim will align with a case label instead of the statement after it in the same line.

```
cino=                        cino=l1
```

```
        switch (a) {              switch (a) {
            case 1: {                 case 1: {
                        break;                    break;
                    }                         }
```

cino-b

bN If N != 0 Vim will align a final "break" with the case label, so that case..break looks like a sort of block. (default: 0). When using 1, consider adding "0=break" to 'cinkeys'.

```
  cino=                cino=b1
    switch (x)           switch(x)
    {                    {
        case 1:              case 1:
            a = b;               a = b;
            break;           break;

        default:             default:
            a = 0;               a = 0;
            break;           break;
    }                    }
```

cino-g

gN Place C++ scope declarations N characters from the indent of the block they are in. (default 'shiftwidth'). A scope declaration can be "public:", "protected:" or "private:".

```
  cino=                cino=g0
    {                    {
        public:              public:
            a = b;               a = b;
        private:             private:
    }                    }
```

cino-h

hN Place statements occurring after a C++ scope declaration N characters from the indent of the label. (default 'shiftwidth').

```
  cino=                cino=h10
     public:              public:   a = a + 1;
         a = a + 1;                b = b + 1;
```

cino-N

NN Indent inside C++ namespace N characters extra compared to a normal block. (default 0).

```
  cino=                      cino=N-s
    namespace {                namespace {
        void function();           void function();
    }                          }

    namespace my               namespace my
    {                          {
```

```
        void function();        void function();
    }                           }
```

cino-E

EN Indent inside C++ linkage specifications (extern "C" or extern "C++") N characters extra compared to a normal block. (default 0).

```
  cino=                     cino=E-s
    extern "C" {              extern "C" {
        void function();        void function();
    }                           }

    extern "C"                extern "C"
    {                         {
        void function();        void function();
    }                           }
```

cino-p

pN Parameter declarations for K&R-style function declarations will be indented N characters from the margin. (default 'shiftwidth').

```
  cino=             cino=p0           cino=p2s
    func(a, b)        func(a, b)        func(a, b)
        int a;          int a;                int a;
        char b;         char b;               char b;
```

cino-t

tN Indent a function return type declaration N characters from the margin. (default 'shiftwidth').

```
  cino=             cino=t0           cino=t7
        int             int                     int
    func()            func()            func()
```

cino-i

iN Indent C++ base class declarations and constructor initializations, if they start in a new line (otherwise they are aligned at the right side of the ':'). (default 'shiftwidth').

```
  cino=                     cino=i0
    class MyClass :           class MyClass :
        public BaseClass        public BaseClass
    {}                        {}
    MyClass::MyClass() :      MyClass::MyClass() :
        BaseClass(3)          BaseClass(3)
    {}                        {}
```

cino-+

+N Indent a continuation line (a line that spills onto the next) inside a function N additional characters. (default 'shiftwidth').

Outside of a function, when the previous line ended in a backslash, the 2 * N is used.

```
  cino=                       cino=+10
    a = b + 9 *                 a = b + 9 *
        c;                              c;
```

cino-c

cN Indent comment lines after the comment opener, when there is no other text with which to align, N characters from the comment opener. (default 3). See also format-comments .

```
  cino=                       cino=c5
    /*                          /*
       text.                       text.
     */                          */
```

cino-C

CN When N is non-zero, indent comment lines by the amount specified with the c flag above even if there is other text behind the comment opener. (default 0).

```
  cino=c0                     cino=c0,C1
    /********                   /********
      text.                      text.
    ********/                    ********/
```

(Example uses ":set comments& comments-=s1:/* comments^=s0:/*")

cino-/

/N Indent comment lines N characters extra. (default 0).

```
  cino=                       cino=/4
    a = b;                      a = b;
    /* comment */                   /* comment */
    c = d;                      c = d;
```

cino-(

(N When in unclosed parentheses, indent N characters from the line with the unclosed parentheses. Add a 'shiftwidth' for every extra unclosed parentheses. When N is 0 or the unclosed parentheses is the first non-white character in its line, line up with the next non-white character after the unclosed parentheses. (default 'shiftwidth' * 2).

```
  cino=                       cino=(0
    if (c1 && (c2 ||            if (c1 && (c2 ||
                c3))                        c3))
        foo;                        foo;
    if (c1 &&                   if (c1 &&
          (c2 || c3))                 (c2 || c3))
       {                           {
```

cino-u

uN Same as (N, but for one nesting level deeper. (default 'shiftwidth').

```
cino=                       cino=u2
  if (c123456789              if (c123456789
          && (c22345                  && (c22345
              || c3))                   || c3))
```

cino-U

UN When N is non-zero, do not ignore the indenting specified by (or u in case that the unclosed parentheses is the first non-white character in its line. (default 0).

```
cino= or cino=(s            cino=(s,U1
  c = c1 &&                   c = c1 &&
      (                           (
       c2 ||                        c2 ||
       c3                           c3
      ) && c4;                    ) && c4;
```

cino-w

wN When in unclosed parentheses and N is non-zero and either using "(0" or "u0", respectively, or using "U0" and the unclosed parentheses is the first non-white character in its line, line up with the character immediately after the unclosed parentheses rather than the first non-white character. (default 0).

```
cino=(0                     cino=(0,w1
  if (   c1                   if (   c1
         && (   c2                && (   c2
                || c3))                  || c3))
      foo;                        foo;
```

cino-W

WN When in unclosed parentheses and N is non-zero and either using "(0" or "u0", respectively and the unclosed parentheses is the last non-white character in its line and it is not the closing parentheses, indent the following line N characters relative to the outer context (i.e. start of the line or the next unclosed parentheses). (default: 0).

```
cino=(0                      cino=(0,W4
  a_long_line(                a_long_line(
              argument,           argument,
              argument);          argument);
  a_short_line(argument,      a_short_line(argument,
               argument);                 argument);
```

cino-k

kN When in unclosed parentheses which follow "if", "for" or "while" and N is non-zero, overrides the behaviour defined by "(N": causes the indent to be N characters relative to the outer context (i.e. the line where "if", "for" or "while" is). Has no effect on deeper levels of nesting. Affects flags like "wN" only for the "if", "for" and "while" conditions. If 0, defaults to behaviour defined by the "(N" flag. (default: 0).

```
cino=(0                    cino=(0,ks
  if (condition1             if (condition1
      && condition2)                 && condition2)
      action();                  action();
  function(argument1         function(argument1
           && argument2);             && argument2);
```

cino-m

mN When N is non-zero, line up a line starting with a closing parentheses with the first character of the line with the matching opening parentheses. (default 0).

```
cino=(s                    cino=(s,m1
  c = c1 && (                c = c1 && (
      c2 ||                      c2 ||
      c3                         c3
      ) && c4;                 ) && c4;
  if (                       if (
      c1 && c2                   c1 && c2
     )                          )
      foo;                       foo;
```

cino-M

MN When N is non-zero, line up a line starting with a closing parentheses with the first character of the previous line. (default 0).

```
cino=                      cino=M1
  if (cond1 &&               if (cond1 &&
          cond2                      cond2
     )                          )
```

java-cinoptions java-indenting cino-j

jN Indent Java anonymous classes correctly. Also works well for Javascript. The value 'N' is currently unused but must be non-zero (e.g. 'j1'). 'j1' will indent for example the following code snippet correctly:

```
object.add(new ChangeListener() {
    public void stateChanged(ChangeEvent e) {
        do_something();
    }
});
```

javascript-cinoptions javascript-indenting cino-J

JN Indent JavaScript object declarations correctly by not confusing them with labels. The value 'N' is currently unused but must be non-zero (e.g. 'J1'). If you enable this you probably also want to set cino-j .

```
var bar = {
    foo: {
        that: this,
```

```
                some: ok,
            },
            "bar":{
                a : 2,
                b: "123abc",
                x: 4,
                "y": 5
            }
        }
```

cino-)

)N Vim searches for unclosed parentheses at most N lines away.
    This limits the time needed to search for parentheses. (default
    20 lines).

cino-star

*N Vim searches for unclosed comments at most N lines away. This
    limits the time needed to search for the start of a comment.
    If your /* */ comments stop indenting after N lines this is the
    value you will want to change.
    (default 70 lines).

cino-#

#N When N is non-zero recognize shell/Perl comments starting with
    '#', do not recognize preprocessor lines; allow right-shifting
    lines that start with "#".
    When N is zero (default): don't recognize '#' comments, do
    recognize preprocessor lines; right-shifting lines that start
    with "#" does not work.

The defaults, spelled out in full, are:

```
    cinoptions=>s,e0,n0,f0,{0,}0,^0,L-1,:s,=s,l0,b0,gs,hs,N0,E0,ps,ts,is,+s,
                c3,C0,/0,(2s,us,U0,w0,W0,k0,m0,j0,J0,)20,*70,#0
```

Vim puts a line in column 1 if:
- It starts with '#' (preprocessor directives), if 'cinkeys' contains '#0'.
- It starts with a label (a keyword followed by ':', other than "case" and
  "default") and 'cinoptions' does not contain an 'L' entry with a positive
  value.
- Any combination of indentations causes the line to have less than 0
  indentation.

==
2. Indenting by expression indent-expression

The basics for using flexible indenting are explained in section 30.3 of the
user manual.

If you want to write your own indent file, it must set the 'indentexpr'
option. Setting the 'indentkeys' option is often useful. See the
$VIMRUNTIME/indent directory for examples.

REMARKS ABOUT SPECIFIC INDENT FILES

CLOJURE ft-clojure-indent clojure-indent

Clojure indentation differs somewhat from traditional Lisps, due in part to the use of square and curly brackets, and otherwise by community convention. These conventions are not universally followed, so the Clojure indent script offers a few configurable options, listed below.

If the current vim does not include searchpairpos(), the indent script falls back to normal 'lisp' indenting, and the following options are ignored.

g:clojure_maxlines

Set maximum scan distance of searchpairpos(). Larger values trade performance for correctness when dealing with very long forms. A value of 0 will scan without limits.

```
" Default
let g:clojure_maxlines = 100
```

g:clojure_fuzzy_indent
g:clojure_fuzzy_indent_patterns
g:clojure_fuzzy_indent_blacklist

The 'lispwords' option is a list of comma-separated words that mark special forms whose subforms must be indented with two spaces.

For example:

```
(defn bad []
      "Incorrect indentation")

(defn good []
  "Correct indentation")
```

If you would like to specify 'lispwords' with a pattern instead, you can use the fuzzy indent feature:

```
" Default
let g:clojure_fuzzy_indent = 1
let g:clojure_fuzzy_indent_patterns = ['^with', '^def', '^let']
let g:clojure_fuzzy_indent_blacklist =
        \ ['-fn$', '\v^with-%(meta|out-str|loading-context)$']

" Legacy comma-delimited string version; the list format above is
" recommended. Note that patterns are implicitly anchored with ^ and $
let g:clojure_fuzzy_indent_patterns = 'with.*,def.*,let.*'
```

g:clojure_fuzzy_indent_patterns and g:clojure_fuzzy_indent_blacklist are Lists of patterns that will be matched against the unquoted, unqualified symbol at the head of a list. This means that a pattern like "^foo" will match all these candidates: "foobar", "my.ns/foobar", and "#'foobar".

Each candidate word is tested for special treatment in this order:

1. Return true if word is literally in 'lispwords'
2. Return false if word matches a pattern in
   g:clojure_fuzzy_indent_blacklist
3. Return true if word matches a pattern in
   g:clojure_fuzzy_indent_patterns
4. Return false and indent normally otherwise

g:clojure_special_indent_words

Some forms in Clojure are indented so that every subform is indented only two spaces, regardless of 'lispwords'. If you have a custom construct that should be indented in this idiosyncratic fashion, you can add your symbols to the default list below.

```
" Default
let g:clojure_special_indent_words =
   \ 'deftype,defrecord,reify,proxy,extend-type,extend-protocol,letfn'
```

g:clojure_align_multiline_strings

Align subsequent lines in multiline strings to the column after the opening quote, instead of the same column.

For example:

```
(def default
  "Lorem ipsum dolor sit amet, consectetur adipisicing elit, sed do
  eiusmod tempor incididunt ut labore et dolore magna aliqua. Ut
  enim ad minim veniam, quis nostrud exercitation ullamco laboris
  nisi ut aliquip ex ea commodo consequat.")

(def aligned
  "Lorem ipsum dolor sit amet, consectetur adipisicing elit, sed do
   eiusmod tempor incididunt ut labore et dolore magna aliqua. Ut
   enim ad minim veniam, quis nostrud exercitation ullamco laboris
   nisi ut aliquip ex ea commodo consequat.")
```

This option is off by default.

```
" Default
let g:clojure_align_multiline_strings = 0
```

g:clojure_align_subforms

By default, parenthesized compound forms that look like function calls and whose head subform is on its own line have subsequent subforms indented by two spaces relative to the opening paren:

```
(foo
  bar
  baz)
```

Setting this option changes this behavior so that all subforms are aligned to the same column, emulating the default behavior of clojure-mode.el:

```
(foo
 bar
 baz)
```

This option is off by default.

```
" Default
let g:clojure_align_subforms = 0
```

FORTRAN ft-fortran-indent

Block if, select case, where, and forall constructs are indented. So are type, interface, associate, block, and enum constructs. The indenting of subroutines, functions, modules, and program blocks is optional. Comments, labelled statements and continuation lines are indented if the Fortran is in free source form, whereas they are not indented if the Fortran is in fixed source form because of the left margin requirements. Hence manual indent corrections will be necessary for labelled statements and continuation lines when fixed source form is being used. For further discussion of the method used for the detection of source format see ft-fortran-syntax .

Do loops

All do loops are left unindented by default. Do loops can be unstructured in Fortran with (possibly multiple) loops ending on a labelled executable statement of almost arbitrary type. Correct indentation requires compiler-quality parsing. Old code with do loops ending on labelled statements of arbitrary type can be indented with elaborate programs such as Tidy (http://www.unb.ca/chem/ajit/f_tidy.htm). Structured do/continue loops are also left unindented because continue statements are also used for purposes other than ending a do loop. Programs such as Tidy can convert structured do/continue loops to the do/enddo form. Do loops of the do/enddo variety can be indented. If you use only structured loops of the do/enddo form, you should declare this by setting the fortran_do_enddo variable in your .vimrc as follows

```
let fortran_do_enddo=1
```

in which case do loops will be indented. If all your loops are of do/enddo type only in, say, .f90 files, then you should set a buffer flag with an autocommand such as

```
au! BufRead,BufNewFile *.f90 let b:fortran_do_enddo=1
```

to get do loops indented in .f90 files and left alone in Fortran files with other extensions such as .for.

Program units

The indenting of program units (subroutines, functions, modules, and program blocks) is enabled by default but can be suppressed if a lighter, screen-width

preserving indent style is desired. To suppress the indenting of program units for all fortran files set the global fortran_indent_less variable in your .vimrc as follows

```
let fortran_indent_less=1
```

A finer level of suppression can be achieved by setting the corresponding buffer-local variable as follows

```
let b:fortran_indent_less=1
```

HTML ft-html-indent html-indent html-indenting

This is about variables you can set in your vimrc to customize HTML indenting.

You can set the indent for the first line after <script> and <style> "blocktags" (default "zero"):

```
:let g:html_indent_script1 = "inc"
:let g:html_indent_style1 = "inc"
```

VALUE	MEANING
"zero"	zero indent
"auto"	auto indent (same indent as the blocktag)
"inc"	auto indent + one indent step

Many tags increase the indent for what follows per default (see "Add Indent Tags" in the script). You can add further tags with:

```
:let g:html_indent_inctags = "html,body,head,tbody"
```

You can also remove such tags with:

```
:let g:html_indent_autotags = "th,td,tr,tfoot,thead"
```

Default value is empty for both variables. Note: the initial "inctags" are only defined once per Vim session.

User variables are only read when the script is sourced. To enable your changes during a session, without reloading the HTML file, you can manually do:

```
:call HtmlIndent_CheckUserSettings()
```

Detail:
  Calculation of indent inside "blocktags" with "alien" content:

BLOCKTAG	INDENT EXPR	WHEN APPLICABLE
<script>	: {customizable}	if first line of block
	: cindent(v:lnum)	if attributes empty or contain "java"
	: -1	else (vbscript, tcl, ...)
<style>	: {customizable}	if first line of block
	: GetCSSIndent()	else
<!-- -->	: -1	

PHP   ft-php-indent   php-indent   php-indenting

NOTE: PHP files will be indented correctly only if PHP syntax is active.

If you are editing a file in Unix 'fileformat' and '\r' characters are present
before new lines, indentation won't proceed correctly ; you have to remove
those useless characters first with a command like:

```
:%s /\r$//g
```

Or, you can simply :let the variable PHP_removeCRwhenUnix to 1 and the
script will silently remove them when Vim loads a PHP file (at each BufRead).

OPTIONS:

PHP indenting can be altered in several ways by modifying the values of some
global variables:

                                              php-comment   PHP_autoformatcomment
To not enable auto-formatting of comments by default (if you want to use your
own 'formatoptions'):

```
:let g:PHP_autoformatcomment = 0
```

Else, 't' will be removed from the 'formatoptions' string and "qrowcb" will be
added, see fo-table for more information.

                                                          PHP_outdentSLComments
To add extra indentation to single-line comments:

```
:let g:PHP_outdentSLComments = N
```

With N being the number of 'shiftwidth' to add.

Only single-line comments will be affected such as:

```
# Comment
// Comment
/* Comment */
```

                                                        PHP_default_indenting
To add extra indentation to every PHP lines with N being the number of
'shiftwidth' to add:

```
:let g:PHP_default_indenting = N
```

For example, with N = 1, this will give:

```
<?php
    if (!isset($History_lst_sel))
        if (!isset($History_lst_sel))
            if (!isset($History_lst_sel)) {
                $History_lst_sel=0;
            } else
```

```
                    $foo="bar";

        $command_hist = TRUE;
    ?>
```
(Notice the extra indentation between the PHP container markers and the code)

PHP_outdentphpescape

To indent PHP escape tags as the surrounding non-PHP code (only affects the PHP escape tags):
```
:let g:PHP_outdentphpescape = 0
```

PHP_removeCRwhenUnix

To automatically remove '\r' characters when the 'fileformat' is set to Unix:
```
    :let g:PHP_removeCRwhenUnix = 1
```

PHP_BracesAtCodeLevel

To indent braces at the same level than the code they contain:
```
    :let g:PHP_BracesAtCodeLevel = 1
```

This will give the following result:
```
    if ($foo)
        {
        foo();
        }
```
Instead of:
```
    if ($foo)
    {
        foo();
    }
```

NOTE: Indenting will be a bit slower if this option is used because some optimizations won't be available.

PHP_vintage_case_default_indent

To indent 'case:' and 'default:' statements in switch() blocks:
```
    :let g:PHP_vintage_case_default_indent = 1
```

In PHP braces are not required inside 'case/default' blocks therefore 'case:' and 'default:' are indented at the same level than the 'switch()' to avoid meaningless indentation. You can use the above option to return to the traditional way.

PHP_noArrowMatching

By default the indent script will indent multi-line chained calls by matching the position of the '->':

```
    $user_name_very_long->name()
                        ->age()
                        ->info();
```

You can revert to the classic way of indenting by setting this option to 1:
```
:let g:PHP_noArrowMatching = 1
```

You will obtain the following result:

```
$user_name_very_long->name()
    ->age()
    ->info();
```

PYTHON ft-python-indent

The amount of indent can be set for the following situations. The examples given are the defaults. Note that the variables are set to an expression, so that you can change the value of 'shiftwidth' later.

```
Indent after an open paren:
        let g:pyindent_open_paren = '&sw * 2'
Indent after a nested paren:
        let g:pyindent_nested_paren = '&sw'
Indent for a continuation line:
        let g:pyindent_continue = '&sw * 2'
```

R ft-r-indent

Function arguments are aligned if they span for multiple lines. If you prefer do not have the arguments of functions aligned, put in your vimrc :

```
let r_indent_align_args = 0
```

All lines beginning with a comment character, #, get the same indentation level of the normal R code. Users of Emacs/ESS may be used to have lines beginning with a single # indented in the 40th column, ## indented as R code, and ### not indented. If you prefer that lines beginning with comment characters are aligned as they are by Emacs/ESS, put in your vimrc :

```
let r_indent_ess_comments = 1
```

If you prefer that lines beginning with a single # are aligned at a column different from the 40th one, you should set a new value to the variable r_indent_comment_column, as in the example below:

```
let r_indent_comment_column = 30
```

Any code after a line that ends with "<-" is indented. Emacs/ESS does not indent the code if it is a top level function. If you prefer that the Vim-R-plugin behaves like Emacs/ESS in this regard, put in your vimrc :

```
let r_indent_ess_compatible = 1
```

Below is an example of indentation with and without this option enabled:

```
### r_indent_ess_compatible = 1
foo <-
    function(x)
{
    paste(x)
}
```

```
### r_indent_ess_compatible = 0
foo <-
    function(x)
    {
        paste(x)
    }
```

SHELL ft-sh-indent

The amount of indent applied under various circumstances in a shell file can be configured by setting the following keys in the Dictionary b:sh_indent_defaults to a specific amount or to a Funcref that references a function that will return the amount desired:

b:sh_indent_options['default'] Default amount of indent.

b:sh_indent_options['continuation-line']
Amount of indent to add to a continued line.

b:sh_indent_options['case-labels']
Amount of indent to add for case labels.
(not actually implemented)

b:sh_indent_options['case-statements']
Amount of indent to add for case statements.

b:sh_indent_options['case-breaks']
Amount of indent to add (or more likely
remove) for case breaks.

VERILOG ft-verilog-indent

General block statements such as if, for, case, always, initial, function, specify and begin, etc., are indented. The module block statements (first level blocks) are not indented by default. you can turn on the indent with setting a variable in the .vimrc as follows:

```
  let b:verilog_indent_modules = 1
```

then the module blocks will be indented. To stop this, remove the variable:

```
  :unlet b:verilog_indent_modules
```

To set the variable only for Verilog file. The following statements can be used:

```
  au BufReadPost * if exists("b:current_syntax")
  au BufReadPost *   if b:current_syntax == "verilog"
  au BufReadPost *     let b:verilog_indent_modules = 1
  au BufReadPost *   endif
  au BufReadPost * endif
```

Furthermore, setting the variable b:verilog_indent_width to change the
indenting width (default is 'shiftwidth'):

```
  let b:verilog_indent_width = 4
  let b:verilog_indent_width = &sw * 2
```

In addition, you can turn the verbose mode for debug issue:

```
  let b:verilog_indent_verbose = 1
```

Make sure to do ":set cmdheight=2" first to allow the display of the message.

VHDL ft-vhdl-indent

Alignment of generic/port mapping statements are performed by default. This
causes the following alignment example:

```
  ENTITY sync IS
  PORT (
         clk        : IN  STD_LOGIC;
         reset_n    : IN  STD_LOGIC;
         data_input : IN  STD_LOGIC;
         data_out   : OUT STD_LOGIC
       );
  END ENTITY sync;
```

To turn this off, add

```
  let g:vhdl_indent_genportmap = 0
```

to the .vimrc file, which causes the previous alignment example to change:

```
  ENTITY sync IS
  PORT (
    clk        : IN  STD_LOGIC;
    reset_n    : IN  STD_LOGIC;
    data_input : IN  STD_LOGIC;
    data_out   : OUT STD_LOGIC
  );
  END ENTITY sync;
```

Alignment of right-hand side assignment "<=" statements are performed by
default. This causes the following alignment example:

```
  sig_out <= (bus_a(1) AND
              (sig_b OR sig_c)) OR
              (bus_a(0) AND sig_d);
```

To turn this off, add

```
  let g:vhdl_indent_rhsassign = 0
```

to the .vimrc file, which causes the previous alignment example to change:

```
  sig_out <= (bus_a(1) AND
    (sig_b OR sig_c)) OR
    (bus_a(0) AND sig_d);
```

Full-line comments (lines that begin with "--") are indented to be aligned with the very previous line's comment, PROVIDED that a whitespace follows after "--".

For example:

```
  sig_a <= sig_b; -- start of a comment
                  -- continuation of the comment
                  -- more of the same comment
```

While in Insert mode, after typing "-- " (note the space " "), hitting CTRL-F will align the current "-- " with the previous line's "--".

If the very previous line does not contain "--", THEN the full-line comment will be aligned with the start of the next non-blank line that is NOT a full-line comment.

Indenting the following code:

```
  sig_c <= sig_d; -- comment 0
         -- comment 1
               -- comment 2
    --debug_code:
    --PROCESS(debug_in)
         --BEGIN
            --  FOR i IN 15 DOWNTO 0 LOOP
             --    debug_out(8*i+7 DOWNTO 8*i) <= debug_in(15-i);
            --  END LOOP;
     --END PROCESS debug_code;

      -- comment 3
  sig_e <= sig_f; -- comment 4
           -- comment 5
```

results in:

```
  sig_c <= sig_d; -- comment 0
                  -- comment 1
                  -- comment 2
  --debug_code:
  --PROCESS(debug_in)
  --BEGIN
  --  FOR i IN 15 DOWNTO 0 LOOP
  --    debug_out(8*i+7 DOWNTO 8*i) <= debug_in(15-i);
  --  END LOOP;
```

```
  --END PROCESS debug_code;

  -- comment 3
  sig_e <= sig_f; -- comment 4
                  -- comment 5
```

Notice that "--debug_code:" does not align with "-- comment 2"
because there is no whitespace that follows after "--" in "--debug_code:".

Given the dynamic nature of indenting comments, indenting should be done TWICE.
On the first pass, code will be indented. On the second pass, full-line
comments will be indented according to the correctly indented code.

VIM ft-vim-indent

For indenting Vim scripts there is one variable that specifies the amount of
indent for a continuation line, a line that starts with a backslash:

```
        :let g:vim_indent_cont = &sw * 3
```

Three times shiftwidth is the default value.

vim:tw=78:ts=8:noet:ft=help:norl:

undo.txt For Vim version 8.1. Last change: 2014 May 24

VIM REFERENCE MANUAL by Bram Moolenaar

Undo and redo undo-redo

The basics are explained in section 02.5 of the user manual.

==========

1. Undo and redo commands undo-commands

<Undo> or undo <Undo> u

u Undo [count] changes. {Vi: only one level}

:u :un :undo

:u[ndo] Undo one change. {Vi: only one level}

E830

:u[ndo] {N} Jump to after change number {N}. See undo-branches for the meaning of {N}. {not in Vi}

CTRL-R

CTRL-R Redo [count] changes which were undone. {Vi: redraw screen}

:red :redo redo

:red[o] Redo one change which was undone. {Vi: no redo}

U

U Undo all latest changes on one line, the line where the latest change was made. U itself also counts as a change, and thus U undoes a previous U. {Vi: while not moved off of the last modified line}

The last changes are remembered. You can use the undo and redo commands above to revert the text to how it was before each change. You can also apply the changes again, getting back the text before the undo.

The "U" command is treated by undo/redo just like any other command. Thus a "u" command undoes a "U" command and a 'CTRL-R' command redoes it again. When mixing "U", "u" and 'CTRL-R' you will notice that the "U" command will restore the situation of a line to before the previous "U" command. This may be confusing. Try it out to get used to it.
The "U" command will always mark the buffer as changed. When "U" changes the buffer back to how it was without changes, it is still considered changed. Use "u" to undo changes until the buffer becomes unchanged.

==
2. Two ways of undo   undo-two-ways

How undo and redo commands work depends on the 'u' flag in 'cpoptions'.
There is the Vim way ('u' excluded) and the Vi-compatible way ('u' included).
In the Vim way, "uu" undoes two changes. In the Vi-compatible way, "uu" does
nothing (undoes an undo).

'u' excluded, the Vim way:
You can go back in time with the undo command. You can then go forward again
with the redo command. If you make a new change after the undo command,
the redo will not be possible anymore.

'u' included, the Vi-compatible way:
The undo command undoes the previous change, and also the previous undo command.
The redo command repeats the previous undo command. It does NOT repeat a
change command, use "." for that.

Examples   Vim way   Vi-compatible way
"uu"   two times undo   no-op
"u CTRL-R"   no-op   two times undo

Rationale: Nvi uses the "." command instead of CTRL-R. Unfortunately, this
            is not Vi compatible. For example "dwdwu." in Vi deletes two
            words, in Nvi it does nothing.

==
3. Undo blocks   undo-blocks

One undo command normally undoes a typed command, no matter how many changes
that command makes. This sequence of undo-able changes forms an undo block.
Thus if the typed key(s) call a function, all the commands in the function are
undone together.

If you want to write a function or script that doesn't create a new undoable
change but joins in with the previous change use this command:

                                                :undoj   :undojoin   E790
:undoj[oin]   Join further changes with the previous undo block.
                        Warning: Use with care, it may prevent the user from
                        properly undoing changes. Don't use this after undo
                        or redo.
                        {not in Vi}

This is most useful when you need to prompt the user halfway through a change.
For example in a function that calls getchar() . Do make sure that there was
a related change before this that you must join with.

This doesn't work by itself, because the next key press will start a new
change again. But you can do something like this:

        :undojoin | delete

After this an "u" command will undo the delete command and the previous change.

To do the opposite, break a change into two undo blocks, in Insert mode use CTRL-G u. This is useful if you want an insert command to be undoable in parts. E.g., for each sentence. i_CTRL-G_u
Setting the value of 'undolevels' also breaks undo. Even when the new value is equal to the old value.

==
4. Undo branches undo-branches undo-tree

Above we only discussed one line of undo/redo. But it is also possible to branch off. This happens when you undo a few changes and then make a new change. The undone changes become a branch. You can go to that branch with the following commands.

This is explained in the user manual: usr_32.txt .

:undol :undolist
:undol[ist] List the leafs in the tree of changes. Example:

number	changes	when	saved
88	88	2010/01/04 14:25:53	
108	107	08/07 12:47:51	
136	46	13:33:01	7
166	164	3 seconds ago	

The "number" column is the change number. This number continuously increases and can be used to identify a specific undo-able change, see :undo .
The "changes" column is the number of changes to this leaf from the root of the tree.
The "when" column is the date and time when this change was made. The four possible formats are:

N seconds ago	
HH:MM:SS	hour, minute, seconds
MM/DD HH:MM:SS	idem, with month and day
YYYY/MM/DD HH:MM:SS	idem, with year

The "saved" column specifies, if this change was written to disk and which file write it was. This can be used with the :later and :earlier commands.
For more details use the undotree() function.

g-
g- Go to older text state. With a count repeat that many times. {not in Vi}

:ea :earlier
:earlier {count} Go to older text state {count} times.
:earlier {N}s Go to older text state about {N} seconds before.
:earlier {N}m Go to older text state about {N} minutes before.
:earlier {N}h Go to older text state about {N} hours before.
:earlier {N}d Go to older text state about {N} days before.

:earlier {N}f Go to older text state {N} file writes before.

When changes were made since the last write
":earlier 1f" will revert the text to the state when
it was written. Otherwise it will go to the write
before that.
When at the state of the first file write, or when
the file was not written, ":earlier 1f" will go to
before the first change.

g+

g+ Go to newer text state. With a count repeat that many
times. {not in Vi}

:lat :later

:later {count} Go to newer text state {count} times.
:later {N}s Go to newer text state about {N} seconds later.
:later {N}m Go to newer text state about {N} minutes later.
:later {N}h Go to newer text state about {N} hours later.
:later {N}d Go to newer text state about {N} days later.

:later {N}f Go to newer text state {N} file writes later.
When at the state of the last file write, ":later 1f"
will go to the newest text state.

Note that text states will become unreachable when undo information is cleared for 'undolevels'.

Don't be surprised when moving through time shows multiple changes to take place at a time. This happens when moving through the undo tree and then making a new change.

EXAMPLE

Start with this text:
        one two three

Delete the first word by pressing "x" three times:
        ne two three
        e two three
         two three

Now undo that by pressing "u" three times:
        e two three
        ne two three
        one two three

Delete the second word by pressing "x" three times:
        one wo three
        one o three
        one three

Now undo that by using "g-" three times:
        one o three
        one wo three
         two three

You are now back in the first undo branch, after deleting "one". Repeating
"g-" will now bring you back to the original text:
        e two three
        ne two three
        one two three

Jump to the last change with ":later 1h":
        one three

And back to the start again with ":earlier 1h":
        one two three

Note that using "u" and CTRL-R will not get you to all possible text states
while repeating "g-" and "g+" does.

==
5. Undo persistence   undo-persistence   persistent-undo

When unloading a buffer Vim normally destroys the tree of undos created for
that buffer. By setting the 'undofile' option, Vim will automatically save
your undo history when you write a file and restore undo history when you edit
the file again.

The 'undofile' option is checked after writing a file, before the BufWritePost
autocommands. If you want to control what files to write undo information
for, you can use a BufWritePre autocommand:
        au BufWritePre /tmp/* setlocal noundofile

Vim saves undo trees in a separate undo file, one for each edited file, using
a simple scheme that maps filesystem paths directly to undo files. Vim will
detect if an undo file is no longer synchronized with the file it was written
for (with a hash of the file contents) and ignore it when the file was changed
after the undo file was written, to prevent corruption. An undo file is also
ignored if its owner differs from the owner of the edited file, except when
the owner of the undo file is the current user. Set 'verbose' to get a
message about that when opening a file.

Undo files are normally saved in the same directory as the file. This can be
changed with the 'undodir' option.

When the file is encrypted, the text in the undo file is also crypted. The
same key and method is used. encryption

You can also save and restore undo histories by using ":wundo" and ":rundo"
respectively:
                                                        :wundo   :rundo
:wundo[!] {file}
                Write undo history to {file}.
                When {file} exists and it does not look like an undo file
                (the magic number at the start of the file is wrong), then
                this fails, unless the ! was added.
                If it exists and does look like an undo file it is

overwritten. If there is no undo-history, nothing will be written.
Implementation detail: Overwriting happens by first deleting the existing file and then creating a new file with the same name. So it is not possible to overwrite an existing undofile in a write-protected directory.
{not in Vi}

:rundo {file}	Read undo history from {file}.
{not in Vi}

You can use these in autocommands to explicitly specify the name of the history file. E.g.:

```
au BufReadPost * call ReadUndo()
au BufWritePost * call WriteUndo()
func ReadUndo()
  if filereadable(expand('%:h'). '/UNDO/' . expand('%:t'))
    rundo %:h/UNDO/%:t
  endif
endfunc
func WriteUndo()
  let dirname = expand('%:h') . '/UNDO'
  if !isdirectory(dirname)
    call mkdir(dirname)
  endif
  wundo %:h/UNDO/%:t
endfunc
```

You should keep 'undofile' off, otherwise you end up with two undo files for every write.

You can use the undofile() function to find out the file name that Vim would use.

Note that while reading/writing files and 'undofile' is set most errors will be silent, unless 'verbose' is set. With :wundo and :rundo you will get more error messages, e.g., when the file cannot be read or written.

NOTE: undo files are never deleted by Vim. You need to delete them yourself.

Reading an existing undo file may fail for several reasons:
E822	It cannot be opened, because the file permissions don't allow it.
E823	The magic number at the start of the file doesn't match. This usually means it is not an undo file.
E824	The version number of the undo file indicates that it's written by a newer version of Vim. You need that newer version to open it. Don't write the buffer if you want to keep the undo info in the file.
"File contents changed, cannot use undo info"
	The file text differs from when the undo file was written. This means the undo file cannot be used, it would corrupt the text. This also happens when 'encoding' differs from when the undo file was written.
E825	The undo file does not contain valid contents and cannot be used.
E826	The undo file is encrypted but decryption failed.

E827	The undo file is encrypted but this version of Vim does not support
	encryption. Open the file with another Vim.
E832	The undo file is encrypted but 'key' is not set, the text file is not
	encrypted. This would happen if the text file was written by Vim
	encrypted at first, and later overwritten by not encrypted text.
	You probably want to delete this undo file.
"Not reading undo file, owner differs"
	The undo file is owned by someone else than the owner of the text
	file. For safety the undo file is not used.

Writing an undo file may fail for these reasons:
E828	The file to be written cannot be created. Perhaps you do not have
	write permissions in the directory.
"Cannot write undo file in any directory in 'undodir'"
	None of the directories in 'undodir' can be used.
"Will not overwrite with undo file, cannot read"
	A file exists with the name of the undo file to be written, but it
	cannot be read. You may want to delete this file or rename it.
"Will not overwrite, this is not an undo file"
	A file exists with the name of the undo file to be written, but it
	does not start with the right magic number. You may want to delete
	this file or rename it.
"Skipping undo file write, nothing to undo"
	There is no undo information to be written, nothing has been changed
	or 'undolevels' is negative.
E829	An error occurred while writing the undo file. You may want to try
	again.

==
6. Remarks about undo						undo-remarks

The number of changes that are remembered is set with the 'undolevels' option.
If it is zero, the Vi-compatible way is always used. If it is negative no
undo is possible. Use this if you are running out of memory.

							clear-undo
When you set 'undolevels' to -1 the undo information is not immediately
cleared, this happens at the next change. To force clearing the undo
information you can use these commands:
	:let old_undolevels = &undolevels
	:set undolevels=-1
	:exe "normal a \<BS>\<Esc>"
	:let &undolevels = old_undolevels
	:unlet old_undolevels

Marks for the buffer ('a to 'z) are also saved and restored, together with the
text. {Vi does this a little bit different}

When all changes have been undone, the buffer is not considered to be changed.
It is then possible to exit Vim with ":q" instead of ":q!" {not in Vi}. Note
that this is relative to the last write of the file. Typing "u" after ":w"
actually changes the buffer, compared to what was written, so the buffer is
considered changed then.

When manual folding is being used, the folds are not saved and restored.
Only changes completely within a fold will keep the fold as it was, because
the first and last line of the fold don't change.

The numbered registers can also be used for undoing deletes. Each time you
delete text, it is put into register "1. The contents of register "1 are
shifted to "2, etc. The contents of register "9 are lost. You can now get
back the most recent deleted text with the put command: '"1P'. (also, if the
deleted text was the result of the last delete or copy operation, 'P' or 'p'
also works as this puts the contents of the unnamed register). You can get
back the text of three deletes ago with '"3P'.

redo-register

If you want to get back more than one part of deleted text, you can use a
special feature of the repeat command ".". It will increase the number of the
register used. So if you first do ""1P", the following "." will result in a
'"2P'. Repeating this will result in all numbered registers being inserted.

Example: If you deleted text with 'dd....' it can be restored with
'"1P....'.

If you don't know in which register the deleted text is, you can use the
:display command. An alternative is to try the first register with '"1P', and
if it is not what you want do 'u.'. This will remove the contents of the
first put, and repeat the put command for the second register. Repeat the
'u.' until you got what you want.

vim:tw=78:ts=8:ft=help:norl:

repeat.txt For Vim version 8.1. Last change: 2018 Mar 04

VIM REFERENCE MANUAL by Bram Moolenaar

Repeating commands, Vim scripts and debugging repeating

Chapter 26 of the user manual introduces repeating usr_26.txt .

==========

1. Single repeats single-repeat

.

. Repeat last change, with count replaced with [count].
Also repeat a yank command, when the 'y' flag is
included in 'cpoptions'. Does not repeat a
command-line command.

Simple changes can be repeated with the "." command. Without a count, the count of the last change is used. If you enter a count, it will replace the last one. v:count and v:count1 will be set.

If the last change included a specification of a numbered register, the register number will be incremented. See redo-register for an example how to use this.

Note that when repeating a command that used a Visual selection, the same SIZE of area is used, see visual-repeat .

@:

@: Repeat last command-line [count] times.
{not available when compiled without the
 +cmdline_hist feature}

==========

2. Multiple repeats multi-repeat

:g :global E148

:[range]g[lobal]/{pattern}/[cmd]
Execute the Ex command [cmd] (default ":p") on the
lines within [range] where {pattern} matches.

:[range]g[lobal]!/{pattern}/[cmd]

Execute the Ex command [cmd] (default ":p") on the
lines within [range] where {pattern} does NOT match.

:v :vglobal

:[range]v[global]/{pattern}/[cmd]
Same as :g!.

Instead of the '/' which surrounds the {pattern}, you can use any other single byte character, but not an alphabetic character, '\', '"' or '|'. This is useful if you want to include a '/' in the search pattern or replacement string.

For the definition of a pattern, see pattern .

NOTE [cmd] may contain a range; see collapse and edit-paragraph-join for examples.

The global commands work by first scanning through the [range] lines and marking each line where a match occurs (for a multi-line pattern, only the start of the match matters).
In a second scan the [cmd] is executed for each marked line, as if the cursor was in that line. For ":v" and ":g!" the command is executed for each not marked line. If a line is deleted its mark disappears.
The default for [range] is the whole buffer (1,$). Use "CTRL-C" to interrupt the command. If an error message is given for a line, the command for that line is aborted and the global command continues with the next marked or unmarked line.

E147

When the command is used recursively, it only works on one line. Giving a range is then not allowed. This is useful to find all lines that match a pattern and do not match another pattern:

```
:g/found/v/notfound/{cmd}
```

This first finds all lines containing "found", but only executes {cmd} when there is no match for "notfound".

To execute a non-Ex command, you can use the `:normal` command:

```
:g/pat/normal {commands}
```

Make sure that {commands} ends with a whole command, otherwise Vim will wait for you to type the rest of the command for each match. The screen will not have been updated, so you don't know what you are doing. See :normal .

The undo/redo command will undo/redo the whole global command at once.
The previous context mark will only be set once (with "''" you go back to where the cursor was before the global command).

The global command sets both the last used search pattern and the last used substitute pattern (this is vi compatible). This makes it easy to globally replace a string:

```
:g/pat/s//PAT/g
```

This replaces all occurrences of "pat" with "PAT". The same can be done with:

```
:%s/pat/PAT/g
```

Which is two characters shorter!

When using "global" in Ex mode, a special case is using ":visual" as a

command. This will move to a matching line, go to Normal mode to let you execute commands there until you use Q to return to Ex mode. This will be repeated for each matching line. While doing this you cannot use ":global". To abort this type CTRL-C twice.

==
3. Complex repeats   complex-repeat

                                                                q   recording
q{0-9a-zA-Z"}   Record typed characters into register {0-9a-zA-Z"} (uppercase to append). The 'q' command is disabled while executing a register, and it doesn't work inside a mapping and :normal .

                        Note: If the register being used for recording is also used for y and p the result is most likely not what is expected, because the put will paste the recorded macro and the yank will overwrite the recorded macro. {Vi: no recording}

q   Stops recording. (Implementation note: The 'q' that stops recording is not stored in the register, unless it was the result of a mapping) {Vi: no recording}

                                                                @
@{0-9a-z".=*+}   Execute the contents of register {0-9a-z".=*+} [count] times. Note that register '%' (name of the current file) and '#' (name of the alternate file) cannot be used.
                        The register is executed like a mapping, that means that the difference between 'wildchar' and 'wildcharm' applies.
                        For "@=" you are prompted to enter an expression. The result of the expression is then executed.
                        See also @: . {Vi: only named registers}

                                                                @@   E748
@@   Repeat the previous @{0-9a-z":*} [count] times.

:[addr]*{0-9a-z".=+}   :@   :star
:[addr]@{0-9a-z".=*+}   Execute the contents of register {0-9a-z".=*+} as an Ex command. First set cursor at line [addr] (default is current line). When the last line in the register does not have a <CR> it will be added automatically when the 'e' flag is present in 'cpoptions'.
                        Note that the ":*" command is only recognized when the '*' flag is present in 'cpoptions'. This is NOT the default when 'nocompatible' is used.
                        For ":@=" the last used expression is used. The result of evaluating the expression is executed as an Ex command.
                        Mappings are not recognized in these commands.
                        {Vi: only in some versions} Future: Will execute the register for each line in the address range.

:[addr]@: :@:
Repeat last command-line. First set cursor at line [addr] (default is current line). {not in Vi}

:[addr]@ :@@
:[addr]@@
Repeat the previous :@{0-9a-z"}. First set cursor at line [addr] (default is current line). {Vi: only in some versions}

==========

4. Using Vim scripts using-scripts

For writing a Vim script, see chapter 41 of the user manual usr_41.txt .

:so :source load-vim-script
:so[urce] {file}
Read Ex commands from {file}. These are commands that start with a ":".
Triggers the SourcePre autocommand.

:so[urce]! {file}
Read Vim commands from {file}. These are commands that are executed from Normal mode, like you type them.
When used after :global , :argdo , :windo , :bufdo , in a loop or when another command follows the display won't be updated while executing the commands.
{not in Vi}

:ru :runtime
:ru[ntime][!] [where] {file} ..
Read Ex commands from {file} in each directory given by 'runtimepath' and/or 'packpath'. There is no error for non-existing files.

Example:
```
:runtime syntax/c.vim
```

There can be multiple {file} arguments, separated by spaces. Each {file} is searched for in the first directory from 'runtimepath', then in the second directory, etc. Use a backslash to include a space inside {file} (although it's better not to use spaces in file names, it causes trouble).

When [!] is included, all found files are sourced. When it is not included only the first found file is sourced.

When [where] is omitted only 'runtimepath' is used. Other values:
```
START   search under "start" in 'packpath'
OPT     search under "opt" in 'packpath'
PACK    search under "start" and "opt" in
```

'packpath'
ALL first use 'runtimepath', then search under "start" and "opt" in 'packpath'

When {file} contains wildcards it is expanded to all matching files. Example:
```
:runtime! plugin/*.vim
```
This is what Vim uses to load the plugin files when starting up. This similar command:
```
:runtime plugin/*.vim
```
would source the first file only.

When 'verbose' is one or higher, there is a message when no file could be found.
When 'verbose' is two or higher, there is a message about each searched file.
{not in Vi}

:pa :packadd E919

:pa[ckadd][!] {name} Search for an optional plugin directory in 'packpath' and source any plugin files found. The directory must match:
```
pack/*/opt/{name}
```
The directory is added to 'runtimepath' if it wasn't there yet.
If the directory pack/*/opt/{name}/after exists it is added at the end of 'runtimepath'.

If loading packages from "pack/*/start" was skipped, then this directory is searched first:
```
pack/*/start/{name}
```

Note that {name} is the directory name, not the name of the .vim file. All the files matching the pattern
```
pack/*/opt/{name}/plugin/**/*.vim
```
will be sourced. This allows for using subdirectories below "plugin", just like with plugins in 'runtimepath'.

If the filetype detection was not enabled yet (this is usually done with a "syntax enable" or "filetype on" command in your .vimrc file), this will also look for "{name}/ftdetect/*.vim" files.

When the optional ! is added no plugin files or ftdetect scripts are loaded, only the matching directories are added to 'runtimepath'. This is useful in your .vimrc. The plugins will then be loaded during initialization, see load-plugins .

Also see pack-add .
{only available when compiled with |+eval|}

:packl :packloadall

:packl[oadall][!]	Load all packages in the "start" directory under each entry in 'packpath'.

First all the directories found are added to 'runtimepath', then the plugins found in the directories are sourced. This allows for a plugin to depend on something of another plugin, e.g. an "autoload" directory. See packload-two-steps for how this can be useful.

This is normally done automatically during startup, after loading your .vimrc file. With this command it can be done earlier.

Packages will be loaded only once. After this command it won't happen again. When the optional ! is added this command will load packages even when done before.

An error only causes sourcing the script where it happens to be aborted, further plugins will be loaded. See packages .
{only available when compiled with |+eval|}

:scripte[ncoding] [encoding]	:scripte :scriptencoding E167

Specify the character encoding used in the script. The following lines will be converted from [encoding] to the value of the 'encoding' option, if they are different. Examples:

```
scriptencoding iso-8859-5
scriptencoding cp932
```

When [encoding] is empty, no conversion is done. This can be used to restrict conversion to a sequence of lines:

```
scriptencoding euc-jp
... lines to be converted ...
scriptencoding
... not converted ...
```

When conversion isn't supported by the system, there is no error message and no conversion is done. When a line can't be converted there is no error and the original line is kept.

Don't use "ucs-2" or "ucs-4", scripts cannot be in these encodings (they would contain NUL bytes). When a sourced script starts with a BOM (Byte Order Mark) in utf-8 format Vim will recognize it, no need to use ":scriptencoding utf-8" then.

If you set the 'encoding' option in your .vimrc , `:scriptencoding` must be placed after that. E.g.:

```
set encoding=utf-8
scriptencoding utf-8
```

When compiled without the +multi_byte feature this command is ignored.
{not in Vi}

:scr :scriptnames
:scr[iptnames] List all sourced script names, in the order they were first sourced. The number is used for the script ID <SID> .
{not in Vi} {not available when compiled without the +eval feature}

:fini :finish E168
:fini[sh] Stop sourcing a script. Can only be used in a Vim script file. This is a quick way to skip the rest of the file. If it is used after a :try but before the matching :finally (if present), the commands following the ":finally" up to the matching :endtry are executed first. This process applies to all nested ":try"s in the script. The outermost ":endtry" then stops sourcing the script. {not in Vi}

All commands and command sequences can be repeated by putting them in a named register and then executing it. There are two ways to get the commands in the register:
- Use the record command "q". You type the commands once, and while they are being executed they are stored in a register. Easy, because you can see what you are doing. If you make a mistake, "p"ut the register into the file, edit the command sequence, and then delete it into the register again. You can continue recording by appending to the register (use an uppercase letter).
- Delete or yank the command sequence into the register.

Often used command sequences can be put under a function key with the ':map' command.

An alternative is to put the commands in a file, and execute them with the ':source!' command. Useful for long command sequences. Can be combined with the ':map' command to put complicated commands under a function key.

The ':source' command reads Ex commands from a file line by line. You will have to type any needed keyboard input. The ':source!' command reads from a script file character by character, interpreting each character as if you typed it.

Example: When you give the ":!ls" command you get the hit-enter prompt. If you ':source' a file with the line "!ls" in it, you will have to type the <Enter> yourself. But if you ':source!' a file with the line ":!ls" in it, the next characters from that file are read until a <CR> is found. You will not have to type <CR> yourself, unless ":!ls" was the last line in the file.

It is possible to put ':source[!]' commands in the script file, so you can make a top-down hierarchy of script files. The ':source' command can be nested as deep as the number of files that can be opened at one time (about

15). The ':source!' command can be nested up to 15 levels deep.

You can use the "<sfile>" string (literally, this is not a special key) inside of the sourced file, in places where a file name is expected. It will be replaced by the file name of the sourced file. For example, if you have a "other.vimrc" file in the same directory as your ".vimrc" file, you can source it from your ".vimrc" file with this command:

```
:source <sfile>:h/other.vimrc
```

In script files terminal-dependent key codes are represented by terminal-independent two character codes. This means that they can be used in the same way on different kinds of terminals. The first character of a key code is 0x80 or 128, shown on the screen as "~@". The second one can be found in the list key-notation . Any of these codes can also be entered with CTRL-V followed by the three digit decimal code. This does NOT work for the <t_xx> termcap codes, these can only be used in mappings.

:source_crnl W15

MS-DOS, Win32 and OS/2: Files that are read with ":source" normally have <CR><NL> <EOL>s. These always work. If you are using a file with <NL> <EOL>s (for example, a file made on Unix), this will be recognized if 'fileformats' is not empty and the first line does not end in a <CR>. This fails if the first line has something like ":map <F1> :help^M", where "^M" is a <CR>. If the first line ends in a <CR>, but following ones don't, you will get an error message, because the <CR> from the first lines will be lost.

Mac Classic: Files that are read with ":source" normally have <CR> <EOL>s. These always work. If you are using a file with <NL> <EOL>s (for example, a file made on Unix), this will be recognized if 'fileformats' is not empty and the first line does not end in a <CR>. Be careful not to use a file with <NL> linebreaks which has a <CR> in first line.

On other systems, Vim expects ":source"ed files to end in a <NL>. These always work. If you are using a file with <CR><NL> <EOL>s (for example, a file made on MS-DOS), all lines will have a trailing <CR>. This may cause problems for some commands (e.g., mappings). There is no automatic <EOL> detection, because it's common to start with a line that defines a mapping that ends in a <CR>, which will confuse the automaton.

line-continuation

Long lines in a ":source"d Ex command script file can be split by inserting a line continuation symbol "\" (backslash) at the start of the next line. There can be white space before the backslash, which is ignored.

Example: the lines

```
:set comments=sr:/*,mb:*,el:*/,
                \://,
                \b:#,
                \:%,
                \n:>,
                \fb:-
```

are interpreted as if they were given in one line:

```
:set comments=sr:/*,mb:*,el:*/,://,b:#,:%,n:>,fb:-
```

All leading whitespace characters in the line before a backslash are ignored.
Note however that trailing whitespace in the line before it cannot be
inserted freely; it depends on the position where a command is split up
whether additional whitespace is allowed or not.

When a space is required it's best to put it right after the backslash. A
space at the end of a line is hard to see and may be accidentally deleted.

```
        :syn match Comment
                \ "very long regexp"
                \ keepend
```

There is a problem with the ":append" and ":insert" commands:

```
   :1append
   \asdf
   .
```

The backslash is seen as a line-continuation symbol, thus this results in the
command:

```
   :1appendasdf
   .
```

To avoid this, add the 'C' flag to the 'cpoptions' option:

```
   :set cpo+=C
   :1append
   \asdf
   .
   :set cpo-=C
```

Note that when the commands are inside a function, you need to add the 'C'
flag when defining the function, it is not relevant when executing it.

```
   :set cpo+=C
   :function Foo()
   :1append
   \asdf
   .
   :endfunction
   :set cpo-=C
```

Rationale:
        Most programs work with a trailing backslash to indicate line
        continuation. Using this in Vim would cause incompatibility with Vi.
        For example for this Vi mapping:

```
                :map xx  asdf\
```

       Therefore the unusual leading backslash is used.

==
5. Using Vim packages   packages

A Vim package is a directory that contains one or more plugins. The
advantages over normal plugins:
- A package can be downloaded as an archive and unpacked in its own directory.
  Thus the files are not mixed with files of other plugins. That makes it
  easy to update and remove.
- A package can be a git, mercurial, etc. repository. That makes it really
  easy to update.
- A package can contain multiple plugins that depend on each other.

- A package can contain plugins that are automatically loaded on startup and
  ones that are only loaded when needed with `:packadd`.

Using a package and loading automatically

Let's assume your Vim files are in the "~/.vim" directory and you want to add a
package from a zip archive "/tmp/foopack.zip":

```
% mkdir -p ~/.vim/pack/foo
% cd ~/.vim/pack/foo
% unzip /tmp/foopack.zip
```

The directory name "foo" is arbitrary, you can pick anything you like.

You would now have these files under ~/.vim:

```
pack/foo/README.txt
pack/foo/start/foobar/plugin/foo.vim
pack/foo/start/foobar/syntax/some.vim
pack/foo/opt/foodebug/plugin/debugger.vim
```

When Vim starts up, after processing your .vimrc, it scans all directories in
'packpath' for plugins under the "pack/*/start" directory. First all those
directories are added to 'runtimepath'. Then all the plugins are loaded.
See packload-two-steps for how these two steps can be useful.

In the example Vim will find "pack/foo/start/foobar/plugin/foo.vim" and adds
"~/.vim/pack/foo/start/foobar" to 'runtimepath'.

If the "foobar" plugin kicks in and sets the 'filetype' to "some", Vim will
find the syntax/some.vim file, because its directory is in 'runtimepath'.

Vim will also load ftdetect files, if there are any.

Note that the files under "pack/foo/opt" are not loaded automatically, only the
ones under "pack/foo/start". See pack-add below for how the "opt" directory
is used.

Loading packages automatically will not happen if loading plugins is disabled,
see load-plugins .

To load packages earlier, so that 'runtimepath' gets updated:

```
:packloadall
```

This also works when loading plugins is disabled. The automatic loading will
only happen once.

If the package has an "after" directory, that directory is added to the end of
'runtimepath', so that anything there will be loaded later.

Using a single plugin and loading it automatically

If you don't have a package but a single plugin, you need to create the extra
directory level:

```
% mkdir -p ~/.vim/pack/foo/start/foobar
```

```
        % cd ~/.vim/pack/foo/start/foobar
        % unzip /tmp/someplugin.zip

You would now have these files:
        pack/foo/start/foobar/plugin/foo.vim
        pack/foo/start/foobar/syntax/some.vim

From here it works like above.
```

Optional plugins

pack-add

```
To load an optional plugin from a pack use the `:packadd` command:
        :packadd foodebug
This searches for "pack/*/opt/foodebug" in 'packpath' and will find
~/.vim/pack/foo/opt/foodebug/plugin/debugger.vim and source it.

This could be done if some conditions are met.  For example, depending on
whether Vim supports a feature or a dependency is missing.

You can also load an optional plugin at startup, by putting this command in
your  .vimrc :
        :packadd! foodebug
The extra "!" is so that the plugin isn't loaded if Vim was started with
 --noplugin .

It is perfectly normal for a package to only have files in the "opt"
directory.  You then need to load each plugin when you want to use it.
```

Where to put what

```
Since color schemes, loaded with `:colorscheme`, are found below
"pack/*/start" and "pack/*/opt", you could put them anywhere.  We recommend
you put them below "pack/*/opt", for example
".vim/pack/mycolors/opt/dark/colors/very_dark.vim".

Filetype plugins should go under "pack/*/start", so that they are always
found.  Unless you have more than one plugin for a file type and want to
select which one to load with `:packadd`.  E.g. depending on the compiler
version:
        if foo_compiler_version > 34
          packadd foo_new
        else
          packadd foo_old
        endif

The "after" directory is most likely not useful in a package.  It's not
disallowed though.
```

6. Creating Vim packages

package-create

```
This assumes you write one or more plugins that you distribute as a package.
```

If you have two unrelated plugins you would use two packages, so that Vim
users can chose what they include or not. Or you can decide to use one
package with optional plugins, and tell the user to add the ones he wants with
`:packadd`.

Decide how you want to distribute the package. You can create an archive or
you could use a repository. An archive can be used by more users, but is a
bit harder to update to a new version. A repository can usually be kept
up-to-date easily, but it requires a program like "git" to be available.
You can do both, github can automatically create an archive for a release.

Your directory layout would be like this:
```
   start/foobar/plugin/foo.vim          " always loaded, defines commands
   start/foobar/plugin/bar.vim          " always loaded, defines commands
   start/foobar/autoload/foo.vim        " loaded when foo command used
   start/foobar/doc/foo.txt             " help for foo.vim
   start/foobar/doc/tags                " help tags
   opt/fooextra/plugin/extra.vim        " optional plugin, defines commands
   opt/fooextra/autoload/extra.vim      " loaded when extra command used
   opt/fooextra/doc/extra.txt           " help for extra.vim
   opt/fooextra/doc/tags                " help tags
```

This allows for the user to do:
```
        mkdir ~/.vim/pack/myfoobar
        cd ~/.vim/pack/myfoobar
        git clone https://github.com/you/foobar.git
```

Here "myfoobar" is a name that the user can choose, the only condition is that
it differs from other packages.

In your documentation you explain what the plugins do, and tell the user how
to load the optional plugin:
```
        :packadd! fooextra
```

You could add this packadd command in one of your plugins, to be executed when
the optional plugin is needed.

Run the `:helptags` command to generate the doc/tags file. Including this
generated file in the package means that the user can drop the package in his
pack directory and the help command works right away. Don't forget to re-run
the command after changing the plugin help:
```
        :helptags path/start/foobar/doc
        :helptags path/opt/fooextra/doc
```

Dependencies between plugins

packload-two-steps

Suppose you have two plugins that depend on the same functionality. You can
put the common functionality in an autoload directory, so that it will be
found automatically. Your package would have these files:

```
        pack/foo/start/one/plugin/one.vim
                call foolib#getit()
```

```
	pack/foo/start/two/plugin/two.vim
			call foolib#getit()
	pack/foo/start/lib/autoload/foolib.vim
			func foolib#getit()
```

This works, because loading packages will first add all found directories to
'runtimepath' before sourcing the plugins.

==
7. Debugging scripts   debug-scripts

Besides the obvious messages that you can add to your scripts to find out what
they are doing, Vim offers a debug mode. This allows you to step through a
sourced file or user function and set breakpoints.

NOTE: The debugging mode is far from perfect. Debugging will have side
effects on how Vim works. You cannot use it to debug everything. For
example, the display is messed up by the debugging messages.
{Vi does not have a debug mode}

An alternative to debug mode is setting the 'verbose' option. With a bigger
number it will give more verbose messages about what Vim is doing.

STARTING DEBUG MODE   debug-mode

To enter debugging mode use one of these methods:
1. Start Vim with the -D argument:
	vim -D file.txt
   Debugging will start as soon as the first vimrc file is sourced. This is
   useful to find out what is happening when Vim is starting up. A side
   effect is that Vim will switch the terminal mode before initialisations
   have finished, with unpredictable results.
   For a GUI-only version (Windows, Macintosh) the debugging will start as
   soon as the GUI window has been opened. To make this happen early, add a
   ":gui" command in the vimrc file.
                                                            :debug
2. Run a command with ":debug" prepended. Debugging will only be done while
   this command executes. Useful for debugging a specific script or user
   function. And for scripts and functions used by autocommands. Example:
	:debug edit test.txt.gz

3. Set a breakpoint in a sourced file or user function. You could do this in
   the command line:
	vim -c "breakadd file */explorer.vim" .
   This will run Vim and stop in the first line of the "explorer.vim" script.
   Breakpoints can also be set while in debugging mode.

In debugging mode every executed command is displayed before it is executed.
Comment lines, empty lines and lines that are not executed are skipped. When
a line contains two commands, separated by "|", each command will be displayed
separately.

DEBUG MODE

Once in debugging mode, the usual Ex commands can be used. For example, to
inspect the value of a variable:
	echo idx
When inside a user function, this will print the value of the local variable
"idx". Prepend "g:" to get the value of a global variable:
	echo g:idx
All commands are executed in the context of the current function or script.
You can also set options, for example setting or resetting 'verbose' will show
what happens, but you might want to set it just before executing the lines you
are interested in:
	:set verbose=20

Commands that require updating the screen should be avoided, because their
effect won't be noticed until after leaving debug mode. For example:
	:help
won't be very helpful.

There is a separate command-line history for debug mode.

The line number for a function line is relative to the start of the function.
If you have trouble figuring out where you are, edit the file that defines
the function in another Vim, search for the start of the function and do
"99j". Replace "99" with the line number.

Additionally, these commands can be used:

>cont
	cont		Continue execution until the next breakpoint is hit.
>quit
	quit		Abort execution. This is like using CTRL-C, some
			things might still be executed, doesn't abort
			everything. Still stops at the next breakpoint.
>next
	next		Execute the command and come back to debug mode when
			it's finished. This steps over user function calls
			and sourced files.
>step
	step		Execute the command and come back to debug mode for
			the next command. This steps into called user
			functions and sourced files.
>interrupt
	interrupt	This is like using CTRL-C, but unlike ">quit" comes
			back to debug mode for the next command that is
			executed. Useful for testing :finally and :catch
			on interrupt exceptions.
>finish
	finish		Finish the current script or user function and come
			back to debug mode for the command after the one that
			sourced or called it.
>bt
>backtrace
>where
	backtrace	Show the call stacktrace for current debugging session.

bt
where
                                                        >frame
frame N   Goes to N backtrace level. + and - signs make movement
                relative. E.g., ":frame +3" goes three frames up.
                                                        >up
up   Goes one level up from call stacktrace.
                                                        >down
down   Goes one level down from call stacktrace.

About the additional commands in debug mode:
- There is no command-line completion for them, you get the completion for the
  normal Ex commands only.
- You can shorten them, up to a single character, unless more than one command
  starts with the same letter. "f" stands for "finish", use "fr" for "frame".
- Hitting <CR> will repeat the previous one. When doing another command, this
  is reset (because it's not clear what you want to repeat).
- When you want to use the Ex command with the same name, prepend a colon:
  ":cont", ":next", ":finish" (or shorter).

The backtrace shows the hierarchy of function calls, e.g.:
        >bt
          3 function One[3]
          2 Two[3]
        ->1 Three[3]
          0 Four
        line 1: let four = 4

The "->" points to the current frame. Use "up", "down" and "frame N" to
select another frame.

In the current frame you can evaluate the local function variables. There is
no way to see the command at the current line yet.

DEFINING BREAKPOINTS
                                                        :breaka   :breakadd
:breaka[dd] func [lnum] {name}
                Set a breakpoint in a function. Example:
                        :breakadd func Explore
               Doesn't check for a valid function name, thus the breakpoint
                can be set before the function is defined.

:breaka[dd] file [lnum] {name}
                Set a breakpoint in a sourced file. Example:
                        :breakadd file 43 .vimrc

:breaka[dd] here
                Set a breakpoint in the current line of the current file.
                Like doing:
                        :breakadd file <cursor-line> <current-file>
               Note that this only works for commands that are executed when
                sourcing the file, not for a function defined in that file.

:breaka[dd] expr {expression}
		Sets a breakpoint, that will break whenever the {expression}
		evaluates to a different value. Example:
			:breakadd expr g:lnum

		Will break, whenever the global variable lnum changes.
		Note if you watch a script-variable this will break
		when switching scripts, since the script variable is only
		valid in the script where it has been defined and if that
		script is called from several other scripts, this will stop
		whenever that particular variable will become visible or
		unaccessible again.

The [lnum] is the line number of the breakpoint. Vim will stop at or after
this line. When omitted line 1 is used.

:debug-name
{name} is a pattern that is matched with the file or function name. The
pattern is like what is used for autocommands. There must be a full match (as
if the pattern starts with "^" and ends in "$"). A "*" matches any sequence
of characters. 'ignorecase' is not used, but "\c" can be used in the pattern
to ignore case /\c . Don't include the () for the function name!

The match for sourced scripts is done against the full file name. If no path
is specified the current directory is used. Examples:
	breakadd file explorer.vim
matches "explorer.vim" in the current directory.
	breakadd file *explorer.vim
matches ".../plugin/explorer.vim", ".../plugin/iexplorer.vim", etc.
	breakadd file */explorer.vim
matches ".../plugin/explorer.vim" and "explorer.vim" in any other directory.

The match for functions is done against the name as it's shown in the output
of ":function". For local functions this means that something like "<SNR>99_"
is prepended.

Note that functions are first loaded and later executed. When they are loaded
the "file" breakpoints are checked, when they are executed the "func"
breakpoints.

DELETING BREAKPOINTS
:breakd :breakdel E161
:breakd[el] {nr}
		Delete breakpoint {nr}. Use :breaklist to see the number of
		each breakpoint.

:breakd[el] *
		Delete all breakpoints.

:breakd[el] func [lnum] {name}
		Delete a breakpoint in a function.

:breakd[el] file [lnum] {name}

Delete a breakpoint in a sourced file.

:breakd[el] here
Delete a breakpoint at the current line of the current file.

When [lnum] is omitted, the first breakpoint in the function or file is deleted.
The {name} must be exactly the same as what was typed for the ":breakadd" command. "explorer", "*explorer.vim" and "*explorer*" are different.

LISTING BREAKPOINTS

:breakl[ist] :breakl :breaklist
List all breakpoints.

OBSCURE

:debugg[reedy] :debugg :debuggreedy
Read debug mode commands from the normal input stream, instead of getting them directly from the user. Only useful for test scripts. Example:

```
echo 'q^Mq' | vim -e -s -c debuggreedy -c 'breakadd file script.vim' -S s
```

:0debugg[reedy]
Undo ":debuggreedy": get debug mode commands directly from the user, don't use typeahead for debug commands.

==
8. Profiling profile profiling

Profiling means that Vim measures the time that is spent on executing functions and/or scripts. The +profile feature is required for this.
It is only included when Vim was compiled with "huge" features.
{Vi does not have profiling}

You can also use the reltime() function to measure time. This only requires the +reltime feature, which is present more often.

For profiling syntax highlighting see :syntime .

For example, to profile the one_script.vim script file:

```
:profile start /tmp/one_script_profile
:profile file one_script.vim
:source one_script.vim
:exit
```

:prof[ile] start {fname} :prof :profile E750
Start profiling, write the output in {fname} upon exit.
"~/" and environment variables in {fname} will be expanded.
If {fname} already exists it will be silently overwritten.

The variable v:profiling is set to one.

:prof[ile] pause
Don't profile until the following ":profile continue". Can be used when doing something that should not be counted (e.g., an external command). Does not nest.

:prof[ile] continue
Continue profiling after ":profile pause".

:prof[ile] func {pattern}
Profile function that matches the pattern {pattern}.
See :debug-name for how {pattern} is used.

:prof[ile][!] file {pattern}
Profile script file that matches the pattern {pattern}.
See :debug-name for how {pattern} is used.
This only profiles the script itself, not the functions defined in it.
When the [!] is added then all functions defined in the script will also be profiled.
Note that profiling only starts when the script is loaded after this command. A :profile command in the script itself won't work.

:profd[el] ... :profd :profdel
Stop profiling for the arguments specified. See :breakdel for the arguments.

You must always start with a ":profile start fname" command. The resulting file is written when Vim exits. Here is an example of the output, with line numbers prepended for the explanation:

```
 1 FUNCTION  Test2()
 2 Called 1 time
 3 Total time:   0.155251
 4  Self time:   0.002006
 5
 6 count  total (s)   self (s)
 7     9              0.000096   for i in range(8)
 8     8   0.153655   0.000410     call Test3()
 9     8              0.000070   endfor
10                               " Ask a question
11     1              0.001341   echo input("give me an answer: ")
```

The header (lines 1-4) gives the time for the whole function. The "Total" time is the time passed while the function was executing. The "Self" time is the "Total" time reduced by time spent in:
- other user defined functions
- sourced scripts
- executed autocommands
- external (shell) commands

Lines 7-11 show the time spent in each executed line. Lines that are not executed do not count. Thus a comment line is never counted.

The Count column shows how many times a line was executed. Note that the "for" command in line 7 is executed one more time as the following lines. That is because the line is also executed to detect the end of the loop.

The time Vim spends waiting for user input isn't counted at all. Thus how long you take to respond to the input() prompt is irrelevant.

Profiling should give a good indication of where time is spent, but keep in mind there are various things that may clobber the results:

- The accuracy of the time measured depends on the gettimeofday() system function. It may only be as accurate as 1/100 second, even though the times are displayed in micro seconds.

- Real elapsed time is measured, if other processes are busy they may cause delays at unpredictable moments. You may want to run the profiling several times and use the lowest results.

- If you have several commands in one line you only get one time. Split the line to see the time for the individual commands.

- The time of the lines added up is mostly less than the time of the whole function. There is some overhead in between.

- Functions that are deleted before Vim exits will not produce profiling information. You can check the v:profiling variable if needed:
```
:if !v:profiling
:   delfunc MyFunc
:endif
```

- Profiling may give weird results on multi-processor systems, when sleep mode kicks in or the processor frequency is reduced to save power.

- The "self" time is wrong when a function is used recursively.

vim:tw=78:ts=8:noet:ft=help:norl:

visual.txt For Vim version 8.1. Last change: 2017 Sep 02

VIM REFERENCE MANUAL by Bram Moolenaar

Visual mode Visual Visual-mode visual-mode

Visual mode is a flexible and easy way to select a piece of text for an operator. It is the only way to select a block of text.

This is introduced in section 04.4 of the user manual.

{Vi has no Visual mode, the name "visual" is used for Normal mode, to distinguish it from Ex mode}
{Since Vim 7.4.200 the |+visual| feature is always included}

==========

1. Using Visual mode visual-use

Using Visual mode consists of three parts:
1. Mark the start of the text with "v", "V" or CTRL-V.
   The character under the cursor will be used as the start.
2. Move to the end of the text.
   The text from the start of the Visual mode up to and including the character under the cursor is highlighted.
3. Type an operator command.
   The highlighted characters will be operated upon.

The 'highlight' option can be used to set the display mode to use for highlighting in Visual mode.
The 'virtualedit' option can be used to allow positioning the cursor to positions where there is no actual character.

The highlighted text normally includes the character under the cursor. However, when the 'selection' option is set to "exclusive" and the cursor is after the Visual area, the character under the cursor is not included.

With "v" the text before the start position and after the end position will not be highlighted. However, all uppercase and non-alpha operators, except "~" and "U", will work on whole lines anyway. See the list of operators below.

visual-block
With CTRL-V (blockwise Visual mode) the highlighted text will be a rectangle

between start position and the cursor. However, some operators work on whole lines anyway (see the list below). The change and substitute operators will delete the highlighted text and then start insertion at the top left position.

==
2. Starting and stopping Visual mode   visual-start

                                                v   characterwise-visual
[count]v   Start Visual mode per character.
                        With [count] select the same number of characters or
                        lines as used for the last Visual operation, but at
                        the current cursor position, multiplied by [count].
                        When the previous Visual operation was on a block both
                        the width and height of the block are multiplied by
                        [count].
                        When there was no previous Visual operation [count]
                        characters are selected. This is like moving the
                        cursor right N * [count] characters. One less when
                        'selection' is not "exclusive".

                                                V   linewise-visual
[count]V   Start Visual mode linewise.
                        With [count] select the same number of lines as used
                        for the last Visual operation, but at the current
                        cursor position, multiplied by [count]. When there
                        was no previous Visual operation [count] lines are
                        selected.

                                                CTRL-V   blockwise-visual
[count]CTRL-V   Start Visual mode blockwise. Note: Under Windows
                        CTRL-V could be mapped to paste text, it doesn't work
                        to start Visual mode then, see CTRL-V-alternative .
                        [count] is used as with `v` above.

If you use <Esc>, click the left mouse button or use any command that does a jump to another buffer while in Visual mode, the highlighting stops and no text is affected. Also when you hit "v" in characterwise Visual mode, "CTRL-V" in blockwise Visual mode or "V" in linewise Visual mode. If you hit CTRL-Z the highlighting stops and the editor is suspended or a new shell is started CTRL-Z .

              new mode after typing: v_v   v_CTRL-V   v_V
old mode   "v"   "CTRL-V"   "V"

Normal   Visual   blockwise Visual   linewise Visual
Visual   Normal   blockwise Visual   linewise Visual
blockwise Visual   Visual   Normal   linewise Visual
linewise Visual   Visual   blockwise Visual   Normal

                                                gv   v_gv   reselect-Visual
gv   Start Visual mode with the same area as the previous
                        area and the same mode.
                        In Visual mode the current and the previous Visual

area are exchanged.
After using "p" or "P" in Visual mode the text that
was put will be selected.

gn gn v_gn
Search forward for the last used search pattern, like
with `n`, and start Visual mode to select the match.
If the cursor is on the match, visually selects it.
If an operator is pending, operates on the match.
E.g., "dgn" deletes the text of the next match.
If Visual mode is active, extends the selection
until the end of the next match.

gN gN v_gN
Like gn but searches backward, like with `N`.

<LeftMouse> <LeftMouse>
Set the current cursor position. If Visual mode is
active it is stopped. Only when 'mouse' option is
contains 'n' or 'a'. If the position is within 'so'
lines from the last line on the screen the text is
scrolled up. If the position is within 'so' lines from
the first line on the screen the text is scrolled
down.

<RightMouse> <RightMouse>
Start Visual mode if it is not active. The text from
the cursor position to the position of the click is
highlighted. If Visual mode was already active move
the start or end of the highlighted text, which ever
is closest, to the position of the click. Only when
'mouse' option contains 'n' or 'a'.

Note: when 'mousemodel' is set to "popup",
<S-LeftMouse> has to be used instead of <RightMouse>.

<LeftRelease> <LeftRelease>
This works like a <LeftMouse>, if it is not at
the same position as <LeftMouse>. In an older version
of xterm you won't see the selected area until the
button is released, unless there is access to the
display where the xterm is running (via the DISPLAY
environment variable or the -display argument). Only
when 'mouse' option contains 'n' or 'a'.

If Visual mode is not active and the "v", "V" or CTRL-V is preceded with a
count, the size of the previously highlighted area is used for a start. You
can then move the end of the highlighted area and give an operator. The type
of the old area is used (character, line or blockwise).
- Linewise Visual mode: The number of lines is multiplied with the count.
- Blockwise Visual mode: The number of lines and columns is multiplied with
  the count.
- Normal Visual mode within one line: The number of characters is multiplied
  with the count.

- Normal Visual mode with several lines: The number of lines is multiplied
  with the count, in the last line the same number of characters is used as
  in the last line in the previously highlighted area.
The start of the text is the Cursor position. If the "$" command was used as one of the last commands to extend the highlighted text, the area will be extended to the rightmost column of the longest line.

If you want to highlight exactly the same area as the last time, you can use "gv" gv v_gv .

v_<Esc>
<Esc> In Visual mode: Stop Visual mode.

v_CTRL-C
CTRL-C In Visual mode: Stop Visual mode. When insert mode is pending (the mode message shows "-- (insert) VISUAL --"), it is also stopped.

==
3. Changing the Visual area visual-change

v_o
o Go to Other end of highlighted text: The current cursor position becomes the start of the highlighted text and the cursor is moved to the other end of the highlighted text. The highlighted area remains the same.

v_O
O Go to Other end of highlighted text. This is like "o", but in Visual block mode the cursor moves to the other corner in the same line. When the corner is at a character that occupies more than one position on the screen (e.g., a <Tab>), the highlighted text may change.

v_$
When the "$" command is used with blockwise Visual mode, the right end of the highlighted text will be determined by the longest highlighted line. This stops when a motion command is used that does not move straight up or down.

For moving the end of the block many commands can be used, but you cannot use Ex commands, commands that make changes or abandon the file. Commands (starting with) ".", "&", CTRL-^, "Z", CTRL-], CTRL-T, CTRL-R, CTRL-I and CTRL-O cause a beep and Visual mode continues.

When switching to another window on the same buffer, the cursor position in that window is adjusted, so that the same Visual area is still selected. This is especially useful to view the start of the Visual area in one window, and the end in another. You can then use <RightMouse> (or <S-LeftMouse> when 'mousemodel' is "popup") to drag either end of the Visual area.

==
4. Operating on the Visual area visual-operators

```
The operators that can be used are:
        ~       switch case                                         v_~
        d       delete                                              v_d
        c       change (4)                                          v_c
        y       yank                                                v_y
        >       shift right (4)                                     v_>
        <       shift left (4)                                      v_<
        !       filter through external command (1)                 v_!
        =       filter through 'equalprg' option command (1)        v_=
        gq      format lines to 'textwidth' length (1)              v_gq

The objects that can be used are:
        aw      a word (with white space)                           v_aw
        iw      inner word                                          v_iw
        aW      a WORD (with white space)                           v_aW
        iW      inner WORD                                          v_iW
        as      a sentence (with white space)                       v_as
        is      inner sentence                                      v_is
        ap      a paragraph (with white space)                      v_ap
        ip      inner paragraph                                     v_ip
        ab      a () block (with parenthesis)                       v_ab
        ib      inner () block                                      v_ib
        aB      a {} block (with braces)                            v_aB
        iB      inner {} block                                      v_iB
        at      a <tag> </tag> block (with tags)                    v_at
        it      inner <tag> </tag> block                            v_it
        a<      a <> block (with <>)                                v_a<
        i<      inner <> block                                      v_i<
        a[      a [] block (with [])                                v_a[
        i[      inner [] block                                      v_i[
        a"      a double quoted string (with quotes)                v_aquote
        i"      inner double quoted string                          v_iquote
        a'      a single quoted string (with quotes)                v_a'
        i'      inner simple quoted string                          v_i'
        a`      a string in backticks (with backticks)              v_a`
        i`      inner string in backticks                           v_i`

Additionally the following commands can be used:
        :       start Ex command for highlighted lines (1)          v_:
        r       change (4)                                          v_r
        s       change                                              v_s
        C       change (2)(4)                                       v_C
        S       change (2)                                          v_S
        R       change (2)                                          v_R
        x       delete                                              v_x
        D       delete (3)                                          v_D
        X       delete (2)                                          v_X
        Y       yank (2)                                            v_Y
        p       put                                                 v_p
        J       join (1)                                            v_J
        U       make uppercase                                      v_U
        u       make lowercase                                      v_u
        ^]      find tag                                            v_CTRL-]
```

```
        I       block insert                                    v_b_I
        A       block append                                    v_b_A

(1): Always whole lines, see  :visual_example .
(2): Whole lines when not using CTRL-V.
(3): Whole lines when not using CTRL-V, delete until the end of the line when
     using CTRL-V.
(4): When using CTRL-V operates on the block only.

Note that the ":vmap" command can be used to specifically map keys in Visual
mode.  For example, if you would like the "/" command not to extend the Visual
area, but instead take the highlighted text and search for that:
        :vmap / y/<C-R>"<CR>
(In the <> notation  <> , when typing it you should type it literally; you
need to remove the 'B' and '<' flags from 'cpoptions'.)

If you want to give a register name using the """ command, do this just before
typing the operator character: "v{move-around}"xd".

If you want to give a count to the command, do this just before typing the
operator character: "v{move-around}3>" (move lines 3 indents to the right).

                                                        {move-around}
The {move-around} is any sequence of movement commands.  Note the difference
with {motion}, which is only ONE movement command.

Another way to operate on the Visual area is using the  /\%V  item in a
pattern.  For example, to replace all '(' in the Visual area with '#':

        :'<,'>s/\%V(/#/g

Note that the "'<,'>" will appear automatically when you press ":" in Visual
mode.

==============================================================================
5. Blockwise operators                                  blockwise-operators

{not available when compiled without the |+visualextra| feature}

Reminder: Use 'virtualedit' to be able to select blocks that start or end
after the end of a line or halfway a tab.

Visual-block Insert                                             v_b_I
With a blockwise selection, I{string}<ESC> will insert {string} at the start
of block on every line of the block, provided that the line extends into the
block.  Thus lines that are short will remain unmodified.  TABs are split to
retain visual columns.  Works only for adding text to a line, not for
deletions.  See  v_b_I_example .

Visual-block Append                                             v_b_A
With a blockwise selection, A{string}<ESC> will append {string} to the end of
block on every line of the block.  There is some differing behavior where the
block RHS is not straight, due to different line lengths:
```

1. Block was created with <C-v>$
    In this case the string is appended to the end of each line.
2. Block was created with <C-v>{move-around}
    In this case the string is appended to the end of the block on each line,
    and whitespace is inserted to pad to the end-of-block column.
See v_b_A_example .
Note: "I" and "A" behave differently for lines that don't extend into the
selected block. This was done intentionally, so that you can do it the way
you want.
Works only for adding text to a line, not for deletions.

Visual-block change   v_b_c
All selected text in the block will be replaced by the same text string. When
using "c" the selected text is deleted and Insert mode started. You can then
enter text (without a line break). When you hit <Esc>, the same string is
inserted in all previously selected lines.

Visual-block Change   v_b_C
Like using "c", but the selection is extended until the end of the line for
all lines.

                                                                       v_b_<
Visual-block Shift   v_b_>
The block is shifted by 'shiftwidth'. The RHS of the block is irrelevant. The
LHS of the block determines the point from which to apply a right shift, and
padding includes TABs optimally according to 'ts' and 'et'. The LHS of the
block determines the point upto which to shift left.
See v_b_>_example .
See v_b_<_example .

Visual-block Replace   v_b_r
Every screen char in the highlighted region is replaced with the same char, ie
TABs are split and the virtual whitespace is replaced, maintaining screen
layout.
See v_b_r_example .

==
6. Repeating   visual-repeat

When repeating a Visual mode operator, the operator will be applied to the
same amount of text as the last time:
- Linewise Visual mode: The same number of lines.
- Blockwise Visual mode: The same number of lines and columns.
- Normal Visual mode within one line: The same number of characters.
- Normal Visual mode with several lines: The same number of lines, in the
  last line the same number of characters as in the last line the last time.
The start of the text is the Cursor position. If the "$" command was used as
one of the last commands to extend the highlighted text, the repeating will
be applied up to the rightmost column of the longest line.

==
7. Examples   visual-examples

:visual_example
Currently the ":" command works on whole lines only. When you select part of a line, doing something like ":!date" will replace the whole line. If you want only part of the line to be replaced you will have to make a mapping for it. In a future release ":" may work on partial lines.

Here is an example, to replace the selected text with the output of "date":

```
:vmap _a <Esc>`>a<CR><Esc>`<i<CR><Esc>!!date<CR>kJJ
```

(In the <> notation <> , when typing it you should type it literally; you need to remove the 'B' and '<' flags from 'cpoptions')

What this does is:

```
<Esc>           stop Visual mode
`>              go to the end of the Visual area
a<CR><Esc>      break the line after the Visual area
`<              jump to the start of the Visual area
i<CR><Esc>      break the line before the Visual area
!!date<CR>      filter the Visual text through date
kJJ             Join the lines back together
```

visual-search
Here is an idea for a mapping that makes it possible to do a search for the selected text:

```
:vmap X y/<C-R>"<CR>
```

(In the <> notation <> , when typing it you should type it literally; you need to remove the 'B' and '<' flags from 'cpoptions')

Note that special characters (like '.' and '*') will cause problems.

Visual-block Examples blockwise-examples
With the following text, I will indicate the commands to produce the block and the results below. In all cases, the cursor begins on the 'a' in the first line of the test text.
The following modeline settings are assumed ":ts=8:sw=4:".

It will be helpful to

```
:set hls
/<TAB>
```

where <TAB> is a real TAB. This helps visualise the operations.

The test text is:

```
abcdefghijklmnopqrstuvwxyz
abc             defghijklmnopqrstuvwxyz
abcdef  ghi             jklmnopqrstuvwxyz
abcdefghijklmnopqrstuvwxyz
```

1. fo<C-v>3jISTRING<ESC> v_b_I_example

```
abcdefghijklmnSTRINGopqrstuvwxyz
abc           STRING  defghijklmnopqrstuvwxyz
```

```
abcdef  ghi   STRING    jklmnopqrstuvwxyz
abcdefghijklmnSTRINGopqrstuvwxyz

abcdefghijklmnXXXXXXuvwxyz

================================================================================
8. Select mode                                          Select   Select-mode

Select mode looks like Visual mode, but the commands accepted are quite
different.  This resembles the selection mode in Microsoft Windows.
When the 'showmode' option is set, "-- SELECT --" is shown in the last line.

Entering Select mode:
- Using the mouse to select an area, and 'selectmode' contains "mouse".
  'mouse' must also contain a flag for the current mode.
- Using a non-printable movement command, with the Shift key pressed, and
  'selectmode' contains "key".  For example: <S-Left> and <S-End>.  'keymodel'
  must also contain "startsel".
- Using "v", "V" or CTRL-V command, and 'selectmode' contains "cmd".
- Using "gh", "gH" or "g_CTRL-H" command in Normal mode.
- From Visual mode, press CTRL-G.                        v_CTRL-G

Commands in Select mode:
- Printable characters, <NL> and <CR> cause the selection to be deleted, and
  Vim enters Insert mode.  The typed character is inserted.
- Non-printable movement commands, with the Shift key pressed, extend the
  selection.  'keymodel' must include "startsel".
- Non-printable movement commands, with the Shift key NOT pressed, stop Select
```

mode. 'keymodel' must include "stopsel".
- ESC stops Select mode.
- CTRL-O switches to Visual mode for the duration of one command. v_CTRL-O
- CTRL-G switches to Visual mode.

Otherwise, typed characters are handled as in Visual mode.

When using an operator in Select mode, and the selection is linewise, the selected lines are operated upon, but like in characterwise selection. For example, when a whole line is deleted, it can later be pasted halfway a line.

Mappings and menus in Select mode. Select-mode-mapping

When mappings and menus are defined with the :vmap or :vmenu command they work both in Visual mode and in Select mode. When these are used in Select mode Vim automatically switches to Visual mode, so that the same behavior as in Visual mode is effective. If you don't want this use :xmap or :smap .

Users will expect printable characters to replace the selected area. Therefore avoid mapping printable characters in Select mode. Or use :sunmap after :map and :vmap to remove it for Select mode.

After the mapping or menu finishes, the selection is enabled again and Select mode entered, unless the selected area was deleted, another buffer became the current one or the window layout was changed.

When a character was typed that causes the selection to be deleted and Insert mode started, Insert mode mappings are applied to this character. This may cause some confusion, because it means Insert mode mappings apply to a character typed in Select mode. Language mappings apply as well.

gV gV v_gV
gV Avoid the automatic reselection of the Visual area after a Select mode mapping or menu has finished. Put this just before the end of the mapping or menu. At least it should be after any operations on the selection.

gh gh
gh Start Select mode, characterwise. This is like "v", but starts Select mode instead of Visual mode. Mnemonic: "get highlighted".

gH gH
gH Start Select mode, linewise. This is like "V", but starts Select mode instead of Visual mode. Mnemonic: "get Highlighted".

g CTRL-H g_CTRL-H
g CTRL-H Start Select mode, blockwise. This is like CTRL-V, but starts Select mode instead of Visual mode. Mnemonic: "get Highlighted".

vim:tw=78:ts=8:ft=help:norl:

VIM REFERENCE MANUAL by Bram Moolenaar

Various commands various

==========

1. Various commands various-cmds

CTRL-L

CTRL-L Clear and redraw the screen. The redraw may happen later, after processing typeahead.

:redr :redraw

:redr[aw][!] Redraw the screen right now. When ! is included it is cleared first.
Useful to update the screen halfway executing a script or function. Also when halfway a mapping and 'lazyredraw' is set.

:redraws :redrawstatus

:redraws[tatus][!] Redraw the status line of the current window. When ! is included all status lines are redrawn.
Useful to update the status line(s) when 'statusline' includes an item that doesn't cause automatic updating.

N<Del>

<Del> When entering a number: Remove the last digit.
Note: if you like to use <BS> for this, add this mapping to your .vimrc:
:map CTRL-V <BS> CTRL-V <Del>
See :fixdel if your <Del> key does not do what you want.

ga :as :ascii

:as[cii] or
ga Print the ascii value of the character under the cursor in decimal, hexadecimal and octal.
Mnemonic: Get Ascii value.

For example, when the cursor is on a 'R':
<R> 82, Hex 52, Octal 122
When the character is a non-standard ASCII character, but printable according to the 'isprint' option, the non-printable version is also given.

When the character is larger than 127, the <M-x> form is also printed. For example:
<~A> <M-^A> 129, Hex 81, Octal 201

<p> <|~> <M-~> 254, Hex fe, Octal 376
(where <p> is a special character)

The <Nul> character in a file is stored internally as
<NL>, but it will be shown as:
<^@> 0, Hex 00, Octal 000

If the character has composing characters these are
also shown. The value of 'maxcombine' doesn't matter.

If the character can be inserted as a digraph, also
output the two characters that can be used to create
the character:
    <ö> 246, Hex 00f6, Oct 366, Digr o:
This shows you can type CTRL-K o : to insert ö.

{not in Vi}

g8

g8 Print the hex values of the bytes used in the
character under the cursor, assuming it is in UTF-8
encoding. This also shows composing characters. The
value of 'maxcombine' doesn't matter.
Example of a character with two composing characters:
        e0 b8 81 + e0 b8 b9 + e0 b9 89
{not in Vi} {only when compiled with the +multi_byte
feature}

8g8

8g8 Find an illegal UTF-8 byte sequence at or after the
cursor. This works in two situations:
1. when 'encoding' is any 8-bit encoding
2. when 'encoding' is "utf-8" and 'fileencoding' is
   any 8-bit encoding
Thus it can be used when editing a file that was
supposed to be UTF-8 but was read as if it is an 8-bit
encoding because it contains illegal bytes.
Does not wrap around the end of the file.
Note that when the cursor is on an illegal byte or the
cursor is halfway a multi-byte character the command
won't move the cursor.
{not in Vi} {only when compiled with the +multi_byte
feature}

:p :pr :print E749

:[range]p[rint] [flags]
Print [range] lines (default current line).
Note: If you are looking for a way to print your text
on paper see :hardcopy . In the GUI you can use the
File.Print menu entry.
See ex-flags for [flags].
The :filter command can be used to only show lines
matching a pattern.

:[range]p[rint] {count} [flags]
Print {count} lines, starting with [range] (default
current line cmdline-ranges).
See ex-flags for [flags].

:P :Print
:[range]P[rint] [count] [flags]
Just as ":print". Was apparently added to Vi for
people that keep the shift key pressed too long...
Note: A user command can overrule this command.
See ex-flags for [flags].

:l :list
:[range]l[ist] [count] [flags]
Same as :print, but display unprintable characters
with '^' and put $ after the line. This can be
further changed with the 'listchars' option.
See ex-flags for [flags].

:nu :number
:[range]nu[mber] [count] [flags]
Same as :print, but precede each line with its line
number. (See also 'highlight' and 'numberwidth'
option).
See ex-flags for [flags].

:#
:[range]# [count] [flags]
synonym for :number.

:#!
:#!{anything} Ignored, so that you can start a Vim script with:

```
#!vim -S
echo "this is a Vim script"
quit
```

:z E144
:{range}z[+-^.=]{count} Display several lines of text surrounding the line
specified with {range}, or around the current line
if there is no {range}. If there is a {count}, that's
how many lines you'll see; if there is only one window
then twice the value of the 'scroll' option is used,
otherwise the current window height minus 3 is used.

If there is a {count} the 'window' option is set to
its value.

:z can be used either alone or followed by any of
several punctuation marks. These have the following
effect:

mark	first line	last line	new cursor line
+	current line	1 scr forward	1 scr forward

```
                        -       1 scr back    current line   current line
                        ^       2 scr back    1 scr back     1 scr back
                        .       1/2 scr back  1/2 scr fwd    1/2 scr fwd
                        =       1/2 scr back  1/2 scr fwd    current line

                        Specifying no mark at all is the same as "+".
                        If the mark is "=", a line of dashes is printed
                        around the current line.

:{range}z#[+-^.=]{count}                                            :z#
                        Like ":z", but number the lines.
                        {not in all versions of Vi, not with these arguments}

                                                                    :=
:= [flags]              Print the last line number.
                        See  ex-flags  for [flags].

:{range}= [flags]       Prints the last line number in {range}.  For example,
                        this prints the current line number:
                                :.=
                       See  ex-flags  for [flags].

:norm[al][!] {commands}                                     :norm   :normal
                        Execute Normal mode commands {commands}.  This makes
                        it possible to execute Normal mode commands typed on
                        the command-line.  {commands} are executed like they
                        are typed.  For undo all commands are undone together.
                        Execution stops when an error is encountered.

                        If the [!] is given, mappings will not be used.
                        Without it, when this command is called from a
                        non-remappable mapping ( :noremap ), the argument can
                        be mapped anyway.

                        {commands} should be a complete command.  If
                        {commands} does not finish a command, the last one
                        will be aborted as if <Esc> or <C-C> was typed.
                        This implies that an insert command must be completed
                        (to start Insert mode, see  :startinsert ).  A ":"
                        command must be completed as well.  And you can't use
                        "Q" or "gQ" to start Ex mode.

                        The display is not updated while ":normal" is busy.

                        {commands} cannot start with a space.  Put a count of
                        1 (one) before it, "1 " is one space.

                        The 'insertmode' option is ignored for {commands}.

                        This command cannot be followed by another command,
                        since any '|' is considered part of the command.

                        This command can be used recursively, but the depth is
                        limited by 'maxmapdepth'.
```

An alternative is to use :execute , which uses an expression as argument. This allows the use of printable characters to represent special characters.

Example:

```
:exe "normal \<c-w>\<c-w>"
```

{not in Vi, of course}

:{range}norm[al][!] {commands} :normal-range

Execute Normal mode commands {commands} for each line in the {range}. Before executing the {commands}, the cursor is positioned in the first column of the range, for each line. Otherwise it's the same as the ":normal" command without a range.
{not in Vi}

:sh :shell E371

:sh[ell] This command starts a shell. When the shell exits (after the "exit" command) you return to Vim. The name for the shell command comes from 'shell' option.
E360

Note: This doesn't work when Vim on the Amiga was started in QuickFix mode from a compiler, because the compiler will have set stdin to a non-interactive mode.

:!cmd :! E34

:!{cmd} Execute {cmd} with the shell. See also the 'shell' and 'shelltype' option.

Any '!' in {cmd} is replaced with the previous external command (see also 'cpoptions'). But not when there is a backslash before the '!', then that backslash is removed. Example: ":!ls" followed by ":!echo ! \! \\!" executes "echo ls ! \!".

A '|' in {cmd} is passed to the shell, you cannot use it to append a Vim command. See :bar .

If {cmd} contains "%" it is expanded to the current file name. Special characters are not escaped, use quotes to avoid their special meaning:

```
:!ls "%"
```

If the file name contains a "$" single quotes might work better (but a single quote causes trouble):

```
:!ls '%'
```

This should always work, but it's more typing:

```
:exe "!ls " . shellescape(expand("%"))
```

A newline character ends {cmd}, what follows is interpreted as a following ":" command. However, if there is a backslash before the newline it is removed and {cmd} continues. It doesn't matter how many

backslashes are before the newline, only one is
removed.

On Unix the command normally runs in a non-interactive
shell. If you want an interactive shell to be used
(to use aliases) set 'shellcmdflag' to "-ic".
For Win32 also see :!start .

After the command has been executed, the timestamp and
size of the current file is checked timestamp .

Vim redraws the screen after the command is finished,
because it may have printed any text. This requires a
hit-enter prompt, so that you can read any messages.
To avoid this use:
        :silent !{cmd}
The screen is not redrawn then, thus you have to use
CTRL-L or ":redraw!" if the command did display
something.
Also see shell-window .

                                                :!!
:!!   Repeat last ":!{cmd}".

                                                :ve   :version
:ve[rsion]   Print the version number of the editor. If the
compiler used understands "__DATE__" the compilation
date is mentioned. Otherwise a fixed release-date is
shown.
The following lines contain information about which
features were enabled when Vim was compiled. When
there is a preceding '+', the feature is included,
when there is a '-' it is excluded. To change this,
you have to edit feature.h and recompile Vim.
To check for this in an expression, see has() .
Here is an overview of the features.
The first column shows the smallest version in which
they are included:
   T   tiny (always)
   S   small
   N   normal
   B   big
   H   huge
   m   manually enabled or depends on other features
 (none) system dependent
Thus if a feature is marked with "N", it is included
in the normal, big and huge versions of Vim.

                                                +feature-list
    +acl   ACL support included
    +ARP   Amiga only: ARP support included
B   +arabic   Arabic language support
T   +autocmd   :autocmd , automatic commands
H   +autoservername   Automatically enable clientserver

```
m   +balloon_eval        balloon-eval  support in the GUI. Included when
                         compiling with supported GUI (Motif, GTK, GUI) and
                         either Netbeans/Sun Workshop integration or  +eval
                         feature.
H   +balloon_eval_term   balloon-eval  support in the terminal,
                         'balloonevalterm'
N   +browse              :browse  command
N   +builtin_terms       some terminals builtin  builtin-terms
B   ++builtin_terms      maximal terminals builtin  builtin-terms
N   +byte_offset         support for 'o' flag in 'statusline' option, "go"
                         and ":goto" commands.
m   +channel             inter process communication  channel
N   +cindent             'cindent' , C indenting
N   +clientserver        Unix and Win32: Remote invocation  clientserver
    +clipboard           clipboard  support
N   +cmdline_compl       command line completion  cmdline-completion
S   +cmdline_hist        command line history  cmdline-history
N   +cmdline_info        'showcmd'  and  'ruler'
N   +comments            'comments'  support
B   +conceal             "conceal" support, see  conceal   :syn-conceal  etc.
N   +cryptv              encryption support  encryption
B   +cscope              cscope  support
T   +cursorbind          'cursorbind'  support
m   +cursorshape         termcap-cursor-shape  support
m   +debug               Compiled for debugging.
N   +dialog_gui          Support for  :confirm  with GUI dialog.
N   +dialog_con          Support for  :confirm  with console dialog.
N   +dialog_con_gui      Support for  :confirm  with GUI and console dialog.
N   +diff                vimdiff  and 'diff'
N   +digraphs            digraphs   E196
    +directx             Win32 GUI only: DirectX and  'renderoptions'
    +dnd                 Support for DnD into the "~ register  quote_~ .
B   +emacs_tags          emacs-tags  files
N   +eval                expression evaluation  eval.txt
N   +ex_extra            always on now, used to be for Vim's extra Ex commands
N   +extra_search        'hlsearch'  and  'incsearch'  options.
B   +farsi               farsi  language
N   +file_in_path        gf ,  CTRL-W_f  and  <cfile>
N   +find_in_path        include file searches:  [I ,  :isearch ,
                         CTRL-W_CTRL-I ,  :checkpath , etc.
N   +folding             folding
    +footer              gui-footer
    +fork                Unix only:  fork  shell commands
    +float               Floating point support
N   +gettext             message translations  multi-lang
    +GUI_Athena          Unix only: Athena  GUI
    +GUI_neXtaw          Unix only: neXtaw  GUI
    +GUI_GTK             Unix only: GTK+  GUI
    +GUI_Motif           Unix only: Motif  GUI
    +GUI_Photon          QNX only:  Photon  GUI
m   +hangul_input        Hangul input support  hangul
    +iconv               Compiled with the  iconv()  function
    +iconv/dyn           Likewise  iconv-dynamic   /dyn
N   +insert_expand       insert_expand  Insert mode completion
```

```
m   +job                starting and stopping jobs  job
S   +jumplist            jumplist
B   +keymap              'keymap'
N   +lambda              lambda  and  closure
B   +langmap             'langmap'
N   +libcall             libcall()
N   +linebreak           'linebreak' ,  'breakat'  and  'showbreak'
N   +lispindent          'lisp'
T   +listcmds           Vim commands for the list of buffers  buffer-hidden
                        and argument list  :argdelete
N   +localmap           Support for mappings local to a buffer  :map-local
m   +lua                 Lua  interface
m   +lua/dyn             Lua  interface  /dyn
N   +menu                :menu
N   +mksession           :mksession
N   +modify_fname        filename-modifiers
N   +mouse              Mouse handling  mouse-using
N   +mouseshape          'mouseshape'
B   +mouse_dec          Unix only: Dec terminal mouse handling  dec-mouse
N   +mouse_gpm          Unix only: Linux console mouse handling  gpm-mouse
N   +mouse_jsbterm      JSB mouse handling  jsbterm-mouse
B   +mouse_netterm      Unix only: netterm mouse handling  netterm-mouse
N   +mouse_pterm        QNX only: pterm mouse handling  qnx-terminal
N   +mouse_sysmouse     Unix only: *BSD console mouse handling  sysmouse
B   +mouse_sgr          Unix only: sgr mouse handling  sgr-mouse
B   +mouse_urxvt        Unix only: urxvt mouse handling  urxvt-mouse
N   +mouse_xterm        Unix only: xterm mouse handling  xterm-mouse
N   +multi_byte         16 and 32 bit characters  multibyte
    +multi_byte_ime     Win32 input method for multibyte chars  multibyte-ime
N   +multi_lang         non-English language support  multi-lang
m   +mzscheme           Mzscheme interface  mzscheme
m   +mzscheme/dyn       Mzscheme interface  mzscheme-dynamic   /dyn
m   +netbeans_intg       netbeans
    +num64              64-bit Number support  Number
m   +ole                Win32 GUI only:  ole-interface
N   +packages           Loading  packages
N   +path_extra         Up/downwards search in 'path' and 'tags'
m   +perl               Perl interface  perl
m   +perl/dyn           Perl interface  perl-dynamic   /dyn
N   +persistent_undo    Persistent undo  undo-persistence
    +postscript          :hardcopy  writes a PostScript file
N   +printer             :hardcopy  command
H   +profile             :profile  command
m   +python             Python 2 interface  python
m   +python/dyn         Python 2 interface  python-dynamic   /dyn
m   +python3            Python 3 interface  python
m   +python3/dyn        Python 3 interface  python-dynamic   /dyn
N   +quickfix            :make  and  quickfix  commands
N   +reltime             reltime()  function, 'hlsearch'/'incsearch' timeout,
                        'redrawtime' option
B   +rightleft          Right to left typing  'rightleft'
m   +ruby               Ruby interface  ruby
m   +ruby/dyn           Ruby interface  ruby-dynamic   /dyn
T   +scrollbind          'scrollbind'
```

```
B   +signs              :sign
N   +smartindent        'smartindent'
N   +startuptime        --startuptime  argument
N   +statusline         Options 'statusline', 'rulerformat' and special
                        formats of 'titlestring' and 'iconstring'
m   +sun_workshop       workshop
N   +syntax             Syntax highlighting  syntax
    +system()           Unix only: opposite of  +fork
T   +tag_binary         binary searching in tags file  tag-binary-search
N   +tag_old_static     old method for static tags  tag-old-static
m   +tag_any_white      any white space allowed in tags file  tag-any-white
m   +tcl                Tcl interface  tcl
m   +tcl/dyn            Tcl interface  tcl-dynamic   /dyn
m   +terminal           Support for terminal window  terminal
    +terminfo           uses  terminfo  instead of termcap
N   +termresponse       support for  t_RV  and  v:termresponse
B   +termguicolors      24-bit color in xterm-compatible terminals support
N   +textobjects        text-objects  selection
    +tgetent            non-Unix only: able to use external termcap
N   +timers             the  timer_start()  function
N   +title              Setting the window 'title' and 'icon'
N   +toolbar            gui-toolbar
N   +user_commands      User-defined commands.  user-commands
B   +vartabs            Variable-width tabstops.  'vartabstop'
N   +viminfo            'viminfo'
    +vertsplit          Vertically split windows  :vsplit ; Always enabled
                        since 8.0.1118.
                        in sync with the  +windows  feature
N   +virtualedit        'virtualedit'
S   +visual             Visual mode  Visual-mode  Always enabled since 7.4.200.
N   +visualextra        extra Visual mode commands  blockwise-operators
T   +vreplace           gR  and  gr
    +vtp                on MS-Windows console: support for 'termguicolors'
N   +wildignore         'wildignore'
N   +wildmenu           'wildmenu'
    +windows            more than one window; Always enabled since 8.0.1118.
m   +writebackup        'writebackup'  is default on
m   +xim                X input method  xim
    +xfontset           X fontset support  xfontset
    +xpm                pixmap support
m   +xpm_w32            Win32 GUI only: pixmap support  w32-xpm-support
    +xsmp               XSMP (X session management) support
    +xsmp_interact      interactive XSMP (X session management) support
N   +xterm_clipboard    Unix only: xterm clipboard handling
m   +xterm_save         save and restore xterm screen  xterm-screens
N   +X11                Unix only: can restore window title  X11

                                                    /dyn   E370   E448
                        To some of the features "/dyn" is added when the
                        feature is only available when the related library can
                        be dynamically loaded.

:ve[rsion] {nr}         Is now ignored.  This was previously used to check the
                        version number of a .vimrc file.  It was removed,
```

because you can now use the ":if" command for
version-dependent behavior. {not in Vi}

:redi :redir

:redi[r][!] > {file} Redirect messages to file {file}. The messages which are the output of commands are written to that file, until redirection ends. The messages are also still shown on the screen. When [!] is included, an existing file is overwritten. When [!] is omitted, and {file} exists, this command fails.

Only one ":redir" can be active at a time. Calls to ":redir" will close any active redirection before starting redirection to the new target. For recursive use check out execute() .

To stop the messages and commands from being echoed to the screen, put the commands in a function and call it with ":silent call Function()".
An alternative is to use the 'verbosefile' option, this can be used in combination with ":redir".
{not in Vi}

:redi[r] >> {file} Redirect messages to file {file}. Append if {file} already exists. {not in Vi}

:redi[r] @{a-zA-Z}
:redi[r] @{a-zA-Z}> Redirect messages to register {a-z}. Append to the contents of the register if its name is given uppercase {A-Z}. The ">" after the register name is optional. {not in Vi}
:redi[r] @{a-z}>> Append messages to register {a-z}. {not in Vi}

:redi[r] @*>
:redi[r] @+> Redirect messages to the selection or clipboard. For backward compatibility, the ">" after the register name can be omitted. See quotestar and quoteplus . {not in Vi}
:redi[r] @*>>
:redi[r] @+>> Append messages to the selection or clipboard. {not in Vi}

:redi[r] @"> Redirect messages to the unnamed register. For backward compatibility, the ">" after the register name can be omitted. {not in Vi}
:redi[r] @">> Append messages to the unnamed register. {not in Vi}

:redi[r] => {var} Redirect messages to a variable. If the variable doesn't exist, then it is created. If the variable exists, then it is initialized to an empty string. The variable will remain empty until redirection ends. Only string variables can be used. After the redirection starts, if the variable is removed or locked or the variable type is changed, then further

command output messages will cause errors. {not in Vi}
To get the output of one command the execute() function can be used.

:redi[r] =>> {var} Append messages to an existing variable. Only string variables can be used. {not in Vi}

:redi[r] END End redirecting messages. {not in Vi}

:filt :filter

:filt[er][!] {pat} {command}
:filt[er][!] /{pat}/ {command}
Restrict the output of {command} to lines matching with {pat}. For example, to list only xml files:
:filter /\.xml$/ oldfiles
If the [!] is given, restrict the output of {command} to lines that do NOT match {pat}.

{pat} is a Vim search pattern. Instead of enclosing it in / any non-ID character (see 'isident') can be used, so long as it does not appear in {pat}. Without the enclosing character the pattern cannot include the bar character.

The pattern is matched against the relevant part of the output, not necessarily the whole line. Only some commands support filtering, try it out to check if it works.

Only normal messages are filtered, error messages are not.

:sil :silent :silent!

:sil[ent][!] {command} Execute {command} silently. Normal messages will not be given or added to the message history.
When [!] is added, error messages will also be skipped, and commands and mappings will not be aborted when an error is detected. v:errmsg is still set.
When [!] is not used, an error message will cause further messages to be displayed normally.
Redirection, started with :redir , will continue as usual, although there might be small differences.
This will allow redirecting the output of a command without seeing it on the screen. Example:
```
:redir >/tmp/foobar
:silent g/Aap/p
:redir END
```
To execute a Normal mode command silently, use the :normal command. For example, to search for a string without messages:
```
:silent exe "normal /path\<CR>"
```
":silent!" is useful to execute a command that may fail, but the failure is to be ignored. Example:
```
:let v:errmsg = ""
```

```
                        :silent! /^begin
                        :if v:errmsg != ""
                        : ... pattern was not found
                    ":silent" will also avoid the hit-enter prompt.  When
                    using this for an external command, this may cause the
                    screen to be messed up.  Use  CTRL-L  to clean it up
                    then.
                    ":silent menu ..." defines a menu that will not echo a
                    Command-line command.  The command will still produce
                    messages though.  Use ":silent" in the command itself
                    to avoid that: ":silent menu .... :silent command".

                                                        :uns   :unsilent
:uns[ilent] {command}   Execute {command} not silently.  Only makes a
                    difference when  :silent  was used to get to this
                    command.
                    Use this for giving a message even when  :silent  was
                    used.  In this example  :silent  is used to avoid the
                    message about reading the file and  :unsilent  to be
                    able to list the first line of each file.
              :silent argdo unsilent echo expand('%') . ": " . getline(1)

                                                        :verb   :verbose
:[count]verb[ose] {command}
                    Execute {command} with 'verbose' set to [count].  If
                    [count] is omitted one is used. ":0verbose" can be
                    used to set 'verbose' to zero.
                    The additional use of ":silent" makes messages
                    generated but not displayed.
                    The combination of ":silent" and ":verbose" can be
                    used to generate messages and check them with
                     v:statusmsg  and friends.  For example:
                            :let v:statusmsg = ""
                            :silent verbose runtime foobar.vim
                            :if v:statusmsg != ""
                            :  " foobar.vim could not be found
                            :endif
                    When concatenating another command, the ":verbose"
                    only applies to the first one:
                            :4verbose set verbose | set verbose
                             verbose=4
                              verbose=0
                    For logging verbose messages in a file use the
                    'verbosefile' option.

                                                        :verbose-cmd
When 'verbose' is non-zero, listing the value of a Vim option or a key map or
an abbreviation or a user-defined function or a command or a highlight group
or an autocommand will also display where it was last defined.  If it was
defined manually then there will be no "Last set" message.  When it was
defined while executing a function, user command or autocommand, the script in
which it was defined is reported.
{not available when compiled without the |+eval| feature}
```

K

Run a program to lookup the keyword under the cursor. The name of the program is given with the 'keywordprg' (kp) option (default is "man"). The keyword is formed of letters, numbers and the characters in 'iskeyword'. The keyword under or right of the cursor is used. The same can be done with the command

```
:!{program} {keyword}
```

There is an example of a program to use in the tools directory of Vim. It is called "ref" and does a simple spelling check.

Special cases:

- If 'keywordprg' begins with ":" it is invoked as a Vim Ex command with [count].
- If 'keywordprg' is empty, the ":help" command is used. It's a good idea to include more characters in 'iskeyword' then, to be able to find more help.
- When 'keywordprg' is equal to "man" or starts with ":", a [count] before "K" is inserted after keywordprg and before the keyword. For example, using "2K" while the cursor is on "mkdir", results in:

```
!man 2 mkdir
```

- When 'keywordprg' is equal to "man -s", a count before "K" is inserted after the "-s". If there is no count, the "-s" is removed.

{not in Vi}

{Visual}K

Like "K", but use the visually highlighted text for the keyword. Only works when the highlighted text is not more than one line. {not in Vi}

[N]gs
:[N]sl[eep] [N] [m]

Do nothing for [N] seconds. When [m] is included, sleep for [N] milliseconds. The count for "gs" always uses seconds. The default is one second.

```
:sleep          "sleep for one second
:5sleep         "sleep for five seconds
:sleep 100m     "sleep for a hundred milliseconds
10gs            "sleep for ten seconds
```

Can be interrupted with CTRL-C (CTRL-Break on MS-DOS). "gs" stands for "goto sleep". While sleeping the cursor is positioned in the text, if at a visible position. {not in Vi} Also process the received netbeans messages. {only available when compiled with the +netbeans_intg feature}

g CTRL-A

Only when Vim was compiled with MEM_PROFILING defined

(which is very rare): print memory usage statistics.
Only useful for debugging Vim.
For incrementing in Visual mode see v_g_CTRL-A .

==
2. Using Vim like less or more   less

If you use the less or more program to view a file, you don't get syntax
highlighting. Thus you would like to use Vim instead. You can do this by
using the shell script "$VIMRUNTIME/macros/less.sh".

This shell script uses the Vim script "$VIMRUNTIME/macros/less.vim". It sets
up mappings to simulate the commands that less supports. Otherwise, you can
still use the Vim commands.

This isn't perfect. For example, when viewing a short file Vim will still use
the whole screen. But it works good enough for most uses, and you get syntax
highlighting.

The "h" key will give you a short overview of the available commands.

If you want to set options differently when using less, define the
LessInitFunc in your vimrc, for example:

```
func LessInitFunc()
  set nocursorcolumn nocursorline
endfunc
```

vim:tw=78:ts=8:noet:ft=help:norl:

recover.txt For Vim version 8.1. Last change: 2014 Mar 27

VIM REFERENCE MANUAL by Bram Moolenaar

Recovery after a crash crash-recovery

You have spent several hours typing in that text that has to be finished
next morning, and then disaster strikes: Your computer crashes.

DON'T PANIC!

You can recover most of your changes from the files that Vim uses to store
the contents of the file. Mostly you can recover your work with one command:
	vim -r filename

1. The swap file swap-file
2. Recovery recovery

==
1. The swap file swap-file

Vim stores the things you changed in a swap file. Using the original file
you started from plus the swap file you can mostly recover your work.

You can see the name of the current swap file being used with the command:

	:sw[apname] :sw :swapname

The name of the swap file is normally the same as the file you are editing,
with the extension ".swp".
- On Unix, a '.' is prepended to swap file names in the same directory as the
  edited file. This avoids that the swap file shows up in a directory
  listing.
- On MS-DOS machines and when the 'shortname' option is on, any '.' in the
  original file name is replaced with '_'.
- If this file already exists (e.g., when you are recovering from a crash) a
  warning is given and another extension is used, ".swo", ".swn", etc.
- An existing file will never be overwritten.
- The swap file is deleted as soon as Vim stops editing the file.

Technical: The replacement of '.' with '_' is done to avoid problems with
	MS-DOS compatible filesystems (e.g., crossdos, multidos). If Vim
	is able to detect that the file is on an MS-DOS-like filesystem, a
	flag is set that has the same effect as the 'shortname' option.
	This flag is reset when you start editing another file.
	E326
	If the ".swp" file name already exists, the last character is
	decremented until there is no file with that name or ".saa" is
	reached. In the last case, no swap file is created.

By setting the 'directory' option you can place the swap file in another place
than where the edited file is.

Advantages:
- You will not pollute the directories with ".swp" files.
- When the 'directory' is on another partition, reduce the risk of damaging
  the file system where the file is (in a crash).
Disadvantages:
- You can get name collisions from files with the same name but in different
  directories (although Vim tries to avoid that by comparing the path name).
  This will result in bogus ATTENTION warning messages.
- When you use your home directory, and somebody else tries to edit the same
  file, he will not see your swap file and will not get the ATTENTION warning
  message.
On the Amiga you can also use a recoverable ram disk, but there is no 100%
guarantee that this works. Putting swap files in a normal ram disk (like RAM:
on the Amiga) or in a place that is cleared when rebooting (like /tmp on Unix)
makes no sense, you will lose the swap file in a crash.

If you want to put swap files in a fixed place, put a command resembling the
following ones in your .vimrc:
	:set dir=dh2:tmp	(for Amiga)
	:set dir=~/tmp		(for Unix)
	:set dir=c:\\tmp	(for MS-DOS and Win32)
This is also very handy when editing files on floppy. Of course you will have
to create that "tmp" directory for this to work!

For read-only files, a swap file is not used. Unless the file is big, causing
the amount of memory used to be higher than given with 'maxmem' or
'maxmemtot'. And when making a change to a read-only file, the swap file is
created anyway.

The 'swapfile' option can be reset to avoid creating a swapfile. And the
 :noswapfile modifier can be used to not create a swapfile for a new buffer.

:nos[wapfile]   {command}   :nos   :noswapfile
		Execute {command}. If it contains a command that loads a new
		buffer, it will be loaded without creating a swapfile and the
		'swapfile' option will be reset. If a buffer already had a
		swapfile it is not removed and 'swapfile' is not reset.

Detecting an existing swap file

You can find this in the user manual, section 11.3 .

Updating the swapfile

The swap file is updated after typing 200 characters or when you have not
typed anything for four seconds. This only happens if the buffer was
changed, not when you only moved around. The reason why it is not kept up to
date all the time is that this would slow down normal work too much. You can
change the 200 character count with the 'updatecount' option. You can set
the time with the 'updatetime' option. The time is given in milliseconds.
After writing to the swap file Vim syncs the file to disk. This takes some
time, especially on busy Unix systems. If you don't want this you can set the

'swapsync' option to an empty string. The risk of losing work becomes bigger though. On some non-Unix systems (MS-DOS, Amiga) the swap file won't be written at all.

If the writing to the swap file is not wanted, it can be switched off by setting the 'updatecount' option to 0. The same is done when starting Vim with the "-n" option. Writing can be switched back on by setting the 'updatecount' option to non-zero. Swap files will be created for all buffers when doing this. But when setting 'updatecount' to zero, the existing swap files will not be removed, it will only affect files that will be opened after this.

If you want to make sure that your changes are in the swap file use this command:

:pre[serve] Write all text for all buffers into swap file. The original file is no longer needed for recovery. This sets a flag in the current buffer. When the '&' flag is present in 'cpoptions' the swap file will not be deleted for this buffer when Vim exits and the buffer is still loaded cpo-& .
{Vi: might also exit} :pre :preserve E313 E314

A Vim swap file can be recognized by the first six characters: "b0VIM ". After that comes the version number, e.g., "3.0".

Links and symbolic links

On Unix it is possible to have two names for the same file. This can be done with hard links and with symbolic links (symlinks).

For hard links Vim does not know the other name of the file. Therefore, the name of the swapfile will be based on the name you used to edit the file. There is no check for editing the same file by the other name too, because Vim cannot find the other swapfile (except for searching all of your harddisk, which would be very slow).

For symbolic links Vim resolves the links to find the name of the actual file. The swap file name is based on that name. Thus it doesn't matter by what name you edit the file, the swap file name will normally be the same. However, there are exceptions:
- When the directory of the actual file is not writable the swapfile is put elsewhere.
- When the symbolic links somehow create a loop you get an E773 error message and the unmodified file name will be used. You won't be able to save your file normally.

==========
2. Recovery recovery E308 E311

Basic file recovery is explained in the user manual: usr_11.txt .

Another way to do recovery is to start Vim and use the ":recover" command.
This is easy when you start Vim to edit a file and you get the "ATTENTION:
Found a swap file ..." message. In this case the single command ":recover"
will do the work. You can also give the name of the file or the swap file to
the recover command:

:rec :recover E305 E306 E307

:rec[over] [file] Try to recover [file] from the swap file. If [file]
is not given use the file name for the current
buffer. The current contents of the buffer are lost.
This command fails if the buffer was modified.

:rec[over]! [file] Like ":recover", but any changes in the current
buffer are lost.

E312 E309 E310

Vim has some intelligence about what to do if the swap file is corrupt in
some way. If Vim has doubt about what it found, it will give an error
message and insert lines with "???" in the text. If you see an error message
while recovering, search in the file for "???" to see what is wrong. You may
want to cut and paste to get the text you need.

The most common remark is "???LINES MISSING". This means that Vim cannot read
the text from the original file. This can happen if the system crashed and
parts of the original file were not written to disk.

Be sure that the recovery was successful before overwriting the original
file or deleting the swap file. It is good practice to write the recovered
file elsewhere and run 'diff' to find out if the changes you want are in the
recovered file. Or use :DiffOrig .

Once you are sure the recovery is ok delete the swap file. Otherwise, you
will continue to get warning messages that the ".swp" file already exists.

{Vi: recovers in another way and sends mail if there is something to recover}

ENCRYPTION AND THE SWAP FILE :recover-crypt

When the text file is encrypted the swap file is encrypted as well. This
makes recovery a bit more complicated. When recovering from a swap file and
encryption has been used, you will be asked to enter one or two crypt keys.

If the text file does not exist you will only be asked to enter the crypt key
for the swap file.

If the text file does exist, it may be encrypted in a different way than the
swap file. You will be asked for the crypt key twice:

```
Need encryption key for "/tmp/tt"
Enter encryption key: ******
"/tmp/tt" [crypted] 23200L, 522129C
Using swap file "/tmp/.tt.swp"
Original file "/tmp/tt"
Swap file is encrypted: "/tmp/.tt.swp"
```

```
If you entered a new crypt key but did not write the text file,
enter the new crypt key.
If you wrote the text file after changing the crypt key press enter
to use the same key for text file and swap file
Enter encryption key:
```

You can be in one of these two situations:

1. The encryption key was not changed, or after changing the key the text file
   was written. You will be prompted for the crypt key twice. The second
   time you can simply press Enter. That means the same key is used for the
   text file and the swap file.
2. You entered a new encryption key, but did not save the text file. Vim will
   then use the new key for the swap file, and the text file will still be
   encrypted with the old key. At the second prompt enter the new key.

Note that after recovery the key of the swap file will be used for the text
file. Thus if you write the text file, you need to use that new key.

vim:tw=78:ts=8:noet:ft=help:norl:

cmdline.txt For Vim version 8.1. Last change: 2018 May 14

VIM REFERENCE MANUAL by Bram Moolenaar

Command-line mode Cmdline-mode Command-line-mode Cmdline Command-line mode-cmdline :

Command-line mode is used to enter Ex commands (":"), search patterns
("/" and "?"), and filter commands ("!").

Basic command line editing is explained in chapter 20 of the user manual
usr_20.txt .

==
1. Command-line editing cmdline-editing

Normally characters are inserted in front of the cursor position. You can
move around in the command-line with the left and right cursor keys. With the
<Insert> key, you can toggle between inserting and overstriking characters.
{Vi: can only alter the last character in the line}

Note that if your keyboard does not have working cursor keys or any of the
other special keys, you can use ":cnoremap" to define another key for them.
For example, to define tcsh style editing keys: tcsh-style

```
:cnoremap <C-A> <Home>
:cnoremap <C-F> <Right>
:cnoremap <C-B> <Left>
:cnoremap <Esc>b <S-Left>
:cnoremap <Esc>f <S-Right>
```

(<> notation <> ; type all this literally)

cmdline-too-long

When the command line is getting longer than what fits on the screen, only the
part that fits will be shown. The cursor can only move in this visible part,
thus you cannot edit beyond that.

cmdline-history history

The command-lines that you enter are remembered in a history table. You can
recall them with the up and down cursor keys. There are actually five
history tables:
- one for ':' commands
- one for search strings
- one for expressions
- one for input lines, typed for the input() function.

- one for debug mode commands
These are completely separate. Each history can only be accessed when entering the same type of line.
Use the 'history' option to set the number of lines that are remembered (default: 50).
Notes:
- When you enter a command-line that is exactly the same as an older one, the old one is removed (to avoid repeated commands moving older commands out of the history).
- Only commands that are typed are remembered. Ones that completely come from mappings are not put in the history.
- All searches are put in the search history, including the ones that come from commands like "*" and "#". But for a mapping, only the last search is remembered (to avoid that long mappings trash the history).
{Vi: no history}
{not available when compiled without the |+cmdline_hist| feature}

There is an automatic completion of names on the command-line; see cmdline-completion .

c_CTRL-V
CTRL-V Insert next non-digit literally. Up to three digits form the decimal value of a single byte. The non-digit and the three digits are not considered for mapping. This works the same way as in Insert mode (see above, i_CTRL-V).
Note: Under Windows CTRL-V is often mapped to paste text.
Use CTRL-Q instead then.

c_CTRL-Q
CTRL-Q Same as CTRL-V. But with some terminals it is used for control flow, it doesn't work then.

c_<Left> c_Left
<Left> cursor left

c_<Right> c_Right
<Right> cursor right

c_<S-Left>
<S-Left> or <C-Left> c_<C-Left>
cursor one WORD left

c_<S-Right>
<S-Right> or <C-Right> c_<C-Right>
cursor one WORD right

CTRL-B or <Home> c_CTRL-B c_<Home> c_Home
cursor to beginning of command-line

CTRL-E or <End> c_CTRL-E c_<End> c_End
cursor to end of command-line

c_<LeftMouse>
<LeftMouse> Move the cursor to the position of the mouse click.

c_<MiddleMouse>
<MiddleMouse> Paste the contents of the clipboard (for X11 the primary selection). This is similar to using CTRL-R *, but no CR characters are inserted between lines.

CTRL-H   c_<BS> c_CTRL-H c_BS
<BS>   Delete the character in front of the cursor (see :fixdel if
                your <BS> key does not do what you want).
                                                c_<Del> c_Del
<Del>   Delete the character under the cursor (at end of line:
                character before the cursor) (see :fixdel if your <Del>
                key does not do what you want).
                                                c_CTRL-W
CTRL-W   Delete the word before the cursor. This depends on the
                'iskeyword' option.
                                                c_CTRL-U
CTRL-U   Remove all characters between the cursor position and
                the beginning of the line. Previous versions of vim
                deleted all characters on the line. If that is the
                preferred behavior, add the following to your .vimrc:
                        :cnoremap <C-U> <C-E><C-U>

                                                c_<Insert> c_Insert
<Insert>   Toggle between insert and overstrike. {not in Vi}

{char1} <BS> {char2}   or   c_digraph
CTRL-K {char1} {char2}   c_CTRL-K
                enter digraph (see digraphs). When {char1} is a special
                key, the code for that key is inserted in <> form. {not in Vi}

CTRL-R {0-9a-z"%#:-=.}   c_CTRL-R c_<C-R>
                Insert the contents of a numbered or named register. Between
                typing CTRL-R and the second character '"' will be displayed
                to indicate that you are expected to enter the name of a
                register.
                The text is inserted as if you typed it, but mappings and
                abbreviations are not used. Command-line completion through
                'wildchar' is not triggered though. And characters that end
                the command line are inserted literally (<Esc>, <CR>, <NL>,
                <C-C>). A <BS> or CTRL-W could still end the command line
                though, and remaining characters will then be interpreted in
                another mode, which might not be what you intended.
                Special registers:
                        '"'   the unnamed register, containing the text of
                                the last delete or yank
                        '%'   the current file name
                        '#'   the alternate file name
                        '*'   the clipboard contents (X11: primary selection)
                        '+'   the clipboard contents
                        '/'   the last search pattern
                        ':'   the last command-line
                        '-'   the last small (less than a line) delete
                        '.'   the last inserted text
                                                c_CTRL-R_=
                        '='   the expression register: you are prompted to
                                enter an expression (see expression)
                                (doesn't work at the expression prompt; some
                                things such as changing the buffer or current
                                window are not allowed to avoid side effects)

When the result is a List the items are used
as lines. They can have line breaks inside
too.
When the result is a Float it's automatically
converted to a String.
See registers about registers. {not in Vi}
Implementation detail: When using the expression register
and invoking setcmdpos(), this sets the position before
inserting the resulting string. Use CTRL-R CTRL-R to set the
position afterwards.

CTRL-R CTRL-F c_CTRL-R_CTRL-F c_<C-R>_<C-F>
CTRL-R CTRL-P c_CTRL-R_CTRL-P c_<C-R>_<C-P>
CTRL-R CTRL-W c_CTRL-R_CTRL-W c_<C-R>_<C-W>
CTRL-R CTRL-A c_CTRL-R_CTRL-A c_<C-R>_<C-A>
CTRL-R CTRL-L c_CTRL-R_CTRL-L c_<C-R>_<C-L>
Insert the object under the cursor:
CTRL-F the Filename under the cursor
CTRL-P the Filename under the cursor, expanded with
'path' as in gf
CTRL-W the Word under the cursor
CTRL-A the WORD under the cursor; see WORD
CTRL-L the line under the cursor

When 'incsearch' is set the cursor position at the end of the
currently displayed match is used. With CTRL-W the part of
the word that was already typed is not inserted again.

{not in Vi}
CTRL-F and CTRL-P: {only when +file_in_path feature is
included}

c_CTRL-R_CTRL-R c_<C-R>_<C-R>
c_CTRL-R_CTRL-O c_<C-R>_<C-O>
CTRL-R CTRL-R {0-9a-z"%#:-=. CTRL-F CTRL-P CTRL-W CTRL-A CTRL-L}
CTRL-R CTRL-O {0-9a-z"%#:-=. CTRL-F CTRL-P CTRL-W CTRL-A CTRL-L}
Insert register or object under the cursor. Works like
c_CTRL-R but inserts the text literally. For example, if
register a contains "xy^Hz" (where ^H is a backspace),
"CTRL-R a" will insert "xz" while "CTRL-R CTRL-R a" will
insert "xy^Hz".

CTRL-\ e {expr} c_CTRL-_e
Evaluate {expr} and replace the whole command line with the
result. You will be prompted for the expression, type <Enter>
to finish it. It's most useful in mappings though. See
expression .
See c_CTRL-R_= for inserting the result of an expression.
Useful functions are getcmdtype() , getcmdline() and
getcmdpos() .
The cursor position is unchanged, except when the cursor was
at the end of the line, then it stays at the end.
setcmdpos() can be used to set the cursor position.
The sandbox is used for evaluating the expression to avoid

nasty side effects.
Example:

```
:cmap <F7> <C-\>eAppendSome()<CR>
:func AppendSome()
   :let cmd = getcmdline() . " Some()"
   :" place the cursor on the )
   :call setcmdpos(strlen(cmd))
   :return cmd
:endfunc
```

This doesn't work recursively, thus not when already editing an expression. But it is possible to use in a mapping.

c_CTRL-Y

CTRL-Y When there is a modeless selection, copy the selection into the clipboard. modeless-selection
If there is no selection **CTRL-Y** is inserted as a character.

CTRL-M or **CTRL-J** c_CTRL-M c_CTRL-J c_<NL> c_<CR> c_CR

<CR> or <NL> start entered command

CTRL-[c_CTRL-[c_<Esc> c_Esc

<Esc> When typed and 'x' not present in 'cpoptions', quit Command-line mode without executing. In macros or when 'x' present in 'cpoptions', start entered command.
Note: If your <Esc> key is hard to hit on your keyboard, train yourself to use CTRL-[.

c_CTRL-C

CTRL-C quit command-line without executing

c_<Up> c_Up

<Up> recall older command-line from history, whose beginning matches the current command-line (see below).
{not available when compiled without the +cmdline_hist feature}

c_<Down> c_Down

<Down> recall more recent command-line from history, whose beginning matches the current command-line (see below).
{not available when compiled without the +cmdline_hist feature}

c_<S-Up> c_<PageUp>

<S-Up> or <PageUp>
recall older command-line from history
{not available when compiled without the +cmdline_hist feature}

c_<S-Down> c_<PageDown>

<S-Down> or <PageDown>
recall more recent command-line from history
{not available when compiled without the +cmdline_hist feature}

CTRL-D command-line completion (see cmdline-completion)

'wildchar' option
command-line completion (see cmdline-completion)

CTRL-N command-line completion (see cmdline-completion)
CTRL-P command-line completion (see cmdline-completion)
CTRL-A command-line completion (see cmdline-completion)
CTRL-L command-line completion (see cmdline-completion)

c_CTRL-_
CTRL-_ a - switch between Hebrew and English keyboard mode, which is private to the command-line and not related to hkmap. This is useful when Hebrew text entry is required in the command-line, searches, abbreviations, etc. Applies only if Vim is compiled with the +rightleft feature and the 'allowrevins' option is set. See rileft.txt .

b - switch between Farsi and English keyboard mode, which is private to the command-line and not related to fkmap. In Farsi keyboard mode the characters are inserted in reverse insert manner. This is useful when Farsi text entry is required in the command-line, searches, abbreviations, etc. Applies only if Vim is compiled with the +farsi feature. See farsi.txt .

c_CTRL-^
CTRL-^ Toggle the use of language :lmap mappings and/or Input Method.
When typing a pattern for a search command and 'imsearch' is not -1, VAL is the value of 'imsearch', otherwise VAL is the value of 'iminsert'.
When language mappings are defined:
- If VAL is 1 (langmap mappings used) it becomes 0 (no langmap mappings used).
- If VAL was not 1 it becomes 1, thus langmap mappings are enabled.
When no language mappings are defined:
- If VAL is 2 (Input Method is used) it becomes 0 (no input method used)
- If VAL has another value it becomes 2, thus the Input Method is enabled.
These language mappings are normally used to type characters that are different from what the keyboard produces. The 'keymap' option can be used to install a whole number of them.
When entering a command line, langmap mappings are switched off, since you are expected to type a command. After switching it on with CTRL-^, the new state is not used again for the next command or Search pattern.
{not in Vi}

c_CTRL-]
CTRL-] Trigger abbreviation, without inserting a character. {not in Vi}

For Emacs-style editing on the command-line see emacs-keys .

The <Up> and <Down> keys take the current command-line as a search string.

The beginning of the next/previous command-lines are compared with this
string. The first line that matches is the new command-line. When typing
these two keys repeatedly, the same string is used again. For example, this
can be used to find the previous substitute command: Type ":s" and then <Up>.
The same could be done by typing <S-Up> a number of times until the desired
command-line is shown. (Note: the shifted arrow keys do not work on all
terminals)

                                                        :his   :history
:his[tory]   Print the history of last entered commands.
                {not in Vi}
                {not available when compiled without the +cmdline_hist
                feature}

:his[tory] [{name}] [{first}][, [{last}]]
                List the contents of history {name} which can be:
                c[md]   or :   command-line history
                s[earch] or / or ?   search string history
                e[xpr]   or =   expression register history
                i[nput] or @   input line history
                d[ebug] or >   debug command history
                a[ll]   all of the above
                {not in Vi}

                If the numbers {first} and/or {last} are given, the respective
                range of entries from a history is listed. These numbers can
                be specified in the following form:
                                                        :history-indexing
                A positive number represents the absolute index of an entry
                as it is given in the first column of a :history listing.
                This number remains fixed even if other entries are deleted.

                A negative number means the relative position of an entry,
                counted from the newest entry (which has index -1) backwards.

                Examples:
                List entries 6 to 12 from the search history:
                        :history / 6,12

                List the penultimate entry from all histories:
                        :history all -2

                List the most recent two entries from all histories:
                        :history all -2,

:keepp[atterns] {command}   :keepp   :keeppatterns
                Execute {command}, without adding anything to the search
                history

==
2. Command-line completion   cmdline-completion

When editing the command-line, a few commands can be used to complete the
word before the cursor. This is available for:

- Command names: At the start of the command-line.
- Tags: Only after the ":tag" command.
- File names: Only after a command that accepts a file name or a setting for
  an option that can be set to a file name. This is called file name
  completion.
- Shell command names: After ":!cmd", ":r !cmd" and ":w !cmd". $PATH is used.
- Options: Only after the ":set" command.
- Mappings: Only after a ":map" or similar command.
- Variable and function names: Only after a ":if", ":call" or similar command.

When Vim was compiled without the +cmdline_compl feature only file names,
directories and help items can be completed. The number of help item matches
is limited (currently to 300) to avoid a long delay when there are very many
matches.

These are the commands that can be used:

                                                        c_CTRL-D
CTRL-D   List names that match the pattern in front of the cursor.
                When showing file names, directories are highlighted (see
                'highlight' option). Names where 'suffixes' matches are moved
                to the end.
                The 'wildoptions' option can be set to "tagfile" to list the
                file of matching tags.
                                        c_CTRL-I   c_wildchar   c_<Tab>
'wildchar' option
                A match is done on the pattern in front of the cursor. The
                match (if there are several, the first match) is inserted
                in place of the pattern. (Note: does not work inside a
                macro, because <Tab> or <Esc> are mostly used as 'wildchar',
                and these have a special meaning in some macros.) When typed
                again and there were multiple matches, the next
                match is inserted. After the last match, the first is used
                again (wrap around).
                The behavior can be changed with the 'wildmode' option.
                                                        c_<S-Tab>
<S-Tab>   Like 'wildchar' or <Tab>, but begin with the last match and
                then go to the previous match.
                <S-Tab> does not work everywhere.
                                                        c_CTRL-N
CTRL-N   After using 'wildchar' which got multiple matches, go to next
                match. Otherwise recall more recent command-line from history.
                                                        c_CTRL-P
CTRL-P   After using 'wildchar' which got multiple matches, go to
                previous match. Otherwise recall older command-line from
                history.
                                                        c_CTRL-A
CTRL-A   All names that match the pattern in front of the cursor are
                inserted.
                                                        c_CTRL-L
CTRL-L   A match is done on the pattern in front of the cursor. If
                there is one match, it is inserted in place of the pattern.
                If there are multiple matches the longest common part is

inserted in place of the pattern. If the result is shorter than the pattern, no completion is done.

/_CTRL-L

When 'incsearch' is set, entering a search pattern for "/" or "?" and the current match is displayed then CTRL-L will add one character from the end of the current match. If 'ignorecase' and 'smartcase' are set and the command line has no uppercase characters, the added character is converted to lowercase.

c_CTRL-G /_CTRL-G

CTRL-G When 'incsearch' is set, entering a search pattern for "/" or "?" and the current match is displayed then CTRL-G will move to the next match (does not take search-offset into account) Use CTRL-T to move to the previous match. Hint: on a regular keyboard T is above G.

c_CTRL-T /_CTRL-T

CTRL-T When 'incsearch' is set, entering a search pattern for "/" or "?" and the current match is displayed then CTRL-T will move to the previous match (does not take search-offset into account).
Use CTRL-G to move to the next match. Hint: on a regular keyboard T is above G.

The 'wildchar' option defaults to <Tab> (CTRL-E when in Vi compatible mode; in a previous version <Esc> was used). In the pattern standard wildcards '*' and '?' are accepted when matching file names. '*' matches any string, '?' matches exactly one character.

When repeating 'wildchar' or CTRL-N you cycle through the matches, eventually ending up back to what was typed. If the first match is not what you wanted, you can use <S-Tab> or CTRL-P to go straight back to what you typed.

The 'wildignorecase' option can be set to ignore case in filenames.

The 'wildmenu' option can be set to show the matches just above the command line.

If you like tcsh's autolist completion, you can use this mapping:

```
:cnoremap X <C-L><C-D>
```

(Where X is the command key to use, <C-L> is CTRL-L and <C-D> is CTRL-D) This will find the longest match and then list all matching files.

If you like tcsh's autolist completion, you can use the 'wildmode' option to emulate it. For example, this mimics autolist=ambiguous:

```
:set wildmode=longest,list
```

This will find the longest match with the first 'wildchar', then list all matching files with the next.

suffixes

For file name completion you can use the 'suffixes' option to set a priority between files with almost the same name. If there are multiple matches, those files with an extension that is in the 'suffixes' option are ignored. The default is ".bak,~,.o,.h,.info,.swp,.obj", which means that files ending in ".bak", "~", ".o", ".h", ".info", ".swp" and ".obj" are sometimes ignored.

An empty entry, two consecutive commas, match a file name that does not
contain a ".", thus has no suffix. This is useful to ignore "prog" and prefer
"prog.c".

Examples:

```
  pattern:      files:                      match:
   test*        test.c test.h test.o        test.c
   test*        test.h test.o               test.h and test.o
   test*        test.i test.h test.c        test.i and test.c
```

It is impossible to ignore suffixes with two dots.

If there is more than one matching file (after ignoring the ones matching
the 'suffixes' option) the first file name is inserted. You can see that
there is only one match when you type 'wildchar' twice and the completed
match stays the same. You can get to the other matches by entering
'wildchar', CTRL-N or CTRL-P. All files are included, also the ones with
extensions matching the 'suffixes' option.

To completely ignore files with some extension use 'wildignore'.

To match only files that end at the end of the typed text append a "$". For
example, to match only files that end in ".c":

```
        :e *.c$
```

This will not match a file ending in ".cpp". Without the "$" it does match.

The old value of an option can be obtained by hitting 'wildchar' just after
the '='. For example, typing 'wildchar' after ":set dir=" will insert the
current value of 'dir'. This overrules file name completion for the options
that take a file name.

If you would like using <S-Tab> for CTRL-P in an xterm, put this command in
your .cshrc:

```
        xmodmap -e "keysym Tab = Tab Find"
```

And this in your .vimrc:

```
        :cmap <Esc>[1~ <C-P>
```

==
3. Ex command-lines   cmdline-lines

The Ex commands have a few specialties:

                                                        :quote   :comment
'"' at the start of a line causes the whole line to be ignored. '"'
after a command causes the rest of the line to be ignored. This can be used
to add comments. Example:

```
        :set ai         "set 'autoindent' option
```

It is not possible to add a comment to a shell command ":!cmd" or to the
":map" command and a few others, because they see the '"' as part of their
argument. This is mentioned where the command is explained.

                                                        :bar   :\bar

'|' can be used to separate commands, so you can give multiple commands in one
line. If you want to use '|' in an argument, precede it with '\'.

These commands see the '|' as their argument, and can therefore not be
followed by another Vim command:
    :argdo
    :autocmd
    :bufdo
    :cdo
    :cfdo
    :command
    :cscope
    :debug
    :folddoopen
    :folddoclosed
    :function
    :global
    :help
    :helpfind
    :lcscope
    :ldo
    :lfdo
    :make
    :normal
    :perl
    :perldo
    :promptfind
    :promptrepl
    :pyfile
    :python
    :registers
    :read !
    :scscope
    :sign
    :tcl
    :tcldo
    :tclfile
    :vglobal
    :windo
    :write !
    :[range]!
    a user defined command without the "-bar" argument :command

Note that this is confusing (inherited from Vi): With ":g" the '|' is included
in the command, with ":s" it is not.

To be able to use another command anyway, use the ":execute" command.
Example (append the output of "ls" and jump to the first line):
        :execute 'r !ls' | '[

There is one exception: When the 'b' flag is present in 'cpoptions', with the
":map" and ":abbr" commands and friends CTRL-V needs to be used instead of
'\'. You can also use "<Bar>" instead. See also map_bar .

Examples:

```
        :!ls | wc               view the output of two commands
        :r !ls | wc             insert the same output in the text
        :%g/foo/p|>             moves all matching lines one shiftwidth
        :%s/foo/bar/|>          moves one line one shiftwidth
        :map q 10^V|            map "q" to "10|"
        :map q 10\| map \ l     map "q" to "10\" and map "\" to "l"
                                        (when 'b' is present in 'cpoptions')
```

You can also use <NL> to separate commands in the same way as with '|'. To insert a <NL> use CTRL-V CTRL-J. "^@" will be shown. Using '|' is the preferred method. But for external commands a <NL> must be used, because a '|' is included in the external command. To avoid the special meaning of <NL> it must be preceded with a backslash. Example:

```
        :r !date<NL>-join
```

This reads the current date into the file and joins it with the previous line.

Note that when the command before the '|' generates an error, the following commands will not be executed.

Because of Vi compatibility the following strange commands are supported:

```
        :|                      print current line (like ":p")
        :3|                     print line 3 (like ":3p")
        :3                      goto line 3
```

A colon is allowed between the range and the command name. It is ignored (this is Vi compatible). For example:

```
        :1,$:s/pat/string
```

When the character '%' or '#' is used where a file name is expected, they are expanded to the current and alternate file name (see the chapter "editing files" :_% :_#).

Embedded spaces in file names are allowed on the Amiga if one file name is expected as argument. Trailing spaces will be ignored, unless escaped with a backslash or CTRL-V. Note that the ":next" command uses spaces to separate file names. Escape the spaces to include them in a file name. Example:

```
        :next foo\ bar goes\ to school\
```

starts editing the three files "foo bar", "goes to" and "school ".

When you want to use the special characters '"' or '|' in a command, or want to use '%' or '#' in a file name, precede them with a backslash. The backslash is not required in a range and in the ":substitute" command. See also `= .

:_!

The '!' (bang) character after an Ex command makes the command behave in a different way. The '!' should be placed immediately after the command, without any blanks in between. If you insert blanks the '!' will be seen as an argument for the command, which has a different meaning. For example:

```
        :w! name        write the current buffer to file "name", overwriting
                        any existing file
        :w !name        send the current buffer as standard input to command
```

"name"

==
4. Ex command-line ranges		cmdline-ranges	[range]	E16

Some Ex commands accept a line range in front of them. This is noted as
[range]. It consists of one or more line specifiers, separated with ',' or
';'.

The basics are explained in section 10.3 of the user manual.

:,	:;
When separated with ';' the cursor position will be set to that line
before interpreting the next line specifier. This doesn't happen for ','.
Examples:
   4,/this line/
	from line 4 till match with "this line" after the cursor line.
   5;/that line/
	from line 5 till match with "that line" after line 5.

The default line specifier for most commands is the cursor position, but the
commands ":write" and ":global" have the whole file (1,$) as default.

If more line specifiers are given than required for the command, the first
one(s) will be ignored.

Line numbers may be specified with:		:range	E14	{address}
	{number}	an absolute line number
	.		the current line			:.
	$		the last line in the file		:$
	%		equal to 1,$ (the entire file)		:%
	't		position of mark t (lowercase)		:'
	'T		position of mark T (uppercase); when the mark is in
			another file it cannot be used in a range
	/{pattern}[/]	the next line where {pattern} matches	:/
	?{pattern}[?]	the previous line where {pattern} matches	:?
	\/		the next line where the previously used search
			pattern matches
	\?		the previous line where the previously used search
			pattern matches
	\&		the next line where the previously used substitute
			pattern matches

Each may be followed (several times) by '+' or '-' and an optional number.
This number is added or subtracted from the preceding line number. If the
number is omitted, 1 is used.

The "/" and "?" after {pattern} are required to separate the pattern from
anything that follows.

The "/" and "?" may be preceded with another address. The search starts from
there. The difference from using ';' is that the cursor isn't moved.
Examples:
	/pat1//pat2/	Find line containing "pat2" after line containing

```
                        "pat1", without moving the cursor.
        7;/pat2/        Find line containing "pat2", after line 7, leaving
                        the cursor in line 7.
```

The {number} must be between 0 and the number of lines in the file. When using a 0 (zero) this is interpreted as a 1 by most commands. Commands that use it as a count do use it as a zero (:tag , :pop , etc). Some commands interpret the zero as "before the first line" (:read , search pattern, etc).

Examples:

```
        .+3             three lines below the cursor
        /that/+1        the line below the next line containing "that"
        .,$             from current line until end of file
        0;/that         the first line containing "that", also matches in the
                        first line.
        1;/that         the first line after line 1 containing "that"
```

Some commands allow for a count after the command. This count is used as the number of lines to be used, starting with the line given in the last line specifier (the default is the cursor line). The commands that accept a count are the ones that use a range but do not have a file name argument (because a file name can also be a number).

Examples:

```
        :s/x/X/g 5      substitute 'x' by 'X' in the current line and four
                        following lines
        :23d 4          delete lines 23, 24, 25 and 26
```

Folds and Range

When folds are active the line numbers are rounded off to include the whole closed fold. See fold-behavior .

Reverse Range E493

A range should have the lower line number first. If this is not the case, Vim will ask you if it should swap the line numbers.

```
        Backwards range given, OK to swap
```

This is not done within the global command ":g".

You can use ":silent" before a command to avoid the question, the range will always be swapped then.

Count and Range N:

When giving a count before entering ":", this is translated into:

```
                :.,.+(count - 1)
```

In words: The 'count' lines at and after the cursor. Example: To delete three lines:

```
                3:d<CR>         is translated into: .,.+2d<CR>
```

Visual Mode and Range v_:

{Visual}: Starts a command-line with the Visual selected lines as a range. The code `:'<,'>` is used for this range, which makes it possible to select a similar line from the command-line history for repeating a command on different Visually selected lines.
When Visual mode was already ended, a short way to use the Visual area for a range is `:*`. This requires that "*" does not appear in 'cpo', see cpo-star . Otherwise you will have to type `:'<,'>`

==
5. Ex command-line flags ex-flags

These flags are supported by a selection of Ex commands. They print the line that the cursor ends up after executing the command:

l output like for :list
add line number
p output like for :print

The flags can be combined, thus "l#" uses both a line number and :list style output.

==
6. Ex special characters cmdline-special

Note: These are special characters in the executed command line. If you want to insert special things while typing you can use the CTRL-R command. For example, "%" stands for the current file name, while CTRL-R % inserts the current file name right away. See c_CTRL-R .

Note: If you want to avoid the effects of special characters in a Vim script you may want to use fnameescape() . Also see `= .

In Ex commands, at places where a file name can be used, the following characters have a special meaning. These can also be used in the expression function expand() .

% Is replaced with the current file name. :_% c_%
# Is replaced with the alternate file name. :_# c_#
This is remembered for every window.
#n (where n is a number) is replaced with :_#0 :_#n
the file name of buffer n. "#0" is the same as "#". c_#n
Is replaced with all names in the argument list :_## c_##
concatenated, separated by spaces. Each space in a name
is preceded with a backslash.
#<n (where n is a number > 0) is replaced with old :_#< c_#<
file name n. See :oldfiles or v:oldfiles to get the
number. E809
{only when compiled with the |+eval| and |+viminfo| features}

Note that these, except "#<n", give the file name as it was typed. If an absolute path is needed (when using the file name from a different directory), you need to add ":p". See filename-modifiers .

The "#<n" item returns an absolute path, but it will start with "~/" for files below your home directory.

Note that backslashes are inserted before spaces, so that the command will correctly interpret the file name. But this doesn't happen for shell commands. For those you probably have to use quotes (this fails for files that contain a quote and wildcards):

```
:!ls "%"
:r !spell "%"
```

To avoid the special meaning of '%' and '#' insert a backslash before it. Detail: The special meaning is always escaped when there is a backslash before it, no matter how many backslashes.

you type:	result
#	alternate.file
\#	#
\\#	\#

Also see `= .

:<cword> :<cWORD> :<cfile> <cfile>
:<sfile> <sfile> :<afile> <afile>
:<abuf> <abuf> :<amatch> <amatch>
:<cexpr> <cexpr>
<slnum> E495 E496 E497 E499 E500

Note: these are typed literally, they are not special keys!

- <cword> is replaced with the word under the cursor (like star)
- <cWORD> is replaced with the WORD under the cursor (see WORD)
- <cexpr> is replaced with the word under the cursor, including more to form a C expression. E.g., when the cursor is on "arg" of "ptr->arg" then the result is "ptr->arg"; when the cursor is on "]" of "list[idx]" then the result is "list[idx]". This is used for v:beval_text .
- <cfile> is replaced with the path name under the cursor (like what gf uses)
- <afile> When executing autocommands, is replaced with the file name of the buffer being manipulated, or the file for a read or write.
- <abuf> When executing autocommands, is replaced with the currently effective buffer number (for ":r file" and ":so file" it is the current buffer, the file being read/sourced is not in a buffer).
- <amatch> When executing autocommands, is replaced with the match for which this autocommand was executed. It differs from <afile> only when the file name isn't used to match with (for FileType, Syntax and SpellFileMissing events).
- <sfile> When executing a ":source" command, is replaced with the file name of the sourced file. E498
  When executing a function, is replaced with:
  "function {function-name}[{lnum}]"

function call nesting is indicated like this:
"function {function-name1}[{lnum}]..{function-name2}[{lnum}]"
Note that filename-modifiers are useless when <sfile> is
used inside a function.

<slnum> When executing a ":source" command, is replaced with the line number. E842
When executing a function it's the line number relative to the start of the function.

filename-modifiers

:_%: ::8 ::p ::. ::~ ::h ::t ::r ::e ::s ::gs ::S
%:8 %:p %:. %:~ %:h %:t %:r %:e %:s %:gs %:S

The file name modifiers can be used after "%", "#", "#n", "<cfile>", "<sfile>", "<afile>" or "<abuf>". They are also used with the fnamemodify() function. These are not available when Vim has been compiled without the +modify_fname feature.
These modifiers can be given, in this order:

:p Make file name a full path. Must be the first modifier. Also changes "~/" (and "~user/" for Unix and VMS) to the path for the home directory. If the name is a directory a path separator is added at the end. For a file name that does not exist and does not have an absolute path the result is unpredictable. On MS-Windows an 8.3 filename is expanded to the long name.

:8 Converts the path to 8.3 short format (currently only on MS-Windows). Will act on as much of a path that is an existing path.

:~ Reduce file name to be relative to the home directory, if possible. File name is unmodified if it is not below the home directory.

:. Reduce file name to be relative to current directory, if possible. File name is unmodified if it is not below the current directory, but on MS-Windows the drive is removed if it is the current drive.
For maximum shortness, use ":~:.".

:h Head of the file name (the last component and any separators removed). Cannot be used with :e, :r or :t.
Can be repeated to remove several components at the end.
When the file name ends in a path separator, only the path separator is removed. Thus ":p:h" on a directory name results on the directory name itself (without trailing slash).
When the file name is an absolute path (starts with "/" for Unix; "x:\" for MS-DOS, WIN32, OS/2; "drive:" for Amiga), that part is not removed. When there is no head (path is relative to current directory) the result is empty.

:t Tail of the file name (last component of the name). Must precede any :r or :e.

:r Root of the file name (the last extension removed). When there is only an extension (file name that starts with '.', e.g., ".vimrc"), it is not removed. Can be repeated to remove several extensions (last one first).

:e Extension of the file name. Only makes sense when used alone.
When there is no extension the result is empty.
When there is only an extension (file name that starts with

'.'), the result is empty. Can be repeated to include more
extensions. If there are not enough extensions (but at least
one) as much as possible are included.
:s?pat?sub?
Substitute the first occurrence of "pat" with "sub". This
works like the :s command. "pat" is a regular expression.
Any character can be used for '?', but it must not occur in
"pat" or "sub".
After this, the previous modifiers can be used again. For
example ":p", to make a full path after the substitution.
:gs?pat?sub?
Substitute all occurrences of "pat" with "sub". Otherwise
this works like ":s".
:S Escape special characters for use with a shell command (see
shellescape()). Must be the last one. Examples:
:!dir <cfile>:S
:call system('chmod +w -- ' . expand('%:S'))

Examples, when the file name is "src/version.c", current dir
"/home/mool/vim":
:p /home/mool/vim/src/version.c
:p:. src/version.c
:p:~ ~/vim/src/version.c
:h src
:p:h /home/mool/vim/src
:p:h:h /home/mool/vim
:t version.c
:p:t version.c
:r src/version
:p:r /home/mool/vim/src/version
:t:r version
:e c
:s?version?main? src/main.c
:s?version?main?:p /home/mool/vim/src/main.c
:p:gs?/?\\? \home\mool\vim\src\version.c

Examples, when the file name is "src/version.c.gz":
:p /home/mool/vim/src/version.c.gz
:e gz
:e:e c.gz
:e:e:e c.gz
:e:e:r c
:r src/version.c
:r:e c
:r:r src/version
:r:r:r src/version

extension-removal :_%<
If a "<" is appended to "%", "#", "#n" or "CTRL-V p" the extension of the file
name is removed (everything after and including the last '.' in the file
name). This is included for backwards compatibility with version 3.0, the
":r" form is preferred. Examples:

% current file name

```
        %<              current file name without extension
        #               alternate file name for current window
        #<              idem, without extension
        #31             alternate file number 31
        #31<            idem, without extension
        <cword>         word under the cursor
        <cWORD>         WORD under the cursor (see |WORD|)
        <cfile>         path name under the cursor
        <cfile><        idem, without extension

Note: Where a file name is expected wildcards expansion is done.  On Unix the
shell is used for this, unless it can be done internally (for speed).
Unless in  restricted-mode , backticks work also, like in
        :n `echo *.c`
But expansion is only done if there are any wildcards before expanding the
'%', '#', etc..  This avoids expanding wildcards inside a file name.  If you
want to expand the result of <cfile>, add a wildcard character to it.
Examples: (alternate file name is "?readme?")
        command         expands to
        :e #            :e ?readme?
        :e `ls #`       :e {files matching "?readme?"}
        :e #.*          :e {files matching "?readme?.*"}
        :cd <cfile>     :cd {file name under cursor}
        :cd <cfile>*    :cd {file name under cursor plus "*" and then expanded}
Also see  `= .

When the expanded argument contains a "!" and it is used for a shell command
(":!cmd", ":r !cmd" or ":w !cmd"), the "!" is escaped with a backslash to
avoid it being expanded into a previously used command.  When the 'shell'
option contains "sh", this is done twice, to avoid the shell trying to expand
the "!".

                                                        filename-backslash
For filesystems that use a backslash as directory separator (MS-DOS, Windows,
OS/2), it's a bit difficult to recognize a backslash that is used to escape
the special meaning of the next character.  The general rule is: If the
backslash is followed by a normal file name character, it does not have a
special meaning.  Therefore "\file\foo" is a valid file name, you don't have
to type the backslash twice.

An exception is the '$' sign.  It is a valid character in a file name.  But
to avoid a file name like "$home" to be interpreted as an environment variable,
it needs to be preceded by a backslash.  Therefore you need to use "/\$home"
for the file "$home" in the root directory.  A few examples:

        FILE NAME       INTERPRETED AS
        $home           expanded to value of environment var $home
        \$home          file "$home" in current directory
        /\$home         file "$home" in root directory
        \\$home         file "\\", followed by expanded $home

Also see  `= .

==============================================================================
```

7. Command-line window cmdline-window cmdwin command-line-window

In the command-line window the command line can be edited just like editing text in any window. It is a special kind of window, because you cannot leave it in a normal way.
{not available when compiled without the +cmdline_hist or +vertsplit feature}

OPEN c_CTRL-F q: q/ q?

There are two ways to open the command-line window:
1. From Command-line mode, use the key specified with the 'cedit' option. The default is CTRL-F when 'compatible' is not set.
2. From Normal mode, use the "q:", "q/" or "q?" command. This starts editing an Ex command-line ("q:") or search string ("q/" or "q?"). Note that this is not possible while recording is in progress (the "q" stops recording then).

When the window opens it is filled with the command-line history. The last line contains the command as typed so far. The left column will show a character that indicates the type of command-line being edited, see cmdwin-char .

Vim will be in Normal mode when the editor is opened, except when 'insertmode' is set.

The height of the window is specified with 'cmdwinheight' (or smaller if there is no room). The window is always full width and is positioned just above the command-line.

EDIT

You can now use commands to move around and edit the text in the window. Both in Normal mode and Insert mode.

It is possible to use ":", "/" and other commands that use the command-line, but it's not possible to open another command-line window then. There is no nesting. E11
The command-line window is not a normal window. It is not possible to move to another window or edit another buffer. All commands that would do this are disabled in the command-line window. Of course it _is_ possible to execute any command that you entered in the command-line window. Other text edits are discarded when closing the window.

CLOSE E199

There are several ways to leave the command-line window:

<CR> Execute the command-line under the cursor. Works both in Insert and in Normal mode.

CTRL-C   Continue in Command-line mode. The command-line under the
                cursor is used as the command-line. Works both in Insert and
                in Normal mode. There is no redraw, thus the window will
                remain visible.
:quit   Discard the command line and go back to Normal mode.
                ":close", ":exit", ":xit" and CTRL-\ CTRL-N also work.
:qall   Quit Vim, unless there are changes in some buffer.
:qall!   Quit Vim, discarding changes to any buffer.

Once the command-line window is closed the old window sizes are restored. The
executed command applies to the window and buffer where the command-line was
started from. This works as if the command-line window was not there, except
that there will be an extra screen redraw.
The buffer used for the command-line window is deleted. Any changes to lines
other than the one that is executed with <CR> are lost.

If you would like to execute the command under the cursor and then have the
command-line window open again, you may find this mapping useful:

        :autocmd CmdwinEnter * map <buffer> <F5> <CR>q:

VARIOUS

The command-line window cannot be used:
- when there already is a command-line window (no nesting)
- for entering an encryption key or when using inputsecret()
- when Vim was not compiled with the +vertsplit feature

Some options are set when the command-line window is opened:
'filetype'   "vim", when editing an Ex command-line; this starts Vim syntax
                highlighting if it was enabled
'rightleft'   off
'modifiable'   on
'buftype'   "nofile"
'swapfile'   off

It is allowed to write the buffer contents to a file. This is an easy way to
save the command-line history and read it back later.

If the 'wildchar' option is set to <Tab>, and the command-line window is used
for an Ex command, then two mappings will be added to use <Tab> for completion
in the command-line window, like this:
        :imap <buffer> <Tab> <C-X><C-V>
        :nmap <buffer> <Tab> a<C-X><C-V>
Note that hitting <Tab> in Normal mode will do completion on the next
character. That way it works at the end of the line.
If you don't want these mappings, disable them with:
        au CmdwinEnter [:>] iunmap <Tab>
        au CmdwinEnter [:>] nunmap <Tab>
You could put these lines in your vimrc file.

While in the command-line window you cannot use the mouse to put the cursor in
another window, or drag statuslines of other windows. You can drag the

statusline of the command-line window itself and the statusline above it.
Thus you can resize the command-line window, but not others.

The getcmdwintype() function returns the type of the command-line being edited as described in cmdwin-char .

AUTOCOMMANDS

Two autocommand events are used: CmdwinEnter and CmdwinLeave . Since this window is of a special type, the WinEnter, WinLeave, BufEnter and BufLeave events are not triggered. You can use the Cmdwin events to do settings specifically for the command-line window. Be careful not to cause side effects!
Example:

```
:au CmdwinEnter :  let b:cpt_save = &cpt | set cpt=.
:au CmdwinLeave :  let &cpt = b:cpt_save
```

This sets 'complete' to use completion in the current window for i_CTRL-N .
Another example:

```
:au CmdwinEnter [/?]  startinsert
```

This will make Vim start in Insert mode in the command-line window.

cmdwin-char
The character used for the pattern indicates the type of command-line:

```
:       normal Ex command
>       debug mode command  debug-mode
/       forward search string
?       backward search string
=       expression for "=  expr-register
@       string for  input()
-       text for  :insert  or  :append
```

vim:tw=78:ts=8:noet:ft=help:norl:

VIM REFERENCE MANUAL by Bram Moolenaar

Options options

1. Setting options set-option
2. Automatically setting options auto-setting
3. Options summary option-summary

For an overview of options see quickref.txt option-list .

Vim has a number of internal variables and switches which can be set to
achieve special effects. These options come in three forms:
        boolean   can only be on or off boolean toggle
        number   has a numeric value
        string   has a string value

==========
1. Setting options set-option E764

:se :set
:se[t] Show all options that differ from their default value.

:se[t] all Show all but terminal options.

:se[t] termcap Show all terminal options. Note that in the GUI the
key codes are not shown, because they are generated
internally and can't be changed. Changing the terminal
codes in the GUI is not useful either...

E518 E519
:se[t] {option}? Show value of {option}.

:se[t] {option} Toggle option: set, switch it on.
Number option: show value.
String option: show value.

:se[t] no{option} Toggle option: Reset, switch it off.

:set-! :set-inv
:se[t] {option}! or
:se[t] inv{option} Toggle option: Invert value. {not in Vi}

:set-default :set-& :set-&vi :set-&vim
:se[t] {option}& Reset option to its default value. May depend on the
current value of 'compatible'. {not in Vi}
:se[t] {option}&vi Reset option to its Vi default value. {not in Vi}
:se[t] {option}&vim Reset option to its Vim default value. {not in Vi}

:se[t] all& Set all options to their default value. The values of
these options are not changed:

all terminal options, starting with t_
'columns'
'cryptmethod'
'encoding'
'key'
'lines'
'term'
'ttymouse'
'ttytype'
Warning: This may have a lot of side effects.
{not in Vi}

:set-args E487 E521

:se[t] {option}={value} or
:se[t] {option}:{value}
Set string or number option to {value}.
For numeric options the value can be given in decimal, hex (preceded with 0x) or octal (preceded with '0'). The old value can be inserted by typing 'wildchar' (by default this is a <Tab> or CTRL-E if 'compatible' is set). See cmdline-completion .
White space between {option} and '=' is allowed and will be ignored. White space between '=' and {value} is not allowed.
See option-backslash for using white space and backslashes in {value}.

:se[t] {option}+={value} :set+=
Add the {value} to a number option, or append the {value} to a string option. When the option is a comma separated list, a comma is added, unless the value was empty.
If the option is a list of flags, superfluous flags are removed. When adding a flag that was already present the option value doesn't change.
Also see :set-args above.
{not in Vi}

:se[t] {option}^={value} :set^=
Multiply the {value} to a number option, or prepend the {value} to a string option. When the option is a comma separated list, a comma is added, unless the value was empty.
Also see :set-args above.
{not in Vi}

:se[t] {option}-={value} :set-=
Subtract the {value} from a number option, or remove the {value} from a string option, if it is there.
If the {value} is not found in a string option, there is no error or warning. When the option is a comma separated list, a comma is deleted, unless the option becomes empty.
When the option is a list of flags, {value} must be

exactly as they appear in the option. Remove flags
one by one to avoid problems.
Also see :set-args above.
{not in Vi}

The {option} arguments to ":set" may be repeated. For example:
	:set ai nosi sw=3 ts=3
If you make an error in one of the arguments, an error message will be given
and the following arguments will be ignored.

:set-verbose
When 'verbose' is non-zero, displaying an option value will also tell where it
was last set. Example:
	:verbose set shiftwidth cindent?
	 shiftwidth=4
		Last set from modeline
	  cindent
		Last set from /usr/local/share/vim/vim60/ftplugin/c.vim
This is only done when specific option values are requested, not for ":verbose
set all" or ":verbose set" without an argument.
When the option was set by hand there is no "Last set" message.
When the option was set while executing a function, user command or
autocommand, the script in which it was defined is reported.
Note that an option may also have been set as a side effect of setting
'compatible'.
A few special texts:
	Last set from modeline
		Option was set in a modeline .
	Last set from --cmd argument
		Option was set with command line argument --cmd or +.
	Last set from -c argument
		Option was set with command line argument -c , +, -S or
		 -q .
	Last set from environment variable
		Option was set from an environment variable, $VIMINIT,
		$GVIMINIT or $EXINIT.
	Last set from error handler
		Option was cleared when evaluating it resulted in an error.

{not available when compiled without the |+eval| feature}

:set-termcap E522
For {option} the form "t_xx" may be used to set a terminal option. This will
override the value from the termcap. You can then use it in a mapping. If
the "xx" part contains special characters, use the <t_xx> form:
	:set <t_#4>=^[Ot
This can also be used to translate a special code for a normal key. For
example, if Alt-b produces <Esc>b, use this:
	:set <M-b>=^[b
(the ^[is a real <Esc> here, use CTRL-V <Esc> to enter it)
The advantage over a mapping is that it works in all situations.

You can define any key codes, e.g.:
	:set t_xy=^[foo;

There is no warning for using a name that isn't recognized. You can map these codes as you like:
```
:map <t_xy> something
```
E846
When a key code is not set, it's like it does not exist. Trying to get its value will result in an error:
```
:set t_kb=
:set t_kb
E846: Key code not set: t_kb
```

The t_xx options cannot be set from a modeline or in the sandbox, for security reasons.

The listing from ":set" looks different from Vi. Long string options are put at the end of the list. The number of options is quite large. The output of "set all" probably does not fit on the screen, causing Vim to give the more-prompt.

option-backslash
To include white space in a string option value it has to be preceded with a backslash. To include a backslash you have to use two. Effectively this means that the number of backslashes in an option value is halved (rounded down).
A few examples:
```
:set tags=tags\ /usr/tags        results in "tags /usr/tags"
:set tags=tags\\,file            results in "tags\,file"
:set tags=tags\\\ file           results in "tags\ file"
```

The "|" character separates a ":set" command from a following command. To include the "|" in the option value, use "\|" instead. This example sets the 'titlestring' option to "hi|there":
```
:set titlestring=hi\|there
```
This sets the 'titlestring' option to "hi" and 'iconstring' to "there":
```
:set titlestring=hi|set iconstring=there
```

Similarly, the double quote character starts a comment. To include the '"' in the option value, use '\"' instead. This example sets the 'titlestring' option to 'hi "there"':
```
:set titlestring=hi\ \"there\"
```

For MS-DOS and WIN32 backslashes in file names are mostly not removed. More precise: For options that expect a file name (those where environment variables are expanded) a backslash before a normal file name character is not removed. But a backslash before a special character (space, backslash, comma, etc.) is used like explained above.
There is one special situation, when the value starts with "\\":
```
:set dir=\\machine\path          results in "\\machine\path"
:set dir=\\\\machine\\path       results in "\\machine\path"
:set dir=\\path\\file            results in "\\path\file" (wrong!)
```
For the first one the start is kept, but for the second one the backslashes are halved. This makes sure it works both when you expect backslashes to be halved and when you expect the backslashes to be kept. The third gives a result which is probably not what you want. Avoid it.

add-option-flags remove-option-flags
E539 E550 E551 E552

Some options are a list of flags. When you want to add a flag to such an option, without changing the existing ones, you can do it like this:

```
:set guioptions+=a
```

Remove a flag from an option like this:

```
:set guioptions-=a
```

This removes the 'a' flag from 'guioptions'.
Note that you should add or remove one flag at a time. If 'guioptions' has the value "ab", using "set guioptions-=ba" won't work, because the string "ba" doesn't appear.

:set_env expand-env expand-environment-var

Environment variables in specific string options will be expanded. If the environment variable exists the '$' and the following environment variable name is replaced with its value. If it does not exist the '$' and the name are not modified. Any non-id character (not a letter, digit or '_') may follow the environment variable name. That character and what follows is appended to the value of the environment variable. Examples:

```
:set term=$TERM.new
:set path=/usr/$INCLUDE,$HOME/include,.
```

When adding or removing a string from an option with ":set opt-=val" or ":set opt+=val" the expansion is done before the adding or removing.

Handling of local options local-options

Some of the options only apply to a window or buffer. Each window or buffer has its own copy of this option, thus each can have its own value. This allows you to set 'list' in one window but not in another. And set 'shiftwidth' to 3 in one buffer and 4 in another.

The following explains what happens to these local options in specific situations. You don't really need to know all of this, since Vim mostly uses the option values you would expect. Unfortunately, doing what the user expects is a bit complicated...

When splitting a window, the local options are copied to the new window. Thus right after the split the contents of the two windows look the same.

When editing a new buffer, its local option values must be initialized. Since the local options of the current buffer might be specifically for that buffer, these are not used. Instead, for each buffer-local option there also is a global value, which is used for new buffers. With ":set" both the local and global value is changed. With "setlocal" only the local value is changed, thus this value is not used when editing a new buffer.

When editing a buffer that has been edited before, the options from the window that was last closed are used again. If this buffer has been edited in this window, the values from back then are used. Otherwise the values from the last closed window where the buffer was edited last are used.

It's possible to set a local window option specifically for a type of buffer. When you edit another buffer in the same window, you don't want to keep

using these local window options. Therefore Vim keeps a global value of the local window options, which is used when editing another buffer. Each window has its own copy of these values. Thus these are local to the window, but global to all buffers in the window. With this you can do:

```
:e one
:set list
:e two
```

Now the 'list' option will also be set in "two", since with the ":set list" command you have also set the global value.

```
:set nolist
:e one
:setlocal list
:e two
```

Now the 'list' option is not set, because ":set nolist" resets the global value, ":setlocal list" only changes the local value and ":e two" gets the global value. Note that if you do this next:

```
:e one
```

You will get back the 'list' value as it was the last time you edited "one". The options local to a window are remembered for each buffer. This also happens when the buffer is not loaded, but they are lost when the buffer is wiped out :bwipe .

:setl :setlocal

:setl[ocal] ... Like ":set" but set only the value local to the current buffer or window. Not all options have a local value. If the option does not have a local value the global value is set.
With the "all" argument: display local values for all local options.
Without argument: Display local values for all local options which are different from the default.
When displaying a specific local option, show the local value. For a global/local boolean option, when the global value is being used, "--" is displayed before the option name.
For a global option the global value is shown (but that might change in the future).
{not in Vi}

:setl[ocal] {option}< Set the local value of {option} to its global value by copying the value.
{not in Vi}

:se[t] {option}< For global-local options: Remove the local value of {option}, so that the global value will be used.
{not in Vi}

:setg :setglobal

:setg[lobal] ... Like ":set" but set only the global value for a local option without changing the local value.
When displaying an option, the global value is shown.
With the "all" argument: display global values for all local options.
Without argument: display global values for all local

options which are different from the default.
{not in Vi}

For buffer-local and window-local options:

Command	global value	local value
:set option=value	set	set
:setlocal option=value	-	set
:setglobal option=value	set	-
:set option?	-	display
:setlocal option?	-	display
:setglobal option?	display	-

Global options with a local value global-local

Options are global when you mostly use one value for all buffers and windows.
For some global options it's useful to sometimes have a different local value.
You can set the local value with ":setlocal". That buffer or window will then
use the local value, while other buffers and windows continue using the global
value.

For example, you have two windows, both on C source code. They use the global
'makeprg' option. If you do this in one of the two windows:
:set makeprg=gmake
then the other window will switch to the same value. There is no need to set
the 'makeprg' option in the other C source window too.
However, if you start editing a Perl file in a new window, you want to use
another 'makeprg' for it, without changing the value used for the C source
files. You use this command:
:setlocal makeprg=perlmake
You can switch back to using the global value by making the local value empty:
:setlocal makeprg=
This only works for a string option. For a boolean option you need to use the
"<" flag, like this:
:setlocal autoread<
Note that for non-boolean options using "<" copies the global value to the
local value, it doesn't switch back to using the global value (that matters
when the global value changes later). You can also use:
:set path<
This will make the local value of 'path' empty, so that the global value is
used. Thus it does the same as:
:setlocal path=
Note: In the future more global options can be made global-local. Using
":setlocal" on a global option might work differently then.

Setting the filetype

:setf[iletype] [FALLBACK] {filetype} :setf :setfiletype
Set the 'filetype' option to {filetype}, but only if
not done yet in a sequence of (nested) autocommands.
This is short for:
```
:if !did_filetype()
:  setlocal filetype={filetype}
```

```
                        :endif
                    This command is used in a filetype.vim file to avoid
                     setting the 'filetype' option twice, causing different
                     settings and syntax files to be loaded.

                     When the optional FALLBACK argument is present, a
                     later :setfiletype command will override the
                     'filetype'.  This is to used for filetype detections
                     that are just a guess.   did_filetype()  will return
                     false after this command.

                     {not in Vi}

                              option-window   optwin
:bro[wse] se[t]               :set-browse   :browse-set   :opt   :options
:opt[ions]           Open a window for viewing and setting all options.
                     Options are grouped by function.
                     Offers short help for each option.  Hit <CR> on the
                     short help to open a help window with more help for
                     the option.
                     Modify the value of the option and hit <CR> on the
                     "set" line to set the new value.  For window and
                     buffer specific options, the last accessed window is
                     used to set the option value in, unless this is a help
                     window, in which case the window below help window is
                     used (skipping the option-window).
                     {not available when compiled without the  +eval
                     feature}

                                                                  $HOME
Using "~" is like using "$HOME", but it is only recognized at the start of an
option and after a space or comma.

On Unix systems "~user" can be used too.  It is replaced by the home directory
of user "user".  Example:
    :set path=~mool/include,/usr/include,.

On Unix systems the form "${HOME}" can be used too.  The name between {} can
contain non-id characters then.  Note that if you want to use this for the
"gf" command, you need to add the '{' and '}' characters to 'isfname'.

NOTE: expanding environment variables and "~/" is only done with the ":set"
command, not when assigning a value to an option with ":let".

                                                        $HOME-windows
On MS-Windows, if $HOME is not defined as an environment variable, then
at runtime Vim will set it to the expansion of $HOMEDRIVE$HOMEPATH.
If $HOMEDRIVE is not set then $USERPROFILE is used.

This expanded value is not exported to the environment, this matters when
running an external command:
        :echo system('set | findstr ^HOME=')
and
        :echo luaeval('os.getenv("HOME")')
```

should echo nothing (an empty string) despite exists('$HOME') being true.
When setting $HOME to a non-empty string it will be exported to the
subprocesses.

Note the maximum length of an expanded option is limited. How much depends on
the system, mostly it is something like 256 or 1024 characters.

:fix[del] :fix :fixdel

:fix[del] Set the value of 't_kD':

't_kb' is	't_kD' becomes
CTRL-?	CTRL-H
not CTRL-?	CTRL-?

(CTRL-? is 0177 octal, 0x7f hex) {not in Vi}

If your delete key terminal code is wrong, but the code for backspace is alright, you can put this in your .vimrc:

```
:fixdel
```

This works no matter what the actual code for backspace is.

If the backspace key terminal code is wrong you can use this:

```
:if &term == "termname"
:  set t_kb=^V<BS>
:  fixdel
:endif
```

Where "^V" is CTRL-V and "<BS>" is the backspace key (don't type four characters!). Replace "termname" with your terminal name.

If your <Delete> key sends a strange key sequence (not CTRL-? or CTRL-H) you cannot use ":fixdel". Then use:

```
:if &term == "termname"
:  set t_kD=^V<Delete>
:endif
```

Where "^V" is CTRL-V and "<Delete>" is the delete key (don't type eight characters!). Replace "termname" with your terminal name.

Linux-backspace

Note about Linux: By default the backspace key produces CTRL-?, which is wrong. You can fix it by putting this line in your rc.local:

```
echo "keycode 14 = BackSpace" | loadkeys
```

NetBSD-backspace

Note about NetBSD: If your backspace doesn't produce the right code, try this:

```
xmodmap -e "keycode 22 = BackSpace"
```

If this works, add this in your .Xmodmap file:

```
keysym 22 = BackSpace
```

You need to restart for this to take effect.

==
2. Automatically setting options   auto-setting

Besides changing options with the ":set" command, there are three alternatives
to set options automatically for one or more files:

1. When starting Vim initializations are read from various places. See
    initialization . Most of them are performed for all editing sessions,
   and some of them depend on the directory where Vim is started.
   You can create an initialization file with :mkvimrc , :mkview and
    :mksession .
2. If you start editing a new file, the automatic commands are executed.
   This can be used to set options for files matching a particular pattern and
   many other things. See autocommand .
3. If you start editing a new file, and the 'modeline' option is on, a
   number of lines at the beginning and end of the file are checked for
   modelines. This is explained here.

                                        modeline   vim: vi: ex: E520
There are two forms of modelines. The first form:
        [text]{white}{vi:|vim:|ex:}[white]{options}

[text]   any text or empty
{white}   at least one blank character (<Space> or <Tab>)
{vi:|vim:|ex:}   the string "vi:", "vim:" or "ex:"
[white]   optional white space
{options}   a list of option settings, separated with white space
                        or ':', where each part between ':' is the argument
                        for a ":set" command (can be empty)

Examples:
   vi:noai:sw=3 ts=6
   vim: tw=77

The second form (this is compatible with some versions of Vi):

        [text]{white}{vi:|vim:|Vim:|ex:}[white]se[t] {options}:[text]

[text]   any text or empty
{white}   at least one blank character (<Space> or <Tab>)
{vi:|vim:|Vim:|ex:}   the string "vi:", "vim:", "Vim:" or "ex:"
[white]   optional white space
se[t]   the string "set " or "se " (note the space); When
                        "Vim" is used it must be "set".
{options}   a list of options, separated with white space, which
                        is the argument for a ":set" command
:   a colon
[text]   any text or empty

Examples:
   /* vim: set ai tw=75: */
   /* Vim: set ai tw=75: */

The white space before {vi:|vim:|Vim:|ex:} is required. This minimizes the chance that a normal word like "lex:" is caught. There is one exception: "vi:" and "vim:" can also be at the start of the line (for compatibility with version 3.0). Using "ex:" at the start of the line will be ignored (this could be short for "example:").

modeline-local

The options are set like with ":setlocal": The new value only applies to the buffer and window that contain the file. Although it's possible to set global options from a modeline, this is unusual. If you have two windows open and the files in it set the same global option to a different value, the result depends on which one was opened last.

When editing a file that was already loaded, only the window-local options from the modeline are used. Thus if you manually changed a buffer-local option after opening the file, it won't be changed if you edit the same buffer in another window. But window-local options will be set.

modeline-version

If the modeline is only to be used for some versions of Vim, the version number can be specified where "vim:" or "Vim:" is used:
```
        vim{vers}:      version {vers} or later
        vim<{vers}:     version before {vers}
        vim={vers}:     version {vers}
        vim>{vers}:     version after {vers}
```
{vers} is 700 for Vim 7.0 (hundred times the major version plus minor).
For example, to use a modeline only for Vim 7.0:
```
        /* vim700: set foldmethod=marker */
```
To use a modeline for Vim after version 7.2:
```
        /* vim>702: set cole=2: */
```
There can be no blanks between "vim" and the ":".

The number of lines that are checked can be set with the 'modelines' option.
If 'modeline' is off or 'modelines' is 0 no lines are checked.

Note that for the first form all of the rest of the line is used, thus a line like:
```
   /* vi:ts=4: */
```
will give an error message for the trailing "*/". This line is OK:
```
   /* vi:set ts=4: */
```

If an error is detected the rest of the line is skipped.

If you want to include a ':' in a set command precede it with a '\'. The backslash in front of the ':' will be removed. Example:
```
   /* vi:set dir=c\:\tmp: */
```
This sets the 'dir' option to "c:\tmp". Only a single backslash before the ':' is removed. Thus to include "\:" you have to specify "\\:".

No other commands than "set" are supported, for security reasons (somebody might create a Trojan horse text file with modelines). And not all options can be set. For some options a flag is set, so that when it's used the

sandbox is effective. Still, there is always a small risk that a modeline causes trouble. E.g., when some joker sets 'textwidth' to 5 all your lines are wrapped unexpectedly. So disable modelines before editing untrusted text. The mail ftplugin does this, for example.

Hint: If you would like to do something else than setting an option, you could define an autocommand that checks the file for a specific string. For example:

```
au BufReadPost * if getline(1) =~ "VAR" | call SetVar() | endif
```

And define a function SetVar() that does something with the line containing "VAR".

==

3. Options summary option-summary

In the list below all the options are mentioned with their full name and with an abbreviation if there is one. Both forms may be used.

In this document when a boolean option is "set" that means that ":set option" is entered. When an option is "reset", ":set nooption" is used.

For some options there are two default values: The "Vim default", which is used when 'compatible' is not set, and the "Vi default", which is used when 'compatible' is set.

Most options are the same in all windows and buffers. There are a few that are specific to how the text is presented in a window. These can be set to a different value in each window. For example the 'list' option can be set in one window and reset in another for the same text, giving both types of view at the same time. There are a few options that are specific to a certain file. These can have a different value for each file or buffer. For example the 'textwidth' option can be 78 for a normal text file and 0 for a C program.

global	one option for all buffers and windows
local to window	each window has its own copy of this option
local to buffer	each buffer has its own copy of this option

When creating a new window the option values from the currently active window are used as a default value for the window-specific options. For the buffer-specific options this depends on the 's' and 'S' flags in the 'cpoptions' option. If 's' is included (which is the default) the values for buffer options are copied from the currently active buffer when a buffer is first entered. If 'S' is present the options are copied each time the buffer is entered, this is almost like having global options. If 's' and 'S' are not present, the options are copied from the currently active buffer when the buffer is created.

Hidden options hidden-options

Not all options are supported in all versions. This depends on the supported features and sometimes on the system. A remark about this is in curly braces below. When an option is not supported it may still be set without getting an error, this is called a hidden option. You can't get the value of a hidden

option though, it is not stored.

To test if option "foo" can be used with ":set" use something like this:
	if exists('&foo')
This also returns true for a hidden option. To test if option "foo" is really supported use something like this:
	if exists('+foo')

E355
A jump table for the options with a short description can be found at Q_op .

'aleph' 'al' aleph Aleph
'aleph' 'al'		number (default 128 for MS-DOS, 224 otherwise)
			global
			{not in Vi}
			{only available when compiled with the +rightleft
			feature}
	The ASCII code for the first letter of the Hebrew alphabet. The routine that maps the keyboard in Hebrew mode, both in Insert mode (when hkmap is set) and on the command-line (when hitting CTRL-_) outputs the Hebrew characters in the range [aleph..aleph+26]. aleph=128 applies to PC code, and aleph=224 applies to ISO 8859-8. See rileft.txt .

'allowrevins' 'ari' 'noallowrevins' 'noari'
'allowrevins' 'ari'	boolean (default off)
			global
			{not in Vi}
			{only available when compiled with the +rightleft
			feature}
	Allow CTRL-_ in Insert and Command-line mode. This is default off, to avoid that users that accidentally type CTRL-_ instead of SHIFT-_ get into reverse Insert mode, and don't know how to get out. See 'revins'.
	NOTE: This option is reset when 'compatible' is set.

'altkeymap' 'akm' 'noaltkeymap' 'noakm'
'altkeymap' 'akm'	boolean (default off)
			global
			{not in Vi}
			{only available when compiled with the +farsi
			feature}
	When on, the second language is Farsi. In editing mode CTRL-_ toggles the keyboard map between Farsi and English, when 'allowrevins' set.

	When off, the keyboard map toggles between Hebrew and English. This is useful to start the Vim in native mode i.e. English (left-to-right mode) and have default second language Farsi or Hebrew (right-to-left mode). See farsi.txt .

'ambiwidth' 'ambw'
'ambiwidth' 'ambw'	string (default: "single")
			global
			{not in Vi}

{only available when compiled with the +multi_byte feature}
Only effective when 'encoding' is "utf-8" or another Unicode encoding. Tells Vim what to do with characters with East Asian Width Class Ambiguous (such as Euro, Registered Sign, Copyright Sign, Greek letters, Cyrillic letters).

There are currently two possible values:
"single": Use the same width as characters in US-ASCII. This is expected by most users.
"double": Use twice the width of ASCII characters.
E834 E835
The value "double" cannot be used if 'listchars' or 'fillchars' contains a character that would be double width.

There are a number of CJK fonts for which the width of glyphs for those characters are solely based on how many octets they take in legacy/traditional CJK encodings. In those encodings, Euro, Registered sign, Greek/Cyrillic letters are represented by two octets, therefore those fonts have "wide" glyphs for them. This is also true of some line drawing characters used to make tables in text file. Therefore, when a CJK font is used for GUI Vim or Vim is running inside a terminal (emulators) that uses a CJK font (or Vim is run inside an xterm invoked with "-cjkwidth" option.), this option should be set to "double" to match the width perceived by Vim with the width of glyphs in the font. Perhaps it also has to be set to "double" under CJK Windows 9x/ME or Windows 2k/XP when the system locale is set to one of CJK locales. See Unicode Standard Annex #11 (http://www.unicode.org/reports/tr11).

Vim may set this option automatically at startup time when Vim is compiled with the +termresponse feature and if t_u7 is set to the escape sequence to request cursor position report. The response can be found in v:termu7resp .

'antialias' 'anti' 'noantialias' 'noanti'
'antialias' 'anti' boolean (default: off)
global
{not in Vi}
{only available when compiled with GUI enabled on Mac OS X}
This option only has an effect in the GUI version of Vim on Mac OS X v10.2 or later. When on, Vim will use smooth ("antialiased") fonts, which can be easier to read at certain sizes on certain displays. Setting this option can sometimes cause problems if 'guifont' is set to its default (empty string).
NOTE: This option is reset when 'compatible' is set.

'autochdir' 'acd' 'noautochdir' 'noacd'
'autochdir' 'acd' boolean (default off)
global
{not in Vi}
{only available when compiled with it, use exists("+autochdir") to check}

When on, Vim will change the current working directory whenever you
open a file, switch buffers, delete a buffer or open/close a window.
It will change to the directory containing the file which was opened
or selected.
Note: When this option is on some plugins may not work.

                                'arabic'   'arab'   'noarabic'   'noarab'
'arabic' 'arab'   boolean (default off)
                        local to window
                        {not in Vi}
                        {only available when compiled with the +arabic
                        feature}
This option can be set to start editing Arabic text.
Setting this option will:
- Set the 'rightleft' option, unless 'termbidi' is set.
- Set the 'arabicshape' option, unless 'termbidi' is set.
- Set the 'keymap' option to "arabic"; in Insert mode CTRL-^ toggles
  between typing English and Arabic key mapping.
- Set the 'delcombine' option
Note that 'encoding' must be "utf-8" for working with Arabic text.

Resetting this option will:
- Reset the 'rightleft' option.
- Disable the use of 'keymap' (without changing its value).
Note that 'arabicshape' and 'delcombine' are not reset (it is a global
option).
NOTE: This option is reset when 'compatible' is set.
Also see arabic.txt .

                                        'arabicshape'   'arshape'
                                        'noarabicshape'   'noarshape'
'arabicshape' 'arshape' boolean (default on)
                        global
                        {not in Vi}
                        {only available when compiled with the +arabic
                        feature}
When on and 'termbidi' is off, the required visual character
corrections that need to take place for displaying the Arabic language
take effect. Shaping, in essence, gets enabled; the term is a broad
one which encompasses:
  a) the changing/morphing of characters based on their location
     within a word (initial, medial, final and stand-alone).
  b) the enabling of the ability to compose characters
  c) the enabling of the required combining of some characters
When disabled the display shows each character's true stand-alone
form.
Arabic is a complex language which requires other settings, for
further details see arabic.txt .
NOTE: This option is set when 'compatible' is set.

                         'autoindent'   'ai'   'noautoindent'   'noai'
'autoindent' 'ai'   boolean (default off)
                        local to buffer
Copy indent from current line when starting a new line (typing <CR>

in Insert mode or when using the "o" or "O" command). If you do not type anything on the new line except <BS> or CTRL-D and then type <Esc>, CTRL-O or <CR>, the indent is deleted again. Moving the cursor to another line has the same effect, unless the 'I' flag is included in 'cpoptions'.
When autoindent is on, formatting (with the "gq" command or when you reach 'textwidth' in Insert mode) uses the indentation of the first line.
When 'smartindent' or 'cindent' is on the indent is changed in a different way.
The 'autoindent' option is reset when the 'paste' option is set and restored when 'paste' is reset.
{small difference from Vi: After the indent is deleted when typing <Esc> or <CR>, the cursor position when moving up or down is after the deleted indent; Vi puts the cursor somewhere in the deleted indent}.

'autoread' 'ar' 'noautoread' 'noar'
'autoread' 'ar' boolean (default off)
global or local to buffer global-local
{not in Vi}
When a file has been detected to have been changed outside of Vim and it has not been changed inside of Vim, automatically read it again. When the file has been deleted this is not done, so you have the text from before it was deleted. When it appears again then it is read. timestamp
If this option has a local value, use this command to switch back to using the global value:
:set autoread<

'autowrite' 'aw' 'noautowrite' 'noaw'
'autowrite' 'aw' boolean (default off)
global
Write the contents of the file, if it has been modified, on each :next, :rewind, :last, :first, :previous, :stop, :suspend, :tag, :!, :make, CTRL-] and CTRL-^ command; and when a :buffer, CTRL-O, CTRL-I, '{A-Z0-9}, or `{A-Z0-9} command takes one to another file.
Note that for some commands the 'autowrite' option is not used, see 'autowriteall' for that.

'autowriteall' 'awa' 'noautowriteall' 'noawa'
'autowriteall' 'awa' boolean (default off)
global
{not in Vi}
Like 'autowrite', but also used for commands ":edit", ":enew", ":quit", ":qall", ":exit", ":xit", ":recover" and closing the Vim window.
Setting this option also implies that Vim behaves like 'autowrite' has been set.

'background' 'bg'
'background' 'bg' string (default "dark" or "light", see below)
global
{not in Vi}
When set to "dark", Vim will try to use colors that look good on a dark background. When set to "light", Vim will try to use colors that

look good on a light background. Any other value is illegal.
Vim tries to set the default value according to the terminal used.
This will not always be correct.
Setting this option does not change the background color, it tells Vim
what the background color looks like. For changing the background
color, see :hi-normal .

When 'background' is set Vim will adjust the default color groups for
the new value. But the colors used for syntax highlighting will not
change.   g:colors_name
When a color scheme is loaded (the "g:colors_name" variable is set)
setting 'background' will cause the color scheme to be reloaded. If
the color scheme adjusts to the value of 'background' this will work.
However, if the color scheme sets 'background' itself the effect may
be undone. First delete the "g:colors_name" variable when needed.

When setting 'background' to the default value with:
        :set background&
Vim will guess the value. In the GUI this should work correctly,
in other cases Vim might not be able to guess the right value.

When the t_RB option is set, Vim will use it to request the background
color from the terminal. If the returned RGB value is dark/light and
'background' is not dark/light, 'background' will be set and the
screen is redrawn. This may have side effects, make t_BG empty in
your .vimrc if you suspect this problem. The response to t_RB can
be found in v:termrbgresp .

When starting the GUI, the default value for 'background' will be
"light". When the value is not set in the .gvimrc, and Vim detects
that the background is actually quite dark, 'background' is set to
"dark". But this happens only AFTER the .gvimrc file has been read
(because the window needs to be opened to find the actual background
color). To get around this, force the GUI window to be opened by
putting a ":gui" command in the .gvimrc file, before where the value
of 'background' is used (e.g., before ":syntax on").

For MS-DOS, Windows and OS/2 the default is "dark".
For other systems "dark" is used when 'term' is "linux",
"screen.linux", "cygwin" or "putty", or $COLORFGBG suggests a dark
background. Otherwise the default is "light".

The :terminal command and the term_start() function use the
'background' value to decide whether the terminal window will start
with a white or black background.

Normally this option would be set in the .vimrc file. Possibly
depending on the terminal name. Example:
        :if &term == "pcterm"
        : set background=dark
        :endif
When this option is set, the default settings for the highlight groups
will change. To use other settings, place ":highlight" commands AFTER
the setting of the 'background' option.

This option is also used in the "$VIMRUNTIME/syntax/syntax.vim" file to select the colors for syntax highlighting. After changing this option, you must load syntax.vim again to see the result. This can be done with ":syntax on".

'backspace' 'bs'

'backspace' 'bs' string (default "", set to "indent,eol,start" in defaults.vim)
global
{not in Vi}

Influences the working of <BS>, <Del>, CTRL-W and CTRL-U in Insert mode. This is a list of items, separated by commas. Each item allows a way to backspace over something:

value	effect
indent	allow backspacing over autoindent
eol	allow backspacing over line breaks (join lines)
start	allow backspacing over the start of insert; CTRL-W and CTRL-U stop once at the start of insert.

When the value is empty, Vi compatible backspacing is used.

For backwards compatibility with version 5.4 and earlier:

value	effect
0	same as ":set backspace=" (Vi compatible)
1	same as ":set backspace=indent,eol"
2	same as ":set backspace=indent,eol,start"

See :fixdel if your <BS> or <Del> key does not do what you want.
NOTE: This option is set to "" when 'compatible' is set.

'backup' 'bk' 'nobackup' 'nobk'

'backup' 'bk' boolean (default off)
global
{not in Vi}

Make a backup before overwriting a file. Leave it around after the file has been successfully written. If you do not want to keep the backup file, but you do want a backup while the file is being written, reset this option and set the 'writebackup' option (this is the default). If you do not want a backup file at all reset both options (use this if your file system is almost full). See the backup-table for more explanations.
When the 'backupskip' pattern matches, a backup is not made anyway.
When 'patchmode' is set, the backup may be renamed to become the oldest version of a file.
NOTE: This option is reset when 'compatible' is set.

'backupcopy' 'bkc'

'backupcopy' 'bkc' string (Vi default for Unix: "yes", otherwise: "auto")
global or local to buffer global-local
{not in Vi}

When writing a file and a backup is made, this option tells how it's done. This is a comma separated list of words.

The main values are:

"yes"   make a copy of the file and overwrite the original one
"no"   rename the file and write a new one
"auto" one of the previous, what works best

Extra values that can be combined with the ones above are:
"breaksymlink" always break symlinks when writing
"breakhardlink" always break hardlinks when writing

Making a copy and overwriting the original file:
- Takes extra time to copy the file.
+ When the file has special attributes, is a (hard/symbolic) link or
  has a resource fork, all this is preserved.
- When the file is a link the backup will have the name of the link,
  not of the real file.

Renaming the file and writing a new one:
+ It's fast.
- Sometimes not all attributes of the file can be copied to the new
  file.
- When the file is a link the new file will not be a link.

The "auto" value is the middle way: When Vim sees that renaming file
is possible without side effects (the attributes can be passed on and
the file is not a link) that is used. When problems are expected, a
copy will be made.

The "breaksymlink" and "breakhardlink" values can be used in
combination with any of "yes", "no" and "auto". When included, they
force Vim to always break either symbolic or hard links by doing
exactly what the "no" option does, renaming the original file to
become the backup and writing a new file in its place. This can be
useful for example in source trees where all the files are symbolic or
hard links and any changes should stay in the local source tree, not
be propagated back to the original source.
                                                        crontab
One situation where "no" and "auto" will cause problems: A program
that opens a file, invokes Vim to edit that file, and then tests if
the open file was changed (through the file descriptor) will check the
backup file instead of the newly created file. "crontab -e" is an
example.

When a copy is made, the original file is truncated and then filled
with the new text. This means that protection bits, owner and
symbolic links of the original file are unmodified. The backup file
however, is a new file, owned by the user who edited the file. The
group of the backup is set to the group of the original file. If this
fails, the protection bits for the group are made the same as for
others.

When the file is renamed this is the other way around: The backup has
the same attributes of the original file, and the newly written file
is owned by the current user. When the file was a (hard/symbolic)
link, the new file will not! That's why the "auto" value doesn't
rename when the file is a link. The owner and group of the newly

written file will be set to the same ones as the original file, but the system may refuse to do this. In that case the "auto" value will again not rename the file.

NOTE: This option is set to the Vi default value when 'compatible' is set and to the Vim default value when 'compatible' is reset.

'backupdir' 'bdir' string (default for Amiga: ".,t:",
for MS-DOS and Win32: ".,$TEMP,c:/tmp,c:/temp"
for Unix: ".,~/tmp,~/")
global
{not in Vi}

List of directories for the backup file, separated with commas.
- The backup file will be created in the first directory in the list where this is possible. The directory must exist, Vim will not create it for you.
- Empty means that no backup file will be created ('patchmode' is impossible!). Writing may fail because of this.
- A directory "." means to put the backup file in the same directory as the edited file.
- A directory starting with "./" (or ".\" for MS-DOS et al.) means to put the backup file relative to where the edited file is. The leading "." is replaced with the path name of the edited file. ("." inside a directory name has no special meaning).
- Spaces after the comma are ignored, other spaces are considered part of the directory name. To have a space at the start of a directory name, precede it with a backslash.
- To include a comma in a directory name precede it with a backslash.
- A directory name may end in an '/'.
- For Unix and Win32, if a directory ends in two path separators "//", the swap file name will be built from the complete path to the file with all path separators changed to percent '%' signs. This will ensure file name uniqueness in the backup directory.
On Win32, it is also possible to end with "\\". However, When a separating comma is following, you must use "//", since "\\" will include the comma in the file name. Therefore it is recommended to use '//', instead of '\\'.
- Environment variables are expanded :set_env .
- Careful with '\' characters, type one before a space, type two to get one in the option (see option-backslash), for example:
:set bdir=c:\\tmp,\ dir\\,with\\,commas,\\\ dir\ with\ spaces
- For backwards compatibility with Vim version 3.0 a '>' at the start of the option is removed.

See also 'backup' and 'writebackup' options.
If you want to hide your backup files on Unix, consider this value:
:set backupdir=./.backup,~/.backup,.,/tmp
You must create a ".backup" directory in each directory and in your home directory for this to work properly.
The use of :set+= and :set-= is preferred when adding or removing directories from the list. This avoids problems when a future version uses another default.
This option cannot be set from a modeline or in the sandbox , for security reasons.

'backupext' 'bex' E589
'backupext' 'bex'	string (default "~", for VMS: "_")
			global
			{not in Vi}
	String which is appended to a file name to make the name of the
	backup file. The default is quite unusual, because this avoids
	accidentally overwriting existing files with a backup file. You might
	prefer using ".bak", but make sure that you don't have files with
	".bak" that you want to keep.
	Only normal file name characters can be used, "/*?[|<>" are illegal.

	If you like to keep a lot of backups, you could use a BufWritePre
	autocommand to change 'backupext' just before writing the file to
	include a timestamp.
		:au BufWritePre * let &bex = '-' . strftime("%Y%b%d%X") . '~'
      Use 'backupdir' to put the backup in a different directory.

'backupskip' 'bsk'
'backupskip' 'bsk'	string (default: "$TMPDIR/*,$TMP/*,$TEMP/*"
			 Unix: "/tmp/*,$TMPDIR/*,$TMP/*,$TEMP/*"
			 Mac: "/private/tmp/*,$TMPDIR/*,$TMP/*,$TEMP/*")
			global
			{not in Vi}
			{not available when compiled without the +wildignore
			feature}
	A list of file patterns. When one of the patterns matches with the
	name of the file which is written, no backup file is created. Both
	the specified file name and the full path name of the file are used.
	The pattern is used like with :autocmd , see autocmd-patterns .
	Watch out for special characters, see option-backslash .
	When $TMPDIR, $TMP or $TEMP is not defined, it is not used for the
	default value. "/tmp/*" is only used for Unix.

	WARNING: Not having a backup file means that when Vim fails to write
	your buffer correctly and then, for whatever reason, Vim exits, you
	lose both the original file and what you were writing. Only disable
	backups if you don't care about losing the file.

	Note that environment variables are not expanded. If you want to use
	$HOME you must expand it explicitly, e.g.:
		:let &backupskip = escape(expand('$HOME'), '\') . '/tmp/*'

      Note that the default also makes sure that "crontab -e" works (when a
	backup would be made by renaming the original file crontab won't see
	the newly created file). Also see 'backupcopy' and crontab .

'balloondelay' 'bdlay'
'balloondelay' 'bdlay'	number (default: 600)
			global
			{not in Vi}
			{only available when compiled with the +balloon_eval
			feature}
	Delay in milliseconds before a balloon may pop up. See balloon-eval .

```
                        'balooneval'   'beval'   'noballooneval'   'nobeval'
'balooneval' 'beval'    boolean (default off)
                        global
                        {not in Vi}
                        {only available when compiled with the  +balloon_eval
                        feature}
        Switch on the  balloon-eval  functionality for the GUI.

                        'balloonevalterm'   'bevalterm'   'noballoonevalterm'
                        'nobevalterm'
'balloonevalterm' 'bevalterm'   boolean (default off)
                        global
                        {not in Vi}
                        {only available when compiled with the
                         +balloon_eval_term  feature}
        Switch on the  balloon-eval  functionality for the terminal.

                                                        'balloonexpr'   'bexpr'
'balloonexpr' 'bexpr'   string  (default "")
                        global or local to buffer  global-local
                        {not in Vi}
                        {only available when compiled with the  +balloon_eval
                        feature}
        Expression for text to show in evaluation balloon.  It is only used
        when 'balooneval' is on.  These variables can be used:

        v:beval_bufnr   number of the buffer in which balloon is going to show
        v:beval_winnr   number of the window
        v:beval_winid   ID of the window
        v:beval_lnum    line number
        v:beval_col     column number (byte index)
        v:beval_text    word under or after the mouse pointer

        The evaluation of the expression must not have side effects!
        Example:
    function! MyBalloonExpr()
        return 'Cursor is at line ' . v:beval_lnum .
                \', column ' . v:beval_col .
                \ ' of file ' .  bufname(v:beval_bufnr) .
                \ ' on word "' . v:beval_text . '"'
    endfunction
    set bexpr=MyBalloonExpr()
    set balooneval

        Also see  balloon_show() , can be used if the content of the balloon
        is to be fetched asynchronously.

        NOTE: The balloon is displayed only if the cursor is on a text
        character.  If the result of evaluating 'balloonexpr' is not empty,
        Vim does not try to send a message to an external debugger (Netbeans
        or Sun Workshop).

        The expression will be evaluated in the  sandbox  when set from a
```

modeline, see sandbox-option .

It is not allowed to change text or jump to another window while evaluating 'balloonexpr' textlock .

To check whether line breaks in the balloon text work use this check:

```
if has("balloon_multiline")
```

When they are supported "\n" characters will start a new line. If the expression evaluates to a List this is equal to using each List item as a string and putting "\n" in between them.
NOTE: This option is set to "" when 'compatible' is set.

'belloff' 'bo'

'belloff' 'bo' string (default "")
global
{not in Vi}

Specifies for which events the bell will not be rung. It is a comma separated list of items. For each item that is present, the bell will be silenced. This is most useful to specify specific events in insert mode to be silenced.

item	meaning when present
all	All events.
backspace	When hitting <BS> or <Del> and deleting results in an error.
cursor	Fail to move around using the cursor keys or <PageUp>/<PageDown> in Insert-mode .
complete	Error occurred when using i_CTRL-X_CTRL-K or i_CTRL-X_CTRL-T .
copy	Cannot copy char from insert mode using i_CTRL-Y or i_CTRL-E .
ctrlg	Unknown Char after <C-G> in Insert mode.
error	Other Error occurred (e.g. try to join last line) (mostly used in Normal-mode or Cmdline-mode).
esc	hitting <Esc> in Normal-mode .
ex	In Visual-mode , hitting Q results in an error.
hangul	Error occurred when using hangul input.
insertmode	Pressing <Esc> in 'insertmode'.
lang	Calling the beep module for Lua/Mzscheme/TCL.
mess	No output available for g< .
showmatch	Error occurred for 'showmatch' function.
operator	Empty region error cpo-E .
register	Unknown register after <C-R> in Insert-mode .
shell	Bell from shell output :! .
spell	Error happened on spell suggest.
wildmode	More matches in cmdline-completion available (depends on the 'wildmode' setting).

This is most useful to fine tune when in Insert mode the bell should be rung. For Normal mode and Ex commands, the bell is often rung to indicate that an error occurred. It can be silenced by adding the "error" keyword.

'binary' 'bin' 'nobinary' 'nobin'

'binary' 'bin'		boolean (default off)
			local to buffer
			{not in Vi}
	This option should be set before editing a binary file. You can also
	use the -b Vim argument. When this option is switched on a few
	options will be changed (also when it already was on):
		'textwidth' will be set to 0
		'wrapmargin' will be set to 0
		'modeline' will be off
		'expandtab' will be off
	Also, 'fileformat' and 'fileformats' options will not be used, the
	file is read and written like 'fileformat' was "unix" (a single <NL>
	separates lines).
	The 'fileencoding' and 'fileencodings' options will not be used, the
	file is read without conversion.
	NOTE: When you start editing a(nother) file while the 'bin' option is
	on, settings from autocommands may change the settings again (e.g.,
	'textwidth'), causing trouble when editing. You might want to set
	'bin' again when the file has been loaded.
	The previous values of these options are remembered and restored when
	'bin' is switched from on to off. Each buffer has its own set of
	saved option values.
	To edit a file with 'binary' set you can use the ++bin argument.
	This avoids you have to do ":set bin", which would have effect for all
	files you edit.
	When writing a file the <EOL> for the last line is only written if
	there was one in the original file (normally Vim appends an <EOL> to
	the last line if there is none; this would make the file longer). See
	the 'endofline' option.

			 'bioskey' 'biosk' 'nobioskey' 'nobiosk'
'bioskey' 'biosk'	boolean (default on)
			global
			{not in Vi} {only for MS-DOS}
	This was for MS-DOS and is no longer supported.

							'bomb' 'nobomb'
'bomb'			boolean (default off)
			local to buffer
			{not in Vi}
			{only available when compiled with the +multi_byte
			feature}
	When writing a file and the following conditions are met, a BOM (Byte
	Order Mark) is prepended to the file:
	- this option is on
	- the 'binary' option is off
	- 'fileencoding' is "utf-8", "ucs-2", "ucs-4" or one of the little/big
	  endian variants.
	Some applications use the BOM to recognize the encoding of the file.
	Often used for UCS-2 files on MS-Windows. For other applications it
	causes trouble, for example: "cat file1 file2" makes the BOM of file2
	appear halfway the resulting file. Gcc doesn't accept a BOM.
	When Vim reads a file and 'fileencodings' starts with "ucs-bom", a
	check for the presence of the BOM is done and 'bomb' set accordingly.

Unless 'binary' is set, it is removed from the first line, so that you don't see it when editing. When you don't change the options, the BOM will be restored when writing the file.

'breakat' 'brk'

'breakat' 'brk' string (default " ^I!@*-+;:,./?")
global
{not in Vi}
{not available when compiled without the +linebreak feature}
This option lets you choose which characters might cause a line break if 'linebreak' is on. Only works for ASCII and also for 8-bit characters when 'encoding' is an 8-bit encoding.

'breakindent' 'bri' 'nobreakindent' 'nobri'

'breakindent' 'bri' boolean (default off)
local to window
{not in Vi}
{not available when compiled without the +linebreak feature}
Every wrapped line will continue visually indented (same amount of space as the beginning of that line), thus preserving horizontal blocks of text.
NOTE: This option is reset when 'compatible' is set.

'breakindentopt' 'briopt'

'breakindentopt' 'briopt' string (default empty)
local to window
{not in Vi}
{not available when compiled without the +linebreak feature}
Settings for 'breakindent'. It can consist of the following optional items and must be separated by a comma:

min:{n}	Minimum text width that will be kept after applying 'breakindent', even if the resulting text should normally be narrower. This prevents text indented almost to the right window border occupying lot of vertical space when broken.
shift:{n}	After applying 'breakindent', the wrapped line's beginning will be shifted by the given number of characters. It permits dynamic French paragraph indentation (negative) or emphasizing the line continuation (positive).
sbr	Display the 'showbreak' value before applying the additional indent.

The default value for min is 20 and shift is 0.

'browsedir' 'bsdir'

'browsedir' 'bsdir' string (default: "last")
global
{not in Vi} {only for Motif, Athena, GTK, Mac and Win32 GUI}
Which directory to use for the file browser:

last	Use same directory as with last file browser, where a

```
                        file was opened or saved.
            buffer      Use the directory of the related buffer.
            current     Use the current directory.
            {path}      Use the specified directory

                                                    'bufhidden'   'bh'
'bufhidden' 'bh'        string (default: "")
                        local to buffer
                        {not in Vi}
        This option specifies what happens when a buffer is no longer
        displayed in a window:
          <empty>       follow the global 'hidden' option
          hide          hide the buffer (don't unload it), also when 'hidden'
                        is not set
          unload        unload the buffer, also when 'hidden' is set or using
                         :hide
          delete        delete the buffer from the buffer list, also when
                        'hidden' is set or using  :hide , like using
                         :bdelete
          wipe          wipe out the buffer from the buffer list, also when
                        'hidden' is set or using  :hide , like using
                         :bwipeout

        CAREFUL: when "unload", "delete" or "wipe" is used changes in a buffer
        are lost without a warning.  Also, these values may break autocommands
        that switch between buffers temporarily.
        This option is used together with 'buftype' and 'swapfile' to specify
        special kinds of buffers.   See  special-buffers .

                         'buflisted'   'bl'   'nobuflisted'   'nobl'   E85
'buflisted' 'bl'        boolean (default: on)
                        local to buffer
                        {not in Vi}
        When this option is set, the buffer shows up in the buffer list.  If
        it is reset it is not used for ":bnext", "ls", the Buffers menu, etc.
        This option is reset by Vim for buffers that are only used to remember
        a file name or marks.  Vim sets it when starting to edit a buffer.
        But not when moving to a buffer with ":buffer".

                                                    'buftype'   'bt'   E382
'buftype' 'bt'          string (default: "")
                        local to buffer
                        {not in Vi}
        The value of this option specifies the type of a buffer:
          <empty>       normal buffer
          nofile        buffer which is not related to a file and will not be
                        written
          nowrite       buffer which will not be written
          acwrite       buffer which will always be written with BufWriteCmd
                        autocommands.
          quickfix      quickfix buffer, contains list of errors  :cwindow
                        or list of locations  :lwindow
          help          help buffer (you are not supposed to set this
                        manually)
```

terminal buffer for a terminal (you are not supposed to set this manually)
prompt buffer where only the last line can be edited, meant to be used by a plugin, see prompt-buffer {only when compiled with the |+channel| feature}

This option is used together with 'bufhidden' and 'swapfile' to specify special kinds of buffers. See special-buffers .

Be careful with changing this option, it can have many side effects!

A "quickfix" buffer is only used for the error list and the location list. This value is set by the :cwindow and :lwindow commands and you are not supposed to change it.

"nofile" and "nowrite" buffers are similar:
both: The buffer is not to be written to disk, ":w" doesn't work (":w filename" does work though).
both: The buffer is never considered to be 'modified' . There is no warning when the changes will be lost, for example when you quit Vim.
both: A swap file is only created when using too much memory (when 'swapfile' has been reset there is never a swap file).
nofile only: The buffer name is fixed, it is not handled like a file name. It is not modified in response to a :cd command.
both: When using ":e bufname" and already editing "bufname" the buffer is made empty and autocommands are triggered as usual for :edit . E676
"acwrite" implies that the buffer name is not related to a file, like "nofile", but it will be written. Thus, in contrast to "nofile" and "nowrite", ":w" does work and a modified buffer can't be abandoned without saving. For writing there must be matching BufWriteCmd , FileWriteCmd or FileAppendCmd autocommands.

'casemap' 'cmp'
'casemap' 'cmp' string (default: "internal,keepascii")
global
{not in Vi}
{only available when compiled with the +multi_byte feature}
Specifies details about changing the case of letters. It may contain these words, separated by a comma:
internal Use internal case mapping functions, the current locale does not change the case mapping. This only matters when 'encoding' is a Unicode encoding, "latin1" or "iso-8859-15". When "internal" is omitted, the towupper() and towlower() system library functions are used when available.
keepascii For the ASCII characters (0x00 to 0x7f) use the US case mapping, the current locale is not effective. This probably only matters for Turkish.

'cdpath' 'cd'

'cdpath' 'cd' E344 E346

'cdpath' 'cd' string (default: equivalent to $CDPATH or ",,")
global
{not in Vi}
{not available when compiled without the
+file_in_path feature}
This is a list of directories which will be searched when using the
:cd and :lcd commands, provided that the directory being searched
for has a relative path, not an absolute part starting with "/", "./"
or "../", the 'cdpath' option is not used then.
The 'cdpath' option's value has the same form and semantics as
'path' . Also see file-searching .
The default value is taken from $CDPATH, with a "," prepended to look
in the current directory first.
If the default value taken from $CDPATH is not what you want, include
a modified version of the following command in your vimrc file to
override it:
:let &cdpath = ',' . substitute(substitute($CDPATH, '[,]', '\\\0', 'g'), ':', '
This option cannot be set from a modeline or in the sandbox , for
security reasons.
(parts of 'cdpath' can be passed to the shell to expand file names).

'cedit'

'cedit' string (Vi default: "", Vim default: CTRL-F)
global
{not in Vi}
{not available when compiled without the +vertsplit
feature}
The key used in Command-line Mode to open the command-line window.
The default is CTRL-F when 'compatible' is off.
Only non-printable keys are allowed.
The key can be specified as a single character, but it is difficult to
type. The preferred way is to use the <> notation. Examples:
:exe "set cedit=\<C-Y>"
:exe "set cedit=\<Esc>"
Nvi also has this option, but it only uses the first character.
See cmdwin .
NOTE: This option is set to the Vim default value when 'compatible'
is reset.

'charconvert' 'ccv' E202 E214 E513

'charconvert' 'ccv' string (default "")
global
{only available when compiled with the +multi_byte
and +eval features}
{not in Vi}
An expression that is used for character encoding conversion. It is
evaluated when a file that is to be read or has been written has a
different encoding from what is desired.
'charconvert' is not used when the internal iconv() function is
supported and is able to do the conversion. Using iconv() is
preferred, because it is much faster.
'charconvert' is not used when reading stdin -- , because there is no

```
        file to convert from.  You will have to save the text in a file first.
        The expression must return zero or an empty string for success,
        non-zero for failure.
        The possible encoding names encountered are in 'encoding'.
        Additionally, names given in 'fileencodings' and 'fileencoding' are
        used.
        Conversion between "latin1", "unicode", "ucs-2", "ucs-4" and "utf-8"
        is done internally by Vim, 'charconvert' is not used for this.
        'charconvert' is also used to convert the viminfo file, if the 'c'
        flag is present in 'viminfo'.  Also used for Unicode conversion.
        Example:
                set charconvert=CharConvert()
                fun CharConvert()
                  system("recode "
                        \ . v:charconvert_from . ".." . v:charconvert_to
                        \ . " <" . v:fname_in . " >" v:fname_out)
                  return v:shell_error
                endfun
      The related Vim variables are:
                v:charconvert_from      name of the current encoding
                v:charconvert_to        name of the desired encoding
                v:fname_in              name of the input file
                v:fname_out             name of the output file
        Note that v:fname_in and v:fname_out will never be the same.
        Note that v:charconvert_from and v:charconvert_to may be different
        from 'encoding'.  Vim internally uses UTF-8 instead of UCS-2 or UCS-4.
        Encryption is not done by Vim when using 'charconvert'.  If you want
        to encrypt the file after conversion, 'charconvert' should take care
        of this.
        This option cannot be set from a  modeline  or in the  sandbox , for
        security reasons.

                                        'cindent'   'cin'   'nocindent'   'nocin'
'cindent' 'cin'         boolean (default off)
                        local to buffer
                        {not in Vi}
                        {not available when compiled without the  +cindent
                        feature}
        Enables automatic C program indenting.  See 'cinkeys' to set the keys
        that trigger reindenting in insert mode and 'cinoptions' to set your
        preferred indent style.
        If 'indentexpr' is not empty, it overrules 'cindent'.
        If 'lisp' is not on and both 'indentexpr' and 'equalprg' are empty,
        the "=" operator indents using this algorithm rather than calling an
        external program.
        See  C-indenting .
        When you don't like the way 'cindent' works, try the 'smartindent'
        option or 'indentexpr'.
        This option is not used when 'paste' is set.
        NOTE: This option is reset when 'compatible' is set.

                                                        'cinkeys'   'cink'
'cinkeys' 'cink'        string  (default "0{,0},0),:,0#,!^F,o,O,e")
                        local to buffer
```

{not in Vi}
{not available when compiled without the +cindent feature}

A list of keys that, when typed in Insert mode, cause reindenting of the current line. Only used if 'cindent' is on and 'indentexpr' is empty.
For the format of this option see cinkeys-format .
See C-indenting .

'cinoptions' 'cino'

'cinoptions' 'cino' string (default "")
local to buffer
{not in Vi}
{not available when compiled without the +cindent feature}

The 'cinoptions' affect the way 'cindent' reindents lines in a C program. See cinoptions-values for the values of this option, and C-indenting for info on C indenting in general.

'cinwords' 'cinw'

'cinwords' 'cinw' string (default "if,else,while,do,for,switch")
local to buffer
{not in Vi}
{not available when compiled without both the +cindent and the +smartindent features}

These keywords start an extra indent in the next line when 'smartindent' or 'cindent' is set. For 'cindent' this is only done at an appropriate place (inside {}).
Note that 'ignorecase' isn't used for 'cinwords'. If case doesn't matter, include the keyword both the uppercase and lowercase: "if,If,IF".

'clipboard' 'cb'

'clipboard' 'cb' string (default "autoselect,exclude:cons\|linux" for X-windows, "" otherwise)
global
{not in Vi}
{only in GUI versions or when the +xterm_clipboard feature is included}

This option is a list of comma separated names.
These names are recognized:

clipboard-unnamed

unnamed When included, Vim will use the clipboard register '*' for all yank, delete, change and put operations which would normally go to the unnamed register. When a register is explicitly specified, it will always be used regardless of whether "unnamed" is in 'clipboard' or not. The clipboard register can always be explicitly accessed using the "* notation. Also see gui-clipboard .

clipboard-unnamedplus

unnamedplus	A variant of the "unnamed" flag which uses the
		clipboard register '+' (quoteplus) instead of
		register '*' for all yank, delete, change and put
		operations which would normally go to the unnamed
		register. When "unnamed" is also included to the
		option, yank operations (but not delete, change or
		put) will additionally copy the text into register
		'*'.
		Only available with the +X11 feature.
		Availability can be checked with:
			if has('unnamedplus')

clipboard-autoselect
autoselect	Works like the 'a' flag in 'guioptions': If present,
		then whenever Visual mode is started, or the Visual
		area extended, Vim tries to become the owner of the
		windowing system's global selection or put the
		selected text on the clipboard used by the selection
		register "*. See guioptions_a and quotestar for
		details. When the GUI is active, the 'a' flag in
		'guioptions' is used, when the GUI is not active, this
		"autoselect" flag is used.
		Also applies to the modeless selection.

clipboard-autoselectplus
autoselectplus	Like "autoselect" but using the + register instead of
		the * register. Compare to the 'P' flag in
		'guioptions'.

clipboard-autoselectml
autoselectml	Like "autoselect", but for the modeless selection
		only. Compare to the 'A' flag in 'guioptions'.

clipboard-html
html		When the clipboard contains HTML, use this when
		pasting. When putting text on the clipboard, mark it
		as HTML. This works to copy rendered HTML from
		Firefox, paste it as raw HTML in Vim, select the HTML
		in Vim and paste it in a rich edit box in Firefox.
		You probably want to add this only temporarily,
		possibly use BufEnter autocommands.
		Only supported for GTK version 2 and later.
		Only available with the +multi_byte feature.

clipboard-exclude
exclude:{pattern}
		Defines a pattern that is matched against the name of
		the terminal 'term'. If there is a match, no
		connection will be made to the X server. This is
		useful in this situation:
		- Running Vim in a console.
		- $DISPLAY is set to start applications on another
		  display.
		- You do not want to connect to the X server in the

console, but do want this in a terminal emulator.
To never connect to the X server use:
exclude:.*
This has the same effect as using the -X argument.
Note that when there is no connection to the X server
the window title won't be restored and the clipboard
cannot be accessed.
The value of 'magic' is ignored, {pattern} is
interpreted as if 'magic' was on.
The rest of the option value will be used for
{pattern}, this must be the last entry.

'cmdheight' 'ch'

'cmdheight' 'ch' number (default 1)
global
{not in Vi}
Number of screen lines to use for the command-line. Helps avoiding hit-enter prompts.
The value of this option is stored with the tab page, so that each tab page can have a different value.

'cmdwinheight' 'cwh'

'cmdwinheight' 'cwh' number (default 7)
global
{not in Vi}
{not available when compiled without the +vertsplit feature}
Number of screen lines to use for the command-line window. cmdwin

'colorcolumn' 'cc'

'colorcolumn' 'cc' string (default "")
local to window
{not in Vi}
{not available when compiled without the +syntax feature}
'colorcolumn' is a comma separated list of screen columns that are highlighted with ColorColumn hl-ColorColumn . Useful to align text. Will make screen redrawing slower.
The screen column can be an absolute number, or a number preceded with '+' or '-', which is added to or subtracted from 'textwidth'.

```
:set cc=+1  " highlight column after 'textwidth'
:set cc=+1,+2,+3  " highlight three columns after 'textwidth'
:hi ColorColumn ctermbg=lightgrey guibg=lightgrey
```

When 'textwidth' is zero then the items with '-' and '+' are not used.
A maximum of 256 columns are highlighted.

'columns' 'co' E594

'columns' 'co' number (default 80 or terminal width)
global
{not in Vi}
Number of columns of the screen. Normally this is set by the terminal initialization and does not have to be set by hand. Also see

posix-screen-size .
When Vim is running in the GUI or in a resizable window, setting this option will cause the window size to be changed. When you only want to use the size for the GUI, put the command in your gvimrc file. When you set this option and Vim is unable to change the physical number of columns of the display, the display may be messed up. For the GUI it is always possible and Vim limits the number of columns to what fits on the screen. You can use this command to get the widest window possible:

```
:set columns=9999
```

Minimum value is 12, maximum value is 10000.

'comments' 'com' 'comments' 'com' E524 E525

'comments' 'com' string (default "s1:/*,mb:*,ex:*/,://,b:#,:%,:XCOMM,n:>,fb:-")
local to buffer
{not in Vi}
{not available when compiled without the +comments feature}

A comma separated list of strings that can start a comment line. See format-comments . See option-backslash about using backslashes to insert a space.

'commentstring' 'cms' 'commentstring' 'cms' E537

'commentstring' 'cms' string (default "/*%s*/")
local to buffer
{not in Vi}
{not available when compiled without the +folding feature}

A template for a comment. The "%s" in the value is replaced with the comment text. Currently only used to add markers for folding, see fold-marker .

'compatible' 'cp' 'nocompatible' 'nocp'

'compatible' 'cp' boolean (default on, off when a vimrc or gvimrc file is found, reset in defaults.vim)
global
{not in Vi}

This option has the effect of making Vim either more Vi-compatible, or make Vim behave in a more useful way.

This is a special kind of option, because when it's set or reset, other options are also changed as a side effect.
NOTE: Setting or resetting this option can have a lot of unexpected effects: Mappings are interpreted in another way, undo behaves differently, etc. If you set this option in your vimrc file, you should probably put it at the very start.

By default this option is on and the Vi defaults are used for the options. This default was chosen for those people who want to use Vim just like Vi, and don't even (want to) know about the 'compatible' option.
When a vimrc or gvimrc file is found while Vim is starting up, this option is switched off, and all options that have not been

modified will be set to the Vim defaults. Effectively, this means that when a vimrc or gvimrc file exists, Vim will use the Vim defaults, otherwise it will use the Vi defaults. (Note: This doesn't happen for the system-wide vimrc or gvimrc file, nor for a file given with the -u argument). Also see compatible-default and posix-compliance .
You can also set this option with the "-C" argument, and reset it with "-N". See -C and -N .
See 'cpoptions' for more fine tuning of Vi compatibility.

When this option is set, numerous other options are set to make Vim as Vi-compatible as possible. When this option is unset, various options are set to make Vim more useful. The table below lists all the options affected.
The {?} column indicates when the options are affected:
+ Means that the option is set to the value given in {set value} when 'compatible' is set.
& Means that the option is set to the value given in {set value} when 'compatible' is set AND is set to its Vim default value when 'compatible' is unset.
- Means the option is NOT changed when setting 'compatible' but IS set to its Vim default when 'compatible' is unset.
The {effect} column summarises the change when 'compatible' is set.

option	?	set value	effect
'allowrevins'	+	off	no CTRL-_ command
'antialias'	+	off	don't use antialiased fonts
'arabic'	+	off	reset arabic-related options
'arabicshape'	+	on	correct character shapes
'backspace'	+	""	normal backspace
'backup'	+	off	no backup file
'backupcopy'	&	Unix: "yes"	backup file is a copy
		else: "auto"	copy or rename backup file
'balloonexpr'	+	""	text to show in evaluation balloon
'breakindent'	+	off	don't indent when wrapping lines
'cedit'	-	{unchanged}	{set vim default only on resetting 'cp'}
'cindent'	+	off	no C code indentation
'compatible'	-	{unchanged}	{set vim default only on resetting 'cp'}
'copyindent'	+	off	don't copy indent structure
'cpoptions'	&	(all flags)	Vi-compatible flags
'cscopepathcomp'	+	0	don't show directories in tags list
'cscoperelative'	+	off	don't use basename of path as prefix
'cscopetag'	+	off	don't use cscope for ":tag"
'cscopetagorder'	+	0	see cscopetagorder
'cscopeverbose'	+	off	see cscopeverbose
'delcombine'	+	off	unicode: delete whole char combination
'digraph'	+	off	no digraphs
'esckeys'	&	off	no <Esc>-keys in Insert mode
'expandtab'	+	off	tabs not expanded to spaces
'fileformats'	&	""	no automatic file format detection,
		"dos,unix"	except for DOS, Windows and OS/2
'formatexpr'	+	""	use 'formatprg' for auto-formatting
'formatoptions'	&	"vt"	Vi compatible formatting

```
        'gdefault'      + off           no default 'g' flag for ":s"
        'history'       & 0             no commandline history
        'hkmap'         + off           no Hebrew keyboard mapping
        'hkmapp'        + off           no phonetic Hebrew keyboard mapping
        'hlsearch'      + off           no highlighting of search matches
        'incsearch'     + off           no incremental searching
        'indentexpr'    + ""            no indenting by expression
        'insertmode'    + off           do not start in Insert mode
        'iskeyword'     & "@,48-57,_"   keywords contain alphanumeric
                                                characters and '_'
        'joinspaces'    + on            insert 2 spaces after period
        'modeline'      & off           no modelines
        'more'          & off           no pauses in listings
        'mzquantum'     - {unchanged}   {set vim default only on resetting 'cp'}
        'numberwidth'   & 8             min number of columns for line number
        'preserveindent'+ off           don't preserve current indent structure
                                                when changing it
        'revins'        + off           no reverse insert
        'ruler'         + off           no ruler
        'scrolljump'    + 1             no jump scroll
        'scrolloff'     + 0             no scroll offset
        'shelltemp'     - {unchanged}   {set vim default only on resetting 'cp'}
        'shiftround'    + off           indent not rounded to shiftwidth
        'shortmess'     & ""            no shortening of messages
        'showcmd'       & off           command characters not shown
        'showmode'      & off           current mode not shown
        'sidescrolloff' + 0             cursor moves to edge of screen in scroll
        'smartcase'     + off           no automatic ignore case switch
        'smartindent'   + off           no smart indentation
        'smarttab'      + off           no smart tab size
        'softtabstop'   + 0             tabs are always 'tabstop' positions
        'startofline'   + on            goto startofline with some commands
        'tagcase'       & "followic"    'ignorecase' when searching tags file
        'tagrelative'   & off           tag file names are not relative
        'termguicolors' + off           don't use highlight-(guifg|guibg)
        'textauto'      & off           no automatic textmode detection
        'textwidth'     + 0             no automatic line wrap
        'tildeop'       + off           tilde is not an operator
        'ttimeout'      + off           no terminal timeout
        'undofile'      + off           don't use an undo file
        'viminfo'       - {unchanged}   {set Vim default only on resetting 'cp'}
        'virtualedit'   + ""            cursor can only be placed on characters
        'whichwrap'     & ""            left-right movements don't wrap
        'wildchar'      & CTRL-E        only when the current value is <Tab>
                                        use CTRL-E for cmdline completion
        'writebackup'   + on or off     depends on the  +writebackup  feature

                                                'complete'   'cpt'   E535
'complete' 'cpt'        string  (default: ".,w,b,u,t,i")
                        local to buffer
                        {not in Vi}
        This option specifies how keyword completion  ins-completion  works
        when CTRL-P or CTRL-N are used.  It is also used for whole-line
        completion  i_CTRL-X_CTRL-L .  It indicates the type of completion
```

```
        and the places to scan.  It is a comma separated list of flags:
        .       scan the current buffer ('wrapscan' is ignored)
        w       scan buffers from other windows
        b       scan other loaded buffers that are in the buffer list
        u       scan the unloaded buffers that are in the buffer list
        U       scan the buffers that are not in the buffer list
        k       scan the files given with the 'dictionary' option
        kspell  use the currently active spell checking  spell
        k{dict} scan the file {dict}.  Several "k" flags can be given,
                patterns are valid too.  For example:
                        :set cpt=k/usr/dict/*,k~/spanish
       s       scan the files given with the 'thesaurus' option
        s{tsr}  scan the file {tsr}.  Several "s" flags can be given, patterns
                are valid too.
        i       scan current and included files
        d       scan current and included files for defined name or macro
                 i_CTRL-X_CTRL-D
        ]       tag completion
        t       same as "]"

        Unloaded buffers are not loaded, thus their autocmds  :autocmd  are
        not executed, this may lead to unexpected completions from some files
        (gzipped files for example).  Unloaded buffers are not scanned for
        whole-line completion.

        The default is ".,w,b,u,t,i", which means to scan:
           1. the current buffer
           2. buffers in other windows
           3. other loaded buffers
           4. unloaded buffers
           5. tags
           6. included files

        As you can see, CTRL-N and CTRL-P can be used to do any 'iskeyword'-
        based expansion (e.g., dictionary  i_CTRL-X_CTRL-K , included patterns
         i_CTRL-X_CTRL-I , tags  i_CTRL-X_CTRL-]  and normal expansions).

                                                    'completefunc'   'cfu'
'completefunc' 'cfu'    string  (default: empty)
                        local to buffer
                        {not in Vi}
                        {not available when compiled without the  +eval
                        or  +insert_expand  features}
        This option specifies a function to be used for Insert mode completion
        with CTRL-X CTRL-U.  i_CTRL-X_CTRL-U
        See  complete-functions  for an explanation of how the function is
        invoked and what it should return.
        This option cannot be set from a  modeline  or in the  sandbox , for
        security reasons.

                                                    'completeopt'   'cot'
'completeopt' 'cot'     string  (default: "menu,preview")
                        global
                        {not available when compiled without the
```

+insert_expand feature}
{not in Vi}
A comma separated list of options for Insert mode completion
ins-completion . The supported values are:

menu Use a popup menu to show the possible completions. The
menu is only shown when there is more than one match and
sufficient colors are available. ins-completion-menu

menuone Use the popup menu also when there is only one match.
Useful when there is additional information about the
match, e.g., what file it comes from.

longest Only insert the longest common text of the matches. If
the menu is displayed you can use CTRL-L to add more
characters. Whether case is ignored depends on the kind
of completion. For buffer text the 'ignorecase' option is
used.

preview Show extra information about the currently selected
completion in the preview window. Only works in
combination with "menu" or "menuone".

noinsert Do not insert any text for a match until the user selects
a match from the menu. Only works in combination with
"menu" or "menuone". No effect if "longest" is present.

noselect Do not select a match in the menu, force the user to
select one from the menu. Only works in combination with
"menu" or "menuone".

'concealcursor' 'cocu'
'concealcursor' 'cocu' string (default: "")
local to window
{not in Vi}
{not available when compiled without the +conceal
feature}
Sets the modes in which text in the cursor line can also be concealed.
When the current mode is listed then concealing happens just like in
other lines.
n Normal mode
v Visual mode
i Insert mode
c Command line editing, for 'incsearch'

'v' applies to all lines in the Visual area, not only the cursor.
A useful value is "nc". This is used in help files. So long as you
are moving around text is concealed, but when starting to insert text
or selecting a Visual area the concealed text is displayed, so that
you can see what you are doing.
Keep in mind that the cursor position is not always where it's
displayed. E.g., when moving vertically it may change column.

'conceallevel' 'cole' 'conceallevel' 'cole'
number (default 0)
local to window
{not in Vi}
{not available when compiled without the +conceal feature}

Determine how text with the "conceal" syntax attribute :syn-conceal is shown:

Value	Effect
0	Text is shown normally
1	Each block of concealed text is replaced with one character. If the syntax item does not have a custom replacement character defined (see :syn-cchar) the character defined in 'listchars' is used (default is a space). It is highlighted with the "Conceal" highlight group.
2	Concealed text is completely hidden unless it has a custom replacement character defined (see :syn-cchar).
3	Concealed text is completely hidden.

Note: in the cursor line concealed text is not hidden, so that you can edit and copy the text. This can be changed with the 'concealcursor' option.

'confirm' 'cf' 'confirm' 'cf' 'noconfirm' 'nocf'
boolean (default off)
global
{not in Vi}

When 'confirm' is on, certain operations that would normally fail because of unsaved changes to a buffer, e.g. ":q" and ":e", instead raise a dialog asking if you wish to save the current file(s). You can still use a ! to unconditionally abandon a buffer. If 'confirm' is off you can still activate confirmation for one command only (this is most useful in mappings) with the :confirm command.
Also see the confirm() function and the 'v' flag in 'guioptions'.

'conskey' 'consk' 'conskey' 'consk' 'noconskey' 'noconsk'
boolean (default off)
global
{not in Vi} {only for MS-DOS}

This was for MS-DOS and is no longer supported.

'copyindent' 'ci' 'copyindent' 'ci' 'nocopyindent' 'noci'
boolean (default off)
local to buffer
{not in Vi}

Copy the structure of the existing lines indent when autoindenting a new line. Normally the new indent is reconstructed by a series of tabs followed by spaces as required (unless 'expandtab' is enabled, in which case only spaces are used). Enabling this option makes the

new line copy whatever characters were used for indenting on the existing line. 'expandtab' has no effect on these characters, a Tab remains a Tab. If the new indent is greater than on the existing line, the remaining space is filled in the normal manner.
NOTE: This option is reset when 'compatible' is set.
Also see 'preserveindent'.

'cpoptions' 'cpo' 'cpoptions' 'cpo' 'cpoptions' 'cpo' cpo

'cpoptions' 'cpo' string (Vim default: "aABceFs", Vi default: all flags)
global
{not in Vi}

A sequence of single character flags. When a character is present this indicates Vi-compatible behavior. This is used for things where not being Vi-compatible is mostly or sometimes preferred.
'cpoptions' stands for "compatible-options".
Commas can be added for readability.
To avoid problems with flags that are added in the future, use the "+=" and "-=" feature of ":set" add-option-flags .
NOTE: This option is set to the Vi default value when 'compatible' is set and to the Vim default value when 'compatible' is reset.
NOTE: This option is set to the POSIX default value at startup when the Vi default value would be used and the $VIM_POSIX environment variable exists posix . This means Vim tries to behave like the POSIX specification.

contains behavior

cpo-a
a When included, a ":read" command with a file name argument will set the alternate file name for the current window.

cpo-A
A When included, a ":write" command with a file name argument will set the alternate file name for the current window.

cpo-b
b "\|" in a ":map" command is recognized as the end of the map command. The '\' is included in the mapping, the text after the '|' is interpreted as the next command. Use a CTRL-V instead of a backslash to include the '|' in the mapping. Applies to all mapping, abbreviation, menu and autocmd commands. See also map_bar .

cpo-B
B A backslash has no special meaning in mappings, abbreviations, user commands and the "to" part of the menu commands. Remove this flag to be able to use a backslash like a CTRL-V. For example, the command ":map X \<Esc>" results in X being mapped to:
'B' included: "\^[" (^[is a real <Esc>)
'B' excluded: "<Esc>" (5 characters)
('<' excluded in both cases)

cpo-c
c Searching continues at the end of any match at the

cursor position, but not further than the start of the next line. When not present searching continues one character from the cursor position. With 'c' "abababababab" only gets three matches when repeating "/abab", without 'c' there are five matches.

cpo-C

C Do not concatenate sourced lines that start with a backslash. See line-continuation .

cpo-d

d Using "./" in the 'tags' option doesn't mean to use the tags file relative to the current file, but the tags file in the current directory.

cpo-D

D Can't use CTRL-K to enter a digraph after Normal mode commands with a character argument, like r , f and t .

cpo-e

e When executing a register with ":@r", always add a <CR> to the last line, also when the register is not linewise. If this flag is not present, the register is not linewise and the last line does not end in a <CR>, then the last line is put on the command-line and can be edited before hitting <CR>.

cpo-E

E It is an error when using "y", "d", "c", "g~", "gu" or "gU" on an Empty region. The operators only work when at least one character is to be operated on. Example: This makes "y0" fail in the first column.

cpo-f

f When included, a ":read" command with a file name argument will set the file name for the current buffer, if the current buffer doesn't have a file name yet.

cpo-F

F When included, a ":write" command with a file name argument will set the file name for the current buffer, if the current buffer doesn't have a file name yet. Also see cpo-P .

cpo-g

g Goto line 1 when using ":edit" without argument.

cpo-H

H When using "I" on a line with only blanks, insert before the last blank. Without this flag insert after the last blank.

cpo-i

i When included, interrupting the reading of a file will leave it modified.

cpo-I

I When moving the cursor up or down just after inserting indent for 'autoindent', do not delete the indent.

cpo-j

j When joining lines, only add two spaces after a '.', not after '!' or '?'. Also see 'joinspaces'.

cpo-J

J A sentence has to be followed by two spaces after

the '.', '!' or '?'. A <Tab> is not recognized as white space.

cpo-k

k	Disable the recognition of raw key codes in mappings, abbreviations, and the "to" part of menu commands. For example, if <Key> sends ^[OA (where ^[is <Esc>), the command ":map X ^[OA" results in X being mapped to:
		'k' included: "^[OA" (3 characters)
		'k' excluded: "<Key>" (one key code)
	Also see the '<' flag below.

cpo-K

K	Don't wait for a key code to complete when it is halfway a mapping. This breaks mapping <F1><F1> when only part of the second <F1> has been read. It enables cancelling the mapping by typing <F1><Esc>.

cpo-l

l	Backslash in a [] range in a search pattern is taken literally, only "\]", "\^", "\-" and "\\" are special. See /[]
	   'l' included: "/[\t]" finds <Space>, '\' and 't'
	   'l' excluded: "/[\t]" finds <Space> and <Tab>
	Also see cpo-\ .

cpo-L

L	When the 'list' option is set, 'wrapmargin', 'textwidth', 'softtabstop' and Virtual Replace mode (see gR) count a <Tab> as two characters, instead of the normal behavior of a <Tab>.

cpo-m

m	When included, a showmatch will always wait half a second. When not included, a showmatch will wait half a second or until a character is typed. 'showmatch'

cpo-M

M	When excluded, "%" matching will take backslashes into account. Thus in "(\( )" and "\((\)" the outer parenthesis match. When included "%" ignores backslashes, which is Vi compatible.

cpo-n

n	When included, the column used for 'number' and 'relativenumber' will also be used for text of wrapped lines.

cpo-o

o	Line offset to search command is not remembered for next search.

cpo-O

O	Don't complain if a file is being overwritten, even when it didn't exist when editing it. This is a protection against a file unexpectedly created by someone else. Vi didn't complain about this.

cpo-p

p	Vi compatible Lisp indenting. When not present, a slightly better algorithm is used.

cpo-P

P	When included, a ":write" command that appends to a

file will set the file name for the current buffer, if the current buffer doesn't have a file name yet and the 'F' flag is also included cpo-F .

cpo-q

q When joining multiple lines leave the cursor at the position where it would be when joining two lines.

cpo-r

r Redo ("." command) uses "/" to repeat a search command, instead of the actually used search string.

cpo-R

R Remove marks from filtered lines. Without this flag marks are kept like :keepmarks was used.

cpo-s

s Set buffer options when entering the buffer for the first time. This is like it is in Vim version 3.0. And it is the default. If not present the options are set when the buffer is created.

cpo-S

S Set buffer options always when entering a buffer (except 'readonly', 'fileformat', 'filetype' and 'syntax'). This is the (most) Vi compatible setting. The options are set to the values in the current buffer. When you change an option and go to another buffer, the value is copied. Effectively makes the buffer options global to all buffers.

's'	'S'	copy buffer options
no	no	when buffer created
yes	no	when buffer first entered (default)
X	yes	each time when buffer entered (vi comp.)

cpo-t

t Search pattern for the tag command is remembered for "n" command. Otherwise Vim only puts the pattern in the history for search pattern, but doesn't change the last used search pattern.

cpo-u

u Undo is Vi compatible. See undo-two-ways .

cpo-v

v Backspaced characters remain visible on the screen in Insert mode. Without this flag the characters are erased from the screen right away. With this flag the screen newly typed text overwrites backspaced characters.

cpo-w

w When using "cw" on a blank character, only change one character and not all blanks until the start of the next word.

cpo-W

W Don't overwrite a readonly file. When omitted, ":w!" overwrites a readonly file, if possible.

cpo-x

x <Esc> on the command-line executes the command-line. The default in Vim is to abandon the command-line, because <Esc> normally aborts a command. c_<Esc>

cpo-X

X	When using a count with "R" the replaced text is
	deleted only once. Also when repeating "R" with "."
	and a count.

cpo-y

y	A yank command can be redone with ".".

cpo-Z

Z	When using "w!" while the 'readonly' option is set,
	don't reset 'readonly'.

cpo-!

!	When redoing a filter command, use the last used
	external command, whatever it was. Otherwise the last
	used -filter- command is used.

cpo-$

$	When making a change to one line, don't redisplay the
	line, but put a '$' at the end of the changed text.
	The changed text will be overwritten when you type the
	new text. The line is redisplayed if you type any
	command that moves the cursor from the insertion
	point.

cpo-%

%	Vi-compatible matching is done for the "%" command.
	Does not recognize "#if", "#endif", etc.
	Does not recognize "/*" and "*/".
	Parens inside single and double quotes are also
	counted, causing a string that contains a paren to
	disturb the matching. For example, in a line like
	"if (strcmp("foo(", s))" the first paren does not
	match the last one. When this flag is not included,
	parens inside single and double quotes are treated
	specially. When matching a paren outside of quotes,
	everything inside quotes is ignored. When matching a
	paren inside quotes, it will find the matching one (if
	there is one). This works very well for C programs.
	This flag is also used for other features, such as
	C-indenting.

cpo--

-	When included, a vertical movement command fails when
	it would go above the first line or below the last
	line. Without it the cursor moves to the first or
	last line, unless it already was in that line.
	Applies to the commands "-", "k", CTRL-P, "+", "j",
	CTRL-N, CTRL-J and ":1234".

cpo-+

+	When included, a ":write file" command will reset the
	'modified' flag of the buffer, even though the buffer
	itself may still be different from its file.

cpo-star

*	Use ":*" in the same way as ":@". When not included,
	":*" is an alias for ":'<,'>", select the Visual area.

cpo-<

<	Disable the recognition of special key codes in |<>|
	form in mappings, abbreviations, and the "to" part of
	menu commands. For example, the command

":map X <Tab>" results in X being mapped to:
'<' included: "<Tab>" (5 characters)
'<' excluded: "^I" (^I is a real <Tab>)
Also see the 'k' flag above.

cpo->

> When appending to a register, put a line break before the appended text.

cpo-;

; When using , or ; to repeat the last t search and the cursor is right in front of the searched character, the cursor won't move. When not included, the cursor would skip over it and jump to the following occurrence.

POSIX flags. These are not included in the Vi default value, except when $VIM_POSIX was set on startup. posix

contains behavior

cpo-#

A count before "D", "o" and "O" has no effect.

cpo-&

& When ":preserve" was used keep the swap file when exiting normally while this buffer is still loaded. This flag is tested when exiting.

cpo-\

\ Backslash in a [] range in a search pattern is taken literally, only "\]" is special See /[]
'\' included: "/[\-]" finds <Space>, '\' and '-'
'\' excluded: "/[\-]" finds <Space> and '-'
Also see cpo-l .

cpo-/

/ When "%" is used as the replacement string in a :s command, use the previous replacement string. :s%

cpo-{

{ The |{| and |}| commands also stop at a "{" character at the start of a line.

cpo-.

. The ":chdir" and ":cd" commands fail if the current buffer is modified, unless ! is used. Vim doesn't need this, since it remembers the full path of an opened file.

cpo-bar

| The value of the $LINES and $COLUMNS environment variables overrule the terminal size values obtained with system specific functions.

'cryptmethod' 'cm'

'cryptmethod' 'cm' string (default "zip")
global or local to buffer global-local
{not in Vi}
Method used for encryption when the buffer is written to a file:

pkzip

zip PkZip compatible method. A weak kind of encryption.

Backwards compatible with Vim 7.2 and older.
blowfish

blowfish Blowfish method. Medium strong encryption but it has an implementation flaw. Requires Vim 7.3 or later, files can NOT be read by Vim 7.2 and older. This adds a "seed" to the file, every time you write the file the encrypted bytes will be different.
blowfish2

blowfish2 Blowfish method. Medium strong encryption. Requires Vim 7.4.401 or later, files can NOT be read by Vim 7.3 and older. This adds a "seed" to the file, every time you write the file the encrypted bytes will be different. The whole undo file is encrypted, not just the pieces of text.

You should use "blowfish2", also to re-encrypt older files.

When reading an encrypted file 'cryptmethod' will be set automatically to the detected method of the file being read. Thus if you write it without changing 'cryptmethod' the same method will be used. Changing 'cryptmethod' does not mark the file as modified, you have to explicitly write it, you don't get a warning unless there are other modifications. Also see :X .

When setting the global value to an empty string, it will end up with the value "zip". When setting the local value to an empty string the buffer will use the global value.

When a new encryption method is added in a later version of Vim, and the current version does not recognize it, you will get E821 . You need to edit this file with the later version of Vim.

'cscopepathcomp' *'cspc'*
'cscopepathcomp' 'cspc' number (default 0)
global
{not available when compiled without the +cscope feature}
{not in Vi}

Determines how many components of the path to show in a list of tags. See cscopepathcomp .
NOTE: This option is set to 0 when 'compatible' is set.

'cscopeprg' *'csprg'*
'cscopeprg' 'csprg' string (default "cscope")
global
{not available when compiled without the +cscope feature}
{not in Vi}

Specifies the command to execute cscope. See cscopeprg .
This option cannot be set from a modeline or in the sandbox , for security reasons.

'cscopequickfix' *'csqf'*

'cscopequickfix' 'csqf' string (default "")
                        global
                        {not available when compiled without the +cscope
                        or +quickfix features}
                        {not in Vi}
        Specifies whether to use quickfix window to show cscope results.
        See cscopequickfix .

                'cscoperelative'   'csre'   'nocscoperelative'   'nocsre'
'cscoperelative' 'csre' boolean (default off)
                        global
                        {not available when compiled without the +cscope
                        feature}
                        {not in Vi}
        In the absence of a prefix (-P) for cscope. setting this option enables
        to use the basename of cscope.out path as the prefix.
        See cscoperelative .
        NOTE: This option is reset when 'compatible' is set.

                                'cscopetag'   'cst'   'nocscopetag'   'nocst'
'cscopetag' 'cst'   boolean (default off)
                        global
                        {not available when compiled without the +cscope
                        feature}
                        {not in Vi}
        Use cscope for tag commands. See cscope-options .
        NOTE: This option is reset when 'compatible' is set.

                                                'cscopetagorder'   'csto'
'cscopetagorder' 'csto' number (default 0)
                        global
                        {not available when compiled without the +cscope
                        feature}
                        {not in Vi}
        Determines the order in which ":cstag" performs a search. See
         cscopetagorder .
        NOTE: This option is set to 0 when 'compatible' is set.

                                        'cscopeverbose'   'csverb'
                                        'nocscopeverbose'   'nocsverb'
'cscopeverbose' 'csverb' boolean (default off)
                        global
                        {not available when compiled without the +cscope
                        feature}
                        {not in Vi}
        Give messages when adding a cscope database. See cscopeverbose .
        NOTE: This option is reset when 'compatible' is set.

                         'cursorbind'   'crb'   'nocursorbind'   'nocrb'
'cursorbind' 'crb'   boolean (default off)
                        local to window
                        {not in Vi}
        When this option is set, as the cursor in the current
        window moves other cursorbound windows (windows that also have

this option set) move their cursors to the corresponding line and column. This option is useful for viewing the differences between two versions of a file (see 'diff'); in diff mode, inserted and deleted lines (though not characters within a line) are taken into account.

'cursorcolumn' *'cuc'* *'nocursorcolumn'* *'nocuc'*
'cursorcolumn' 'cuc' boolean (default off)
local to window
{not in Vi}
{not available when compiled without the +syntax feature}
Highlight the screen column of the cursor with CursorColumn hl-CursorColumn . Useful to align text. Will make screen redrawing slower.
If you only want the highlighting in the current window you can use these autocommands:

```
au WinLeave * set nocursorline nocursorcolumn
au WinEnter * set cursorline cursorcolumn
```

'cursorline' *'cul'* *'nocursorline'* *'nocul'*
'cursorline' 'cul' boolean (default off)
local to window
{not in Vi}
{not available when compiled without the +syntax feature}
Highlight the screen line of the cursor with CursorLine hl-CursorLine . Useful to easily spot the cursor. Will make screen redrawing slower.
When Visual mode is active the highlighting isn't used to make it easier to see the selected text.

'debug'
'debug' string (default "")
global
{not in Vi}
These values can be used:

msg	Error messages that would otherwise be omitted will be given anyway.
throw	Error messages that would otherwise be omitted will be given anyway and also throw an exception and set v:errmsg .
beep	A message will be given when otherwise only a beep would be produced.

The values can be combined, separated by a comma.
"msg" and "throw" are useful for debugging 'foldexpr', 'formatexpr' or 'indentexpr'.

'define' *'def'*
'define' 'def' string (default "^\s*#\s*define")
global or local to buffer global-local
{not in Vi}

Pattern to be used to find a macro definition. It is a search pattern, just like for the "/" command. This option is used for the commands like "[i" and "[d" include-search . The 'isident' option is used to recognize the defined name after the match:
{match with 'define'}{non-ID chars}{defined name}{non-ID char}
See option-backslash about inserting backslashes to include a space or backslash.
The default value is for C programs. For C++ this value would be useful, to include const type declarations:
^\(#\s*define\|[a-z]*\s*const\s*[a-z]*\)
When using the ":set" command, you need to double the backslashes!

'delcombine' 'deco' 'nodelcombine' 'nodeco'
'delcombine' 'deco' boolean (default off)
global
{not in Vi}
{only available when compiled with the +multi_byte feature}
If editing Unicode and this option is set, backspace and Normal mode "x" delete each combining character on its own. When it is off (the default) the character along with its combining characters are deleted.
Note: When 'delcombine' is set "xx" may work different from "2x"!

This is useful for Arabic, Hebrew and many other languages where one may have combining characters overtop of base characters, and want to remove only the combining ones.
NOTE: This option is reset when 'compatible' is set.

'dictionary' 'dict'
'dictionary' 'dict' string (default "")
global or local to buffer global-local
{not in Vi}
List of file names, separated by commas, that are used to lookup words for keyword completion commands i_CTRL-X_CTRL-K . Each file should contain a list of words. This can be one word per line, or several words per line, separated by non-keyword characters (white space is preferred). Maximum line length is 510 bytes.

When this option is empty or an entry "spell" is present, and spell checking is enabled, words in the word lists for the currently active 'spelllang' are used. See spell .

To include a comma in a file name precede it with a backslash. Spaces after a comma are ignored, otherwise spaces are included in the file name. See option-backslash about using backslashes.
This has nothing to do with the Dictionary variable type.
Where to find a list of words?
- On FreeBSD, there is the file "/usr/share/dict/words".
- In the Simtel archive, look in the "msdos/linguist" directory.
- In "miscfiles" of the GNU collection.
The use of :set+= and :set-= is preferred when adding or removing directories from the list. This avoids problems when a future version uses another default.

Backticks cannot be used in this option for security reasons.

'diff' 'nodiff'

'diff' boolean (default off)
local to window
{not in Vi}
{not available when compiled without the +diff feature}
Join the current window in the group of windows that shows differences between files. See vimdiff .

'dex' 'diffexpr'

'diffexpr' 'dex' string (default "")
global
{not in Vi}
{not available when compiled without the +diff feature}
Expression which is evaluated to obtain an ed-style diff file from two versions of a file. See diff-diffexpr .
This option cannot be set from a modeline or in the sandbox , for security reasons.

'dip' 'diffopt'

'diffopt' 'dip' string (default "filler")
global
{not in Vi}
{not available when compiled without the +diff feature}
Option settings for diff mode. It can consist of the following items. All are optional. Items must be separated by a comma.

filler	Show filler lines, to keep the text synchronized with a window that has inserted lines at the same position. Mostly useful when windows are side-by-side and 'scrollbind' is set.
context:{n}	Use a context of {n} lines between a change and a fold that contains unchanged lines. When omitted a context of six lines is used. See fold-diff .
icase	Ignore changes in case of text. "a" and "A" are considered the same. Adds the "-i" flag to the "diff" command if 'diffexpr' is empty.
iwhite	Ignore changes in amount of white space. Adds the "-b" flag to the "diff" command if 'diffexpr' is empty. Check the documentation of the "diff" command for what this does exactly. It should ignore adding trailing white space, but not leading white space.
horizontal	Start diff mode with horizontal splits (unless

```
                                explicitly specified otherwise).

                vertical        Start diff mode with vertical splits (unless
                                explicitly specified otherwise).

                hiddenoff       Do not use diff mode for a buffer when it
                                becomes hidden.

                foldcolumn:{n}  Set the 'foldcolumn' option to {n} when
                                starting diff mode.  Without this 2 is used.

        Examples:

                :set diffopt=filler,context:4
                :set diffopt=
                :set diffopt=filler,foldcolumn:3

                                                'digraph'   'dg'   'nodigraph'   'nodg'
'digraph' 'dg'          boolean (default off)
                        global
                        {not in Vi}
                        {not available when compiled without the  +digraphs
                        feature}
        Enable the entering of digraphs in Insert mode with {char1} <BS>
        {char2}.  See  digraphs .
        NOTE: This option is reset when 'compatible' is set.

                                                        'directory'   'dir'
'directory' 'dir'       string  (default for Amiga: ".,t:",
                                 for MS-DOS and Win32: ".,$TEMP,c:\tmp,c:\temp"
                                 for Unix: ".,~/tmp,/var/tmp,/tmp")
                        global
        List of directory names for the swap file, separated with commas.
        - The swap file will be created in the first directory where this is
          possible.
        - Empty means that no swap file will be used (recovery is
          impossible!).
        - A directory "." means to put the swap file in the same directory as
          the edited file.  On Unix, a dot is prepended to the file name, so
          it doesn't show in a directory listing.  On MS-Windows the "hidden"
          attribute is set and a dot prepended if possible.
        - A directory starting with "./" (or ".\" for MS-DOS et al.) means to
          put the swap file relative to where the edited file is.  The leading
          "." is replaced with the path name of the edited file.
        - For Unix and Win32, if a directory ends in two path separators "//",
          the swap file name will be built from the complete path to the file
          with all path separators substituted to percent '%' signs. This will
          ensure file name uniqueness in the preserve directory.
          On Win32, it is also possible to end with "\\".  However, When a
          separating comma is following, you must use "//", since "\\" will
          include the comma in the file name. Therefore it is recommended to
          use '//', instead of '\\'.
        - Spaces after the comma are ignored, other spaces are considered part
          of the directory name.  To have a space at the start of a directory
```

```
          name, precede it with a backslash.
        - To include a comma in a directory name precede it with a backslash.
        - A directory name may end in an ':' or '/'.
        - Environment variables are expanded  :set_env .
        - Careful with '\' characters, type one before a space, type two to
          get one in the option (see  option-backslash ), for example:
            :set dir=c:\\tmp,\ dir\\,with\\,commas,\\\ dir\ with\ spaces
      - For backwards compatibility with Vim version 3.0 a '>' at the start
        of the option is removed.
      Using "." first in the list is recommended.  This means that editing
      the same file twice will result in a warning.  Using "/tmp" on Unix is
      discouraged: When the system crashes you lose the swap file.
      "/var/tmp" is often not cleared when rebooting, thus is a better
      choice than "/tmp".  But it can contain a lot of files, your swap
      files get lost in the crowd.  That is why a "tmp" directory in your
      home directory is tried first.
      The use of  :set+=  and  :set-=  is preferred when adding or removing
      directories from the list.  This avoids problems when a future version
      uses another default.
      This option cannot be set from a  modeline  or in the  sandbox , for
      security reasons.
      {Vi: directory to put temp file in, defaults to "/tmp"}

                                          'display'   'dy'
'display' 'dy'          string  (default "", set to "truncate" in
                                                          defaults.vim )
                        global
                        {not in Vi}
      Change the way text is displayed.  This is comma separated list of
      flags:
      lastline          When included, as much as possible of the last line
                        in a window will be displayed.  "@@@" is put in the
                        last columns of the last screen line to indicate the
                        rest of the line is not displayed.
      truncate          Like "lastline", but "@@@" is displayed in the first
                        column of the last screen line.  Overrules "lastline".
      uhex              Show unprintable characters hexadecimal as <xx>
                        instead of using ^C and ~C.

      When neither "lastline" nor "truncate" is included, a last line that
      doesn't fit is replaced with "@" lines.

                                                 'eadirection'   'ead'
'eadirection' 'ead'     string  (default "both")
                        global
                        {not in Vi}
                        {not available when compiled without the  +vertsplit
                        feature}
      Tells when the 'equalalways' option applies:
              ver       vertically, width of windows is not affected
              hor       horizontally, height of windows is not affected
              both      width and height of windows is affected

                            'ed'   'edcompatible'   'noed'   'noedcompatible'
```

'edcompatible' 'ed'	boolean (default off)
		global
	Makes the 'g' and 'c' flags of the ":substitute" command to be
	toggled each time the flag is given. See complex-change . See
	also 'gdefault' option.
	Switching this option on may break plugins!

'emoji' 'emo' 'noemoji' 'noemo'
'emoji' 'emo'	boolean (default: on)
		global
		{not in Vi}
		{only available when compiled with the +multi_byte
		feature}
	When on all Unicode emoji characters are considered to be full width.

'encoding' 'enc' E543
'encoding' 'enc'	string (default: "latin1" or value from $LANG)
		global
		{only available when compiled with the +multi_byte
		feature}
		{not in Vi}
	Sets the character encoding used inside Vim. It applies to text in
	the buffers, registers, Strings in expressions, text stored in the
	viminfo file, etc. It sets the kind of characters which Vim can work
	with. See encoding-names for the possible values.

	NOTE: Changing this option will not change the encoding of the
	existing text in Vim. It may cause non-ASCII text to become invalid.
	It should normally be kept at its default value, or set when Vim
	starts up. See multibyte . To reload the menus see :menutrans .

	This option cannot be set from a modeline . It would most likely
	corrupt the text.

	NOTE: For GTK+ 2 or later, it is highly recommended to set 'encoding'
	to "utf-8". Although care has been taken to allow different values of
	'encoding', "utf-8" is the natural choice for the environment and
	avoids unnecessary conversion overhead. "utf-8" has not been made
	the default to prevent different behavior of the GUI and terminal
	versions, and to avoid changing the encoding of newly created files
	without your knowledge (in case 'fileencodings' is empty).

	The character encoding of files can be different from 'encoding'.
	This is specified with 'fileencoding'. The conversion is done with
	iconv() or as specified with 'charconvert'.

	If you need to know whether 'encoding' is a multi-byte encoding, you
	can use:
		if has("multi_byte_encoding")

	Normally 'encoding' will be equal to your current locale. This will
	be the default if Vim recognizes your environment settings. If
	'encoding' is not set to the current locale, 'termencoding' must be

set to convert typed and displayed text. See encoding-table .

When you set this option, it fires the EncodingChanged autocommand event so that you can set up fonts if necessary.

When the option is set, the value is converted to lowercase. Thus you can set it with uppercase values too. Underscores are translated to '-' signs.
When the encoding is recognized, it is changed to the standard name. For example "Latin-1" becomes "latin1", "ISO_88592" becomes "iso-8859-2" and "utf8" becomes "utf-8".

Note: "latin1" is also used when the encoding could not be detected. This only works when editing files in the same encoding! When the actual character set is not latin1, make sure 'fileencoding' and 'fileencodings' are empty. When conversion is needed, switch to using utf-8.

When "unicode", "ucs-2" or "ucs-4" is used, Vim internally uses utf-8. You don't notice this while editing, but it does matter for the viminfo-file . And Vim expects the terminal to use utf-8 too. Thus setting 'encoding' to one of these values instead of utf-8 only has effect for encoding used for files when 'fileencoding' is empty.

When 'encoding' is set to a Unicode encoding, and 'fileencodings' was not set yet, the default for 'fileencodings' is changed.

'endofline' 'eol' 'noendofline' 'noeol'
'endofline' 'eol' boolean (default on)
local to buffer
{not in Vi}
When writing a file and this option is off and the 'binary' option is on, or 'fixeol' option is off, no <EOL> will be written for the last line in the file. This option is automatically set or reset when starting to edit a new file, depending on whether file has an <EOL> for the last line in the file. Normally you don't have to set or reset this option.
When 'binary' is off and 'fixeol' is on the value is not used when writing the file. When 'binary' is on or 'fixeol' is off it is used to remember the presence of a <EOL> for the last line in the file, so that when you write the file the situation from the original file can be kept. But you can change it if you want to.

'equalalways' 'ea' 'noequalalways' 'noea'
'equalalways' 'ea' boolean (default on)
global
{not in Vi}
When on, all the windows are automatically made the same size after splitting or closing a window. This also happens the moment the option is switched on. When off, splitting a window will reduce the size of the current window and leave the other windows the same. When closing a window the extra lines are given to the window next to it (depending on 'splitbelow' and 'splitright').
When mixing vertically and horizontally split windows, a minimal size

is computed and some windows may be larger if there is room. The 'eadirection' option tells in which direction the size is affected. Changing the height and width of a window can be avoided by setting 'winfixheight' and 'winfixwidth', respectively.
If a window size is specified when creating a new window sizes are currently not equalized (it's complicated, but may be implemented in the future).

'equalprg' 'ep'

'equalprg' 'ep' string (default "")
global or local to buffer global-local
{not in Vi}
External program to use for "=" command. When this option is empty the internal formatting functions are used; either 'lisp', 'cindent' or 'indentexpr'. When Vim was compiled without internal formatting, the "indent" program is used.
Environment variables are expanded :set_env . See option-backslash about including spaces and backslashes.
This option cannot be set from a modeline or in the sandbox , for security reasons.

'errorbells' 'eb' 'noerrorbells' 'noeb'

'errorbells' 'eb' boolean (default off)
global
Ring the bell (beep or screen flash) for error messages. This only makes a difference for error messages, the bell will be used always for a lot of errors without a message (e.g., hitting <Esc> in Normal mode). See 'visualbell' on how to make the bell behave like a beep, screen flash or do nothing. See 'belloff' to finetune when to ring the bell.

'errorfile' 'ef'

'errorfile' 'ef' string (Amiga default: "AztecC.Err",
others: "errors.err")
global
{not in Vi}
{not available when compiled without the +quickfix feature}
Name of the errorfile for the QuickFix mode (see :cf).
When the "-q" command-line argument is used, 'errorfile' is set to the following argument. See -q .
NOT used for the ":make" command. See 'makeef' for that.
Environment variables are expanded :set_env .
See option-backslash about including spaces and backslashes.
This option cannot be set from a modeline or in the sandbox , for security reasons.

'errorformat' 'efm'

'errorformat' 'efm' string (default is very long)
global or local to buffer global-local
{not in Vi}
{not available when compiled without the +quickfix feature}
Scanf-like description of the format for the lines in the error file

(see errorformat).

'esckeys' 'ek' 'noesckeys' 'noek'
'esckeys' 'ek' boolean (Vim default: on, Vi default: off)
global
{not in Vi}
Function keys that start with an <Esc> are recognized in Insert mode. When this option is off, the cursor and function keys cannot be used in Insert mode if they start with an <Esc>. The advantage of this is that the single <Esc> is recognized immediately, instead of after one second. Instead of resetting this option, you might want to try changing the values for 'timeoutlen' and 'ttimeoutlen'. Note that when 'esckeys' is off, you can still map anything, but the cursor keys won't work by default.
NOTE: This option is set to the Vi default value when 'compatible' is set and to the Vim default value when 'compatible' is reset.

'eventignore' 'ei'
'eventignore' 'ei' string (default "")
global
{not in Vi}
A list of autocommand event names, which are to be ignored.
When set to "all" or when "all" is one of the items, all autocommand events are ignored, autocommands will not be executed.
Otherwise this is a comma separated list of event names. Example:
:set ei=WinEnter,WinLeave

'expandtab' 'et' 'noexpandtab' 'noet'
'expandtab' 'et' boolean (default off)
local to buffer
{not in Vi}
In Insert mode: Use the appropriate number of spaces to insert a <Tab>. Spaces are used in indents with the '>' and '<' commands and when 'autoindent' is on. To insert a real tab when 'expandtab' is on, use CTRL-V<Tab>. See also :retab and ins-expandtab .
This option is reset when the 'paste' option is set and restored when the 'paste' option is reset.
NOTE: This option is reset when 'compatible' is set.

'exrc' 'ex' 'noexrc' 'noex'
'exrc' 'ex' boolean (default off)
global
{not in Vi}
Enables the reading of .vimrc, .exrc and .gvimrc in the current directory.

Setting this option is a potential security leak. E.g., consider unpacking a package or fetching files from github, a .vimrc in there might be a trojan horse. BETTER NOT SET THIS OPTION!
Instead, define an autocommand in your .vimrc to set options for a matching directory.

If you do switch this option on you should also consider setting the 'secure' option (see initialization).

Also see .vimrc and gui-init .
This option cannot be set from a modeline or in the sandbox , for
security reasons.

'fileencoding' 'fenc' E213
'fileencoding' 'fenc' string (default: "")
local to buffer
{only available when compiled with the +multi_byte
feature}
{not in Vi}
Sets the character encoding for the file of this buffer.

When 'fileencoding' is different from 'encoding', conversion will be
done when writing the file. For reading see below.
When 'fileencoding' is empty, the same value as 'encoding' will be
used (no conversion when reading or writing a file).
No error will be given when the value is set, only when it is used,
only when writing a file.
Conversion will also be done when 'encoding' and 'fileencoding' are
both a Unicode encoding and 'fileencoding' is not utf-8. That's
because internally Unicode is always stored as utf-8.
WARNING: Conversion can cause loss of information! When
'encoding' is "utf-8" or another Unicode encoding, conversion
is most likely done in a way that the reverse conversion
results in the same text. When 'encoding' is not "utf-8" some
characters may be lost!

See 'encoding' for the possible values. Additionally, values may be
specified that can be handled by the converter, see
mbyte-conversion .

When reading a file 'fileencoding' will be set from 'fileencodings'.
To read a file in a certain encoding it won't work by setting
'fileencoding', use the ++enc argument. One exception: when
'fileencodings' is empty the value of 'fileencoding' is used.
For a new file the global value of 'fileencoding' is used.

Prepending "8bit-" and "2byte-" has no meaning here, they are ignored.
When the option is set, the value is converted to lowercase. Thus
you can set it with uppercase values too. '_' characters are
replaced with '-'. If a name is recognized from the list for
'encoding', it is replaced by the standard name. For example
"ISO8859-2" becomes "iso-8859-2".

When this option is set, after starting to edit a file, the 'modified'
option is set, because the file would be different when written.

Keep in mind that changing 'fenc' from a modeline happens
AFTER the text has been read, thus it applies to when the file will be
written. If you do set 'fenc' in a modeline, you might want to set
'nomodified' to avoid not being able to ":q".

This option can not be changed when 'modifiable' is off.

'fe'
NOTE: Before version 6.0 this option specified the encoding for the whole of Vim, this was a mistake. Now use 'encoding' instead. The old short name was 'fe', which is no longer used.

'fileencodings' 'fencs'
'fileencodings' 'fencs' string (default: "ucs-bom",
"ucs-bom,utf-8,default,latin1" when
'encoding' is set to a Unicode value)
global
{only available when compiled with the +multi_byte feature}
{not in Vi}
This is a list of character encodings considered when starting to edit an existing file. When a file is read, Vim tries to use the first mentioned character encoding. If an error is detected, the next one in the list is tried. When an encoding is found that works, 'fileencoding' is set to it. If all fail, 'fileencoding' is set to an empty string, which means the value of 'encoding' is used.
WARNING: Conversion can cause loss of information! When 'encoding' is "utf-8" (or one of the other Unicode variants) conversion is most likely done in a way that the reverse conversion results in the same text. When 'encoding' is not "utf-8" some non-ASCII characters may be lost! You can use the ++bad argument to specify what is done with characters that can't be converted.
For an empty file or a file with only ASCII characters most encodings will work and the first entry of 'fileencodings' will be used (except "ucs-bom", which requires the BOM to be present). If you prefer another encoding use an BufReadPost autocommand event to test if your preferred encoding is to be used. Example:
```
au BufReadPost * if search('\S', 'w') == 0 |
\ set fenc=iso-2022-jp | endif
```
This sets 'fileencoding' to "iso-2022-jp" if the file does not contain non-blank characters.
When the ++enc argument is used then the value of 'fileencodings' is not used.
Note that 'fileencodings' is not used for a new file, the global value of 'fileencoding' is used instead. You can set it with:
```
:setglobal fenc=iso-8859-2
```
This means that a non-existing file may get a different encoding than an empty file.
The special value "ucs-bom" can be used to check for a Unicode BOM (Byte Order Mark) at the start of the file. It must not be preceded by "utf-8" or another Unicode encoding for this to work properly.
An entry for an 8-bit encoding (e.g., "latin1") should be the last, because Vim cannot detect an error, thus the encoding is always accepted.
The special value "default" can be used for the encoding from the environment. This is the default value for 'encoding'. It is useful when 'encoding' is set to "utf-8" and your environment uses a non-latin1 encoding, such as Russian.
When 'encoding' is "utf-8" and a file contains an illegal byte sequence it won't be recognized as UTF-8. You can use the 8g8

command to find the illegal byte sequence.
WRONG VALUES: WHAT'S WRONG:
latin1,utf-8 "latin1" will always be used
utf-8,ucs-bom,latin1 BOM won't be recognized in an utf-8 file
cp1250,latin1 "cp1250" will always be used
If 'fileencodings' is empty, 'fileencoding' is not modified.
See 'fileencoding' for the possible values.
Setting this option does not have an effect until the next time a file is read.

'fileformat' 'ff'

'fileformat' 'ff' string (MS-DOS, MS-Windows, OS/2 default: "dos",
Unix default: "unix",
Macintosh default: "mac")
local to buffer
{not in Vi}
This gives the <EOL> of the current buffer, which is used for reading/writing the buffer from/to a file:
dos <CR> <NL>
unix <NL>
mac <CR>
When "dos" is used, CTRL-Z at the end of a file is ignored.
See file-formats and file-read .
For the character encoding of the file see 'fileencoding'.
When 'binary' is set, the value of 'fileformat' is ignored, file I/O works like it was set to "unix".
This option is set automatically when starting to edit a file and 'fileformats' is not empty and 'binary' is off.
When this option is set, after starting to edit a file, the 'modified' option is set, because the file would be different when written.
This option can not be changed when 'modifiable' is off.
For backwards compatibility: When this option is set to "dos", 'textmode' is set, otherwise 'textmode' is reset.

'fileformats' 'ffs'

'fileformats' 'ffs' string (default:
Vim+Vi MS-DOS, MS-Windows OS/2: "dos,unix",
Vim Unix: "unix,dos",
Vim Mac: "mac,unix,dos",
Vi Cygwin: "unix,dos",
Vi others: "")
global
{not in Vi}
This gives the end-of-line (<EOL>) formats that will be tried when starting to edit a new buffer and when reading a file into an existing buffer:
- When empty, the format defined with 'fileformat' will be used always. It is not set automatically.
- When set to one name, that format will be used whenever a new buffer is opened. 'fileformat' is set accordingly for that buffer. The 'fileformats' name will be used when a file is read into an existing buffer, no matter what 'fileformat' for that buffer is set to.
- When more than one name is present, separated by commas, automatic

<EOL> detection will be done when reading a file. When starting to
edit a file, a check is done for the <EOL>:
1. If all lines end in <CR><NL>, and 'fileformats' includes "dos",
'fileformat' is set to "dos".
2. If a <NL> is found and 'fileformats' includes "unix", 'fileformat'
is set to "unix". Note that when a <NL> is found without a
preceding <CR>, "unix" is preferred over "dos".
3. If 'fileformat' has not yet been set, and if a <CR> is found, and
if 'fileformats' includes "mac", 'fileformat' is set to "mac".
This means that "mac" is only chosen when:
"unix" is not present or no <NL> is found in the file, and
"dos" is not present or no <CR><NL> is found in the file.
Except: if "unix" was chosen, but there is a <CR> before
the first <NL>, and there appear to be more <CR>s than <NL>s in
the first few lines, "mac" is used.
4. If 'fileformat' is still not set, the first name from
'fileformats' is used.
When reading a file into an existing buffer, the same is done, but
this happens like 'fileformat' has been set appropriately for that
file only, the option is not changed.
When 'binary' is set, the value of 'fileformats' is not used.

When Vim starts up with an empty buffer the first item is used. You
can overrule this by setting 'fileformat' in your .vimrc.

For systems with a Dos-like <EOL> (<CR><NL>), when reading files that
are ":source"ed and for vimrc files, automatic <EOL> detection may be
done:
- When 'fileformats' is empty, there is no automatic detection. Dos
format will be used.
- When 'fileformats' is set to one or more names, automatic detection
is done. This is based on the first <NL> in the file: If there is a
<CR> in front of it, Dos format is used, otherwise Unix format is
used.
Also see file-formats .
For backwards compatibility: When this option is set to an empty
string or one format (no comma is included), 'textauto' is reset,
otherwise 'textauto' is set.
NOTE: This option is set to the Vi default value when 'compatible' is
set and to the Vim default value when 'compatible' is reset.

'fileignorecase' 'fic' 'nofileignorecase' 'nofic'
'fileignorecase' 'fic' boolean (default on for systems where case in file
names is normally ignored)
global
{not in Vi}
When set case is ignored when using file names and directories.
See 'wildignorecase' for only ignoring case when doing completion.

'filetype' 'ft'
'filetype' 'ft' string (default: "")
local to buffer
{not in Vi}
When this option is set, the FileType autocommand event is triggered.

All autocommands that match with the value of this option will be executed. Thus the value of 'filetype' is used in place of the file name.
Otherwise this option does not always reflect the current file type. This option is normally set when the file type is detected. To enable this use the ":filetype on" command. :filetype
Setting this option to a different value is most useful in a modeline, for a file for which the file type is not automatically recognized. Example, for in an IDL file:
```
	/* vim: set filetype=idl : */
```
FileType filetypes
When a dot appears in the value then this separates two filetype names. Example:
```
	/* vim: set filetype=c.doxygen : */
```
This will use the "c" filetype first, then the "doxygen" filetype. This works both for filetype plugins and for syntax files. More than one dot may appear.
This option is not copied to another buffer, independent of the 's' or 'S' flag in 'cpoptions'.
Only normal file name characters can be used, "/*?[|<>" are illegal.

'fillchars' 'fcs' 'fillchars' 'fcs'

string (default "vert:|,fold:-")
global
{not in Vi}
{not available when compiled without the +windows and +folding features}

Characters to fill the statuslines and vertical separators. It is a comma separated list of items:

item	default	Used for
stl:c	' ' or '^'	statusline of the current window
stlnc:c	' ' or '='	statusline of the non-current windows
vert:c	'|'	vertical separators :vsplit
fold:c	'-'	filling 'foldtext'
diff:c	'-'	deleted lines of the 'diff' option

Any one that is omitted will fall back to the default. For "stl" and "stlnc" the space will be used when there is highlighting, '^' or '=' otherwise.

Example:
```
    :set fillchars=stl:^,stlnc:=,vert:\|,fold:-,diff:-
```
This is similar to the default, except that these characters will also be used when there is highlighting.

for "stl" and "stlnc" only single-byte values are supported.

The highlighting used for these items:

item	highlight group	
stl:c	StatusLine	hl-StatusLine
stlnc:c	StatusLineNC	hl-StatusLineNC
vert:c	VertSplit	hl-VertSplit
fold:c	Folded	hl-Folded

```
          diff:c        DiffDelete              hl-DiffDelete

                  'fixendofline'   'fixeol'   'nofixendofline'   'nofixeol'
'fixendofline' 'fixeol' boolean (default on)
                        local to buffer
                        {not in Vi}
        When writing a file and this option is on, <EOL> at the end of file
        will be restored if missing. Turn this option off if you want to
        preserve the situation from the original file.
        When the 'binary' option is set the value of this option doesn't
        matter.
        See the 'endofline' option.

                                             'fkmap'   'fk'   'nofkmap'   'nofk'
'fkmap' 'fk'            boolean (default off)                    E198
                        global
                        {not in Vi}
                        {only available when compiled with the  +rightleft
                        feature}
        When on, the keyboard is mapped for the Farsi character set.
        Normally you would set 'allowrevins' and use CTRL-_ in insert mode to
        toggle this option  i_CTRL-_ .  See  farsi.txt .

                                                 'foldclose'   'fcl'
'foldclose' 'fcl'       string (default "")
                        global
                        {not in Vi}
                        {not available when compiled without the  +folding
                        feature}
        When set to "all", a fold is closed when the cursor isn't in it and
        its level is higher than 'foldlevel'.  Useful if you want folds to
        automatically close when moving out of them.

                                                 'foldcolumn'   'fdc'
'foldcolumn' 'fdc'      number (default 0)
                        local to window
                        {not in Vi}
                        {not available when compiled without the  +folding
                        feature}
        When non-zero, a column with the specified width is shown at the side
        of the window which indicates open and closed folds.  The maximum
        value is 12.
        See  folding .

                         'foldenable'   'fen'   'nofoldenable'   'nofen'
'foldenable' 'fen'      boolean (default on)
                        local to window
                        {not in Vi}
                        {not available when compiled without the  +folding
                        feature}
        When off, all folds are open.  This option can be used to quickly
        switch between showing all text unfolded and viewing the text with
        folds (including manually opened or closed folds).  It can be toggled
        with the  zi  command.  The 'foldcolumn' will remain blank when
```

'foldenable' is off.
This option is set by commands that create a new fold or close a fold.
See folding .

'foldexpr' 'fde'
'foldexpr' 'fde' string (default: "0")
local to window
{not in Vi}
{not available when compiled without the +folding or +eval features}
The expression used for when 'foldmethod' is "expr". It is evaluated for each line to obtain its fold level. See fold-expr .

The expression will be evaluated in the sandbox if set from a modeline, see sandbox-option .
This option can't be set from a modeline when the 'diff' option is on.

It is not allowed to change text or jump to another window while evaluating 'foldexpr' textlock .

'foldignore' 'fdi'
'foldignore' 'fdi' string (default: "#")
local to window
{not in Vi}
{not available when compiled without the +folding feature}
Used only when 'foldmethod' is "indent". Lines starting with characters in 'foldignore' will get their fold level from surrounding lines. White space is skipped before checking for this character.
The default "#" works well for C programs. See fold-indent .

'foldlevel' 'fdl'
'foldlevel' 'fdl' number (default: 0)
local to window
{not in Vi}
{not available when compiled without the +folding feature}
Sets the fold level: Folds with a higher level will be closed.
Setting this option to zero will close all folds. Higher numbers will close fewer folds.
This option is set by commands like zm , zM and zR .
See fold-foldlevel .

'foldlevelstart' 'fdls'
'foldlevelstart' 'fdls' number (default: -1)
global
{not in Vi}
{not available when compiled without the +folding feature}
Sets 'foldlevel' when starting to edit another buffer in a window. Useful to always start editing with all folds closed (value zero), some folds closed (one) or no folds closed (99).
This is done before reading any modeline, thus a setting in a modeline

overrules this option. Starting to edit a file for diff-mode also
ignores this option and closes all folds.
It is also done before BufReadPre autocommands, to allow an autocmd to
overrule the 'foldlevel' value for specific files.
When the value is negative, it is not used.

                                                    'foldmarker'   'fmr'   E536
'foldmarker' 'fmr'   string (default: "{{{,}}}")
                        local to window
                        {not in Vi}
                        {not available when compiled without the +folding
                        feature}
The start and end marker used when 'foldmethod' is "marker". There
must be one comma, which separates the start and end marker. The
marker is a literal string (a regular expression would be too slow).
See fold-marker .

                                                    'foldmethod'   'fdm'
'foldmethod' 'fdm'   string (default: "manual")
                        local to window
                        {not in Vi}
                        {not available when compiled without the +folding
                        feature}
The kind of folding used for the current window. Possible values:
 fold-manual   manual   Folds are created manually.
 fold-indent   indent   Lines with equal indent form a fold.
 fold-expr   expr   'foldexpr' gives the fold level of a line.
 fold-marker   marker   Markers are used to specify folds.
 fold-syntax   syntax   Syntax highlighting items specify folds.
 fold-diff   diff   Fold text that is not changed.

                                                    'foldminlines'   'fml'
'foldminlines' 'fml'   number (default: 1)
                        local to window
                        {not in Vi}
                        {not available when compiled without the +folding
                        feature}
Sets the number of screen lines above which a fold can be displayed
closed. Also for manually closed folds. With the default value of
one a fold can only be closed if it takes up two or more screen lines.
Set to zero to be able to close folds of just one screen line.
Note that this only has an effect on what is displayed. After using
"zc" to close a fold, which is displayed open because it's smaller
than 'foldminlines', a following "zc" may close a containing fold.

                                                    'foldnestmax'   'fdn'
'foldnestmax' 'fdn'   number (default: 20)
                        local to window
                        {not in Vi}
                        {not available when compiled without the +folding
                        feature}
Sets the maximum nesting of folds for the "indent" and "syntax"
methods. This avoids that too many folds will be created. Using more
than 20 doesn't work, because the internal limit is 20.

'foldopen' 'fdo'

'foldopen' 'fdo'	string (default: "block,hor,mark,percent,quickfix,
search,tag,undo")
global
{not in Vi}
{not available when compiled without the +folding
feature}
Specifies for which type of commands folds will be opened, if the
command moves the cursor into a closed fold. It is a comma separated
list of items.
NOTE: When the command is part of a mapping this option is not used.
Add the zv command to the mapping to get the same effect.
(rationale: the mapping may want to control opening folds itself)

item	commands
all	any
block	"(", "{", "[[", "[{", etc.
hor	horizontal movements: "l", "w", "fx", etc.
insert	any command in Insert mode
jump	far jumps: "G", "gg", etc.
mark	jumping to a mark: "'m", CTRL-O, etc.
percent	"%"
quickfix	":cn", ":crew", ":make", etc.
search	search for a pattern: "/", "n", "*", "gd", etc. (not for a search pattern in a ":" command) Also for [s and]s .
tag	jumping to a tag: ":ta", CTRL-T, etc.
undo	undo or redo: "u" and CTRL-R

When a movement command is used for an operator (e.g., "dl" or "y%")
this option is not used. This means the operator will include the
whole closed fold.
Note that vertical movements are not here, because it would make it
very difficult to move onto a closed fold.
In insert mode the folds containing the cursor will always be open
when text is inserted.
To close folds you can re-apply 'foldlevel' with the zx command or
set the 'foldclose' option to "all".

'foldtext' 'fdt'

'foldtext' 'fdt'	string (default: "foldtext()")
local to window
{not in Vi}
{not available when compiled without the +folding
feature}
An expression which is used to specify the text displayed for a closed
fold. See fold-foldtext .

The expression will be evaluated in the sandbox if set from a
modeline, see sandbox-option .

It is not allowed to change text or jump to another window while
evaluating 'foldtext' textlock .

'formatexpr' 'fex'

'formatexpr' 'fex'	string (default "")
local to buffer
{not in Vi}
{not available when compiled without the +eval feature}

Expression which is evaluated to format a range of lines for the gq operator or automatic formatting (see 'formatoptions'). When this option is empty 'formatprg' is used.

The v:lnum variable holds the first line to be formatted.
The v:count variable holds the number of lines to be formatted.
The v:char variable holds the character that is going to be inserted if the expression is being evaluated due to automatic formatting. This can be empty. Don't insert it yet!

Example:

```
:set formatexpr=mylang#Format()
```

This will invoke the mylang#Format() function in the autoload/mylang.vim file in 'runtimepath'. autoload

The expression is also evaluated when 'textwidth' is set and adding text beyond that limit. This happens under the same conditions as when internal formatting is used. Make sure the cursor is kept in the same spot relative to the text then! The mode() function will return "i" or "R" in this situation.

When the expression evaluates to non-zero Vim will fall back to using the internal format mechanism.

The expression will be evaluated in the sandbox when set from a modeline, see sandbox-option . That stops the option from working, since changing the buffer text is not allowed.
NOTE: This option is set to "" when 'compatible' is set.

'formatoptions' 'fo'

'formatoptions' 'fo'	string (Vim default: "tcq", Vi default: "vt")
local to buffer
{not in Vi}

This is a sequence of letters which describes how automatic formatting is to be done. See fo-table . When the 'paste' option is on, no formatting is done (like 'formatoptions' is empty). Commas can be inserted for readability.
To avoid problems with flags that are added in the future, use the "+=" and "-=" feature of ":set" add-option-flags .
NOTE: This option is set to the Vi default value when 'compatible' is set and to the Vim default value when 'compatible' is reset.

'formatlistpat' 'flp'

'formatlistpat' 'flp'	string (default: "^\s*\d\+[\]:.)}\t]\s*")
local to buffer
{not in Vi}

A pattern that is used to recognize a list header. This is used for

the "n" flag in 'formatoptions'.
The pattern must match exactly the text that will be the indent for the line below it. You can use /\ze to mark the end of the match while still checking more characters. There must be a character following the pattern, when it matches the whole line it is handled like there is no match.
The default recognizes a number, followed by an optional punctuation character and white space.

'formatprg' 'fp'

'formatprg' 'fp' string (default "")
global or local to buffer global-local
{not in Vi}

The name of an external program that will be used to format the lines selected with the gq operator. The program must take the input on stdin and produce the output on stdout. The Unix program "fmt" is such a program.
If the 'formatexpr' option is not empty it will be used instead. Otherwise, if 'formatprg' option is an empty string, the internal format function will be used C-indenting .
Environment variables are expanded :set_env . See option-backslash about including spaces and backslashes.
This option cannot be set from a modeline or in the sandbox , for security reasons.

'fsync' 'fs' 'nofsync' 'nofs'

'fsync' 'fs' boolean (default on)
global
{not in Vi}

When on, the library function fsync() will be called after writing a file. This will flush a file to disk, ensuring that it is safely written even on filesystems which do metadata-only journaling. This will force the harddrive to spin up on Linux systems running in laptop mode, so it may be undesirable in some situations. Be warned that turning this off increases the chances of data loss after a crash. On systems without an fsync() implementation, this variable is always off.
Also see 'swapsync' for controlling fsync() on swap files.
'fsync' also applies to writefile() , unless a flag is used to overrule it.

'gdefault' 'gd' 'nogdefault' 'nogd'

'gdefault' 'gd' boolean (default off)
global
{not in Vi}

When on, the ":substitute" flag 'g' is default on. This means that all matches in a line are substituted instead of one. When a 'g' flag is given to a ":substitute" command, this will toggle the substitution of all or one match. See complex-change .

command	'gdefault' on	'gdefault' off
:s///	subst. all	subst. one
:s///g	subst. one	subst. all
:s///gg	subst. all	subst. one

NOTE: This option is reset when 'compatible' is set.
DEPRECATED: Setting this option may break plugins that are not aware of this option. Also, many users get confused that adding the /g flag has the opposite effect of that it normally does.

'grepformat' 'gfm'

'grepformat' 'gfm' string (default "%f:%l:%m,%f:%l%m,%f %l%m")
global
{not in Vi}
Format to recognize for the ":grep" command output.
This is a scanf-like string that uses the same format as the 'errorformat' option: see errorformat .

'grepprg' 'gp'

'grepprg' 'gp' string (default "grep -n ",
Unix: "grep -n $* /dev/null",
Win32: "findstr /n" or "grep -n",
VMS: "SEARCH/NUMBERS ")
global or local to buffer global-local
{not in Vi}
Program to use for the :grep command. This option may contain '%' and '#' characters, which are expanded like when used in a command-line. The placeholder "$*" is allowed to specify where the arguments will be included. Environment variables are expanded :set_env . See option-backslash about including spaces and backslashes.
When your "grep" accepts the "-H" argument, use this to make ":grep" also work well with a single file:

```
:set grepprg=grep\ -nH
```

Special value: When 'grepprg' is set to "internal" the :grep command works like :vimgrep , :lgrep like :lvimgrep , :grepadd like :vimgrepadd and :lgrepadd like :lvimgrepadd .
See also the section :make_makeprg , since most of the comments there apply equally to 'grepprg'.
For Win32, the default is "findstr /n" if "findstr.exe" can be found, otherwise it's "grep -n".
This option cannot be set from a modeline or in the sandbox , for security reasons.

'guicursor' 'gcr' E545 E546 E548 E549

'guicursor' 'gcr' string (default "n-v-c:block-Cursor/lCursor,
ve:ver35-Cursor,
o:hor50-Cursor,
i-ci:ver25-Cursor/lCursor,
r-cr:hor20-Cursor/lCursor,
sm:block-Cursor
-blinkwait175-blinkoff150-blinkon175",
for MS-DOS and Win32 console:
"n-v-c:block,o:hor50,i-ci:hor15,
r-cr:hor30,sm:block")
global
{not in Vi}
{only available when compiled with GUI enabled, and for MS-DOS and Win32 console}

This option tells Vim what the cursor should look like in different
modes. It fully works in the GUI. In an MSDOS or Win32 console, only
the height of the cursor can be changed. This can be done by
specifying a block cursor, or a percentage for a vertical or
horizontal cursor.
For a console the 't_SI', 't_SR', and 't_EI' escape sequences are
used.

The option is a comma separated list of parts. Each part consist of a
mode-list and an argument-list:
        mode-list:argument-list,mode-list:argument-list,..
The mode-list is a dash separated list of these modes:
        n   Normal mode
        v   Visual mode
        ve   Visual mode with 'selection' "exclusive" (same as 'v',
                if not specified)
        o   Operator-pending mode
        i   Insert mode
        r   Replace mode
        c   Command-line Normal (append) mode
        ci   Command-line Insert mode
        cr   Command-line Replace mode
        sm   showmatch in Insert mode
        a   all modes
The argument-list is a dash separated list of these arguments:
        hor{N} horizontal bar, {N} percent of the character height
        ver{N} vertical bar, {N} percent of the character width
        block   block cursor, fills the whole character
                [only one of the above three should be present]
        blinkwait{N}   cursor-blinking
        blinkon{N}
        blinkoff{N}
                blink times for cursor: blinkwait is the delay before
                the cursor starts blinking, blinkon is the time that
                the cursor is shown and blinkoff is the time that the
                cursor is not shown. The times are in msec. When one
                of the numbers is zero, there is no blinking. The
                default is: "blinkwait700-blinkon400-blinkoff250".
                These numbers are used for a missing entry. This
                means that blinking is enabled by default. To switch
                blinking off you can use "blinkon0". The cursor only
                blinks when Vim is waiting for input, not while
                executing a command.
                To make the cursor blink in an xterm, see
                 xterm-blink .
        {group-name}
                a highlight group name, that sets the color and font
                for the cursor
        {group-name}/{group-name}
                Two highlight group names, the first is used when
                no language mappings are used, the other when they
                are. language-mapping

Examples of parts:

```
      n-c-v:block-nCursor  in Normal, Command-line and Visual mode, use a
                           block cursor with colors from the "nCursor"
                           highlight group
      i-ci:ver30-iCursor-blinkwait300-blinkon200-blinkoff150
                           In Insert and Command-line Insert mode, use a
                           30% vertical bar cursor with colors from the
                           "iCursor" highlight group.  Blink a bit
                           faster.

    The 'a' mode is different.  It will set the given argument-list for
    all modes.  It does not reset anything to defaults.  This can be used
    to do a common setting for all modes.  For example, to switch off
    blinking: "a:blinkon0"

    Examples of cursor highlighting:
        :highlight Cursor gui=reverse guifg=NONE guibg=NONE
        :highlight Cursor gui=NONE guifg=bg guibg=fg

                                        'guifont'   'gfn'
                                                  E235   E596
'guifont' 'gfn'         string  (default "")
                        global
                        {not in Vi}
                        {only available when compiled with GUI enabled}
    This is a list of fonts which will be used for the GUI version of Vim.
    In its simplest form the value is just one font name.  When
    the font cannot be found you will get an error message.  To try other
    font names a list can be specified, font names separated with commas.
    The first valid font is used.

    On systems where 'guifontset' is supported (X11) and 'guifontset' is
    not empty, then 'guifont' is not used.

    Note: As to the GTK GUIs, no error is given against any invalid names,
    and the first element of the list is always picked up and made use of.
    This is because, instead of identifying a given name with a font, the
    GTK GUIs use it to construct a pattern and try to look up a font which
    best matches the pattern among available fonts, and this way, the
    matching never fails.  An invalid name doesn't matter because a number
    of font properties other than name will do to get the matching done.

    Spaces after a comma are ignored.  To include a comma in a font name
    precede it with a backslash.  Setting an option requires an extra
    backslash before a space and a backslash.  See also
     option-backslash .  For example:
        :set guifont=Screen15,\ 7x13,font\\,with\\,commas
   will make Vim try to use the font "Screen15" first, and if it fails it
    will try to use "7x13" and then "font,with,commas" instead.

    If none of the fonts can be loaded, Vim will keep the current setting.
    If an empty font list is given, Vim will try using other resource
    settings (for X, it will use the Vim.font resource), and finally it
    will try some builtin default which should always be there ("7x13" in
    the case of X).  The font names given should be "normal" fonts.  Vim
```

will try to find the related bold and italic fonts.

For Win32, GTK, Motif, Mac OS and Photon:
    :set guifont=*
will bring up a font requester, where you can pick the font you want.

The font name depends on the GUI used. See setting-guifont for a way to set 'guifont' for various systems.

For the GTK+ 2 and 3 GUIs, the font name looks like this:
    :set guifont=Andale\ Mono\ 11
That's all. XLFDs are not used. For Chinese this is reported to work well:
    if has("gui_gtk2")
      set guifont=Bitstream\ Vera\ Sans\ Mono\ 12,Fixed\ 12
      set guifontwide=Microsoft\ Yahei\ 12,WenQuanYi\ Zen\ Hei\ 12
    endif

(Replace gui_gtk2 with gui_gtk3 for the GTK+ 3 GUI)

For Mac OSX you can use something like this:
    :set guifont=Monaco:h10
Also see 'macatsui', it can help fix display problems.
                                                                E236
Note that the fonts must be mono-spaced (all characters have the same width). An exception is GTK: all fonts are accepted, but mono-spaced fonts look best.

To preview a font on X11, you might be able to use the "xfontsel" program. The "xlsfonts" program gives a list of all available fonts.

For the Win32 GUI   E244 E245
- takes these options in the font name:
        hXX - height is XX (points, can be floating-point)
        wXX - width is XX (points, can be floating-point)
        b   - bold
        i   - italic
        u   - underline
        s   - strikeout
        cXX - character set XX. Valid charsets are: ANSI, ARABIC,
              BALTIC, CHINESEBIG5, DEFAULT, EASTEUROPE, GB2312, GREEK,
              HANGEUL, HEBREW, JOHAB, MAC, OEM, RUSSIAN, SHIFTJIS,
              SYMBOL, THAI, TURKISH, VIETNAMESE ANSI and BALTIC.
              Normally you would use "cDEFAULT".
        qXX - quality XX. Valid quality names are: PROOF, DRAFT,
              ANTIALIASED, NONANTIALIASED, CLEARTYPE, DEFAULT.
              Normally you would use "qDEFAULT".
              Some quality values are not supported in legacy OSs.

  Use a ':' to separate the options.
- A '_' can be used in the place of a space, so you don't need to use
  backslashes to escape the spaces.
- Examples:
    :set guifont=courier_new:h12:w5:b:cRUSSIAN

```
            :set guifont=Andale_Mono:h7.5:w4.5
        See also  font-sizes .

                                            'guifontset'   'gfs'
                                            E250   E252   E234   E597   E598
'guifontset' 'gfs'      string  (default "")
                        global
                        {not in Vi}
                        {only available when compiled with GUI enabled and
                        with the  +xfontset  feature}
                        {not available in the GTK+ GUI}
        When not empty, specifies two (or more) fonts to be used.  The first
        one for normal English, the second one for your special language.  See
         xfontset .
        Setting this option also means that all font names will be handled as
        a fontset name.  Also the ones used for the "font" argument of the
         :highlight  command.
        The fonts must match with the current locale.  If fonts for the
        character sets that the current locale uses are not included, setting
        'guifontset' will fail.
        Note the difference between 'guifont' and 'guifontset': In 'guifont'
        the comma-separated names are alternative names, one of which will be
        used.  In 'guifontset' the whole string is one fontset name,
        including the commas.  It is not possible to specify alternative
        fontset names.
        This example works on many X11 systems:
                :set guifontset=-*-*-medium-r-normal--16-*-*-*-c-*-*-*

                                    'guifontwide'   'gfw'   E231   E533   E534
'guifontwide' 'gfw'     string  (default "")
                        global
                        {not in Vi}
                        {only available when compiled with GUI enabled}
        When not empty, specifies a comma-separated list of fonts to be used
        for double-width characters.  The first font that can be loaded is
        used.
        Note: The size of these fonts must be exactly twice as wide as the one
        specified with 'guifont' and the same height.

        All GUI versions but GTK+:

        'guifontwide' is only used when 'encoding' is set to "utf-8" and
        'guifontset' is empty or invalid.
        When 'guifont' is set and a valid font is found in it and
        'guifontwide' is empty Vim will attempt to find a matching
        double-width font and set 'guifontwide' to it.

        GTK+ GUI only:                              guifontwide_gtk

        If set and valid, 'guifontwide' is always used for double width
        characters, even if 'encoding' is not set to "utf-8".
        Vim does not attempt to find an appropriate value for 'guifontwide'
        automatically.  If 'guifontwide' is empty Pango/Xft will choose the
        font for characters not available in 'guifont'.  Thus you do not need
```

to set 'guifontwide' at all unless you want to override the choice made by Pango/Xft.

Windows +multibyte only: guifontwide_win_mbyte

If set and valid, 'guifontwide' is used for IME instead of 'guifont'.

'guiheadroom' 'ghr'

'guiheadroom' 'ghr' number (default 50)
global
{not in Vi} {only for GTK and X11 GUI}

The number of pixels subtracted from the screen height when fitting the GUI window on the screen. Set this before the GUI is started, e.g., in your gvimrc file. When zero, the whole screen height will be used by the window. When positive, the specified number of pixel lines will be left for window decorations and other items on the screen. Set it to a negative value to allow windows taller than the screen.

'guioptions' 'go'

'guioptions' 'go' string (default "egmrLtT" (MS-Windows, "t" is removed in defaults.vim), "aegimrLtT" (GTK, Motif and Athena),)
global
{not in Vi}
{only available when compiled with GUI enabled}

This option only has an effect in the GUI version of Vim. It is a sequence of letters which describes what components and options of the GUI should be used.
To avoid problems with flags that are added in the future, use the "+=" and "-=" feature of ":set" add-option-flags .

Valid characters are as follows:

'go-!'

'!' External commands are executed in a terminal window. Without this flag the MS-Windows GUI will open a console window to execute the command. The Unix GUI will simulate a dumb terminal to list the command output.
The terminal window will be positioned at the bottom, and grow upwards as needed.

guioptions_a 'go-a'

'a' Autoselect: If present, then whenever VISUAL mode is started, or the Visual area extended, Vim tries to become the owner of the windowing system's global selection. This means that the Visually highlighted text is available for pasting into other applications as well as into Vim itself. When the Visual mode ends, possibly due to an operation on the text, or when an application wants to paste the selection, the highlighted text is automatically yanked into the "* selection register.
Thus the selection is still available for pasting into other applications after the VISUAL mode has ended.
If not present, then Vim won't become the owner of the windowing system's global selection unless explicitly told to

by a yank or delete operation for the "* register.
The same applies to the modeless selection.
'go-P'

'P' Like autoselect but using the "+ register instead of the "* register.
'go-A'

'A' Autoselect for the modeless selection. Like 'a', but only applies to the modeless selection.

'guioptions'	autoselect Visual	autoselect modeless
""	-	-
"a"	yes	yes
"A"	-	yes
"aA"	yes	yes

'go-c'

'c' Use console dialogs instead of popup dialogs for simple choices.
'go-e'

'e' Add tab pages when indicated with 'showtabline'.
'guitablabel' can be used to change the text in the labels.
When 'e' is missing a non-GUI tab pages line may be used.
The GUI tabs are only supported on some systems, currently GTK, Motif, Mac OS/X and MS-Windows.
'go-f'

'f' Foreground: Don't use fork() to detach the GUI from the shell where it was started. Use this for programs that wait for the editor to finish (e.g., an e-mail program). Alternatively you can use "gvim -f" or ":gui -f" to start the GUI in the foreground. gui-fork
Note: Set this option in the vimrc file. The forking may have happened already when the gvimrc file is read.
'go-i'

'i' Use a Vim icon. For GTK with KDE it is used in the left-upper corner of the window. It's black&white on non-GTK, because of limitations of X11. For a color icon, see X11-icon .
'go-m'

'm' Menu bar is present.
'go-M'

'M' The system menu "$VIMRUNTIME/menu.vim" is not sourced. Note that this flag must be added in the .vimrc file, before switching on syntax or filetype recognition (when the gvimrc file is sourced the system menu has already been loaded; the `:syntax on` and `:filetype on` commands load the menu too).
'go-g'

'g' Grey menu items: Make menu items that are not active grey. If 'g' is not included inactive menu items are not shown at all. Exception: Athena will always use grey menu items.
'go-t'

't' Include tearoff menu items. Currently only works for Win32, GTK+, and Motif 1.2 GUI.
'go-T'

'T' Include Toolbar. Currently only in Win32, GTK+, Motif, Photon and Athena GUIs.

'go-r'
'r'	Right-hand scrollbar is always present.
'go-R'
'R'	Right-hand scrollbar is present when there is a vertically
	split window.
'go-l'
'l'	Left-hand scrollbar is always present.
'go-L'
'L'	Left-hand scrollbar is present when there is a vertically
	split window.
'go-b'
'b'	Bottom (horizontal) scrollbar is present. Its size depends on
	the longest visible line, or on the cursor line if the 'h'
	flag is included. gui-horiz-scroll
'go-h'
'h'	Limit horizontal scrollbar size to the length of the cursor
	line. Reduces computations. gui-horiz-scroll

And yes, you may even have scrollbars on the left AND the right if
you really want to :-). See gui-scrollbars for more information.

'go-v'
'v'	Use a vertical button layout for dialogs. When not included,
	a horizontal layout is preferred, but when it doesn't fit a
	vertical layout is used anyway.
'go-p'
'p'	Use Pointer callbacks for X11 GUI. This is required for some
	window managers. If the cursor is not blinking or hollow at
	the right moment, try adding this flag. This must be done
	before starting the GUI. Set it in your gvimrc . Adding or
	removing it after the GUI has started has no effect.
'go-F'
'F'	Add a footer. Only for Motif. See gui-footer .
'go-k'
'k'	Keep the GUI window size when adding/removing a scrollbar, or
	toolbar, tabline, etc. Instead, the behavior is similar to
	when the window is maximized and will adjust 'lines' and
	'columns' to fit to the window. Without the 'k' flag Vim will
	try to keep 'lines' and 'columns' the same when adding and
	removing GUI components.

'guipty'	'noguipty'
'guipty'		boolean (default on)
			global
			{not in Vi}
			{only available when compiled with GUI enabled}
Only in the GUI: If on, an attempt is made to open a pseudo-tty for
I/O to/from shell commands. See gui-pty .

'guitablabel'	'gtl'
'guitablabel' 'gtl'	string (default empty)
			global
			{not in Vi}
			{only available when compiled with GUI enabled and

with the +windows feature}
When nonempty describes the text to use in a label of the GUI tab pages line. When empty and when the result is empty Vim will use a default label. See setting-guitablabel for more info.

The format of this option is like that of 'statusline'.
'guitabtooltip' is used for the tooltip, see below.
The expression will be evaluated in the sandbox when set from a modeline, see sandbox-option .

Only used when the GUI tab pages line is displayed. 'e' must be present in 'guioptions'. For the non-GUI tab pages line 'tabline' is used.

'guitabtooltip' 'gtt'

'guitabtooltip' 'gtt' string (default empty)
global
{not in Vi}
{only available when compiled with GUI enabled and with the +windows feature}
When nonempty describes the text to use in a tooltip for the GUI tab pages line. When empty Vim will use a default tooltip.
This option is otherwise just like 'guitablabel' above.
You can include a line break. Simplest method is to use :let :

```
:let &guitabtooltip = "line one\nline two"
```

'helpfile' 'hf'

'helpfile' 'hf' string (default (MSDOS) "$VIMRUNTIME\doc\help.txt"
(others) "$VIMRUNTIME/doc/help.txt")
global
{not in Vi}
Name of the main help file. All distributed help files should be placed together in one directory. Additionally, all "doc" directories in 'runtimepath' will be used.
Environment variables are expanded :set_env . For example: "$VIMRUNTIME/doc/help.txt". If $VIMRUNTIME is not set, $VIM is also tried. Also see $VIMRUNTIME and option-backslash about including spaces and backslashes.
This option cannot be set from a modeline or in the sandbox , for security reasons.

'helpheight' 'hh'

'helpheight' 'hh' number (default 20)
global
{not in Vi}
{not available when compiled without the +windows feature}
Minimal initial height of the help window when it is opened with the ":help" command. The initial height of the help window is half of the current window, or (when the 'ea' option is on) the same as other windows. When the height is less than 'helpheight', the height is set to 'helpheight'. Set to zero to disable.

'helplang' 'hlg'

'helplang' 'hlg' string (default: messages language or empty)
global
{only available when compiled with the +multi_lang
feature}
{not in Vi}
Comma separated list of languages. Vim will use the first language
for which the desired help can be found. The English help will always
be used as a last resort. You can add "en" to prefer English over
another language, but that will only find tags that exist in that
language and not in the English help.
Example:
:set helplang=de,it
This will first search German, then Italian and finally English help
files.
When using CTRL-] and ":help!" in a non-English help file Vim will
try to find the tag in the current language before using this option.
See help-translated .

'hidden' 'hid' 'nohidden' 'nohid'

'hidden' 'hid' boolean (default off)
global
{not in Vi}
When off a buffer is unloaded when it is abandon ed. When on a
buffer becomes hidden when it is abandon ed. If the buffer is still
displayed in another window, it does not become hidden, of course.
The commands that move through the buffer list sometimes make a buffer
hidden although the 'hidden' option is off: When the buffer is
modified, 'autowrite' is off or writing is not possible, and the '!'
flag was used. See also windows.txt .
To only make one buffer hidden use the 'bufhidden' option.
This option is set for one command with ":hide {command}" :hide .
WARNING: It's easy to forget that you have changes in hidden buffers.
Think twice when using ":q!" or ":qa!".

'highlight' 'hl'

'highlight' 'hl' string (default (as a single string):
"8:SpecialKey,~:EndOfBuffer,@:NonText,
d:Directory,e:ErrorMsg,i:IncSearch,
l:Search,m:MoreMsg,M:ModeMsg,n:LineNr,
N:CursorLineNr,r:Question,s:StatusLine,
S:StatusLineNC,c:VertSplit,t:Title,
v:Visual,w:WarningMsg,W:WildMenu,f:Folded,
F:FoldColumn,A:DiffAdd,C:DiffChange,
D:DiffDelete,T:DiffText,>:SignColumn,
B:SpellBad,P:SpellCap,R:SpellRare,
L:SpellLocal,-:Conceal,+:Pmenu,=:PmenuSel,
x:PmenuSbar,X:PmenuThumb,*:TabLine,
#:TabLineSel,_:TabLineFill,!:CursorColumn,
.:CursorLine,o:ColorColumn,q:QuickFixLine,
z:StatusLineTerm,Z:StatusLineTermNC")
global
{not in Vi}
This option can be used to set highlighting mode for various

occasions. It is a comma separated list of character pairs. The
first character in a pair gives the occasion, the second the mode to
use for that occasion. The occasions are:
 hl-SpecialKey   8 Meta and special keys listed with ":map"
 hl-EndOfBuffer   ~ lines after the last line in the buffer
 hl-NonText   @ '@' at the end of the window and
                    characters from 'showbreak'
 hl-Directory   d directories in CTRL-D listing and other special
                    things in listings
 hl-ErrorMsg   e error messages
                 h (obsolete, ignored)
 hl-IncSearch   i 'incsearch' highlighting
 hl-Search   l last search pattern highlighting (see 'hlsearch')
 hl-MoreMsg   m   more-prompt
 hl-ModeMsg   M Mode (e.g., "-- INSERT --")
 hl-LineNr   n line number for ":number" and ":#" commands, and
                    when 'number' or 'relativenumber' option is set.
 hl-CursorLineNr   N like n for when 'cursorline' or 'relativenumber' is
                    set.
 hl-Question   r   hit-enter prompt and yes/no questions
 hl-StatusLine   s status line of current window status-line
 hl-StatusLineNC   S status lines of not-current windows
 hl-Title   t Titles for output from ":set all", ":autocmd" etc.
 hl-VertSplit   c column used to separate vertically split windows
 hl-Visual   v Visual mode
 hl-VisualNOS   V Visual mode when Vim does is "Not Owning the
                    Selection" Only X11 Gui's gui-x11 and
                     xterm-clipboard .
 hl-WarningMsg   w warning messages
 hl-WildMenu   W wildcard matches displayed for 'wildmenu'
 hl-Folded   f line used for closed folds
 hl-FoldColumn   F 'foldcolumn'
 hl-DiffAdd   A added line in diff mode
 hl-DiffChange   C changed line in diff mode
 hl-DiffDelete   D deleted line in diff mode
 hl-DiffText   T inserted text in diff mode
 hl-SignColumn   > column used for signs
 hl-SpellBad   B misspelled word spell
 hl-SpellCap   P word that should start with capital spell
 hl-SpellRare   R rare word spell
 hl-SpellLocal   L word from other region spell
 hl-Conceal   - the placeholders used for concealed characters
                    (see 'conceallevel')
 hl-Pmenu   + popup menu normal line
 hl-PmenuSel   = popup menu normal line
 hl-PmenuSbar   x popup menu scrollbar
 hl-PmenuThumb   X popup menu scrollbar thumb

The display modes are:
        r   reverse   (termcap entry "mr" and "me")
        i   italic   (termcap entry "ZH" and "ZR")
        b   bold   (termcap entry "md" and "me")
        s   standout   (termcap entry "so" and "se")
        u   underline   (termcap entry "us" and "ue")

```
                c       undercurl       (termcap entry "Cs" and "Ce")
                t       strikethrough   (termcap entry "Ts" and "Te")
                n       no highlighting
                -       no highlighting
                :       use a highlight group
        The default is used for occasions that are not included.
        If you want to change what the display modes do, see  dos-colors
        for an example.
        When using the ':' display mode, this must be followed by the name of
        a highlight group.  A highlight group can be used to define any type
        of highlighting, including using color.  See  :highlight  on how to
        define one.  The default uses a different group for each occasion.
        See  highlight-default  for the default highlight groups.

                                                'history'   'hi'
'history' 'hi'          number  (Vim default: 50, Vi default: 0,
                                                set to 200 in  defaults.vim )
                        global
                        {not in Vi}
        A history of ":" commands, and a history of previous search patterns
        is remembered.  This option decides how many entries may be stored in
        each of these histories (see  cmdline-editing ).
        The maximum value is 10000.
        NOTE: This option is set to the Vi default value when 'compatible' is
        set and to the Vim default value when 'compatible' is reset.

                                            'hkmap'   'hk'   'nohkmap'   'nohk'
'hkmap' 'hk'            boolean (default off)
                        global
                        {not in Vi}
                        {only available when compiled with the  +rightleft
                        feature}
        When on, the keyboard is mapped for the Hebrew character set.
        Normally you would set 'allowrevins' and use CTRL-_ in insert mode to
        toggle this option.  See  rileft.txt .
        NOTE: This option is reset when 'compatible' is set.

                                    'hkmapp'   'hkp'   'nohkmapp'   'nohkp'
'hkmapp' 'hkp'          boolean (default off)
                        global
                        {not in Vi}
                        {only available when compiled with the  +rightleft
                        feature}
        When on, phonetic keyboard mapping is used.  'hkmap' must also be on.
        This is useful if you have a non-Hebrew keyboard.
        See  rileft.txt .
        NOTE: This option is reset when 'compatible' is set.

                                    'hlsearch'   'hls'   'nohlsearch'   'nohls'
'hlsearch' 'hls'        boolean (default off)
                        global
                        {not in Vi}
                        {not available when compiled without the
                         +extra_search  feature}
```

When there is a previous search pattern, highlight all its matches.
The type of highlighting used can be set with the 'l' occasion in the
'highlight' option. This uses the "Search" highlight group by
default. Note that only the matching text is highlighted, any offsets
are not applied.
See also: 'incsearch' and :match .
When you get bored looking at the highlighted matches, you can turn it
off with :nohlsearch . This does not change the option value, as
soon as you use a search command, the highlighting comes back.
'redrawtime' specifies the maximum time spent on finding matches.
When the search pattern can match an end-of-line, Vim will try to
highlight all of the matched text. However, this depends on where the
search starts. This will be the first line in the window or the first
line below a closed fold. A match in a previous line which is not
drawn may not continue in a newly drawn line.
You can specify whether the highlight status is restored on startup
with the 'h' flag in 'viminfo' viminfo-h .
NOTE: This option is reset when 'compatible' is set.

'icon' 'noicon'

'icon' boolean (default off, on when title can be restored)
global
{not in Vi}
{not available when compiled without the +title
feature}
When on, the icon text of the window will be set to the value of
'iconstring' (if it is not empty), or to the name of the file
currently being edited. Only the last part of the name is used.
Overridden by the 'iconstring' option.
Only works if the terminal supports setting window icons (currently
only X11 GUI and terminals with a non-empty 't_IS' option - these are
Unix xterm and iris-ansi by default, where 't_IS' is taken from the
builtin termcap).
When Vim was compiled with HAVE_X11 defined, the original icon will be
restored if possible X11 . See X11-icon for changing the icon on
X11.
For MS-Windows the icon can be changed, see windows-icon .

'iconstring'

'iconstring' string (default "")
global
{not in Vi}
{not available when compiled without the +title
feature}
When this option is not empty, it will be used for the icon text of
the window. This happens only when the 'icon' option is on.
Only works if the terminal supports setting window icon text
(currently only X11 GUI and terminals with a non-empty 't_IS' option).
Does not work for MS Windows.
When Vim was compiled with HAVE_X11 defined, the original icon will be
restored if possible X11 .
When this option contains printf-style '%' items, they will be
expanded according to the rules used for 'statusline'. See
'titlestring' for example settings.

{not available when compiled without the |+statusline| feature}

'ignorecase' 'ic' 'noignorecase' 'noic'
'ignorecase' 'ic' boolean (default off)
global
Ignore case in search patterns. Also used when searching in the tags file.
Also see 'smartcase' and 'tagcase'.
Can be overruled by using "\c" or "\C" in the pattern, see /ignorecase .

'imactivatefunc' 'imaf'
'imactivatefunc' 'imaf' string (default "")
global
{not in Vi}
{only available when compiled with +multi_byte feature}
This option specifies a function that will be called to activate or deactivate the Input Method.
It is not used in the GUI.

Example:

```
function ImActivateFunc(active)
  if a:active
    ... do something
  else
    ... do something
  endif
  " return value is not used
endfunction
set imactivatefunc=ImActivateFunc
```

'imactivatekey' 'imak'
'imactivatekey' 'imak' string (default "")
global
{not in Vi}
{only available when compiled with +xim and +GUI_GTK } E599
Specifies the key that your Input Method in X-Windows uses for activation. When this is specified correctly, vim can fully control IM with 'imcmdline', 'iminsert' and 'imsearch'.
You can't use this option to change the activation key, the option tells Vim what the key is.
Format:

```
[MODIFIER_FLAG-]KEY_STRING
```

These characters can be used for MODIFIER_FLAG (case is ignored):

S	Shift key
L	Lock key
C	Control key
1	Mod1 key
2	Mod2 key
3	Mod3 key
4	Mod4 key

```
                5           Mod5 key
        Combinations are allowed, for example "S-C-space" or "SC-space" are
        both shift+ctrl+space.
        See <X11/keysymdef.h> and XStringToKeysym for KEY_STRING.

        Example:
                :set imactivatekey=S-space
       "S-space" means shift+space.  This is the activation key for kinput2 +
        canna (Japanese), and ami (Korean).

                                        'imcmdline'   'imc'   'noimcmdline'   'noimc'
'imcmdline' 'imc'       boolean (default off)
                        global
                        {not in Vi}
                        {only available when compiled with the  +multi_byte
                        feature}
        When set the Input Method is always on when starting to edit a command
        line, unless entering a search pattern (see 'imsearch' for that).
        Setting this option is useful when your input method allows entering
        English characters directly, e.g., when it's used to type accented
        characters with dead keys.

                                        'imdisable'   'imd'   'noimdisable'   'noimd'
'imdisable' 'imd'       boolean (default off, on for some systems (SGI))
                        global
                        {not in Vi}
                        {only available when compiled with the  +multi_byte
                        feature}
        When set the Input Method is never used.  This is useful to disable
        the IM when it doesn't work properly.
        Currently this option is on by default for SGI/IRIX machines.  This
        may change in later releases.

                                                    'iminsert'   'imi'
'iminsert' 'imi'        number (default 0)
                        local to buffer
                        {not in Vi}
        Specifies whether :lmap or an Input Method (IM) is to be used in
        Insert mode.  Valid values:
                0       :lmap is off and IM is off
                1       :lmap is ON and IM is off
                2       :lmap is off and IM is ON
        To always reset the option to zero when leaving Insert mode with <Esc>
        this can be used:
                :inoremap <ESC> <ESC>:set iminsert=0<CR>
       This makes :lmap and IM turn off automatically when leaving Insert
        mode.
        Note that this option changes when using CTRL-^ in Insert mode
         i_CTRL-^ .
        The value is set to 1 when setting 'keymap' to a valid keymap name.
        It is also used for the argument of commands like "r" and "f".
        The value 0 may not work correctly with Athena and Motif with some XIM
        methods.  Use 'imdisable' to disable XIM then.
```

You can set 'imactivatefunc' and 'imstatusfunc' to handle IME/XIM
via external command if vim is not compiled with the +xim ,
+multi_byte_ime or global-ime .

'imsearch' 'ims' number (default -1)
local to buffer
{not in Vi}
Specifies whether :lmap or an Input Method (IM) is to be used when
entering a search pattern. Valid values:
-1 the value of 'iminsert' is used, makes it look like
'iminsert' is also used when typing a search pattern
0 :lmap is off and IM is off
1 :lmap is ON and IM is off
2 :lmap is off and IM is ON
Note that this option changes when using CTRL-^ in Command-line mode
c_CTRL-^ .
The value is set to 1 when it is not -1 and setting the 'keymap'
option to a valid keymap name.
The value 0 may not work correctly with Athena and Motif with some XIM
methods. Use 'imdisable' to disable XIM then.

'imstatusfunc' 'imsf' string (default "")
global
{not in Vi}
{only available when compiled with the +multi_byte
feature}
This option specifies a function that is called to obtain the status
of Input Method. It must return a positive number when IME is active.
It is not used in the GUI.

Example:

```
function ImStatusFunc()
  let is_active = ...do something
  return is_active ? 1 : 0
endfunction
set imstatusfunc=ImStatusFunc
```

NOTE: This function is invoked very often. Keep it fast.

'imstyle' 'imst' number (default 1)
global
{not in Vi}
{only available when compiled with +xim and
+GUI_GTK }
This option specifies the input style of Input Method:
0 use on-the-spot style
1 over-the-spot style
See: xim-input-style

For a long time on-the-spot style had been used in the GTK version of
vim, however, it is known that it causes troubles when using mappings,
